
The BlueNRG-LP ARM Cortex-M0+based

Introduction

This reference manual provides complete information on how to use the BlueNRG-LP microcontroller memory and peripherals.

The BlueNRG-LP is a powerful and ultra-low-power 2.4 GHz RF transceiver with a Cortex®-M0+ microcontroller that can operate up to 64 MHz.

The BlueNRG-LP is suitable to implement applications compliant with Bluetooth® Low Energy SIG specification.

1 Documentation conventions

1.1 List of abbreviations for registers

The following abbreviations are used in register descriptions:

Table 1. List of abbreviations for registers

read/write (rw or R/W)	Software can read and write to these bits
read-only (r or R)	Software can only read these bits
write-only (w or W)	Software can only write to this bit. Reading the bit returns the reset value
read/write-once (RWOnce)	Software can read these bits but write is only allowed once
read/clear (rc_w1 or RWC1)	Software can read as well as clear this bit by writing 1. Writing '0' has no effect on the bit value
read/clear (rc_w0 or RWC0)	Software can read as well as clear this bit by writing 0. Writing '1' has no effect on the bit value
read/clear by read (rc_r or RC)	Software can read this bit. Reading this bit automatically clears it to '0'. Writing '0' has no effect on the bit value
read/set (rs or RWS1)	Software can read as well as set this bit. Writing '0' has no effect on the bit value
read-only write trigger (rt_w or RWH)	Software can read this bit. Writing '0' or '1' triggers an event but has no effect on the bit value
toggle (t or RWT1)	Software can only toggle this bit by writing '1'. Writing '0' has no effect
Reserved (Res.)	Reserved bit, must be kept at reset value

1.2 Glossary

This section gives a brief definition of the abbreviations used in this document:

The SoC integrates the SWD debug port (SWD-DP) which provides a 2-pin (clock and data) interface based on the serial wire debug (SWD) protocol.

- Word: data/instruction of 32-bit length
- Half word: data/instruction of 16-bit length
- Byte: data of 8-bit length
- Double word: data of 64-bit length
- AHB: advanced high-performance bus
- APB: advanced peripheral bus
- CPU: refers to the Cortex®-M0+core

1.3 Acronyms

Table 2. Acronyms

Acronym	Description
ADC	Analog to digital converter
AES	Advanced encryption standard hardware accelerator
AHB	Advanced high-performance bus
APB	Advanced peripheral bus
ART	Adaptive real-time memory accelerator
BLE	Bluetooth Low Energy (Bluetooth standard)
BOR	Brown-Out Reset
BPU	Breakpoint unit (ARM debug component)
COMP	COMParator
CPU	Central processor unit
CRC	Cyclic redundancy check
CTI	Cross trigger interface (ARM debug component)
DBG	DeBuG
DMA	Direct memory access
DMAMUX	Direct memory access MULTiplexor
DWT	Data watchpoint and trace (ARM debug component)
GPIO	General purpose input output
HSE	High speed external clock oscillator
HSI	High speed internal clock oscillator
HW	Hardware
I2C	Inter integrated circuit (communication standard)
I2S	Inter integrated (communication standard)
IRQ	Interrupt request
ITM	Instrumentation trace macrocell (ARM debug component)
IWDG	Independent watchdoG
JTAG	Joint test access group (test interface standard)
LCD	Liquid crystal display
LDO	Low-dropoutput
LP	Low power
LPUART	Universal asynchronous receiver transmitter (communication standard)
LSB	Least significant byte
LSE	Low speed external clock oscillator
LSI	Low speed internal clock oscillator
MCU	Micro controller unit
MPU	Memory protection unit
MR_BLE	Radio sub-system
MSB	Most significant byte

Acronym	Description
NVIC	Nested vector interrupt controller
OBL	Option byte loading
OSC	Oscillator
OTP	One time programmable
PDR	Power-down reset
PDM	Pulse density modulation
PKA	Public key accelerator
PLL	Phase locked loop
POR	Power-on reset
PVD	Programmable voltage detector
PVM	Peripheral voltage monitoring
PWR	Power controller
RC	Resistor capacitor oscillator
RCC	Reset and clock controller
RF	Radio frequency
RNG	True random number Generator
ROM	Read-only memory
RTC	Real-time clock
SAI	Serial audio interface
SMPS	Switch mode power supply
SPI	Serial peripheral interface (communication standard)
SRAM	Static random access memory
SW	Software
SWD	Single-wire debug
SWJ-DP	Single-wire joint test access group - debug port (ARM debug component)
SYSCFG	System configuration
TIM	Timer
USART	Universal synchronous asynchronous receiver transmitter (communication standard)
VCO	Voltage controlled oscillator
VREF	Voltage reference
WFI	Wait for instruction (ARM instruction entering low-power mode)
WKUP	Wakeup
WRP	Write protection
WWDG	Window watchdog
XIP	Execute in place

Note: For information about MR_BLE/Radio sub-system refer to "The BlueNRG-LP radio controller" Reference Manual (RM0480).

2 System and memory overview

2.1 System architecture

The main system consists of a 32-bit multilayer AHB bus matrix that interconnects:

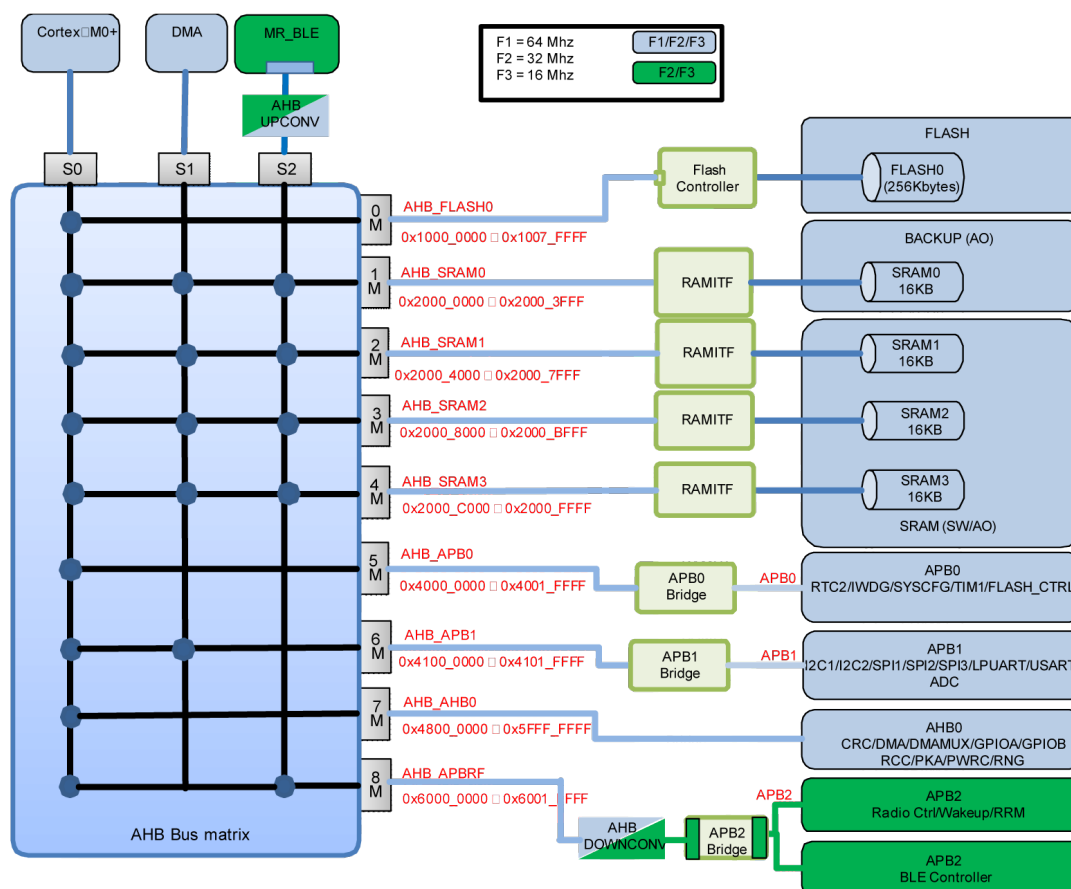

- Three masters:
 - CPU (Cortex®-M0+) core S-bus
 - DMA1
 - Radio system
- Nine slaves:
 - Internal Flash memory on CPU (Cortex®-M0+) S bus
 - Internal SRAM0 (16 kB)
 - Internal SRAM1 (16 kB)
 - Internal SRAM2 (16 kB)
 - Internal SRAM3 (16 kB)
 - APB0 peripherals (through an AHB to APB bridge)
 - APB1 peripherals (through an AHB to APB bridge)
 - AHB0 peripherals
 - AHBRF including AHB to APB bridge and radio peripherals (connected to APB2)

The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in [Figure 1. BlueNRG-LP system architecture](#).

The system consists of a Cortex®-M0+ “Radio protocol and application” processor with its radio sub-system.

There is a single Flash memory to be used by the CPU for both Bluetooth protocol and application management.

The peripherals are located on the different system buses (AHB, APB0, APB1, APB2 for the radio system). There are 4 SRAM banks, an SRAM0 always power supplied and three SRAM (SRAM1, SRAM2 and SRAM3) that can be programmed to be always on or switchable. For more information see [Section 5.6.2 Control register 2 \(PWRC_CR2\)](#).

Figure 1. BlueNRG-LP system architecture

2.1.1 S0: CPU (Cortex®-M0+) S-bus

This bus connects the system bus of the CPU core to the BusMatrix. This bus is used by the core to fetch instructions, for literal load and debug access, and access data located in a peripheral or SRAM area. The targets of this bus are all the possible peripherals (the internal Flash and SRAM memories, the AHB0, APB0, APB1 and APB2 peripherals).

2.1.2 S1: DMA-bus

This bus connects the AHB master interface of the DMA to the BusMatrix. The targets of this bus are the four banks of SRAM and the APB1 peripheral.

2.1.3 S2: Radio system-bus

This bus connects the AHB master interface of the radio system to the BusMatrix. The targets of this bus are the four banks of SRAM and the APB2 peripherals (internal APB blocks of the MR_BLE/Radio sub-system IP).

2.1.4 BusMatrix

The BusMatrix manages the access arbitration between masters. The arbitration uses a "Round Robin" algorithm. The BusMatrix is composed of three masters (CPU, DMA1-bus and radio system-bus) and nine slaves (FLASH, SRAM0, SRAM1, SRAM2 & SRAM3, APB0 and APB1, AHB0 and AHB1).

AHB/APB bridges

The two bridges AHB to APB0 and AHB to APB1 provide full synchronous connections between the AHB and the two APB buses.

The bridge AHB to APB2 provides synchronous connections between the AHB and the APB bus. Two blocks are added to the AHB/APB path to manage potential prescaled MR_BLE frequency versus the system frequency:

- AHB up converter is used for the MR_BLE AHB master transactions towards the SRAM
- AHB down converter is used for the CPU AHB master transactions towards the MR_BLE APB registers.

Refer to [Section 2.2.2 Memory map and register boundary addresses](#) for the address mapping of the peripherals connected to this bridge.

After each device reset, all peripheral clocks are disabled (except for the SRAM and Flash memory interface). Before using a peripheral the user has to enable its clock in the RCC_AHBxENR and the RCC_APBxENR registers.

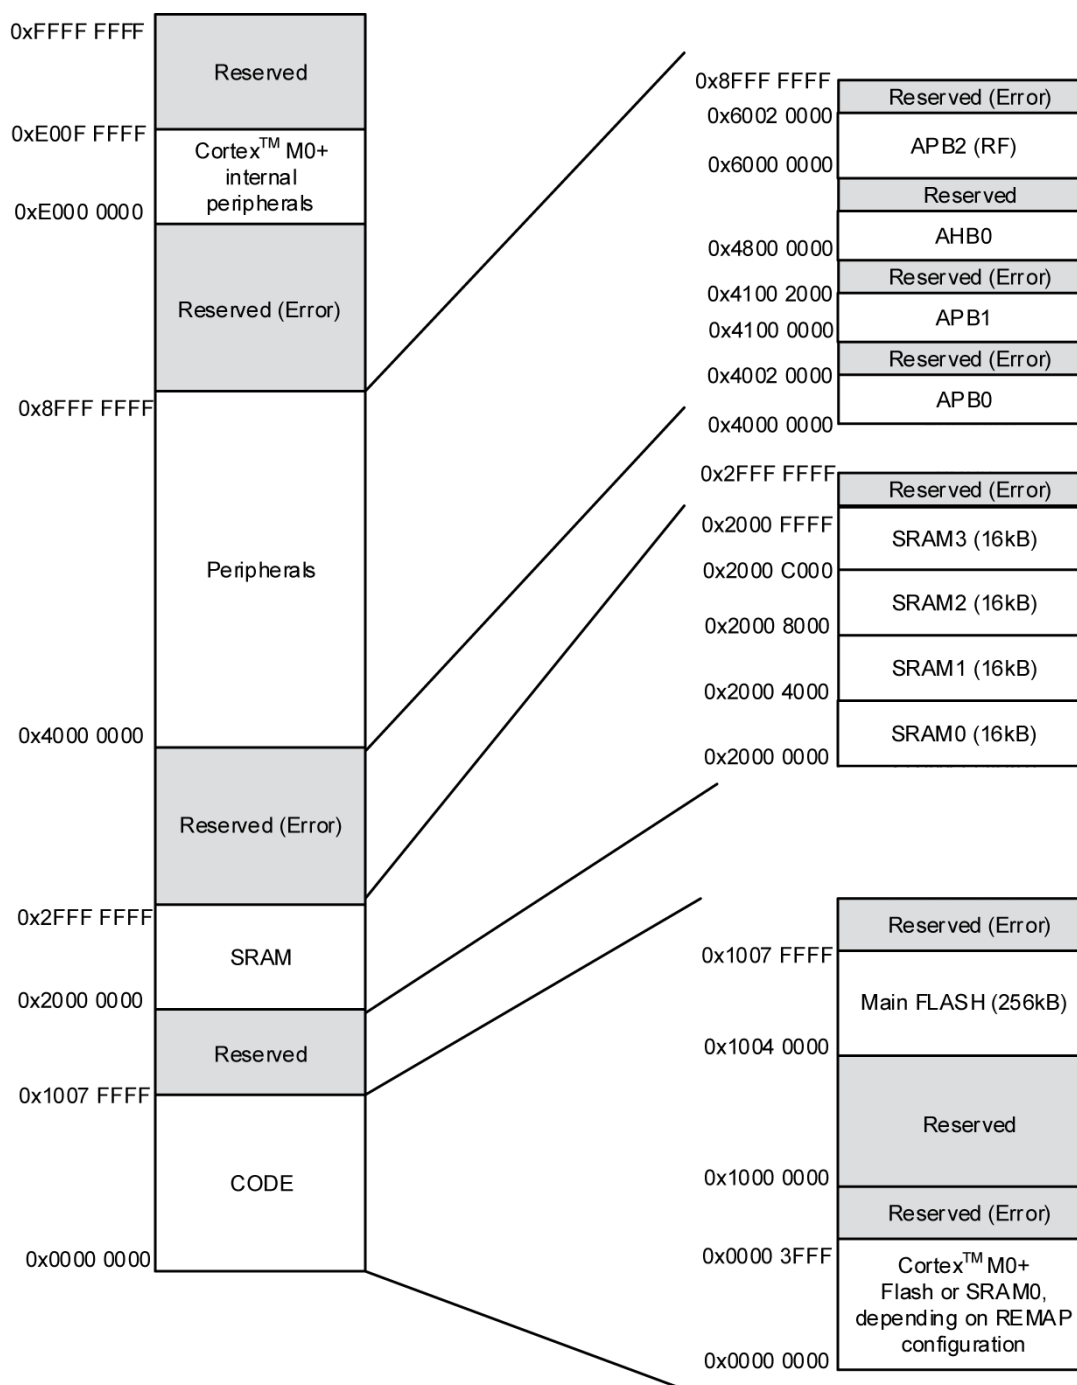

Note: When a 16- or 8-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 16- or 8-bit data to feed the 32-bit vector.

2.2 Memory organization

2.2.1 Introduction

Program memory, data memory and registers are organized within the same linear 4-Gbyte address space.

These bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word least significant byte and the highest numbered byte the most significant.

Figure 2. Memory map

All the memory areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. For the detailed mapping of available memory and registers areas, please refer to Section 2.2.2 Memory map and register boundary addresses and to each peripheral register map section.

2.2.2 Memory map and register boundary addresses

Table 3. BlueNRG-LP memory map and peripheral register boundary addresses gives the boundary addresses of the peripherals available in the device.

Table 3. BlueNRG-LP memory map and peripheral register boundary addresses

Bus	Boundary address	Actual size (bytes)	Peripheral	Peripheral register map
Misc	0xE010 0800 - 0xFFFF FFFF	255 MB	Reserved	
	0xE000 0000 - 0xE00F FFFF	1 MB	Private peripheral bus	Cortex-M0+ registers (interrupt controller, SysTick, etc.)
APB2	0x6000 1800 - 0x6000 1BFF	1 kB	WAKEUP	Wakeup registers of the MR_BLE
	0x6000 1500 - 0x6000 17FF	1 kB	Radio registers	Radio registers through APB direct access
	0x6000 1400 - 0x6000 14FF		RRM	RRM registers of the MR_BLE
	0x6000 1000 - 0x6000 13FF	1 kB	RADIO_CTRL	Radio controller registers of the MR_BLE
	0x6000 0000 - 0x6000 00FF	256 B	BLE	BLE link layer registers of the MR_BLE
AHB0	0x4880 0000 - 0x4880 03FF	1 kB	DMAMUX	See Table 28. DMAMUX register map and reset values
	0x4870 0000 - 0x4870 00FF	256 B	DMA slave	See Table 25. DMA register map and reset values
	0x4860 0000 - 0x4860 03FF	4 kB	RNG	See Table 37. RNG register list
	0x4850 0000 - 0x485F FFFF	156 B	PWRC	See Table 10. PWRC register map
	0x4840 0000 - 0x484F FFFF	156 B	RCC	See Section 6.7 RCC register map
	0x4830 0400 - 0x4830 07FF	1 kB	PKA RAM	See Table 41. PKA register list
	0x4830 0000 - 0x4830 03FF	1 kB	PKA slave	
	0x4820 0000 - 0x4820 03FF	1 kB	CRC	See Table 47. CRC register map and reset values
	0x4810 0000 - 0x4810 03FF	1 kB	GPIOB	See Section 7.5 GPIO register map
	0x4800 0000 - 0x4800 03FF	1 kB	GPIOA	See Section 7.5 GPIO register map
APB1	0x4100 7000 - 0x4100 73FF	1 kB	SPI3	See Section 22.10 SPI/I2S register map
	0x4100 6000 - 0x4100 60FF	256 B	ADC	See Section 12.7 ADC registers map
	0x4100 5000 - 0x4100 53FF	1 kB	LPUART	See Section 21.5 LPUART registers
	0x4100 4000 - 0x4100 43FF	1 kB	USART	See Section 20.7 USART registers
	0x4100 3000 - 0x4100 33FF	1 kB	SPI2	See Section 22.10 SPI/I2S register map
	0x4100 2000 - 0x4100 23FF	1 kB	SPI1	See Section 22.10 SPI/I2S register map
	0x4100 1000 - 0x4100 13FF	1 kB	I2C2	See Section 19.7 I2C register map
	0x4100 0000 - 0x4100 03FF	1 kB	I2C1	See Section 19.7 I2C register map
APB0	0x4000 4000 - 0x4000 43FF	1 kB	RTC	See Section 17.7 RTC register map
	0x4000 3000 - 0x4000 33FF	1 kB	IWDG	See Section 18.5 IWDG register map
	0x4000 2000 - 0x4000 23FF	1 kB	TIM1	See Section 16.5 TIM1 register map
	0x4000 1000 - 0x4000 1FFF	4 kB	FLASH_CTRL	See Section 9.3 Flash controller register map
	0x4000 0000 - 0x4000 003F	64 B	SYSTEM_CTRL	See Section 8.3 System controller register map
SRAM	0x2000 C000 - 0x2000 FFFF	16 kB	SRAM3	
	0x2000 8000 - 0x2000 BFFF	16 kB	SRAM2	
	0x2000 4000 - 0x2000 7FFF	16 kB	SRAM1	
	0x2000 0000 - 0x2000 3FFF	16 kB	SRAM0	
Flash	0x1004 0000 - 0x1007 FFFF	256 kB	Main Flash	
OTP	0x1000 1800 - 0x1000 1BFF	1 kB	OTP area	
Boot ⁽¹⁾	0x0000 0000 - 0x0000 3FFF	16 kB	CPU boot area	Mirroring of Flash or SRAM0

1. This area is a mirroring area. The CPU accesses are redirected to other memory map depending on REMAP and PREMAP bits located in the Flash controller CONFIG register. See Table 4. Address remapping depending on REMAP bit for remapping detail.

Table 4. Address remapping depending on REMAP bit

REMAP	Memory mapped
0	Main Flash
1	SRAM0

2.3 ARM® Cortex®-M0+

The ARM® Cortex®-M0+ processor was developed to provide a low-cost platform that meets the needs of MCU implementation, with a reduced pin count and low-power consumption, while delivering outstanding computational performance and an advanced response to interrupts.

The embedded Cortex-M0+ embeds:

- four breakpoints
- two watchpoints
- an MPU (memory protection unit) providing eight unified protection regions
- a SysTick running only with the system clock (external clock option not supported)

2.3.1 CPU memory remap

Following a CPU boot the application software can modify the memory map at address 0x0000 0000. This modification is performed by programming the REMAP bit in the Flash controller (see [Section 9.4.2 Configuration register \(CONFIG\)](#)).

The following memory can be remapped:

- Main Flash memory
- SRAM0 memory

Embedded boot loader

ST provides a boot loader executed after each CPU reboot. This boot loader has its own documentation.

Note: *The BlueNRG-LP device latches the PA8 / PA9 / PA10 / PA11 pads value at POR. The information is available in the PWRC_SR2 register (see [Section 5.6.6 Status register 2 \(PWRC_SR2\)](#)). One of those four I/Os can be used by the boot loader as boot indication between a normal boot or a boot on serial interface.*

2.3.2

Interrupts

Interrupts are handled by the Cortex-M0+ nested vector interrupt controller (NVIC). The NVIC controls specific Cortex-M0+ interrupts (address 0x00 to 0x3C) as well as 32 user interrupts (address 0x40 to 0xBC). In the BlueNRG-LP device, the user interrupts have been connected to the interrupt signals of the different peripherals (GPIO, Flash controller, timers, UART,...). These interrupts can be controlled using the ISER, ICER, ISPR and ICOR registers.

Vector table

On reset, the Cortex-M0+ vector table is fixed at address 0x0000_0000. The software may relocate the vector table address to a different memory location, in a range 0x0000_0000 to 0xFFFF_FF80 in multiples of 256 bytes through the vector table offset register (VTOR) located in the Cortex-M0+ registers area.

The interrupt mapping for the vector table of the BlueNRG-LP device is described in [Table 5. Interrupt vectors](#).

Table 5. Interrupt vectors

Position	Priority	Type of priority	Acronym	Description	Address offset
				Initial main SP	0x0000_0000
	-3	Fixed	Reset	Reset_Handler	0x0000_0004
	-2	Fixed	NmiSR	NMI_Handler	0x0000_0008
	-1	Fixed	FaultISR	HardFault_handler	0x0000_000C
		RESERVED	RESERVED	RESERVED	0x0000_000C - 0x0000_0038
	6	Settable	SysTick	System tick timer	0x0000_003C
0	Init 0	Settable	NVM	Non-volatile memory (Flash) controller	0x0000_0040
1	Init 0	Settable	RCC	Reset and clock controller	0x0000_0044
2	Init 0	Settable	BATTERY	PVD	0x0000_0048
3	Init 0	Settable	I2C1	I2C1 interrupt	0x0000_004C
4	Init 0	Settable	I2C2	I2C2 interrupt	0x0000_0050
5	Init 0	Settable	SPI1	SPI1 interrupt	0x0000_0054
6	Init 0	Settable	SPI2	SPI2 interrupt	0x0000_0058
7	Init 0	Settable	SPI3	SPI3 interrupt	0x0000_005C
8	Init 0	Settable	USART	USART interrupt	0x0000_0060
9	Init 0	Settable	LPUART	LPUART interrupt	0x0000_0064
10	Init 0	Settable	TIM1	TIM1 interrupt	0x0000_0068
11	Init 0	Settable	RTC	RTC interrupt	0x0000_006C
12	Init 0	Settable	RESERVED	RESERVED	0x0000_0070
12	Init 0	Settable	ADC	ADC interrupt	0x0000_0070
13	Init 0	Settable	PKA	PKA interrupt	0x0000_0074
14	Init 0	Settable	-	-	0x0000_0078
15	Init 0	Settable	GPIOA	GPIOA interrupt	0x0000_007C
16	Init 0	Settable	GPIOB	GPIOB interrupt	0x0000_0080
17	Init 0	Settable	DMA	DMA interrupt	0x0000_0084
18	Init 0	Settable	BLE_TXRX ⁽¹⁾	BLE end of transfer interrupt	0x0000_0088
19	Init 0	Settable	-(¹)	-	0x0000_008C
20	Init 0	Settable	-(¹)	-	0x0000_0090
21	Init 0	Settable	RADIO_CTRL ⁽¹⁾	Radio control slow clock measurement interrupt	0x0000_0094

Position	Priority	Type of priority	Acronym	Description	Address offset
22	Init 0	Settable	MR_BLE ⁽¹⁾	RRM and radio FSM interrupt	0x0000_0098
23	Init 0	Settable	CPU_WKUP ⁽¹⁾	CPU wake-up interrupt	0x0000_009C
24	Init 0	Settable	BLE_WKUP ⁽¹⁾	BLE wake-up interrupt	0x0000_00A0
25	Init 0	Settable	BLE_SEQ	BLE RX/TX sequence interrupt	0x0000_00A4
26 - 31	Init 0	Settable	-	RESERVED	0x0000_00A8 - 0x0000_00BC

1. Some specific cares are needed at SW level to clear the interrupt: see *Warning for interrupt clearance when system clock is faster than MR_BLE clock*.

Interrupt activation sequence

Safely activating a peripheral interrupt requires the following steps:

- make sure the interrupt is disabled and cleared on the peripheral side (this prevents receiving an interrupt due to a previous event)
- clear pending requests for this interrupt on the Cortex-M0+ side using the NVIC ICPR register
- set the priority using the NVIC IPR0-IPR7 registers
- activate on the Cortex-M0+ side using the NVIC ISER register
- activate on the peripheral side

Note that most peripherals require clearing interrupt requests on the peripheral side when handling interrupt service requests to prevent triggering continuous interrupts for the same event.

For more details on the Cortex-M0+ exception model, see “ARMv6-M Architecture Reference Manual”, §B1.5.

For more details on the Cortex-M0+ NVIC behavior and registers, see “ARMv6-M Architecture Reference Manual”, §B3.4.

3 AHB up/down converter

The BlueNRG-LP device can support several system clock frequencies from 1 MHz to 64 MHz.

The MR_BLE/Radio sub-system IP does not need more than 32 MHz to achieve the processing of the radio transfers while the system (CPU, DMA, memories) may require higher performance for application purpose.

To avoid useless overconsumption, AHB up/down converter block has been added to introduce an adjustable divider by one, two or four on AHB and APB bus of the MR_BLE (linked to AHBRF / APB2 bridge) versus the system bus matrix frequency. This block allows dividing by one, two or four the system clock for the MR_BLE IP of the device.

When the system and the MR_BLE share the same frequency, the AHB up/down converter block only transfers the AHB signals from one clock domain to the other.

Note: *The system clock must be at 16/32/64 MHz and always equal or faster than MR_BLE clock when radio is used (no other frequencies).*

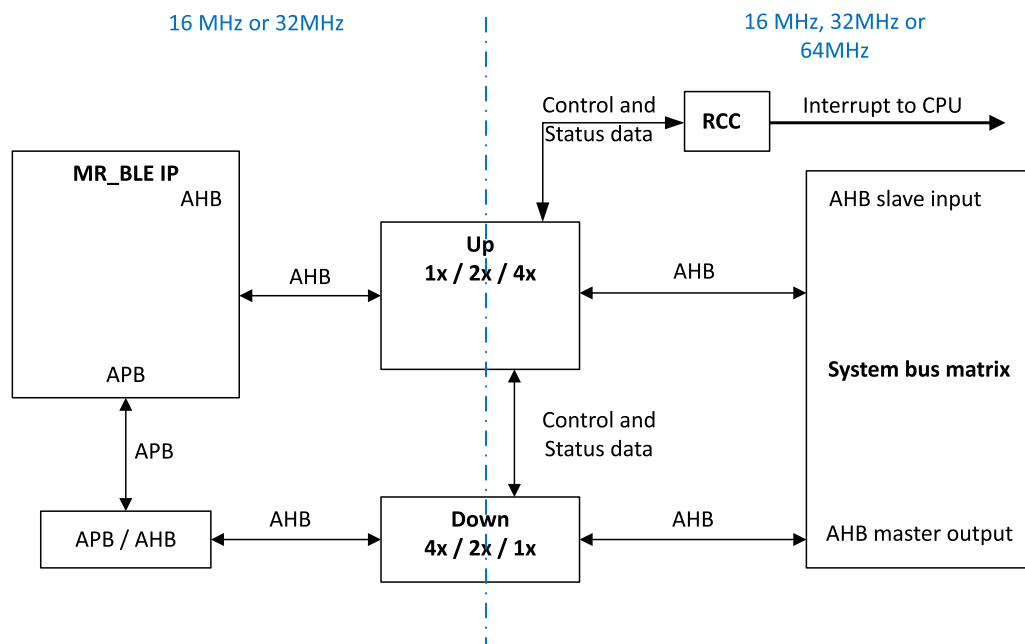

3.1 AHB up/down converter description

The AHB up/down converter role is to allow BlueNRG-LP device to support a fast system clock (up to 64 MHz).

The AHBUPCONV block manages:

- proper on-the-fly (up-to-down and down-to-up) frequency switching by safely updating the ratio (one, two, four) between the system and the MR_BLE IP frequencies.
- AHB and APB data transfer between MR_BLE running at the same frequency or half or quarter of the frequency of the rest of the system (AHB and APB) that may run up to 64 MHz.

Figure 3. AHB up/down converter

The management of data transfer versus clock domain and possible clock switch request is done using state machines:

- one for the AHB master up converter
- one for the AHB slave down converter

When a CPU/system clock frequency switch is needed (activate or deactivate the divider by two or four between the system and the MR_BLE), the user must request the new system clock targeted frequency in the RCC_CSCMDR.REQUEST bit (see [Section 6.6.5 Clock switch command register \(RCC_CSCMDR\)](#) for details).

When receiving a new divider ratio to apply (from the RCC), the AHBUPCONV block:

- Informs the AHBDOWNCONV block (managing the APB transfer from the CPU to the MR_BLE APB registers)
- Checks the traffic on the AHB bus between MR_BLE and CPU:
 - if no transfer is on-going, it uses the HREADY signal on the bus to hold any potential transaction that could occur during the clock frequency switch

Note:

To respect the AHB lite protocol, the HREADY signal is fallen down only after the address phase of a new transfer, the new transfer phase data being stored internally in the converter.

If an AHB transfer is on-going, it waits until the current AHB transfer ends and then holds the AHB traffic as explained above.

- In parallel, the AHBDOWNCONV block does the same action to hold any new transfer on the slave path of the data path (CPU access to MR_BLE APB registers).
- Once the AHBUPCONV block has held its AHB line and has the confirmation from the AHBDOWNCONV, the other AHB2APB data path is also safely held; it allows the RCC block to change the system clock frequency to the requested one.
- When the new system clock frequency is stable, the RCC informs the AHBUPCONV it is done. Then:
 - the AHBUPCONV releases the AHB transfers
 - the AHBUPCONV informs the AHBDOWNCONV that it can also release the AHB/APB transfers.

4 I/O operating modes

The BlueNRG-LP device proposes up to 32 programmable I/Os (depending on the package).

Each I/O can be programmed in several modes:

- Input mode
- General purpose output mode
- Alternate function
- Analog mode (when available)

The BlueNRG-LP device supports eight alternate modes called AF_x (x = 0 to 7). The configuration of each I/O for those alternate modes is detailed in [Table 7. GPIO alternate options AF3 - AF4](#) and [Table 8. I/O analog feature mapping](#).

Caution: When an external slow clock XO is used (LSE on PB12 and PB13 I/Os), the USART transfers done on PB14 / PB15 I/Os in AF7 generate some disturbances on the slow clock.

Note: I/Os features presented in [Table 7. GPIO alternate options AF3 - AF4](#) and [Table 8. I/O analog feature mapping](#) are valid only when the associated I/O is programmed as alternate function.

Refer to [Section 7 General-purpose I/Os \(GPIO\)](#) for more details on all configurations.

The number of I/Os available in the BlueNRG-LP device depends on the package:

- 20 I/Os in QFN32
- 30 I/Os in CSP49
- 32 I/Os in QFN48

Type acronyms correspond to:

- I: input
- O: output
- I/O: input output
- OD: open drain

Please note that in [Table 6. GPIO alternate options AF0 - AF2](#) the green cells correspond to I/Os available on QFN32 package. The blue cells correspond to the additional I/Os available on CSP49 package from a QFN32. The salmon cells correspond to the additional I/Os available on QFN48 package from a CSP49. Pin name in bold indicates the I/O is able to wake up the device and is able to be in input or output during DEEPSLEEP.

Table 6. GPIO alternate options AF0 - AF2

Pin name	AF0 mode		AF1 mode		AF2 mode

1. This I/O is able to be configured as analog (mixed I/O) in QFN32 package.
2. This I/O is shared with OSC32_OUT (low speed clock oscillator pin) available on QFN48 package from a CSP49.
3. This I/O is shared with OSC32_IN (low speed clock oscillator pin).

Consider the following information about the meaning of the colors in [Table 7. GPIO alternate options AF3 - AF4](#) . The green cells correspond to I/Os available on QFN32 package. The blue cells correspond to the additional I/Os available on CSP49 package from a QFN32. The salmon cells correspond to the additional I/Os available on QFN48 package from a CSP49. Pin name in bold indicates the I/O is able to wake up the device and is able to be in input or output during DEEPSTOP.

Table 7. GPIO alternate options AF3 - AF4

1. This I/O is able to be configured in open-drain.
2. This I/O is able to be configured as analog (mixed I/O).
3. This I/O is shared with OSC32_OUT (low speed clock oscillator pin).
4. This I/O is shared with OSC32_IN (low speed clock oscillator pin).

Note: AF5, AF6, AF7 alternate functions:

PA2: TMS_SWDIO (AF5, AF7)

PA3: TCK_SWCLK (AF5, AF7)

PB14: USART_RX (AF7)

PB15: USART_TX (AF7)

Note: The BlueNRG-LP is provided with the TX_SEQUENCE and RX_SEQUENCE signals which alert, respectively, transmission and reception activities. A signal can be enabled for TX and RX on two pins, through alternate functions:

- TX_SEQUENCE is available on PA10 (AF2) or PB15 (AF1)
- RX_SEQUENCE is available on PA8 (AF2) or PA11 (AF2)

The signal is high when radio is in TX (or RX), low otherwise.

The signals can be used to control external antenna switching and support coexistence with other wireless technologies.

Note: Concerning the ADC block present in the BlueNRG-LP device:

- The eight ADC channels are available on PA12, PA13, PA14, PA15, PB0, PB1, PB2, PB3
- The two analog microphone pins are available on PB4 and PB5.

The ADC features on those pins are available if the associated pin is configured in analog mode (see [Section 7.3.1 General-purpose I/O \(GPIO\)](#) for more details)

The table below shows the mapping associated to analog configuration (for pins which can support analog mode).

In [Table 8. I/O analog feature mapping](#), the green cells correspond to I/Os available on QFN32 package, the blue cells correspond to the additional I/Os available on CSP49 package and the salmon cells correspond to the additional I/Os available on QFN48 package.

Note: Programming an alternate function sets the output value of the pin: I2C_SDA, I2C_SCL, I2C_SMBA set to 1, SPI_SCK, SPI_NSS, SPI_MISO, SPI_MOSI, SPI_MCKO set to 0, UART_RX set to 0 and UART_TX set to 1.

Table 8. I/O analog feature mapping

Pin name	Analog feature	Pin name	Analog feature	Parallel analog feature
Port A		Port B		
PA0	N/A ⁽¹⁾	PB0	ADC_VINM1	N/A ⁽¹⁾
PA1	N/A ⁽¹⁾	PB1	ADC_VINP1	N/A ⁽¹⁾

PA3	N/A ⁽¹⁾	PB3	ADC_VINP0	PGA_CAP1 ⁽²⁾
PA4	N/A ⁽¹⁾	PB4	PGA_VIN	N/A ⁽¹⁾
PA5	N/A ⁽¹⁾	PB5	PGA_VBIAS_MIC ⁽³⁾	N/A ⁽¹⁾
PA6	N/A ⁽¹⁾	PB6	N/A ⁽¹⁾	N/A ⁽¹⁾
PA7	N/A ⁽¹⁾	PB7	N/A ⁽¹⁾	N/A ⁽¹⁾
PA8	N/A ⁽¹⁾	PB8	N/A ⁽¹⁾	N/A ⁽¹⁾
PA9	N/A ⁽¹⁾	PB9	N/A ⁽¹⁾	N/A ⁽¹⁾
PA10	N/A ⁽¹⁾	PB10	N/A ⁽¹⁾	N/A ⁽¹⁾
PA11	N/A ⁽¹⁾	PB11	N/A ⁽¹⁾	N/A ⁽¹⁾
PA12	ADC_VINM3	PB12	N/A ⁽¹⁾	SXTAL0 ⁽⁴⁾
PA13	ADC_VINP3	PB13	N/A ⁽¹⁾	SXTAL1 ⁽⁴⁾
PA14	ADC_VINM2	PB14	N/A ⁽¹⁾	PVD input voltage
PA15	ADC_VINP2	PB15	N/A ⁽¹⁾	N/A

1. N/A means not applicable as the associated I/O does not support analog option.
2. The selection between ADC_VINx0 and PGA_CAPx is done through a register in the SYSCFG block. See [Section 8.2.11 I/O analog switch control register \(GPIO_SWA_CTRL\)](#).
3. This pin is not 5 V tolerant. All other 31 pins are 5 V tolerant.
4. The parallel analog feature is obtained by setting the RCC_CR.LSEON bit in the RCC registers. Then the PB12 and PB13 are forced by hardware to manage the LSE through SXTAL0/SXTAL1 whatever the selected mode in the associated GPIO_MODERx register.

5 Power controller (PWRC)

The power controller block controls the analog supplies block and manages the startup, active and low-power phase of the device including the transition from one state to another.

5.1 Features

The Power controller block supports the following features:

- Low-power mode choice and entry/exit sequences
- Flash memory power (ON/OFF) and the power-down sequence
- RAM banks retention control
- Power monitoring:
 - POR/PDR reset on rising/falling VDDIO voltage
 - Programmable voltage detector (PVD) monitoring of the VDDIO with programmable threshold or of an external analog input voltage (compared to the internal VBGp)
- I/Os pull-up/down during low-power mode

Wake-up I/O configuration.

5.2 Power supply domains

The BlueNRG-LP device embeds three power domains:

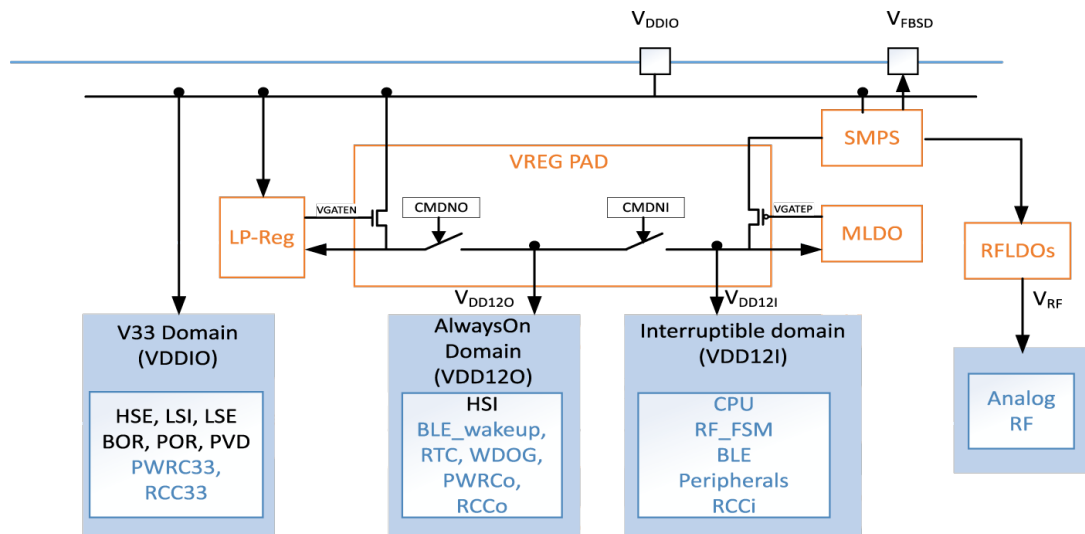

- VDD33 aka VDDIO or VDD:
 - the voltage range is between 1.7 V and 3.6 V,
 - it supplies a part of the I/O ring, the embedded regulators and the system analog IPs such as power management block and embedded oscillators
- VDD12o:
 - always-on digital power domain
 - this domain is generally supplied at 1.2 V during active phase of the device
 - this domain is supplied at 1.0 V during low-power mode (DEEPSTOP)
- VDD12i:
 - interruptible digital power domain
 - this domain is generally supplied at 1.2 V during active phase of the device
 - this domain is shut down during low-power mode (DEEPSTOP)

The digital power supplies are provided by different regulators:

- a main LDO(MLDO):
 - providing the 1.2 V from a 1.4-3.3 V input voltage
 - supplies both VDD12i and VDD12o when the device is active
 - is disabled during the low-power mode (DEEPSTOP)
- a low-power LDO(LPREG):
 - stays enabled during both active and low-power phases
 - provides a 1.0 V voltage
 - is not connected to the digital domain when the device is active
 - is connected to the VDD12o domain during low-power mode (DEEPSTOP)
- a dedicated LDO (RFLDO) to provide a 1.2 V to the analog RF block

An embedded SMPS step-down converter is available (inserted between the external power and the LDOs).

[Figure 4. Power supply domain overview](#) shows an overview of the different regulators and connections between the power supply domains.

Figure 4. Power supply domain overview

5.3 Power voltage supervisor

The BlueNRG-LP devices embed several power voltage monitoring:

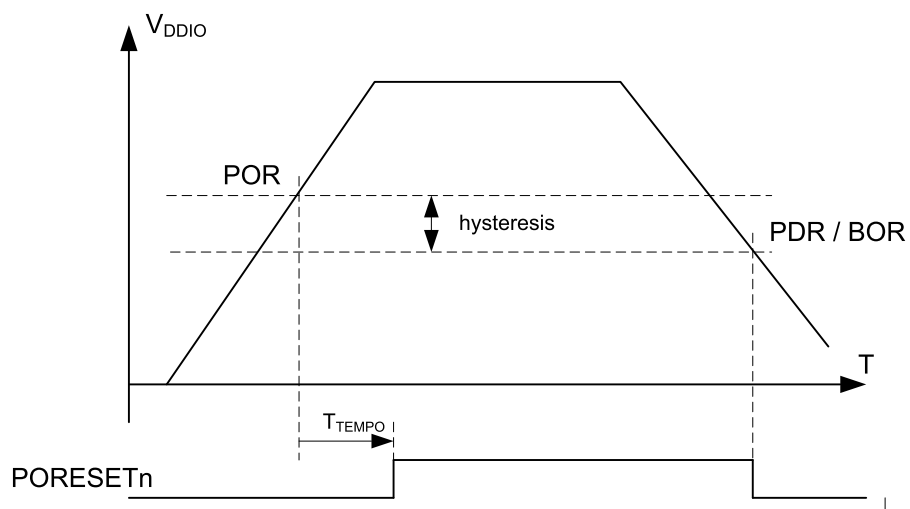

- Power-on reset (POR) / power-down reset (PDR) / Brown-Out Reset (BOR)
- Power voltage detector (PVD)

5.3.1 Power-on reset POR / power-down reset (PDR) / Brown-Out Reset (BOR)

The device has an integrated power-on reset / power-down reset, coupled with a Brown-Out Reset circuitry.

During the power-on, the device remains in reset mode as long as V_{DDIO} is below a V_{POR} threshold (typically 1.65 V).

During power-down, the PDR puts the device under reset when the supply voltage (VDD) drops below the V_{PDR} threshold (around 20 mV below V_{POR}). The PDR feature is always enabled.

Figure 5. Power-on reset/power-down reset waveform

With typical values as follows:

- V_{POR} : 1.65 V

- Hysteresis: 20 mV (so V_{PDR} : 1.63 V)
- T_{TEMPO} : 250 μ s

The Brown-Out Reset (BOR) generates a device reset when the power supply (VDD) drops under V_{PDR} .

This feature is always active except during SHUTDOWN mode where the software can decide to enable it or not (through `PWRC_CR1.ENSDBOR` bit).

5.3.2 Power voltage detection (PVD)

The PVD can be used to monitor:

- the VDDIO:
 - VDDIO is compared to a programmed threshold (between 2.05 V and 2.91 V)
 - The threshold programming is done through `PWRC_CR2.PVDLS[2:0]` bit field
- an external analog input signal:
 - an external analog signal is compared to an internal VBG (at 1.2 V) voltage
 - the feature is selected through `PWRC_CR2.PVDLS[2:0]` bit field

The PVD can be enabled or disabled through the `PWRC_CR2.PVDE` bit.

When the feature is enabled and the PVD measures a voltage below the comparator, a status flag is raised in the SYSCFG block that can generate an interrupt to the CPU if unmasked (see [Section 8.2.10 Power controller interrupt status and clear register \(PWRC_ISR\)](#)).

5.4 Operating modes

The BlueNRG-LP supports 3 main operating modes:

- RUN mode
- DEEPSLEEP mode
- SHUTDOWN mode

The transition from one mode to another is managed through a PMU state machine.

5.4.1 RUN mode

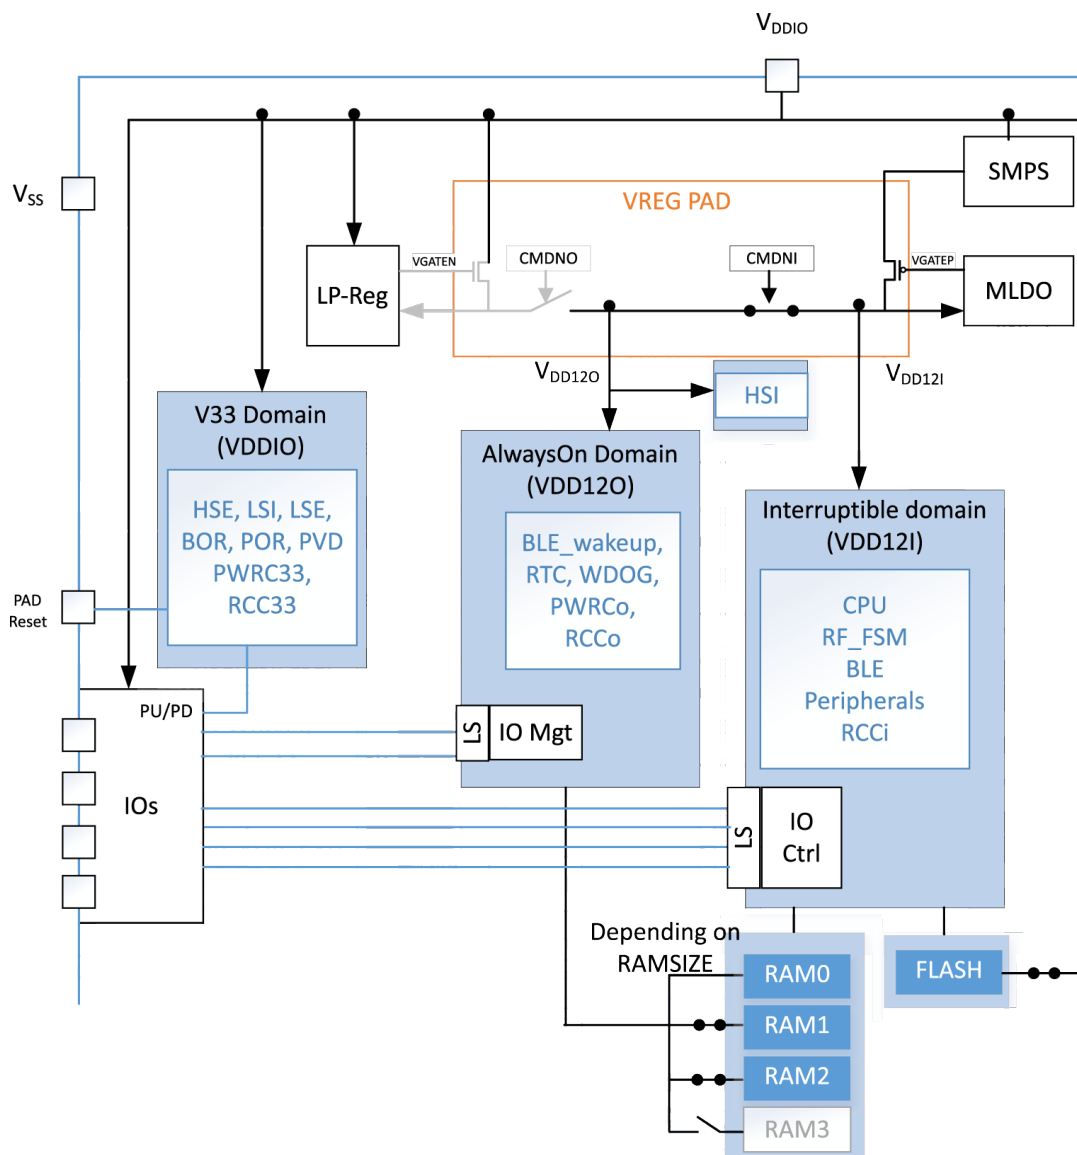

In RUN mode:

- both regulators (MLDO and LPREG) are enabled
- MLDO provides the power supply for both VDD12i and VDD12o
- System clock and bus clock are running
- the CPU and the radio can be used

The power consumption may be reduced by gating the clock of the unused peripherals through the RCC clock enable registers (see [Section 6.7 RCC register map](#)).

[Figure 6. Power regulators and SMPS configuration in RUN mode](#) shows the regulators and SMPS configuration in RUN mode with a product with only 48 kB of RAM.

Figure 6. Power regulators and SMPS configuration in RUN mode

5.4.2 DEEPSTOP mode

The DEEPSTOP is the only low-power mode of the BlueNRG-LP in order to restart from a saved context environment and go on running the application at wakeup.

The conditions to enter DEEPSTOP mode are:

- Radio (MR_BLE) is sleeping
- CPU is sleeping (WFI with SLEEPDEEP information active)
- No unmasked wake-up sources are active (including those from a previous wake-up sequence for which the software did not clear the associated flag after wakeup)
- System is clocked on RC64MPLL (HSI or pll locked mode)
- PWRC_CR1.LPMS bit is equal to 0

Note:

If the MR_BLE is not used at all by the SoC (or not yet started), the following steps need to be done after any reset to allow low-power modes (DEEPSTOP and SHUTDOWN):

- *Enable the MR_BLE clock by setting the RCC_APB2ENR.MRBLEEN bit*
- *Set the BLUE_SLEEP_REQUEST_MODE.FORCE_SLEEPING bit inside the wake-up block of the MR_BLE to have the MR_BLE IP requesting low-power mode to the SoC*
- *Gate again the MR_BLE clock by clearing the RCC_APB2ENR.MRBLEEN bit*

In DEEPSTOP mode:

- the system and bus clocks are stopped as the RC64MPLL block is OFF
- the VDD12i power domain is switched off
- the VDDI2o power domain is ON and supplied at 1.0 V
- the RAM0 bank is kept in retention
- if PWRC_CR1.APC = 1, the I/Os pull-up/down are controlled by the PWRC_PUCRx/PWRC_PDCRx during DEEPSTOP mode
- the other RAM banks are in retention or not, depending on software choice in PWRC_CR2 register
- the slow clock can be running or stopped, depending on the software configuration present before DEEPSTOP entry:
 - ON or OFF
 - LSE or LSI source
- RTC and the IWDG stay active (if enabled and one slow clock source is ON)
- MR_BLE wake-up block including its timer stay active (if enabled and one slow clock source is ON)
- eight I/Os (PA4/PA5/PA6/PA7/PA8/PA9/PA10/PA11) are able to be in output driving either a static low or high level, the slow clock information or the RTC_OUT (see [Section 5.6.15 I/O DEEPSTOP drive configuration register \(PWRC_IoCFG\)](#) for details).

A version of DEEPSTOP mode called DEEPSTOP2 has been implemented to emulate DEEPSTOP mode without losing the debugger connection and breakpoints or watchpoints.

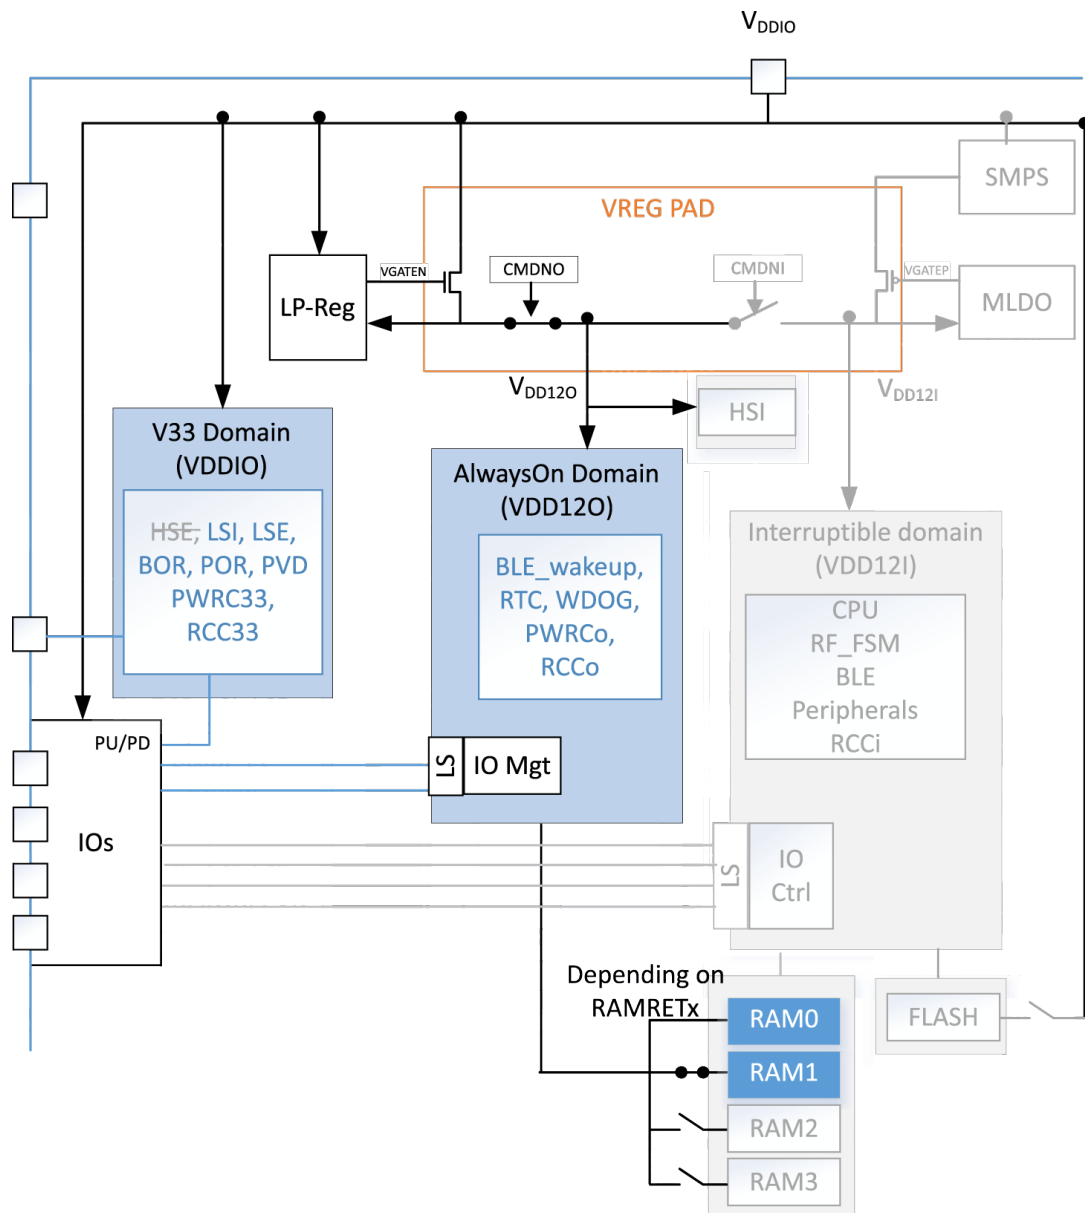

- This variant can be selected by setting the PWRC_DBGR.DEEPSTOP2 bit
- In this case, the DEEPSTOP mode sequence (entry and exit) is done without shutting down the VDD12i power domain

Possible wake-up sources:

- the MR_BLE block is able to generate two events to wake up the system through its embedded wake-up timer running on slow clock:
 - BLE IP wake-up time is reached
- the RTC is able to generate a wake-up event
- the IWDG is able to generate a reset event
- up to 28 GPIOs are able to wake up the system (PA0 to PA15 and PB0 to PB11)

At wakeup, the hardware resources located in the VDD12i power domain are reset, the CPU reboots. The wake-up reason is visible in a PWRC register (see [Section 5.6.5 Status register 1 \(PWRC_SR1\)](#) for details).

[Figure 7. Power regulators and SMPS configuration in DEEPSTOP mode](#) shows the regulators and SMPS configuration in DEEPSTOP mode, with a configuration requesting retention only on RAM0 and RAM1 banks.

Figure 7. Power regulators and SMPS configuration in DEEPSTOP mode

5.4.3 SHUTDOWN mode

SHUTDOWN mode is the least power consuming mode.

The conditions to enter SHUTDOWN mode are the same conditions needed to enter DEEPSTOP mode except that the PWRC_CR1.LPMS bit must be equal to 1 and the PWRC_DBGR.DEEPSTOP2 bit must be kept reset.

In SHUTDOWN mode:

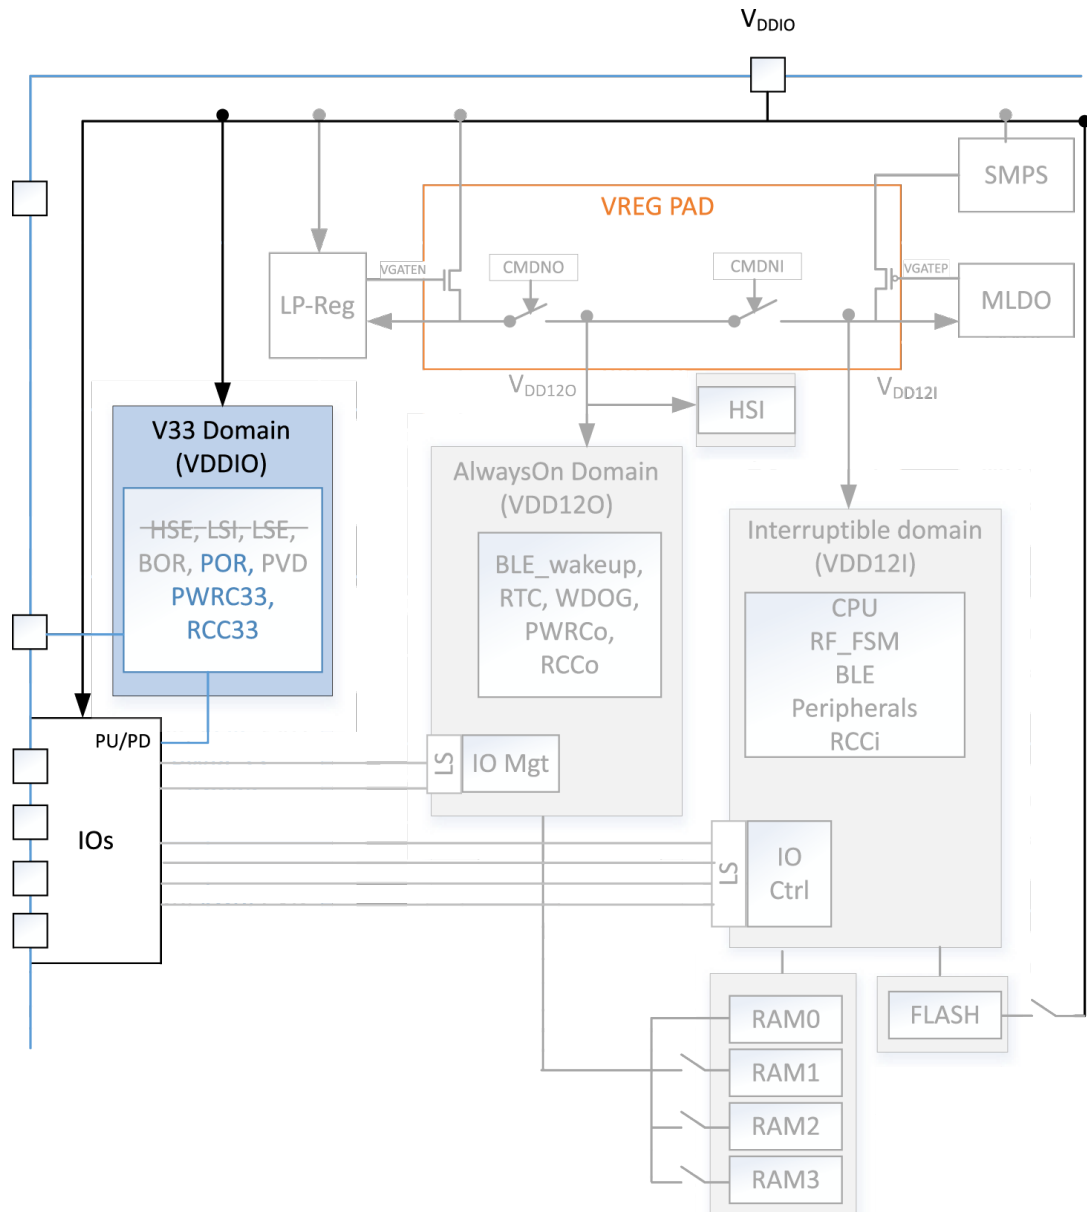

- The system is powered down as both regulators are OFF (so both VDD12i and VDD12o power domains are OFF)
- only the VDDIO power domain is ON
- All clocks are OFF (system and slow clock tree) as RC64MPLL, LSI and LSE are OFF,
- if PWRC_CR1.APC = 1, the I/Os pull-up/down are controlled by the PWRC_PUCRx/PWRC_PDCRx during SHUTDOWN mode
- the only wake-up source is a low pulse on the RSTN pad

A SHUTDOWN exit is similar to a POR startup of the board. The associated reset reason is the PORSTF flag (see Section 6.6.14 V33 reset status register (RCC_CSR) for reset reason flag detail).

The BOR feature may be enabled or disabled during SHUTDOWN through the PWRC_CR1.ENSDBOR bit.

Figure 8. Power regulators and SMPS configuration in SHUTDOWN mode shows the regulators and SMPS configuration in SHUTDOWN mode, configured with the BOR reset disabled.

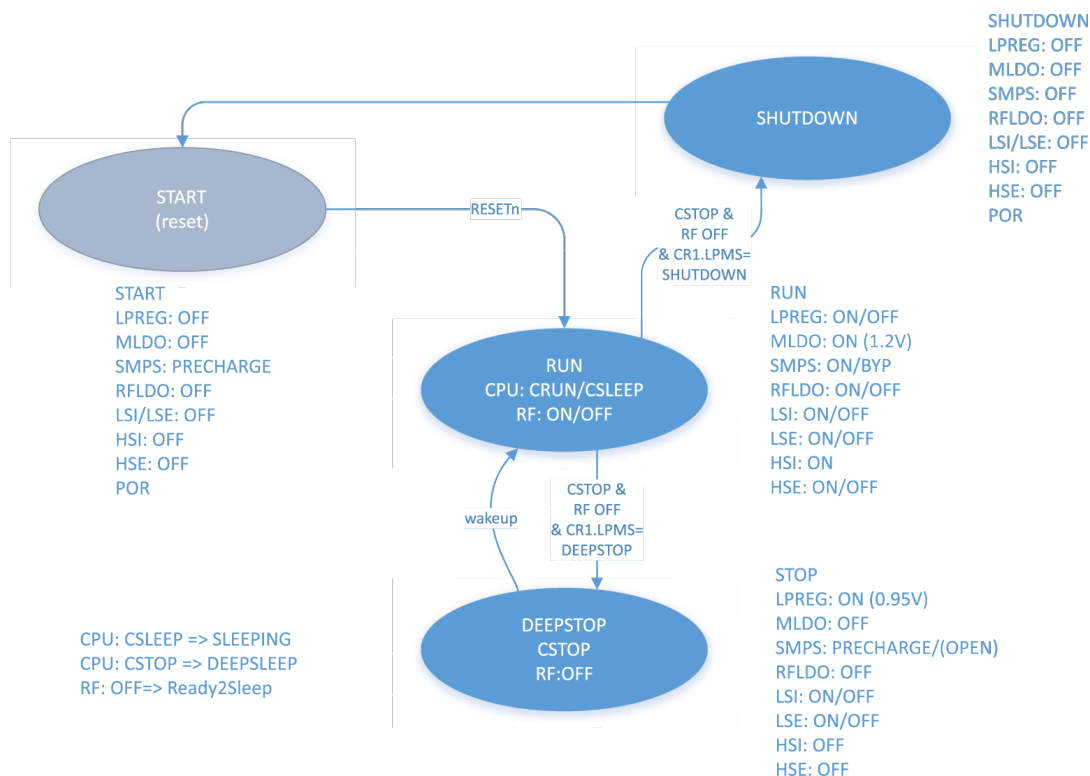

Figure 8. Power regulators and SMPS configuration in SHUTDOWN mode

5.4.4 Operating mode transition management

The PWRC block manages the switches from an operating mode to another through a state machine.

Figure 9. PWRC state machine for operating modes transition

5.5 SMPS step-down regulator

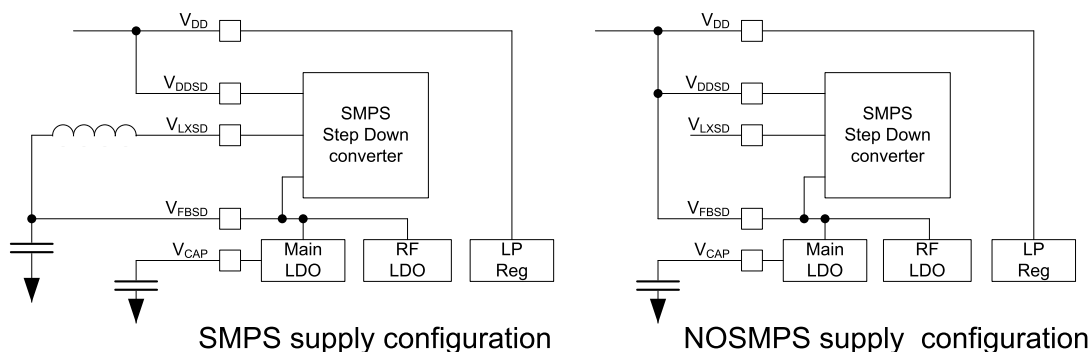

The BlueNRG-LP SMPS is a 20 mA output step-down SMPS (switch mode power supply) converter.

The SMPS output voltage can be programmed from 1.2 V to 1.90 V. It is internally clocked at 4 MHz or 8 MHz.

The SMPS can be in different configurations:

- **ON:**
 - the VFBS pin of the SMPS outputs a regulated voltage (from 1.2 V to 1.9 V)
 - the SMPS needs a clock
- **OFF:**
 - the VFBS pin has to be forced externally with VDDIO
 - the SMPS does not need a clock
- **PRECHARGE (aka BYPASS):**
 - the VFBS pin outputs the VDDIO without regulation
 - the SMPS does not need a clock
- **OPEN:**
 - the VFBS pin is floating
 - the SMPS does not need a clock

Except for the configuration SMPS OFF, an L/C BOM must be present on the board and connected to the VFBS pad (see [Figure 10. Power supply configuration](#)).

Figure 10. Power supply configuration

The user must configure the PWRC_CR5.SMPSBOMSEL[1:0] according to the BOM implemented on their board. The value to program is indicated in [Table 9. SMPS BOM information](#).

Table 9. SMPS BOM information

BOM	Inductance (L)	Output capacitance (C)	SMPS BOMSEL[1:0]
BOM1	1.5 uH	2.2 uF	00
BOM2	2.2 uH	4.7 uF	01
BOM3	10 uH	4.7 uF	10

The SMPS is managed by the PWRC through a state machine shown in [Figure 11. PWRC SMPS state machine overview](#).

Figure 11. PWRC SMPS state machine overview

After a power-on reset sequence, the SMPS FSM always goes up to RUN state. From there, the SMPS FSM can stay in three states (others are transition states):

- **RUN:**
 - the SMPS is ON in a RUN mode
 - the SMPS clock is running
 - the VFBS is regulated and voltage amplitude is the one programmed in the PWRC_CR5.SMPSLV bit field
 - the L/C BOM is present on the board and is connected on the VFBS pad of the BlueNRG-LP (see [Figure 10. Power supply configuration](#))
- **NO SMPS** (if the software configures PWRC_CR5.NOSMPS=1):
 - the SMPS is OFF
 - the SMPS clock is stopped
 - the VFBS is directly connected to the VDDIO through the VFBS pad of the BlueNRG-LP (see [Figure 10. Power supply configuration](#))
 - the PWRC does not control any specific sequencing on the SMPS during low-power entry/exit phases
- **PRECHARGE aka BYPASS** (if the software configures PWRC_CR5.SMPSFBYP=1):
 - the SMPS is ON in a precharge mode
 - the SMPS clock is stopped
 - the VFBS is the VDDIO voltage crossing the SMPS block
 - the PWRC does not control any specific sequencing on the SMPS during low-power entry/exit phases
 - this mode is compliant with an L/C BOM connected on the VFBS pad of the BlueNRG-LP

When the device enters DEEPSTOP mode, the PWRC automatically switches the SMPS from RUN to STOP mode which can be:

- if PWRC_CR5.SMPSLPOPEN = 0: SMPS output is the VDDIO (as in PRECHARGE FSM state)
- if PWRC_CR5.SMPSLPOPEN = 1: the SMPS output is floating

5.6 PWRC register description

All PWRC APB registers are only 16-bit registers. The 16 MSB bits are always stuck to 0.

5.6.1 Control register 1 (PWRC_CR1)

This register controls the BOR in SHUTDOWN, the low-power mode selection and the IO control owner.

Address offset: 0x00

Reset value: 0x0000 0010

r	r	r	r	r		r	r						r	r	r

Bits 31:16	Reserved, must be kept at reset value.
Bits 15:12	IOBOOTVAL : I/Os value latched at POR. <ul style="list-style-type: none"> bit 3: PA11 input value latched at POR, bit 2: PA10 input value latched at POR, bit 1: PA9 input value latched at POR, bit 0: PA8 input value latched at POR. <p>Note: This information may be used by the boot loader to manage boot on serial interfaces for instance.</p>
Bit 11	PVDO : Power voltage Detector Output. When the Power voltage Detector is enabled (PWRC_CR2.PVDE=1), this bit indicates when the VDDIO is lower than the selected threshold (through PWRC_CR2.PVDLS bit field). <ul style="list-style-type: none"> 0: The VDDIO is not lower than threshold or PVD feature is not enabled 1: The VDDIO is lower than the selected threshold
Bit 10	Reserved, must be kept at reset value.
Bit 9	REGMS : Main regulator ready status. <ul style="list-style-type: none"> 0: The main regulator is not ready 1: The main regulator is ready
Bit 8	REGLPS : Low-power regulator ready status. <ul style="list-style-type: none"> 0: The low-power regulator is not ready 1: The low-power regulator is ready
Bits 7:3	Reserved, must be kept at reset value.
Bit 2	SMPSRDY : SMPS ready status. <ul style="list-style-type: none"> 0: SMPS regulator is not ready 1: SMPS regulator is ready
Bit 1	SMPSENR : SMPS RUN mode status. This bit mirrors the internal ENABLE_3V3 control signal connected to the SMPS and driven by the hardware. <ul style="list-style-type: none"> 0: SMPS regulator is not regulating (in PRECHARGE or NOSMPS mode) 1: SMPS regulator is in RUN mode
Bit 0	SMPSBYPR : SMPS PRECHARGE mode status. This bit mirrors the PRECHARGE control state of the SMPS. <ul style="list-style-type: none"> 0: SMPS regulator is not in PRECHARGE mode 1: SMPS regulator is in PRECHARGE mode (VSMPS connected to VDDIO)

5.6.7 Control register 5 (PWRC_CR5)

This register is used to configure the SMPS.

Address offset: 0x1C

Reset value: 0x0000 0014

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	CLKDETR_DISABLE	SMPS_ENA_DCM	NOSMPS	SMPSFBYP	SMPSLPOPEN	Res.	Res.	SMPSBOMSEL[1:0]		SMPSLV[3:0]			
			rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:13	Reserved, must be kept at reset value.
Bit 12	CLKDETR_DISABLE : Disables the SMPS clock detection. The SMPS clock detection enables an automatic SMPS bypass switching in case of unexpected loss of the SMPS clock. <ul style="list-style-type: none"> 0: SMPS clock detection mechanism enabled (default) 1: SMPS clock detection mechanism disabled
Bit 11	SMPS_ENA_DCM : Discontinuous conduction mode enable. <ul style="list-style-type: none"> 0: SMPS DCM is disabled (default) 1: SMPS DCM is enabled
Bit 10	NOSMPS : No SMPS mode. <ul style="list-style-type: none"> 0: SMPS is enabled (default) 1: SMPS is disabled <i>Note: This configuration (SMPS disabled) should be used only when the SMPS_FB pad is directly connected to the VBATT (external voltage), without L/C BOM.</i>
Bit 9	SMPSFBYP : Forces the SMPS in PRECHARGE mode. <ul style="list-style-type: none"> 0: No effect (default) 1: SMPS is disabled and bypassed <i>Note: When this bit is set, the VSMPS output is connected to the VDDIO. The actual state of the SMPS is visible in the SMPS mode status bits in PWRC_SR2 register.</i>
Bit 8	SMPSLPOPEN : Select OPEN mode instead of PRECHARGE mode for the SMPS during DEEPSTOP. <ul style="list-style-type: none"> 0: In DEEPSTOP, the SMPS is in PRECHARGE mode with output connected to VDDIO (default) 1: In DEEPSTOP, the SMPS is disabled with floating output
Bits 7:6	Reserved, must be kept at reset value.
Bits 5:4	SMPSBOMSEL[1:0] : Select the SMPS BOM. <ul style="list-style-type: none"> 00: BOM1 01: BOM2(default) 10: BOM3 11: Not applicable <i>Note: BOM correspondence/details is available in Table 9. SMPS BOM information.</i>

Bits 3:0	SMPSLVL[3:0]: Select the SMPS output voltage level. This bit field selects the SMPS voltage output level with a granularity of 50 mV. The SMPS output voltage level, VSMPS, must be configured such that $V_{BAT} - V_{SMPS} \geq 0.2 \text{ V}$. [e.g. For $V_{BAT}=2 \text{ V}$, VSMPS must be no higher than 1.8 V] <ul style="list-style-type: none"> • -0000: 1.2 V • -0001: 1.25 V • -0010: 1.3 V • -0011: 1.35 V • -0100: 1.4 V • -0101: 1.45 V • -0110: 1.5 V • -0111: 1.55 V • -1000: 1.6 V • -1001: 1.65 V • -1010: 1.7 V • -1011: 1.75 V • -1100: 1.8 V • -1101: 1.85 V • -1110: 1.9 V • -1111: 1.9 V
	Warning: The SMPS output voltage must not be changed by more than one step while the SMPS is in use. The sequence to reprogram a new SMPS output voltage is described in Section 5.8.2 SMPS output level re-programming .

5.6.8 I/O port A pull-up control register (PWRC_PUCRA)

This register is used to control the pull-up for the PA0 to PA15 I/O when the PWRC_CR1.APC bit is set.

Caution: If both pull-up and pull-down are enabled in the PWRC_PUCRA and PWRC_PDCRA registers for an I/O, then pull-down is applied.

The user must take care to disable the pull-on I/O programmed in analog mode.

Address offset: 0x20

5.6.10 I/O port B pull-up control register (PWRC_PUCRB)

This register is used to control the pull-up for the PB0 to PB15 I/O when the PWRC_CR1.APC bit is set.

Caution: If both pull-up and pull-down are enabled in the PWRC_PUCRA and PWRC_PDCRA registers for an I/O, then pull-down is applied.

The user must take care to disable the pull-on I/O programmed in analog mode.

5.6.15 I/O DEEPSTOP drive configuration register (PWRC_IOxCFG)

This register is used to configure the behavior for the eight I/Os able to output a signal during DEEPSTOP mode (PA4/PA5/PA6/PA7/PA8/PA9/PA10/PA11).

Note: The configuration defined in PWRC_IOxCFG register overloads the configuration programmed in the GPIO block through GPIOx_MODER and GPIOx_ODR when different from BYPASS mode.

Address offset: 0x40

Reset value: 0x0000 0000

Bits 8:0	Reserved, must be kept at reset value.

5.7 PWRC register map

Refer to [Table 3. BlueNRG-LP memory map and peripheral register boundary addresses](#) for the PWRC base address location in the BlueNRG-LP.

Note: All the PWRC registers are retained during DEEPSTOP mode. The salmon cells indicates the bit fields located in the VDD33 power domain. This implies the associated feature is applied even during SHUTDOWN state (but are lost at SHUTDOWN mode exit as a PORESETn is generated).

Table 10. PWRC register map

5.8 Programmer model

5.8.1 Reset reason management

CPU has many reasons to be reset and executes its reset handler. The table below provides an overview of the flags that can help the embedded software to get the root cause of the CPU reset.

Table 11. Flags versus CPU reboot reason

	RCC_CSR					PWRC_ISCR (in SYSCFG)	PWRC_EXT SRR
	LOCKUPRSTF	WDGRSTF	SFTRSTF	PORRSTF	PADRSTF	WAKEUP_ISC	DEEPSTOPF
POR/BOR reset				1	1		
NRSTn pad reset					1		
Watchdog reset		1			1		
System reset (CPU request)			1		1		
LOCKUP reset	1				1		
DEEPSTOP exit on wake-up event						1	1
DEEPSTOP exit on watchdog reset		1			1		
DEEPSTOP exit on NRSTn pad reset					1		
DEEPSTOP exit on POR/BOR				1	1		
SHUTDOWN exit				1	1		

If the reboot reason is a wakeup from DEEPSTOP, then the wake-up source(s) can be read in the PWRC_SR1 register as shown in [Table 12. Wake-up reason flags](#).

Table 12. Wake-up reason flags

	PWRC_SR1			
	IWUF	WBLEHCPUF	WBLEF	WUFx (x=8..11)
Wakeup on BLE event			1	
Wakeup on Host timer in MR_BLE event		1		
Wakeup on RTC event	1			
Wakeup on I/Os (PA0..PA15, PB0..PB11)				1

Note: *If several (enabled) wake-up events occur, several bits are high in the PWRC_SR1. The wake-up flags are set as soon as a wake-up event (enabled in PWRC_CR3 register) occurs, the associated flag is set in the PWRC_SR1 register even if the device is in active mode or in the sleep exit sequence (initiated by another wake-up source).*

Caution: *Those flags have to be cleared by software knowing a DEEPSTOP entry sequence cannot happen if a wake-up flag is already active when the system requests a DEEPSTOP mode.*

5.8.2 SMPS output level re-programming

The SMPS output voltage cannot be modified on-the-fly when the SMPS is in use for more than one step. When the software needs to re-program the SMPS output voltage to another value, the following sequence must be respected:

- Set PWRC_CR5.SMPSBYP =1
- Wait for PWRC_SR2.SMPSRDY =0
- Program the new targeted value in PWRC_CR5.SMPSLVL[3:0]
- Clear PWRC_CR5.SMPSBYP =0
- Wait for PWRC_SR2.SMPSRDY =1

Caution: This sequence must be launched when no radio activity only / Bluetooth transfer is on-going.

6.1.2 Power reset

The PORESETn signal is active when the power supply of the device is below a threshold value or when the regulator does not provide the target voltage. The PORESETn resets all the resources of the device.

6.1.3 Watchdog reset

The BlueNRG-LP device embeds a watchdog timer which may be used to recover from software crashes. See [Section 18 Independent watchdog \(IWDG\)](#) for details about watchdog usage and programming.

6.1.4 LOCKUP reset

The Cortex-M0+ generates a LOCKUP to indicate the core is in the lock-up state resulting from an unrecoverable exception. The LOCKUP reset is masked if a debugger is connected to the Cortex-M0+. The user can use the SWD to reset or recover the code in this case.

6.1.5 System reset request

The system reset request is generated by the debug circuitry of the Cortex-M0+. The debugger sets the SYSRESETREQ bit of the application interrupt and reset control register (AIRCR). This system reset request through the AIRCR can also be done by the embedded software (in hard fault handler for instance). For more details on the Cortex-M0+ system control and ID registers, refer to section B3.2.2 of the "ARMv6-M Architecture" reference manual.

6.1.6 DEEPSTOP exit

The low-power DEEPSTOP state leads to switching off a part of the 1.2 V (power domain called V12i), while keeping the rest of the 1.2 V at 1 V (power domain called V12o) and the 3.3 V (VDDIO).

When the device exits the DEEPSTOP mode, only the V12i power domain is reset as it is the only power domain that lost the power supply.

6.2 Clocks management

Three different clock sources may be used to drive the system clock (CLK_SYS) in the BlueNRG-LP:

- HSI: high speed internal 64 MHz RC oscillator (provided by the RC64MPLL analog block),
- PLL64M: 64 MHz PLL clock (provided by the RC64MPLL analog block),
- HSE (high speed external):
 - high speed 32 MHz external crystal
 - or provided by a single-ended 32 MHz input instead of a crystal.

The BlueNRG-LP device has also a slow frequency clock tree used by some timers (RTC, watchdog and MR_BLE radio timer). Four different clock sources can be used for this slow clock tree:

- LSI: low speed low drift internal RC with a fixed frequency between 24 kHz and 49 kHz depending on the sample. It is called 32 kHz clock inside this document to simplify.
- LSE:
 - 32.768 kHz low speed external crystal.
 - or provided by a single-ended 32.768 kHz input instead of a crystal.
- The system clock divided by 2048. In this case, the slow clock is available in DEEPSTOP low-power mode.
- LSI_LPMU: 32 kHz clock used by the LPMU analog block.

6.2.1 System clock details

The HSI and the PLL64M clocks are provided by the same analog block called RC64MPLL. The 64 MHz clock output by this block can be:

- a non accurate clock (target is 1% typical) when no external XO provides an input clock to this block
- an accurate clock when the external XO provides the 32 MHz and once its internal PLL is locked

Note: *The usage of PLL64M or HSE as clock source is mandatory for Bluetooth radio operations (need of a high accuracy on the clock).*

The software process to switch the system on the accurate clock is indicated in [Section 6.8 Programmer model](#). This fast clock source is used to generate all the fast clock of the device through dividers.

After reset, the CLK_SYS is divided by four to provide a 16 MHz to the whole system (CPU, DMA, memories and peripherals).

Then the software can program another system clock frequency in the following list:

- 1 MHz (forbidden when radio or ADC is in use)
- 2 MHz (forbidden when radio or ADC is in use)
- 4 MHz (forbidden when radio or ADC is in use)
- 8 MHz (forbidden when radio is in use)
- 16 MHz
- 32 MHz
- 64 MHz (forbidden when I²S is in use)

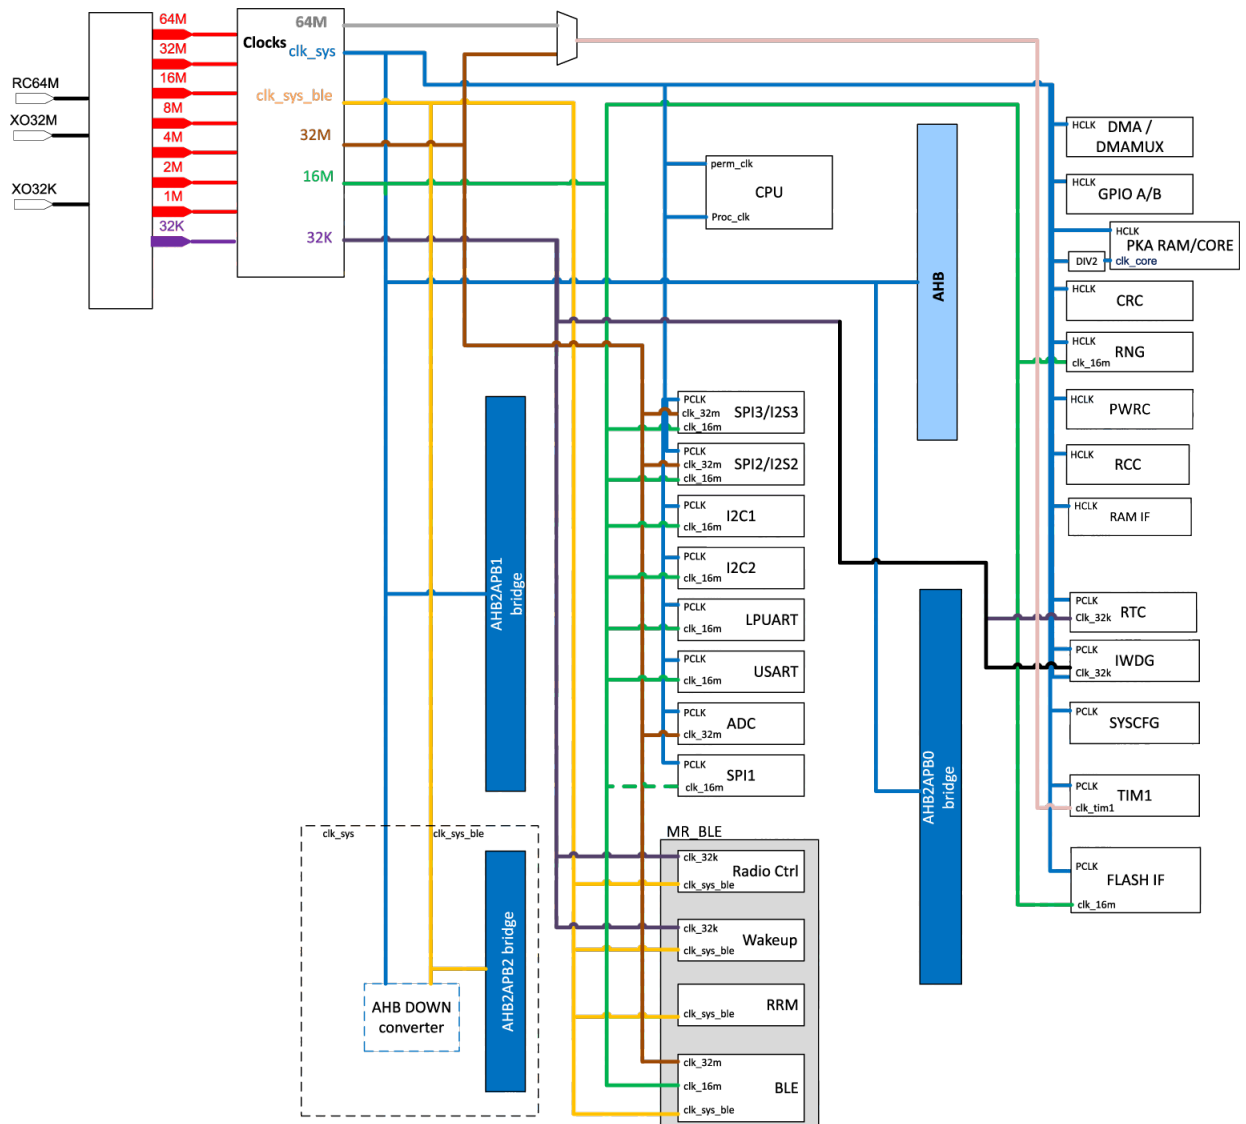

Note: *Forbidden configuration means that the “in use” feature cannot work if the system clock runs at this frequency. Special care must be taken when programming the CLK_SYS as some constraints need to be respected: CLK_SYS frequency must be greater or equal to CLK_SYS_BLE.*

6.2.2 Peripherals clock details

This fast clock source is also used to generate several internal fast clocks in the system:

- A TIM1 kernel clock that is the maximum reachable frequency of the system (64 Mhz in RC64MPLL configuration and 32 MHz in HSE).
- An always 32 MHz requested by few peripherals such as: the MR_BLE radio IP for instance
- An always 16 MHz requested by few peripherals like serial interfaces (to maintain fixed baud rate while system clock is switching from one frequency to another) or like Flash controller and MR_BLE radio IP (to have a fixed reference clock to manage delays).

Figure 13. [Peripheral clock tree overview](#) shows an overview of the peripheral clock tree.

Figure 13. Peripheral clock tree overview

Most of the peripherals use the system clock only (CLK_SYS) except:

- I2C, USART, LPUART:
 - In parallel with the system clock, they use an always 16 MHz clock to have a fixed reference clock for baud rate management. The goal is to allow the CPU to boost or slow down the system clock (depending on on-going activities) without impacting a potential on-going serial interface transfer on external I/Os.
- SPI:
 - When using the I²S mode, the baud rate is managed through the always 16 MHz or always 32 MHz clock

Note: The CPU/system clock frequency must be equal or slower than the I²S clock frequency.

- When running in other modes than the I2S, the baud rate is managed by the system clock. This implies the baud rate is impacted by dynamic system clock frequency changes.
- **RNG:**
 - In parallel with the system clock, the RNG uses an always 16 MHz clock to generate at a constant frequency the random number whatever the system clock frequency.
- **Flash controller:**
 - In parallel with the system clock, the Flash controller uses an always 16 MHz clock to generate specific delays required by the Flash memory during programming and erase operation for instance
- **PKA:**
 - In parallel with the system clock, the PKA uses a clock at half of the system clock frequency as PKA RAM is a single port RAM
- **MR_BLE IP**
 - MR_BLE IP does not use directly the system clock for its APB / AHB interfaces but the system clock with a potential divider (1 or 2 or 4). [Table 13. CPU versus MR_BLE clock dependency](#)
 - In parallel with the CLK_SYS_BLE, the MR_BLE uses an always 16 MHz and an always 32 MHz for modulator, demodulator and to have a fixed reference clock to manage specific delays

Table 13. CPU versus MR_BLE clock dependency

CLK_SYS	CLK_SYS_BLE
1 MHz / 2 MHz / 4 MHz / 8 MHz	Not possible to use MR_BLE IP
16 MHz	16 MHz (CLKBLEDIV = 4)
32 MHz	<ul style="list-style-type: none"> • 16 MHz (CLKBLEDIV = 4) • or 32 MHz (CLKBLEDIV = 2)
64 MHz	<ul style="list-style-type: none"> • 16 MHz (CLKBLEDIV = 4) • or 32 MHz (CLKBLEDIV = 2)

- **ADC**
 - In parallel with the system clock, the ADC uses a 64 MHz prescaled clock (called CLKANA_ADC) running at 16 MHz

Note: When the ADC is used, the system clock must run at minimum 8 Mhz to be able to read the ADC sample before they are overloaded by a new sample.

- This CLKANA_ADC is divided by 2 or 4 to feed the SMPS analog block.

Note: To avoid SNR degradation of the ADC, SMPS and ADC clocks must be synchronous

6.2.3 Slow clock frequency details

As explained at the beginning of the clock management sub-chapter, four different clock sources can be used for this slow clock tree:

- LSI: low speed low drift internal RC with a fixed frequency between 24 kHz and 49 kHz depending on the sample. It is called 32 kHz clock inside this document to simplify.
- LSE: 32.768 kHz low speed external crystal (or single-ended input frequency).

Note: *If the external oscillator is used, the PB12/PB13 I/Os are automatically connected to this feature when RCC_CR.LSEON bit is set (GPIO_MODERX configuration is overloaded).*

Caution: *The user has to disable the pulls on PB12/PB13 by software to have the feature working fine. If the single-ended input option is used, then the PB13 I/O must be configured as digital input mode.*

The system clock divided by 2048. In this case, the slow clock is not available in DEEPSTOP low-power mode.

LSI_LPMU: 32 kHz clock used by the LPMU analog block. Only one source at a time drives the whole low speed clock tree.

Note: *By default after a PORESETn, all low speed sources are OFF. After a PADRESETn, the slow clock configuration is the one programmed before the PADRESETn.*

The slow clock activation and selection are relevant during the DEEPSTOP low-power mode and at wakeup as they clock the timers involved in wake-up events generation.

Note: *If LSI configuration is used, the software must measure the slow clock frequency to know the associated period that is used by the timers. A slow clock measurement feature is available in the MR_BLE IP.*

6.3 System frequency switch while MR_BLE is used

The CPU/system clock frequency can be from 1 MHz to 64 MHz while the MR_BLE clock frequency can be 16 MHz or 32 MHz.

When the radio is used on the device, the system clock frequency selection must respect some rules:

- the system clock frequency must be 16 MHz, 32 MHz or 64 MHz and greater than or equal to the MR_BLE frequency. Other options make the radio not functional.
- changing the frequency of the system must be done through the RCC_CSCMDR register mechanism to avoid any risk of crashing the radio scenarios.

This proper system frequency switch is managed through the collaboration of several blocks:

- the RCC (see [Section 6.6.5 Clock switch command register \(RCC_CSCMDR\)](#))
- the AHBUPCONV and the AHBDOWNCONV blocks (see [Section 3 AHB up/down converter](#))

Using this safe mechanism, the software requests a system clock frequency change and is informed by the hardware when the new frequency is really in place through a status bit (see [Section 6.6.5 Clock switch command register \(RCC_CSCMDR\)](#)) and an associated interrupt line on the CPU (see [Section 2.3.2 Interrupts](#)).

The software sequence is described in [Section 6.8.3 Changing the system clock frequency while the MR_BLE is enabled](#).

6.4 Clock observation on external pad

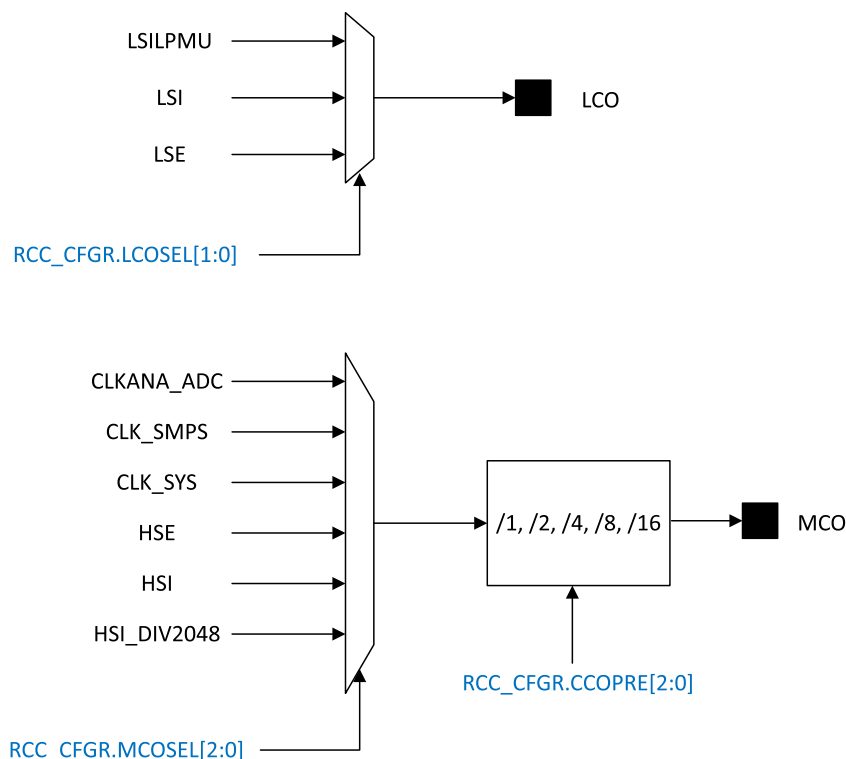

It is possible to output some internal clocks on external pads:

- the low speed clocks can be output on the LCOI/O
- the high speed clocks can be output on the MCOI/O

This is possible by programming the associated I/O in the good alternate function (see [Table 6. GPIO alternate options AF0 - AF2](#)).

The selection of the clock to output for each I/O is programmable through an RCC register (see [Section 6.6.2 Clocks configuration register \(RCC_CFGR\)](#) for more details).

[Figure 14. LCO / MCO output clocks](#) shows the possible configurations to output an internal clock.

Figure 14. LCO / MCO output clocks

6.5 Miscellaneous

6.5.1 IO BOOSTER

Some analog switches are used to select the analog VINM/P pair input signals to be used by the ADC.

An IO BOOSTER block has been added to boost the voltage on the command of those analog switches when the VBAT goes below a threshold (2.7 V) to guarantee the good behavior of those switches. This block has to be enabled by the software when needed through RCC_CFGR.IOBOOSTEN bit.

6.6 RCC register description

Refer to [Table 3. BlueNRG-LP memory map and peripheral register boundary addresses](#) for the RCC base address location in the BlueNRG-LP.

The green cells indicate the register is in the V12o power domain and the salmon cell indicates the register is in the VBAT (aka V33) power domain. This implies those registers are not reset on DEEPSTOP exit.

6.6.1 Clock source control register (RCC_CR)

This register controls the enable on the different clock sources (low and high speed).

Note: *The control bits linked to high speed clock source are reset on PADRESETn. The control bits linked to slow speed clock source are reset on PORESETn only (identified by the table footnote). As this register is in V12o power domain, its content is not modified after a wakeup from DEEPSTOP and system clock is restored with configuration present before DEEPSTOP mode entry.*

Address offset: 0x00

Reset value: 0x0000 1400

Bits 31:18	Reserved, must be kept at reset value.
Bit 17	HSE RDY: External high speed clock flag. This bit is set by hardware to indicate that HSE oscillator (32 MHz XO) is stable. <ul style="list-style-type: none"> 0: HSE oscillator is not ready 1: HSE oscillator is ready
Bit 16	HSEON: External high speed clock enable. The software has to set the bit to start the XO 32 MHz and clear the bit to stop it. <ul style="list-style-type: none"> 0: HSE oscillator is OFF 1: HSE oscillator is ON
Bit 15	Reserved, must be kept at reset value.
Bit 14	HSI PLL RDY: Internal high speed clock PLL flag. This bit is set by hardware to indicate that the RC64MPLL pll is locked. <ul style="list-style-type: none"> 0: RC64MPLL pll is unlocked 1: RC64MPLL pll is locked
Bit 13	HSI PLL ON: Internal high speed clock PLL enable. The software has to set the bit to request an RC64MPLL lock on HSE and clear the bit to stop it. <ul style="list-style-type: none"> 0: RC64MPLL PLL is OFF 1: RC64MPLL PLL is ON
Bit 12	HSE PLL BUFO N: External high speed clock buffer for PLL RF2G4 enable. The software has to set the bit when the radio is used (to have the 2.4 GHz PLL working). <ul style="list-style-type: none"> 0: HSE PLL RF2G4 buffer is OFF 1: HSE PLL RF2G4 buffer is ON

	Warning: This bit must be set when the radio is used. The only reason to clear this bit would be to reduce power consumption for application not using the radio on this device.
Bit 11	Reserved, must be kept at reset value.
Bit 10	HSIRDY: Internal high speed clock flag. This bit is set by hardware to indicate that internal 64 MHz RC is stable. <ul style="list-style-type: none"> 0: Internal 64 MHz RC is not ready 1: Internal 64 MHz RC is ready
Bits 9:7	LOCKDET_NSTOP: Defines a time window target for the counter of the lock detector block in charge to manage the HSIPLLRDY information (PLL indicated as locked if the analog lock signal stays high and stable during this time window). The formula to define the time window target is the following: time window target = (LOCKDET_NSTOP + 1) x 64.
Bit 6 ⁽¹⁾⁽²⁾	LSEBYP: External low speed clock bypass. This bit needs to be set when the slow clock is directly provided through SXTALI pin. <ul style="list-style-type: none"> 0: No LSE oscillator bypass 1: LSE oscillator bypass is enabled
Bit 5 ⁽¹⁾	LSERDY: External low speed clock flag. This bit is set by hardware to indicate that the slow clock has started. <ul style="list-style-type: none"> 0: LSE oscillator is not ready 1: LSE oscillator is ready Note: This status bit is true whatever the chosen configuration (external 32 kHz oscillator == LSEON or external clock provided on SXTALI = LSEBYP).
Bit 4 ⁽¹⁾⁽²⁾	LSEON: External low speed clock enable. The software has to set the bit to start the XO 32 kHz and clear the bit to stop it. <ul style="list-style-type: none"> 0: LSE oscillator is OFF 1: LSE oscillator is ON
Bit 3 ⁽¹⁾	LSIRDY: Internal low speed clock flag. This bit is set by hardware to indicate that internal low speed RC is stable. <ul style="list-style-type: none"> 0: Internal low speed RC is not ready 1: Internal low speed RC is ready
Bit 2 ⁽¹⁾	LSION: Internal low speed RC clock enable. The software has to set the bit to start the internal slow clock RO and clear the bit to stop it. <ul style="list-style-type: none"> 0: LSI RC is OFF 1: LSI RC is ON
Bits 1:0	Reserved, must be kept at reset value.

1. This bit is reset on PORESETn only.

2. The LSEBYP and LSEON bits must not be used at the same time. If the user decides to dynamically change the slow clock source between external XO and clock injection on SXTALI, they have to ensure both LSEON and LSEBYP are low at a time to reset the LSERDY flag.

6.6.2 Clocks configuration register (RCC_CFGR)

Note: The control bits linked to high speed clock source are reset on PADRESETn. The control bits linked to slow speed clock source are reset on PORESETn only (identified by the table footnote).

Bit 0	LSIRDYF : LSI ready flag. <ul style="list-style-type: none"> 0: No LSI ready event occurred 1: LSI ready event occurred. Cleared by writing 1 in this bit

6.6.5 Clock switch command register (RCC_CSCMDR)

This register allows switching the CPU / system clock frequency safely while the MR_BLE is active.

Requesting a frequency clock switch holds the AHB/APB transfers between the MR_BLE and the rest of the system to execute safely the clock switching and release AHB / APB transfers as soon as the new frequency is in place.

A dedicated line of interrupt (instead of the RCC line) is used on the NVIC for the EOFSEQ_IRQ information (see [Table 5. Interrupt vectors](#)).

Note: Anyway, the user must keep the CPU/system frequency at minimum 16 MHz clock when the radio is used.

This register is reset on PADRESETn.

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

													rw	rw	rw

Bits 31:22	Reserved, must be kept at reset value.
Bit 21	<p>CLKBLEDIV: MR_BLE (Bluetooth® Low Energy radio) clock frequency selection when RCC_APB2ENR.MRBLEEN=1.</p> <ul style="list-style-type: none"> 00: Reserved <p>Note: Writing “00” by software is replace by a write “01” in hardware.</p> <ul style="list-style-type: none"> 01: 32 MHz 10: 16 MHz 11: Reserved <p>Warning:</p> <ul style="list-style-type: none"> MR_BLE frequency must always be equal or less than the CPU/system clock to have functional radio. When the ratio between system clock frequency and MR_BLE frequency is modified, the AHBUPCONV block must adapt the clock ratio on APB/AHB bus. Only dynamic CPU system clock switching is managed (see Section 6.6.5 Clock switch command register (RCC_CSCMDR)) . <p>For this reason, using a static MR_BLE clock configuration is strongly recommended.</p>
Bit 0	<p>MRBLEEN: MR_BLE (Bluetooth® Low Energy radio) enable.</p> <ul style="list-style-type: none"> 0: MR_BLE IP is clock gated 1: MR_BLE IP is clocked

6.6.14 V33 reset status register (RCC_CSR)

This register provides the reset reason flags. It is set automatically by hardware on any new reset event and must be cleared by software.

Table 12. Wake-up reason flags provides a summary of active flags versus reset reason.

This register is reset on PORESETn.

Address offset: 0x94

Reset value: 0x0C00 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31	Reserved, must be kept at reset value.
Bit 30	LOCKUPRSTF : CPU lock-up reset flag. Set by the hardware when a CPU lock-up reset occurs. Reset by writing 1 in RMVF bit.
Bit 29	WDGRSTF : Watchdog reset flag. Set by the hardware when a watchdog reset occurs. Reset by writing 1 in RMVF bit.
Bit 28	SFTRSTF : Software reset flag. Set by the hardware when a CPU system reset occurs. Reset by writing 1 in RMVF bit.
Bit 27	PORRSTF : Power-on reset flag. Set by the hardware when a PORESETn or a BOR reset occurs. Reset by writing 1 in RMVF bit.
Bit 26	PADRSTF : NRSTn pad reset flag. Set by the hardware when a reset from external NRSTn pad occurs but also after any reset. This means the source of the reset is the NRSTn pad only if all flags are low except this one. Reset by writing 1 in RMVF bit.
Bits 25:24	Reserved, must be kept at reset value.
Bit 23	RMVF : Remove flag reset. Writing 1 in this bit clears all the reset flags of this register. This bit is auto-cleared by the hardware.
Bits 22:0	Reserved, must be kept at reset value.

6.6.15 RF software high speed external register (RCC_RFSWHSECR)

This register is reset on PADRESETn.

Address offset: 0x98

Reset value: 0x0000 0030

Bits 31:14	Reserved, must be kept at reset value.
Bits 13:8	SWXOTUNE : RF HSE capacitor bank tuning value set by software. This value is taken into account instead of the trimming value loaded by HW at reset if SWXOTUNEEN bit is set.
Bit 7	SWXOTUNEEN : RF HSE software capacitor bank tuning enable. <ul style="list-style-type: none"> 0: Trimming value readable in RCC_RFHSECR.XOTUNE[5:0] bit field is used as trimming value on HSE 1: Trimming value written in RCC_RFSWHSECR.SWXOTUNE[5:0] bit field is used as trimming value on HSE
Bits 6:4	GMC : High speed external IO current control. <ul style="list-style-type: none"> – 000: max. 0.18 mA/V – 001: max. 0.57 mA/V – 010: Max. 0.78 mA/V – 011: Max. 1.13 mA/V – 100: Max. 0.61 mA/V – 101: Max. 1.65 mA/V – 110: Max. 2.12 mA/V – 111: Max. 2.84 mA/V Note: This value is set only by software.
Bit 3	SATRG : Sense amplifier threshold. <ul style="list-style-type: none"> 0: The bias current is confronted to a reference current with a ratio of 1/2 1: The bias current is confronted to a reference current with a ratio of 3/4
Bits 2:0	Reserved, must be kept at reset value.

6.6.16 RF high speed external register (RCC_RFHSECR)

This register is reset on PADRESETn.

Address offset: 0x9C

Reset value: 0x0000 0000 when BlueNRG-LP flash is empty, or else depends on trimmed values flashed in the sample.

Note: The XOTUNE value depends on the choice of the external XO component. For this reason, the RCC_RFSWHSECR.SWXOTUNE bit field is the one to program and select before starting the XO.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	XOTUNE[5:0]					
										r	r	r	r	r	r

Bits 31:6	Reserved, must be kept at reset value.
Bits 5:0	XOTUNE: RF-HSE capacitor bank tuning. This value is loaded by HW at reset as soon as the Flash controller achieves the reading of the information in Flash memory.

6.7

RCC register map

Refer to [Table 3. BlueNRG-LP memory map and peripheral register boundary addresses](#) for the RCC base address location in the BlueNRG-LP.

The green cells indicate the register is in the V12o power domain and the salmon cell indicates the register is in the VBAT (aka V33) power domain. This implies those registers are not reset on DEEPSTOP exit.

6.8 Programmer model

6.8.1 Switch the system on the PLL64M clock tree

To switch the system from the HSI clock source to the PLL64M clock source, the user has to:

1. Enable the HSE (32 MHz external crystal)
2. Wait for the HSE ready flag information (through interrupt or by polling)
3. Request to enable the PLL
4. Wait for the PLL ready flag information (through interrupt or by polling). From this point, the clock source for the whole fast clock tree is the accurate PLL64M source.

Note: A status flag and an associated interrupt are available to inform the software in case of HSIPLL64M unlock event. See `RCC_CIER` and `RCC_CIFR` registers.

6.8.2 Use the direct HSE instead of the RC64MPLL block

If the application does not target to use the 64 MHz system clock frequency, the system can be configured to use directly the 32 MHz provided by the external XO (HSE).

This configuration choice is supposed to be static and to be used when 64 MHz is never used.

In this case, the software has to:

1. Ensure the `RCC_CR.CLKSYSDIV` bit field is programmed with a system frequency less than 64 MHz
2. Enable the external XO (by setting the `RCC_CR.HSEON` if not yet done)
3. Wait for the HSE ready flag information (through interrupt or by polling)
4. Set the `RCC_CFGR.HSESEL` bit to switch the fast clock tree on HSE path. If both clocks (HSI and HSE) are present, the switch should take around 4 clock cycles
5. To save power, the software can stop the RC64MPLL analog block by setting the `RCC_CFGR.STOPHSI` bit.

Note: A hardware mechanism is in place to restart the RC64MPLL and switch back the clock tree on it if the `HSERDY` is low or if the `CLKSYSDIV` bit field has been programmed to request 64 MHz.

Caution: The HSE configuration is not lost on a DEEPSTOP sequence. So at wakeup, the system restarts the HSE (thanks to `HEON` bit). However, the SW has to switch the system clock back to HSI or PLL64M path to be able to enter in DEEPSTOP/SHUTDOWN, so at wakeup:

- the clock tree runs on RC64MPLL block (HSI or PLL64M)
- the SW has to reprogram the HSE mode. However, it is important to avoid the switch of clock tree between HSI and HSE while the `MR_BLE` already triggered a wake-up event and started its sequence. The SW has to anticipate the CPU wakeup to ensure the final clock source is restored before the radio starts any activity.

6.8.3 Changing the system clock frequency while the MR_BLE is enabled

As long as the `MR_BLE` is enabled (by setting the `RCC_APB2ENR.MRBLEEN`), the application software has no guarantee the radio is running or about to start a sequence that makes the `MR_BLE` IP perform an AHB access to the RAM. Changing the system clock and by this action changing the ratio between `MR_BLE` clock domain and system clock domain could create a crash if not managed carefully.

For this reason, a hardware mechanism has been put in place and must be used to change the system frequency when `MR_BLE` is ON.

The sequence to execute to change the system clock is the following:

1. Ensure the targeted frequency is greater than or equal to the `MR_BLE` frequency (visible in `RCC_APB2ENR.CLKBLEDIV[1:0]`)
2. Program the wanted frequency in the `RCC_CSCMDR.CLKSYDIV` bit field and set the `RCC_CSCMDR.REQUEST` bit
3. Wait for the `RCC_CSCMDR.EOFSEQ_IRQ` flag information (through interrupt or by polling)
4. When the flag (and the interrupt if enabled) is set, the system is running on the new frequency
5. The `RCC_CFGR.CLKSYSDIV[1:0]` bit field has been updated by hardware to the new frequency value.

Note: If the software requested a frequency below 16 MHz, the current final frequency is 16 MHz (associated value is readable in the `RCC_CFGR.CLKSYSDIV[1:0]`). If the software requested a frequency at 16 MHz while the `MR_BLE` is clocked at 32 MHz, the wanted frequency is used but the radio scenario is no longer functional.

7 General-purpose I/Os (GPIO)

7.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR) and a 32-bit set/reset register (GPIOx_BSRR). In addition all GPIOs have a 32-bit locking register (GPIOx_LCKR) and two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

7.2 GPIO main features

- Output states: push-pull or open drain +pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_BSRR) for bitwise write access to GPIOx_ODR
- Locking mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every clock cycle
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

7.3 GPIO functional description

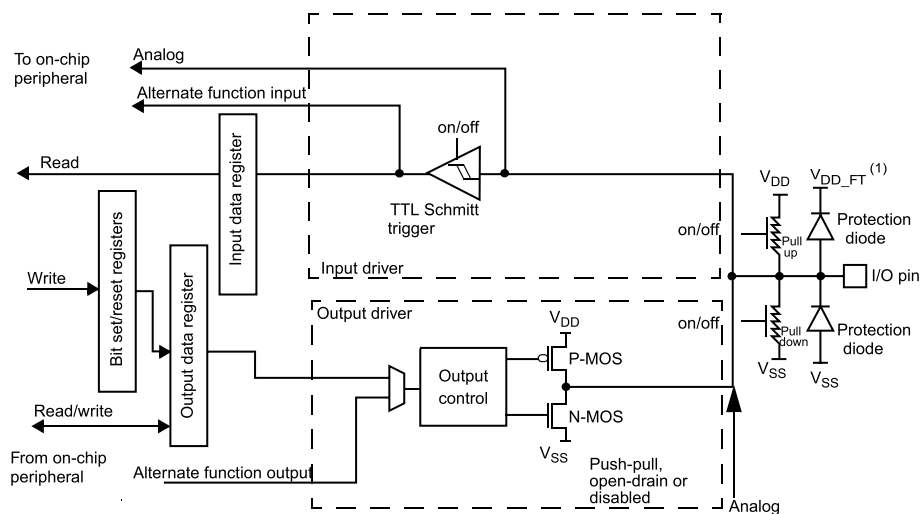

Subject to the specific hardware characteristics of each I/O port listed in [Section 4 I/O operating modes](#), each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

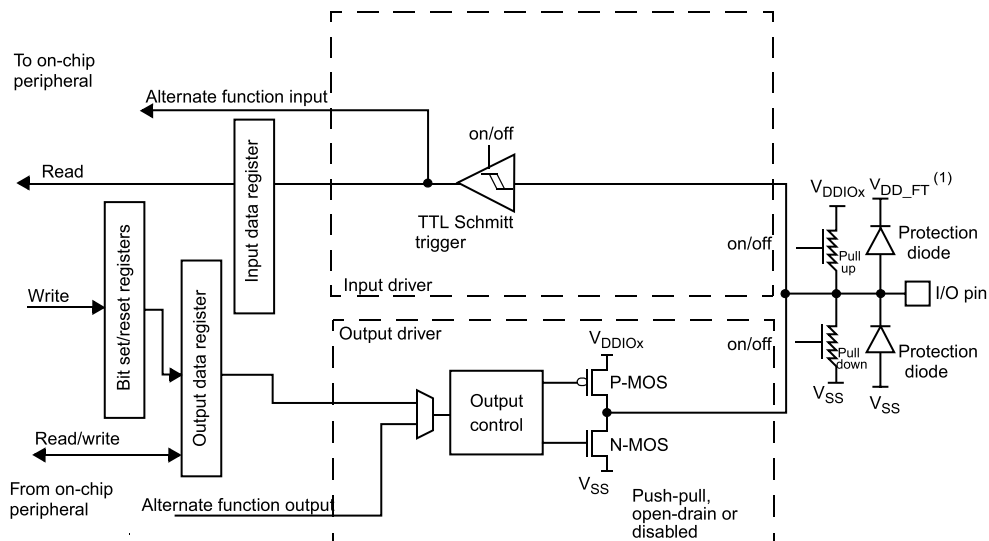

Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx_BSRR and GPIOx_BRR registers is to allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

Note: *Open-drain and analog features are not available on all the I/Os of the BlueNRG-LP. Refer to [Table 7. GPIO alternate options AF3 - AF4](#) and [Table 8. I/O analog feature mapping footnotes](#).*

Figure 15. Basic structure of a mixed analog/digital five-volt tolerant I/O port bit and Figure 16. Basic structure of a digital only five-volt tolerant I/O port bit show the basic structures of a mixed analog/digital 5 V tolerant I/O port bit and a digital only 5 V tolerant, respectively. [Table 15. Port bit configuration](#) gives the possible port bit configurations.

Figure 15. Basic structure of a mixed analog/digital five-volt tolerant I/O port bit

1. V_{DD_FT} is a potential specific to five-volt tolerant I/Os and different from V_{DD} .

Figure 16. Basic structure of a digital only five-volt tolerant I/O port bit

1. V_{DD_FT} is a potential specific to five-volt tolerant I/Os and different from V_{DD} .

Note: GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function

Table 15. Port bit configuration

MODE(i) [1:0]	OTYPER(i)	OSPEED(i) [1:0]		PUPD(i) [1:0]		I/O configuration	
01	0	SPEED [1:0]		0	0	GP output	PP

	0			1	0	AF	PP + PD
	0			1	1	Reserved	
	1			0	0	AF	OD
	1			0	1	AF	OD + PU
	1			1	0	AF	OD + PD
	1			1	1	Reserved	
00	x	x	x	0	0	Input	Floating
	x	x	x	0	1	Input	PU
	x	x	x	1	0	Input	PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0		
	x	x	x	1	1		

Note: Open-drain and analog features are not available on all the I/Os of the BlueNRG-LP. Refer to [Table 7. GPIO alternate options AF3 - AF4](#) and [Table 8. I/O analog feature mapping](#).

7.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in GPIO input pull-up mode except the SWD debug pins. The debug pins are in AF0 pull-up/pull-down after reset:

- PA2: SWDIO in pull-up
- PA3: SWDCLK in pull-down

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx_PUPDR register.

7.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to eight alternate function inputs (AF0 to AF7) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in [Section 4 I/O operating modes](#).

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user has to proceed as follows:

- **Debug function:** after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host
- **System function:** MCO and LCO pins have to be configured in alternate function mode
- **GPIO:** configures the desired I/O as output, input or analog in the GPIOx_MODER register
- **Peripheral alternate function:**
 - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH registers.
 - Select the type, pull-up/pull-down and output speed via GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDER registers, respectively.
 - Configure the desired I/O as an alternate function in the GPIOx_MODER register.
- **Additional functions:**
 - For the ADC, configure the desired I/O in analog mode in GPIOx_MODER register and configure the required function in the ADC registers

Note: The user has to disable the pulls by software on I/Os they configure in analog mode.
For the additional functions like Wakeup I/Os and LSE oscillator, configure the required function in the related PWRC and RCC registers. These functions have priority over the configuration in the standard GPIO registers.
Please refer to [Table 6. GPIO alternate options AF0 - AF2](#) and [Table 7. GPIO alternate options AF3 - AF4](#) for the detailed mapping of the alternate function I/O pins.

7.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

7.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR and GPIOx_ODR). GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register. See [Section 7.4.5 GPIO port input data register \(GPIOx_IDR\) \(x = A, B\)](#) and [Section 7.4.6 GPIO port output data register \(GPIOx_ODR\) \(x = A, B\)](#).

7.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register, which allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, two control bits in GPIOx_BSRR: BS(i) and BR(i) correspond. When written to 1, bit BS(i) **sets** the corresponding ODR(i) bit. When written to 1, bit BR(i) **resets** the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

7.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH).

The LOCK sequence (refer to [Section 7.4.8 GPIO port configuration lock register \(GPIOx_LCKR\)](#) (x = A, B)) can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details please refer to LCKR register description in [Section 7.4.8 GPIO port configuration lock register \(GPIOx_LCKR\)](#) (x = A, B).

7.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by their application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to [Section 4 I/O operating modes](#).

7.3.8 External interrupt/wake-up lines

All ports have external interrupt capability. To use external interrupt lines, the IO port must be configured in input mode. The interruption configuration (level/edge, polarity, mask) has to be done in the system controller (SYSCFG). See [Section 8 System controller \(SYSCFG\)](#).

7.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O state.

[Figure 17. Input floating/pull-up/pull-down configurations](#) shows the input configuration of the I/O port bit.

Figure 17. Input floating/pull-up/pull-down configurations

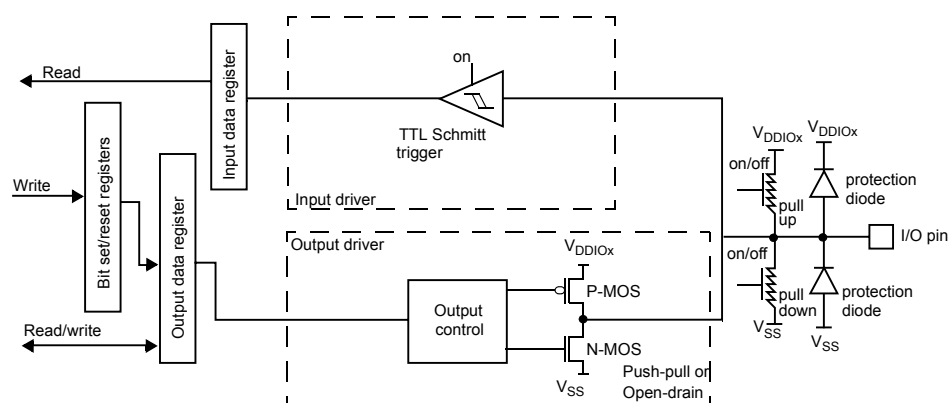

7.3.10

Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
 - Open drain mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register leaves the port in Hi-Z (the P-MOS is never activated)
 - Push-pull mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register activates the P-MOS
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/Ostate
- A read access to the output data register gets the last written value

Figure 18. Output configuration shows the output configuration of the I/O port bit.

Figure 18. Output configuration

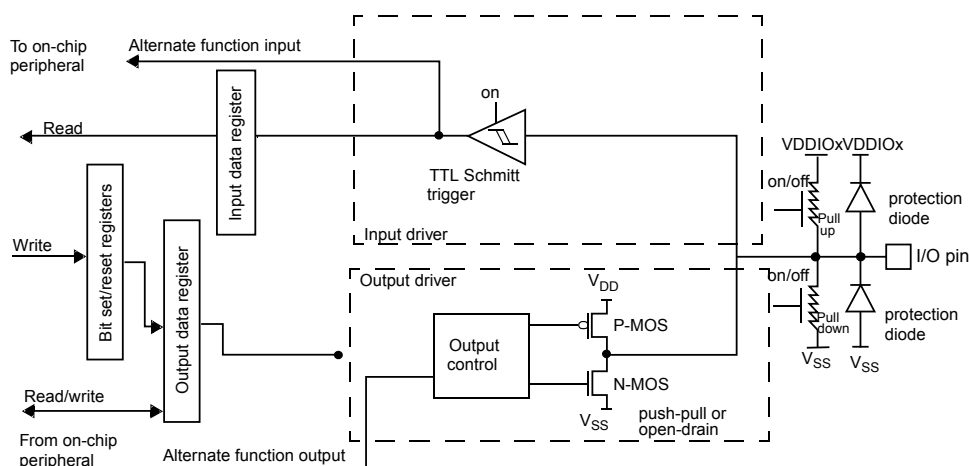

7.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state.

Figure 19. Alternate function configuration shows the alternate function configuration of the I/O port bit.

Figure 19. Alternate function configuration

7.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The pull-up and pull-down resistors have to be disabled by the software or else the associated analog feature does not work as expected.
- Read access to the input data register gets the value "0".

Figure 20. High impedance-analog configuration shows the high-impedance, analog-input configuration of the I/O port bit.

Figure 20. High impedance-analog configuration

7.3.13 Using the LSE oscillator pins as GPIOs

When the LSE oscillator is switched OFF (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the oscillator is configured in user external clock mode, only the OSC32_IN pin is reserved for clock input and the OSC32_OUT pin can still be used as normal GPIO.

Caution: There is no hardware mechanism to isolate software configuration automatically for the I/Os shared with OSC32_IN (PB13) and OSC32_OUT (PB12) when the external low speed oscillator (LSE) is used. The user has to take care to program the concerned I/O as input floating.

Note: The high speed oscillator (HSE) OSC_IN and OSC_OUT pins are dedicated oscillator pins and can not be used as GPIO.

7.4 GPIO registers

This section gives a detailed description of the GPIO registers.

For a summary of register bits, register address offsets and reset values, refer to [Table 16. GPIO register map and reset values](#). The peripheral registers can be written in word, half word or byte mode.

7.4.1 GPIO port mode register (GPIOx_MODER) (x = A, B)

Address offset: 0x00 reset values:

- 0x0000 00A0 for portA
- 0x0000 0000 for port B

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODE15[1:0]		MODE14[1:0]		MODE13[1:0]		MODE12[1:0]		MODE11[1:0]		MODE10[1:0]		MODE9[1:0]		MODE8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

MODE7[1:0]		MODE6[1:0]		MODE5[1:0]		MODE4[1:0]		MODE3[1:0]		MODE2[1:0]		MODE1[1:0]		MODE0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 2y+1:2y	MODEy[1:0]: Port x configuration bits (y = 0..15).
	These bits are written by software to configure the I/O mode. 00: Input mode
	01: General purpose output mode
	10: Alternate function mode
	11: Analog mode
	<i>Note:</i> When configuring a pad in analog mode, the user must take care to disable the associated pull-up/down to avoid pollution on the analog signal.

7.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A, B)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PUPD7[1:0]		PUPD6[1:0]		PUPD5[1:0]		PUPD4[1:0]		PUPD3[1:0]		PUPD2[1:0]		PUPD1[1:0]		PUPD0[1:0]	
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 2y+1:2y	PUPDy[1:0]: Port x configuration bits (y = 0..15).
	These bits are written by software to configure the I/O pull-up or pull-down.
	00: No pull-up, pull-down
	01: Pull-up
	10: Pull-down
	11: Reserved

Note: When PWRC_CR1[4] = APC bit is set, GPIOx_PUPDR has no effect on the behavior. When PWRC_CR1[4] = APC bit is not set, GPIOx_PUPDR pull configuration is not effective under low power modes.

7.4.5 GPIO port input data register (GPIOx_IDR) (x = A, B)

Address offset: 0x10

Reset value: 0x0000 XXXX (where X means undefined)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16	Reserved, must be kept at reset value.
Bits 15:0	ODy : Port output data bit (y = 0..15). These bits can be read and written by software. <i>Note:</i> For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the GPIOx_BSRR or GPIOx_BRR registers (x = A, B).

7.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A, B)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BR15	BR14	BR13	BR12	BR11	BR10	BR9	BR8	BR7	BR6	BR5	BR4	BR3	BR2	BR1	BR0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BS15	BS14	BS13	BS12	BS11	BS10	BS9	BS8	BS7	BS6	BS5	BS4	BS3	BS2	BS1	BS0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16	BRy : Port x reset bit y (y = 0..15). These bits are write-only. A read to these bits returns the value 0x0000. 0: No action on the corresponding ODx bit 1: Resets the corresponding ODx bit <i>Note:</i> If both BSx and BRx are set, BSx has priority.
Bits 15:0	BSy : Port x set bit y (y = 0..15). These bits are write-only. A read to these bits returns the value 0x0000. 0: No action on the corresponding ODx bit 1: Set the corresponding ODx bit

7.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A, B)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral resets.

Note: *A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.*

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to [Table 3. BlueNRG-LP memory map and peripheral register boundary addresses](#) for the register boundary addresses.

8 System controller (SYSCFG)

The system Controller is a set of registers (configuration, control and status) linked to system features of the BlueNRG-LP device.

8.1 SYSCFG main features

The system controller set of registers are mainly linked to:

- Provide the JTAG_ID, Die ID and cut version
- Manage the interrupts linked to GPIO feature
- Manage the interrupts linked to the power controller (PWRC)
- Manage the interrupt linked to MR_BLE reception and transmission sequences
- Enable/disable I²C fast-mode plus driving capability on some I/Os

Note: This peripheral is in the non-retained power domain so all settings done in the associated registers are lost after a DEEPSTOP.

8.2 System controller register description

8.2.1 Die ID register (DIE_ID)

This register provides the device version and cut information.

Address offset: 0x00

Reset value: 0x0000 0120

Bits 15:0	PAx_ISC (x=15 to 0): Interrupt status (before mask) for port A I/Os. <ul style="list-style-type: none"> 0: No pending interrupt 1: Event occurred on corresponding I/O / interrupt occurred (if enabled). Cleared by writing 1 in the bit

8.2.9 Power controller interrupt enable register (PWRC_IER)

This register allows control of the enable or mask on the interrupt sources of the power controller (PWRC) block.

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.										WKUP_I E	PVD_I E	Res.
													rw	rw	

Bits 31:3	Reserved, must be kept at reset value.
Bit 2	WKUP_I E : Power controller wake-up event interrupt enable. <ul style="list-style-type: none"> 0: Interrupt on wake-up event seen by the PWRC is disabled 1: Interrupt on wake-up event seen by the PWRC is enabled
Bit 1	PVD_I E : Programmable voltage detector interrupt enable. <ul style="list-style-type: none"> 0: PVD interrupt is disabled 1: PVD interrupt is enabled
Bit 0	Reserved, must be kept at reset value.

8.2.10 Power controller interrupt status and clear register (PWRC_ISCR)

This register allows checking the status and clear the interrupt sources of the power controller (PWRC) block.

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PGACA P_nVIN 0	ATB1_n PVD
														rw	rw

Bits 31:2	Reserved, must be kept at reset value.
Bit 1	<p>PGACAP_nVIN0: Select the analog feature on PB2/PB3 between connecting external capacitors on PGA (for analog audio mode) and VINM/P0 for ADC measurements when the PB2/3 I/Os are programmed in analog mode (in the associated GPIO_MODER register):</p> <ul style="list-style-type: none"> 0: VINM/P0 feature is selected (default) 1: External capacitors for PGA feature is selected <p>WARNING: No specific HW protection is in place if the configuration selects the PGA external capacitor and the SW enables the ADC in analog measurements through VINM/P0 pins.</p>
Bit 0	<p>ATB1_nPVD: Select the analog feature on PB14 between ATB1 and PVD when the PB14 I/O is programmed in analog mode (in the associated GPIO_MODER register):</p> <ul style="list-style-type: none"> 0: PVD external voltage feature is selected (default) 1: ATB1 feature is selected

8.2.12 MR_BLE RX or TX sequence information detection type register (BLERXTX_DTR)

This register allows selecting the type of detection (level or edge) on RX_SEQUENCE and TX_SEQUENCE coming from the MR_BLE IP.

Address offset: 0x2C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RX_DT	TX_DT
														rw	rw

Bits 31:2	Reserved, must be kept at reset value.
Bit 1	RX_DT : Detection type on RX_SEQUENCE signal: <ul style="list-style-type: none"> 0: Detection on edge (default) 1: Detection on level
Bit 0	TX_DT : Detection type on TX_SEQUENCE signal: <ul style="list-style-type: none"> 0: Detection on edge (default) 1: Detection on level

8.2.13

MR_BLE RX or TX sequence information detection type register (BLERXTX_IBER)

This register is used to activate RX_SEQUENCE and TX_SEQUENCE signal detection on single edge or both edges when edge detection type is active.

Address offset: 0x30

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

9 Embedded Flash memory

The Flash controller implements the erase and programs Flash memory operation. The Flash controller also implements the read and write protection.

9.1 Flash main features

Flash memory features:

- Up to 256 kBytes of Flash memory single bank architecture.
- Memory organization: 1 bank
 - main memory: up to 256 kbytes
 - page size: 2 kBytes
- 32-bit wide data read
- 32-bit wide data write
- Page erase (2 kbytes) and mass erase.

Flash controller features:

- Flash memory read operations
- Flash memory write operations: single data write or 4x32-bits burst write (to reduce programming time by 4)
- Flash memory erase operations
- Flash readout protection and disable of debug access
- Page write protect mechanism

9.2 Description

The Flash memory is organized as follows:

- Main memory block containing 128 pages of 2 kBytes. Each page is made of 8 rows of 256 bytes (64 words).

Erasing the whole Flash results in every bit cell of the Flash.

In parallel, the Flash controller manages 1 kB OTP (one-time programmable) for user data. The OTP data cannot be erased. The OTP data area can no longer be written only as soon as the last word (address 0x1000_1BFC) is different from 0xFFFF_FFFF and a system reset occurred.

The Flash is mapped on the AHB-Lite bus with the range described below.

Table 18. Flash memory section address

Section	Flash AHB start address	Flash AHB end address
main Flash	0x1004_0000	0x1007_FFFF ⁽¹⁾
User OTP	0x1000_1800	0x1000_1BFF

1. Depends on Flash size. See Table 21. Flash size information.

9.3 Flash controller register map

Refer to [Table 3. BlueNRG-LP memory map and peripheral register boundary addresses](#) for the Flash controller base address location in the BlueNRG-LP.

Table 19. Flash APB registers

Address offset	Name	Width	RW ⁽¹⁾	Reset	Description
0x00	COMMAND	8	RW	0x0000_0000	Commands for the module. See Section 9.4.1 Command register (COMMAND) .
0x04	CONFIG	2	RW	0x000_0018	Configure the wrapper. See Section 9.4.2 Configuration register (CONFIG) .
0x08	IRQSTAT	5	RC	0x0000_0000	Flash status interrupts (masked). See Section 9.4.3 Interrupt status register (IRQSTAT) .
0x0C	IRQMASK	5	RW	0x0000_003F	Mask for interrupts. See Section 9.4.4 Interrupt mask register (IRQMASK) .
0x10	IRQRAW	5	RC	0x0000_0001	Status interrupts (unmasked). See Section 9.4.5 Raw status register (IRQRAW) .
0x14	FLASH_SIZE	16	RO	0x000-_-----	Indicates the last usable address of the main Flash and the RAM size. See Section 9.4.6 SIZE register .
0x18	ADDRESS	14	RW	0x0000_0000	Address for programming Flash, auto-increments. See Section 9.4.7 Address register (ADDRESS) .
0x24	LFSRVAL	32	RO	0xFFFF_FFFF	LFSR register needed for check after MASS READ command. See Section 9.4.8 Linear feedback shift register (LFSRVAL) .
0x34	PAGEPROT0	32	RW	0x0000_0000	Write/page erase protection management register. See Section 9.4.9 Main Flash page protection registers (PAGEPROTx) (PAGEPRT0) .
0x38	PAGEPROT1	32	RW	0x0000_0000	Write/page erase protection management register. See Section 9.4.9 Main Flash page protection registers (PAGEPROTx) (PAGEPRT1) .
0x3C	RESERVED	32	RW	0x0000_0000	UNUSED
0x40	DATA0	32	RW	0xFFFF_FFFF	Program cycle data. See Section 9.4.10 Data registers (DATA0-DATA3) .
0x44	DATA1	32	RW	0xFFFF_FFFF	Program cycle data. See Section 9.4.10 Data registers (DATA0-DATA3) .
0x48	DATA2	32	RW	0xFFFF_FFFF	Program cycle data. See Section 9.4.10 Data registers (DATA0-DATA3) .
0x4C	DATA3	32	RW	0xFFFF_FFFF	Program cycle data. See Section 9.4.10 Data registers (DATA0-DATA3) .

1. Acronym meaning: RW: read and write RC: read and write to clear RO: read only.

9.4 Flash controller register description

9.4.1 Command register (COMMAND)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COMMAND							
								rw							

Bits 31:8	Reserved, must be kept at reset value.
Bit 7:0	COMMAND : Command opcode to launch any operation on Flash memory. Refer to Table 20. Command list available for customer.

Table 20. Command list available for customer

Command	Flash sector	Description	Command Opcode
ERASE	Main memory	Erase page defined by register ADDRESS.	0x11
WRITE ⁽¹⁾	Main memory	Program one location (defined by registers DATA and ADDRESS).	0x33
MASSREAD	Main memory	Read all locations and compare with DATA register value or produce LFSR signature.	0x55
SLEEP	Whole memory	Put Flash in sleep mode. Warning: Once this command is launched, no access (read) nor action (any command except WAKE) on the Flash component is possible until the WAKE command is requested (and associated CMDDONE status is returned)	0xAA
WAKEUP	Whole memory	Get Flash out of sleep mode.	0xBB
BURSTWRITE	Main memory	Program 4 locations (ADDRESS → ADDRESS+3) with data in DATA0-DATA3 registers.	0xCC
OTPWRITE	User OTP	One time writable 1 kBytes for customer. No erase nor second programming is possible.	0xEE
KEYWRITE	Main memory	Write the customer key used to protect the main Flash.	0xFF

1. Each address can be programmed only twice without erase operation in between.

Status bit behavior versus commands:

- Writing to the COMMAND register starts the action that is performed on the Flash
- The CMDSTART flag goes and stays high until it is cleared
- When the command has finished the CMDDONE flag goes high
- When a MASS READ command was given and when CMDDONE is high, the READOK flag can be checked or the LFSRVAL register can be read (contains the signature of the mass read)

The sequences to use the different commands are described in [Section 9.5 Programmer model](#).

9.4.2 Configuration register (CONFIG)

Address offset: 0x04

Reset value: 0x0000 0018

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WAIT_STATES		Res.	DIS_GROUP_WRITE	REMAP	Res.
										rw	rw			rw	

Bits 31:6	Reserved, must be kept at reset value.
Bits 5:4	WAIT_STATES: Number of wait states to be inserted on Flash read (AHB accesses). The Flash embedded in the BlueNRG-LP device requires 1 wait_state when system clock frequency is 64 MHz.
Bit 3	Reserved, must be kept at reset value.
Bit 2	DIS_GROUP_WRITE: <ul style="list-style-type: none"> 0: Burst write operations are allowed/enabled 1: Burst write operations are blocked and result on a single write Note: If this bit is set during an on-going burst write operation, the Flash controller stops the write operation at the end of the current word writing even if some words are still to be written.
Bit 1	REMAP: Bit to redirect boot area on SRAM0.
Bit 0	Reserved, must be kept at reset value.

The Flash can be read in one system clock cycle (the best for power consumption) when the system clock is 32 MHz maximum.

9.4.3 Interrupt status register (IRQSTAT)

The interrupt status register shows the masked version of the interrupt raw register.

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	READOK_MIS	ILLCMD_MIS	CMDERR_MIS	CMDSTART_MIS	CMDDONE_MIS
											rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:5	Reserved, must be kept at reset value.
Bit 4	READOK_MIS : Mass read OK masked interrupt status. This bit is set at the end of a MASSREAD operation if all the words read in the memory match the DATA0 register value. Cleared by writing 1.
Bit 3	ILLCMD_MIS : Illegal command masked interrupt status. This bit is set when a bad opcode command is written in the COMMAND register. Cleared by writing 1.
Bit 2	CMDERR_MIS : Command error masked interrupt status. This bit is set if a command opcode is written in COMMAND register while the Flash is busy. Cleared by writing 1.
Bit 1	CMDSTART_MIS : Command started masked interrupt status. This bit is set once the requested command execution has started. Cleared by writing 1.
Bit 0	CMDDONE_MIS : Command done masked interrupt status. This it is set once the requested command execution is completed. Cleared by writing 1.

The CMDDONE and CMDSTART bits are updated a few clock cycles after the requested command has been started by writing to the COMMAND register.

Note: *Clearing a bit by writing in IRQSTAT (respectively IRQRAW) register also cleared the same bit in IRQRAW (respectively IRQSTAT) register as they are referring to a common condition/event.*

9.4.4 Interrupt mask register (IRQMASK)

The mask bit in IRQMASK masks the condition in the status register IRQSTAT and prevents the generation from the interrupt.

Address offset: 0x0C

Reset value: 0x0000 003F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	READOK M	ILLCMD M	CMDERRM	CMDSTART M	CMDDONE M
											rw	rw	rw	rw	rw

Bits 31:5	Reserved, must be kept at reset value.
Bit 4	READOKM : Mass read OK mask. <ul style="list-style-type: none"> 0: Enable interrupt on "Mass read OK" event 1: Disable interrupt on "Mass read OK" event
Bit 3	ILLCMDM : Illegal command mask. <ul style="list-style-type: none"> 0: Enable interrupt on "illegal command" event 1: Disable interrupt on "illegal command" event
Bit 2	CMDERRM : Command error mask. <ul style="list-style-type: none"> 0: Enable interrupt on "command error" event 1: Disable interrupt on "command error" event
Bit 1	CMDSTARTM : Command started mask. <ul style="list-style-type: none"> 0: Enable interrupt on "command started" event 1: Disable interrupt on "command started" event
Bit 0	CMDDONEM : Command done mask. <ul style="list-style-type: none"> 0: Enable interrupt on "command done" event 1: Disable interrupt on "command done" event

9.4.5 Raw status register (IRQRAW)

The raw status register shows the unmasked condition of interrupt events.

Address offset: 0x10

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	READOK_RIS	ILLCMD_RIS	CMDERR_RIS	CMDSTART_RIS	CMDDONE_RIS
											rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:5	Reserved, must be kept at reset value.
Bit 4	READOK_RIS : Mass read OK raw/unmasked interrupt status. This bit is set at the end of a MASSREAD operation if all the words read in the memory match the DATA0 register value. Cleared by writing 1.
Bit 3	ILLCMD_RIS : Illegal command raw/unmasked interrupt status. This bit is set when a bad opcode command is written in the COMMAND register. Cleared by writing 1.
Bit 2	CMDERR_RIS : Command error raw/unmasked interrupt status. This bit is set if a command opcode is written in COMMAND register while the Flash is busy. Cleared by writing 1.
Bit 1	CMDSTART_RIS : Command started raw/unmasked interrupt status. This bit is set once the requested command execution has started. Cleared by writing 1.
Bit 0	CMDDONE_RIS : Command done raw/unmasked interrupt status. This bit is set once the requested command execution is completed. Cleared by writing 1.

The CMDDONE and CMDSTART bits are updated a few clock cycles after the requested command has been started by writing to the COMMAND register.

9.4.6 SIZE register

Address offset: 0x14

Reset value: 0x000- ---- (depends on the device)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWD_DISABLE	FLASH_SECURE	RAM_SIZE[1:0]		Res.
													r		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLASH_SIZE[15:0]															
r															

Bits 31:21	Reserved, must be kept at reset value.
Bit 20	SWD_DISABLE : Flash+SWD protection: <ul style="list-style-type: none"> 0: No SWD protection (refer to FLASH_SECURE) 1: Flash and SWD protected
Bit 19	FLASH_SECURE : Flash memory protection: <ul style="list-style-type: none"> 0: The main FLASH is not protected 1: The main FLASH is protected through a customer key
Bits 18:17	RAM_SIZE : Indicates the size of RAM available in the device: <ul style="list-style-type: none"> 00: 32 kB of RAM available (RAM0 and RAM1 banks) 01: 32 kB of RAM available (RAM0 and RAM1 banks) 10: 48 kB of RAM available (RAM0, RAM1 and RAM2 banks) 11: 64 kB of RAM available (RAM0, RAM1, RAM2 and RAM3 banks)
Bit 16	Reserved, must be kept at reset value.
Bits 15:0	FLASH_SIZE : Indicates the last usable address of the Flash using memory component address format. See Table 21. Flash size information for relation between address at Flash component level and AHB address mapping. <ul style="list-style-type: none"> 0x7FFF: 128 kB of main Flash are available on this device 0xBFFF: 192 kB of main Flash are available on this device 0xFFFF: 256 kB of main Flash are available on this device

Table 21. Flash size information

Main flash size	Highest usable address at Flash level ⁽¹⁾	Highest usable address at AHB level
128 kB	0x7FFF	0x1005_FFFC
192 kB	0xBFFF	0x1006_FFFC
256 kB	0xFFFF	0x1007_FFFC

1. Value seen in FLASH_SIZE bit field.

9.4.7 Address register (ADDRESS)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
XADDR[9:0]										YADDR[5:0]					
rw										rw					

Bits 31:16	Reserved, must be kept at reset value.
Bits 15:6	XADDR[9:0]: <ul style="list-style-type: none"> XADDR[9:3]: Page number (from 0 to 127) XADDR[2:0]: Row number (from 0 to 7)
Bits 5:0	YADDR[5:0]: Word number inside the selected row (from 0 to 63)

Address to provide to the Flash is not the AHB device mapping address but the address respecting Flash component format.

The main Flash is composed of 128 pages containing 8 rows each with 64 words = 256 bytes by row.

To program the ADDRESS register, the formula is the following:

- XADDR[9:0] = AHB address bit [17:8]
- YADDR[5:0] = AHB address bit [7:2]

Example 1: To program a word (32-bit) at AHB address 0x1005_0454:

- XADDR[9:0] = AHB address bit [17:8] = 0x104
- YADDR[5:0] = AHB address bit [7:2] = 0x15
- ADDRESS register = 0x4115

9.4.8 Linear feedback shift register (LFSRVAL)

The LFSRVAL register contains the signature issued by a MASSREAD command.

The LFSRVAL register is initialized with all ones when the MASS READ command is written to the COMMAND register. Then every read value is put through the LFSR.

The final signature can be read in this register once the CMDDONE information is set.

Address offset: 0x24

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LFSRVAL[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LFSRVAL[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0	LFSRVAL: Signature after a MASSREAD command, generated through a linear feedback. Shift Register block.
-----------	--

9.4.9 Main Flash page protection registers (PAGEPROTx)

The PAGEPROTx register allows protecting from accidental write a contiguous set of pages called segment in the following description. A maximum of four segments can be defined.

An example of usage is available in Section 9.5.7: Write page protection example.

PAGEPROT0

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SEG1[15:0]															
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SEG0[15:0]															
rw															

Bits 31:16	SEG1: Second segment definition. See SEG0 description for details on SEG1[31:16] content.
Bit 15:0	SEG0: First segment definition. A segment SEGx is built as follows: <ul style="list-style-type: none"> • SEGx[15]: Reserved • SEGx[14:8] = OFFSET: Page number to start the write protection (value between 0 and 0x7F) • SEGx[7]: Reserved • SEGx[6:0] = SIZE: number of 2 kB pages to protect including the starting page (provided in SEGx[14:8]) <i>Note:</i> <ul style="list-style-type: none"> • <i>SIZE=0 means no segment defined so if all segments have SIZE=0, then no write protection is applied on the whole FLASH.</i> • <i>The segments can overlap, the protection on a page is guaranteed if at least one segment covers this page.</i> • <i>If OFFSET + SIZE > 127d so exceeds the maximum size of the FLASH, the end of the segment is positioned on the maximum allowed address.</i>

PAGEPROT01

Address offset: 0x38

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SEG2[15:0]															
rw															

Bits 31:16	SEG3: Fourth segment definition. See PAGEPROT0 SEG0 description for details on SEG3[15:0] content.
Bit 15:0	SEG2: Third segment definition. See PAGEPROT0 SEG0 description for details on SEG2[15:0] content.

9.4.10

Data registers (DATA0-DATA3)

The DATA0 register needs to be written with:

- The desired value written to the Flash location (for single write or mass write).
- The desired compare value for a (mass) read operation, the flag READOK indicates if there was a match or not. For mass read, all read values must match for READOK.

The DATA1-DATA3 registers need to be written only for burst write.

DATA0

Address offset: 0x40

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw															

Bits 31:0	DATA3: Data that are written at ADDRESS+3 during a BURSTWRITE command. Note: This register is used only on burst write.
-----------	---

9.5 Programmer model

The BlueNRG-LP embeds up to 256 Kbytes (65536 x 32-bit) of internal Flash memory. A Flash interface implements instruction access and data access based on the AHB protocol. It implements the logic necessary to carry out the Flash memory operations (program/erase) controlled through the Flash registers.

9.5.1 General information

Writing to Flash only allows clearing bits from '1' to '0'. This means any write from '0' to '1' implies erasing before performing a write.

Flash memory is composed of 128 pages containing 8 rows of 64 words (128 x 8 x 64 = 65536 words). Each word is 32-bit = 4 bytes long which means 256 kB of Flash.

The address inside the Flash controller ADDRESS register is built as follows: ADDRESS[15:0] = XADR[9:0] & YADR[5:0] with:

- XADR[9:3] = page address
- XADR[2:0] = row address
- YADR[5:0] = word address (one word = four bytes)

Note: One specific address can be written only twice between two erase actions even if each writing only clears bit 1.

9.5.2 Read function examples

There are two possible read accesses:

- Read one single word: simple read as if SRAM memory: read the desired Flash address and get read data on the bus
- MASSREAD command: read the full Flash memory and compare with expected content

There are two ways of using MASSREAD:

- Full Flash contains a fixed 32-bit pattern: indicate the expected pattern (value to be compared with each read value inside Flash) in the Flash controller DATA register and check the READOK flag in the Flash controller interrupt register once the command is completed
- Otherwise: request a MASSREAD command without specifying any expected read value and check the LFSRVAL register once the command is completed. This LFSRVAL register contains a signature of the memory read

MASSREAD sequence:

- Write in the Flash controller DATA register the expected value (if MASSREAD is used in combination with the READOK flag)
- Write the MASSREAD command (0x55) in the Flash controller COMMAND register
- Wait for the CMDSTART flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command has been taken into account and is under execution
- Clear the CMDSTART flag by writing CMDSTART to '1' in the Flash controller IRQSTAT register
- Then, wait for the CMDDONE flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command is completed
- Check the READOK flag (expected high) in the IRQSTAT register or the LFSRVAL register value to ensure Flash memory content is the expected result
- Clear the CMDDONE flag by writing CMDDONE to '1' in the Flash controller IRQSTAT register.

9.5.3 Erase function examples

The Flash controller allows erasing one page.

ERASE sequence (erase one page):

- Write the page address to be erased by writing in the Flash controller ADDRESS register the following value:
 - ADDRESS[15:9] = XADR[9:3] = page address to erase
 - ADDRESS[8:0] = 9'b0 (row and word addresses at zero)
- Write the ERASE command (0x11) in the Flash controller COMMAND register
- Wait for the CMDSTART flag in the IRQSTAT register (polling mode or interrupt mode) indicating command is taken into account and under execution
- Clear the CMDSTART flag by writing CMDSTART to '1' in the Flash controller IRQSTAT register
- Wait for the CMDDONE flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command is completed
- Clear the CMDDONE flag by writing CMDDONE to '1' in the Flash controller IRQSTAT register
- After this command, the erased page contains bits set to '1' only.

9.5.4 Write function examples

The Flash controller allows writing one word (WRITE), up to 4 words (BURSWRITE) or the full main Flash memory (with a single fixed word).

Note: As a write can only program to '0' on bits already set to '1', it is necessary to erase the page and request that the bits are set to '1' (instead of '0') in order to re-write to '0'.

WRITE sequence:

- Indicate the location to write by filling the Flash controller ADDRESS register with the targeted address (page, row and word number)
- Write the value to program in the Flash controller DATA register
- Write the WRITE command (0x33) in the Flash controller COMMAND register
- Wait for the CMDSTART flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command has been taken into account and is under execution
- Clear the CMDSTART flag by writing CMDSTART to '1' in the Flash controller IRQSTAT register
- Wait for the CMDDONE flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command is completed
- Clear the CMDDONE flag by writing CMDDONE to '1' in the Flash controller IRQSTAT register.

BURSTWRITE sequence:

- Indicate the location to write by filling the Flash controller ADDRESS register with the targeted address of the first data to write (page, row and word number). DATA0 is written at ADDRESS, DATA1 at ADDRESS+1, etc.
- Write the values to program in the Flash controller DATA0-3 registers. To write less than four words, write 0xFFFFFFFF in the unused DATA1-3 registers
- Write the BURSTWRITE command (0xCC) in the Flash controller COMMAND register
- Wait for the CMDSTART flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command has been taken into account and is under execution
- Clear the CMDSTART flag by writing CMDSTART to '1' in the Flash controller IRQSTAT register
- Wait for the CMDDONE flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command is completed
- Clear the CMDDONE flag by writing CMDDONE to '1' in the Flash controller IRQSTAT register.

9.5.5 Enabling protection example

The device offers three levels of protection to prevent application cloning and/or altering of application code. The different levels are described in [Table 22. System memory protection](#). It is important to note that disabling of SWD access is an irreversible operation.

Table 22. System memory protection

Protection	Userkey[DATA0]	Userkey[DATA1]	Disable protection	Description
None	0xFFFFFFFF	0xFFFFFFFF	Not applicable	Debugger can access and modify Flash memory and RAM content. This is the default configuration.
Readout	0xAAAAAAAA	0xAAAAAAAA	Perform mass erase	Debugger cannot read or modify both Flash memory and RAM content.
SWD	0xABACABAD	0xABACABAD	This selection is irreversible	Debugger connection is not possible.
Not specified	Any other value	Any other value	Not applicable	This configuration is forbidden and can lead to unrecoverable damage of the device.

In order to activate the desired level of protection, the following KEYWRITE sequence should be used:

- Write DATA0 (LSB key) and DATA1 (MSB key) registers with the value to program
- Write 0xC7EF584D to DATA2 and 0xB3A21096 to DATA3
- Write the KEYWRITE command (0xFF) in the Flash controller COMMAND register
- Wait for the CMDSTART flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command has been taken into account and is under execution
- Clear the CMDSTART flag by writing CMDSTART to '1' in the Flash controller IRQSTAT register
- Wait for the CMDDONE flag in the IRQSTAT register (polling mode or interrupt mode), indicating that the command is completed
- Clear the CMDDONE flag by writing CMDDONE to '1' in the Flash controller IRQSTAT register.

The keys are activated (and Flash and RAM banks are protected) after a reset.

9.5.6 OTP function example

OTPWRITE sequence:

- Write DATA0 register with the value to program (no burst write feature is available as only few bytes to be written once only)
- Write ADDRESS register according to the following rule:
 - ADDRESS[15:9] = do not care (page number frozen by hardware on this command)
 - ADDRESS[8:6] = 0, 1, 2 or 3
 - ADDRESS[5:0] = full area possible (from 0x00 to 0x3F)
- Write the OTPWRITE command (0xEE) in the Flash controller COMMAND register
- Wait for the CMDSTART flag in the IRQSTAT register (polling mode or interrupt mode) indicating that the command has been taken into account and is under execution
- Clear the CMDSTART flag by writing CMDSTART to '1' in the Flash controller IRQSTAT register
- Wait for the CMDDONE flag in the IRQSTAT register (polling mode or interrupt mode), indicating that the command is completed
- Clear the CMDDONE flag by writing CMDDONE to '1' in the FlashController IRQSTAT register.

Note: *The OTP locations are following Flash memory rules, that is, a second write only flips bit from 1 to 0. If the user wishes to lock the OTP values and prevent any further modification in the OTP area, they must write the last OTP word (address 0x10001BFC) with a value different from 0xFFFFFFFF and perform system reset. The operation of locking the OTP area is irreversible.*

9.5.7 Write page protection example

Example to write protect against accidental programming knowing the Flash starts at address 0x1004_0000 and contains 128 pages of 2 kB (pages 0 to 127)

- the address ranges 0x1004C000-0x1004FFFF

Starting page: $0xC000 / 0x800 = 0x18$

- $SEG0[14:8] = 0x18$ (OFFSET = 0x18)

Number of pages: $(0x10000 - 0xC000) / 0x800 = 0x8$

- $SEG0[6:0] = 0x8$ (SIZE = 0x8)
- and the address ranges 0x1005E000-0x1005FFFF

Starting page: $0x1E000 / 0x800 = 0x3C$

- $SEG1[14:8] = 0x3C$ (OFFSET = 0x3C)

Number of pages: $(0x20000 - 0x1E000) / 0x800 = 0x4$

Conclusion: program the PAGEPROT0 = 0x3C041808.

10 DMA controller (DMA)

10.1 DMA introduction

Direct memory access (DMA) is used in order to provide high-speed data transfer between peripherals and memory as well as memory-to-memory. Data can be quickly moved by DMA without any CPU actions. This keeps CPU resources free for other operations.

The DMA has an arbiter to handle the priority between DMA requests.

10.2 DMA main features

- Eight independently configurable channels (requests)
- Each of the eight channels is connected to dedicated hardware DMA requests, software trigger is also supported on each channel. This configuration is done by software
- Priorities between requests from channels of the DMA are software programmable (4 levels consisting of very high, high, medium, low) or hardware in case of equality (request 1 has priority over request 2, etc.)
- Independent source and destination transfer size (byte, half word, word), emulating packing and unpacking. Source/destination addresses must be aligned on the data size
- Support for circular buffer management
- 3 event flags (DMA Half Transfer, DMA Transfer complete and DMA Transfer Error) logically ORed together in a single interrupt request for each channel
- Memory-to-memory transfer (SRAM0/SRAM1/SRAM2/SRAM3 but not the PKA RAM)
- Peripheral-to-memory and memory-to-peripheral, and peripheral-to-peripheral transfers
- Access to SRAMs and APB1 peripherals as source and destination
- Programmable number of data to be transferred: up to 65536.

10.3 DMA functional description

The DMA controller performs a direct memory transfer by sharing the system bus with the other masters of the device. The DMA request may stop the CPU access to the system bus for some bus cycles, when the CPU and DMA are targeting the same destination (memory or peripheral). The bus matrix implements round-robin scheduling, thus ensuring at least half of the system bus bandwidth (both to memory and peripheral) for the CPU.

10.3.1 DMA transactions

After an event, the peripheral sends a request signal to the DMA controller. The DMA controller serves the request depending on the channel priorities. As soon as the DMA controller accesses the peripheral, an acknowledge is sent to the peripheral by the DMA controller. The peripheral releases its request as soon as it gets the acknowledge from the DMA controller. Once the request is deasserted by the peripheral, the DMA controller releases the acknowledge. If there are more requests, the peripheral can initiate the next transaction. In summary, each DMA transfer consists of three operations:

- The loading of data from the peripheral data register or a location in memory addressed through an internal current peripheral/memory address register. The start address used for the first transfer is the base peripheral/memory address programmed in the DMA_CPARx or DMA_CMARx register
- The storage of the data loaded to the peripheral data register or a location in memory addressed through an internal current peripheral/memory address register. The start address used for the first transfer is the base peripheral/memory address programmed in the DMA_CPARx or DMA_CMARx register
- The post-decrementing of the DMA_CNDTRx register, which contains the number of transactions that has still to be performed.

10.3.2 Arbiter

The arbiter manages the channel requests based on their priority and launches the peripheral/memory access sequences.

The priorities are managed in two stages:

- Software: each channel priority can be configured in the DMA_CCRx register. There are four levels:
 - Very high priority
 - High priority
 - Medium priority
 - Low priority
- Hardware: if 2 requests have the same software priority level, the channel with the lowest number gets the priority versus the channel with the highest number. For example, channel 2 gets the priority over channel 4

10.3.3 DMA channels

Each channel can handle DMA transfer between a peripheral register located at a fixed address and a memory address. The amount of data to be transferred (up to 65535) is programmable. The register which contains the amount of data items to be transferred is decremented after each transaction.

Programmable data sizes

Transfer data sizes of the peripheral and memory are fully programmable through the PSIZE and MSIZE bits in the DMA_CCRx register.

Pointer incrementation

Peripheral and memory pointers can optionally be automatically post-incremented after each transaction depending on the PINC and MINC bits in the DMA_CCRx register. If incremented mode is enabled, the address of the next transfer is the address of the previous one incremented by 1, 2 or 4 depending on the chosen data size. The first transfer address is the one programmed in the DMA_CPARx/DMA_CMARx registers. During transfer operations, these registers keep the initially programmed value. The current transfer addresses (in the current internal peripheral/memory address register) are not accessible by software.

If the channel is configured in non circular mode, no DMA request is served after the last transfer (that is once the number of data items to be transferred has reached zero). In order to reload a new number of data items to be transferred into the DMA_CNDTRx register, the DMA channel must be disabled.

Note: If a DMA channel is disabled, the DMA registers are not reset. The DMA channel registers (DMA_CCRx, DMA_CPARx and DMA_CMARx) retain the initial values programmed during the channel configuration phase.

In circular mode, after the last transfer, the DMA_CNDTRx register is automatically reloaded with the initially programmed value. The current internal address registers are reloaded with the base address values from the DMA_CPARx/DMA_CMARx registers.

Channel configuration procedure

The following sequence should be followed to configure a DMA channelx (where x is the channel number).

1. Set the peripheral register address in the DMA_CPARx register. The data are moved from/to this address to/from the memory after the peripheral event.
2. Set the memory address in the DMA_CMARx register. The data are written to or read from this memory after the peripheral event.
3. Configure the total number of data to be transferred in the DMA_CNDTRx register. After each peripheral event, this value is decremented.
4. Configure the channel priority using the PL[1:0] bits in the DMA_CCRx register.
5. Configure data transfer direction, circular mode, peripheral and memory incremented mode, peripheral and memory data size, and interrupt after half and/or full transfer in the DMA_CCRx register.
6. Activate the channel by setting the ENABLE bit in the DMA_CCRx register.

As soon as the channel is enabled, it can serve any DMA request from the peripheral connected on the channel.

Once half of the bytes are transferred, the half-transfer flag (HTIF) is set and an interrupt is generated if the half-transfer interrupt enable bit (HTIE) is set. At the end of the transfer, the transfer complete flag (TCIF) is set and an interrupt is generated if the transfer complete interrupt enable bit (TCIE) is set.

Circular mode

Circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the DMA_CCRx register. When circular mode is activated, the number of data to be transferred is automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This mode is called memory-to-memory mode.

If the MEM2MEM bit in the DMA_CCRx register is set, then the channel initiates transfers as soon as it is enabled by software by setting the enable bit (EN) in the DMA_CCRx register. The transfer stops once the DMA_CNDTRx register reaches zero. Memory-to-memory mode may not be used at the same time as circular mode.

10.3.4

Programmable data width, data alignment and endians

When PSIZE and MSIZE are not equal, the DMA performs some data alignments as described in [Table 23. Programmable data width and endian behavior \(when PINC=MINC=1 and NDT=4\)](#). Please note that NDT means number of data items to transfer.

Table 23. Programmable data width and endian behavior (when PINC=MINC=1 and NDT=4)

Port width	Source content	Transfer operation	Dest content
Src => Dest	addr / data		addr / data
8 => 8	@0x0 / B0	Read B0[7:0] @0x0 then write B0[7:0] @0x0	@0x0 / B0

	@0x8 / BBBAB9B8	Read BBBAB9B8[31:0] @0x8 then write BBBAB9B8[31:0] @0x8	@0x8 / BBBAB9B8
	@0xC/BFBEBDBC	Read BFBEBDBC[31:0] @0xC then write BFBEBDBC[31:0] @0xC	@0xC/BFBEBDBC

Addressing an AHB peripheral that does not support byte or halfword write operations

When the DMA initiates an AHB byte or halfword write operation, the data are duplicated on the unused lanes of the HWDATA[31:0] bus. So when the used AHB slave peripheral does not support byte or halfword write operations (when HSIZE is not used by the peripheral) and does not generate any error, the DMA writes the 32 HWDATA bits as shown in the two examples below:

- To write the halfword “0xABCD”, the DMA sets the HWDATA bus to “0xABCDABCD” with HSIZE = HalfWord
- To write the byte “0xAB”, the DMA sets the HWDATA bus to “0xABABABAB” with HSIZE = byte

Assuming that the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take the HSIZE data into account, it transforms any AHB byte or halfword operation into a 32-bit APB operation in the following manner:

- an AHB byte write operation of the data “0xB0” to 0x0 (or to 0x1, 0x2 or 0x3) is converted to an APB word write operation of the data “0xB0B0B0B0” to 0x0
- an AHB halfword write operation of the data “0xB1B0” to 0x0 (or to 0x2) is converted to an APB word write operation of the data “0xB1B0B1B0” to 0x0

For instance, if you want to write the APB backup registers (16-bit registers aligned to a 32-bit address boundary), you must configure the memory source size (MSIZE) to “16-bit” and the peripheral destination size (PSIZE) to “32-bit”.

10.3.5 Error management

A DMA transfer error can be generated by reading from or writing to a reserved address space. When a DMA transfer error occurs during a DMA read or a write access, the faulty channel is automatically disabled through a hardware clear of its EN bit in the corresponding channel configuration register (DMA_CCRx). The channel transfer error interrupt flag (TEIF) in the DMA_IFR register is set and an interrupt is generated if the transfer error interrupt enable bit (TEIE) in the DMA_CCRx register is set.

10.3.6 Interrupts

An interrupt can be produced on a half-transfer, transfer complete or transfer error for each DMA channel. Separate interrupt enable bits are available for flexibility.

Table 24. DMA interrupt requests

Interrupt event	Event flag	Enable control bit
Half-transfer	HTIF	HTIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE

10.3.7 DMA request mapping

A DMAMUX is present in the BlueNRG-LP device and allows selecting which requester is connected to which DMA channel. See [Table 27. DMAMUX map](#) for details.

10.4 DMA registers

Refer to [Section 1.3 Acronyms](#) for a list of abbreviations used in register descriptions. The peripheral registers must be accessed by words (32-bit) only.

10.4.1 DMA interrupt status register (DMA_ISR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TEIF8	HTIF8	TCIF8	GIF8	TEIF7	HTIF7	TCIF7	GIF7	TEIF6	HTIF6	TCIF6	GIF6	TEIF5	HTIF5	TCIF5	GIF5
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TEIF4	HTIF4	TCIF4	GIF4	TEIF3	HTIF3	TCIF3	GIF3	TEIF2	HTIF2	TCIF2	GIF2	TEIF1	HTIF1	TCIF1	GIF1
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28	Reserved, must be kept at reset value.
Bits 31, 27, 23, 19, 15, 11, 7, 3	TEIFx : Channel x transfer error flag (x = 1..8). This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_IFCR register. 0: No transfer error (TE) on channel x 1: A transfer error (TE) occurred on channel x
Bits 30, 26, 22, 18, 14, 10, 6, 2	HTIFx : Channel x half transfer flag (x = 1..8). This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_IFCR register. 0: No half transfer (HT) event on channel x 1: A half transfer (HT) event occurred on channel x
Bits 29, 25, 21, 17, 13, 9, 5, 1	TCIFx : Channel x transfer complete flag (x = 1..8). This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_IFCR register. 0: No transfer complete (TC) event on channel x 1: A transfer complete (TC) event occurred on channel x
Bits 28, 24, 20, 16, 12, 8, 4, 0	GIFx : Channel x global interrupt flag (x = 1..8). This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_IFCR register. 0: No TE, HT or TC event on channel x 1: A TE, HT or TC event occurred on channel x

10.4.2 DMA interrupt flag clear register (DMA_IFCR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to [Section 2.2.2 Memory map and register boundary addresses](#) for the register boundary addresses.

11 DMA request multiplexer (DMAMUX)

11.1 Introduction

A peripheral indicates a request for DMA transfer by setting its DMA request signal. The DMA request is pending until it is served by the DMA controller which generates a DMA acknowledge signal and the corresponding DMA request signal is de-asserted.

For simplicity, the functional description of the DMA request/acknowledge protocol and its associated control signals are abstracted in this document and globally named as DMA request lines. The DMA controller response signals are not shown in figures nor described in the text.

The DMAMUX request multiplexer allows routing a DMA request line between the peripherals and the DMA controller of the product. The routing function is ensured by a programmable multi-channel DMA request line multiplexer. Each channel selects a unique DMA request line.

11.2 DMAMUX main features

- 8-channel programmable DMA request line multiplexer output
- Per DMA request line multiplexer channel output:
 - 16 input DMA request lines from peripherals
 - One DMA request line output

11.3 DMAMUX implementation

11.3.1 DMAMUX instantiation

DMAMUX is instantiated with the following hardware configuration parameters.

Table 26. DMAMUX instantiation

Feature	DMAMUX
Number of DMAMUX output request channels	8
Number of DMAMUX request generator channels	16
Number of DMAMUX request trigger inputs	2
Number of DMAMUX synchronization inputs	2
Number of DMAMUX peripheral request inputs	1

11.3.2 DMAMUX mapping

The mapping of resources to DMAMUX is hardwired.

Table 27. DMAMUX map

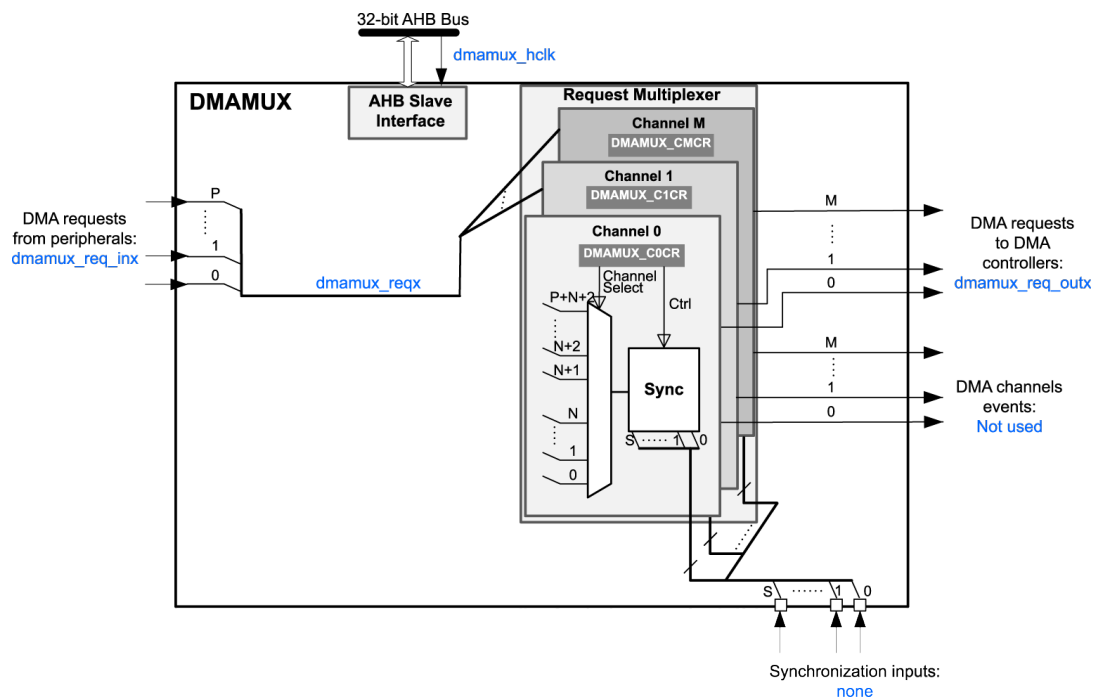

DMA request MUX input	Resource	DMA request MUX input	Resource
1	Reserved	10	I2C2_RX
2	SPI3_RX	11	I2C2_TX
3	SPI3_TX	12	USART_RX
4	SPI1_RX	13	USART_TX
5	SPI1_TX	14	LPUART_RX
6	SPI2_RX	15	LPUART_TX
7	SPI2_TX	16	ADC_CH0 (DS channel)
8	I2C1_RX	17	ADC_CH1 (DF channel)
9	I2C1_TX		

11.4 DMAMUX functional description

11.4.1 DMAMUX block diagram

Figure 21. DMAMUX block diagram shows the DMAMUX block diagram.

Figure 21. DMAMUX block diagram

The implementation assigns:

- DMAMUX request multiplexer sub-block inputs (`dmamux_reqx`) from peripherals (`dmamux_req_inx`)
- DMAMUX requests outputs to channels of DMA controllers (`dmamux_req_outx`)

11.4.2 DMAMUX channels

A DMAMUX channel is a DMAMUX request multiplexer channel which may include, depending on the selected input of the request multiplexer.

A DMAMUX request multiplexer channel is connected and dedicated to one single DMA controller(s) channel.

Channel configuration procedure

The following sequence should be followed to configure both a DMAMUX x channel and the related DMA channel y:

1. Set and configure completely the DMA channel y, except enabling the channel y.
2. Set and configure completely the related DMAMUX y channel.
3. Activate the DMA channel y by setting the EN bit in the DMA y channel register.

11.4.3 DMAMUX request line multiplexer

The DMAMUX request multiplexer with its multiple channels ensures the actual routing of DMA request/acknowledge control signals, named as DMA request lines.

Each DMA request line is connected in parallel to all the channels of the DMAMUX request line multiplexer.

A DMA request is sourced from the peripherals.

The DMAMUX request line multiplexer channel x selects the DMA request line number as configured by the 8-bit DMAREQ_ID field in the DMAMUX_CxCR register.

Note: The null value in the field DMAREQ_ID corresponds to no DMA request line selected. A same non-null DMA_REQ_ID value shall not be programmed to different x and y DMAMUX request multiplexer channels (via DMAMUX1_CxCR and DMAMUX CyCR). It is not allowed to configure a same non-null DMAREQ_ID to two different channels of the DMAMUX request line multiplexer.

On top of the DMA request selection, the synchronization mode and/or the event generation may be configured and enabled, if required.

11.5 DMAMUX registers

Refer to the table about register boundary addresses for the DMAMUX base address. The registers can only be accessed by words (32-bits).

11.5.1 DMAMUX request line multiplexer channel x configuration register (DMAMUX_CxCR)

Address offset: $0x04 * x$ ($x = 0$ to)

Reset value: 0x0000 0000

12 Analog digital converter (ADC)

The BlueNRG-LP embeds a 12-bit ADC. The ADC consists of a 12-bit successive approximation analog-to-digital converter (SAR) with 2 x 8 multiplexed channels allowing measurements of up to eight external sources and up to two internal sources.

12.1 Features

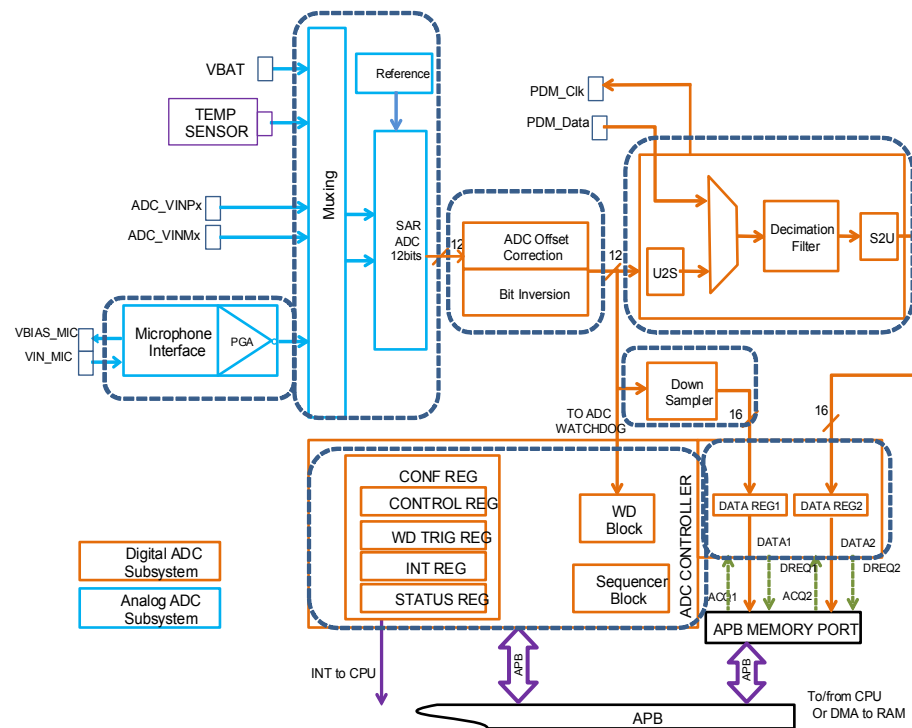

- Conversion frequency is up to 1 Msps
- Three input voltage ranges are supported (0 → 1.2 V, 0 → 2.4 V, 0 → 3.6 V)
- Up to eight analog single-ended channels or four analog differential inputs or a mix of both
- One analog microphone supported through two GPIOs configured in analog mode (an input for the analog microphone and a Vbias output for the analog microphone)
- Temperature sensor conversion
- Battery level conversion up to 3.6 V
- Continuous or single acquisition
- Digital decimation filter to process a digital audio PDM stream provided by 2 GPIOs and for ADC post-processing, especially for analog audio stream
- Five modes of conversion are possible:
 - ADC continuous or single mode
 - Analog continuous audio mode
 - Occasional conversions
 - Digital continuous audio mode
 - Full mode
- ADC down sampler for multi-purpose applications to improve analog performance while off-loading the CPU (ratio adjustable from 1 to 128)
- A watchdog feature to inform when data is outside thresholds (available for all modes except the digital audio mode)
- DMA capability
- Interrupt sources with flags.

12.2 ADC presentation

Figure 22. ADC top level diagram shows the top level diagram of the ADC.

The analog ADC can be configured to interface with the following inputs:

- External signals through ADC_VINPx and ADC_VINMx, where x=0,1,2 or 3
 - Up to 4 differential inputs
 - Up to 8 single-ended inputs
- Analog microphone interface
- Temperature sensor battery level detector up to 3.6 V
- Battery level detector up to 3.6 V

Figure 22. ADC top level diagram

In parallel of the analog ADC, a digital microphone can be supported (PDM interface through two GPIOs).

The input of the data path can come from:

- the analog ADC
- a digital microphone signal

The conversion data path can go through:

- a decimation filter
- a down sampler (for static or low frequency input signals)

The existence of those two different data paths allows some concurrent conversion (specific combinations).

Caution: Do not change the configuration registers related to the function in use. Any change done by the user on the different bits are applied immediately, with an immediate effect on the on-going process (conversion, decimator filter or downsampler). This action can lead to unexpected results.

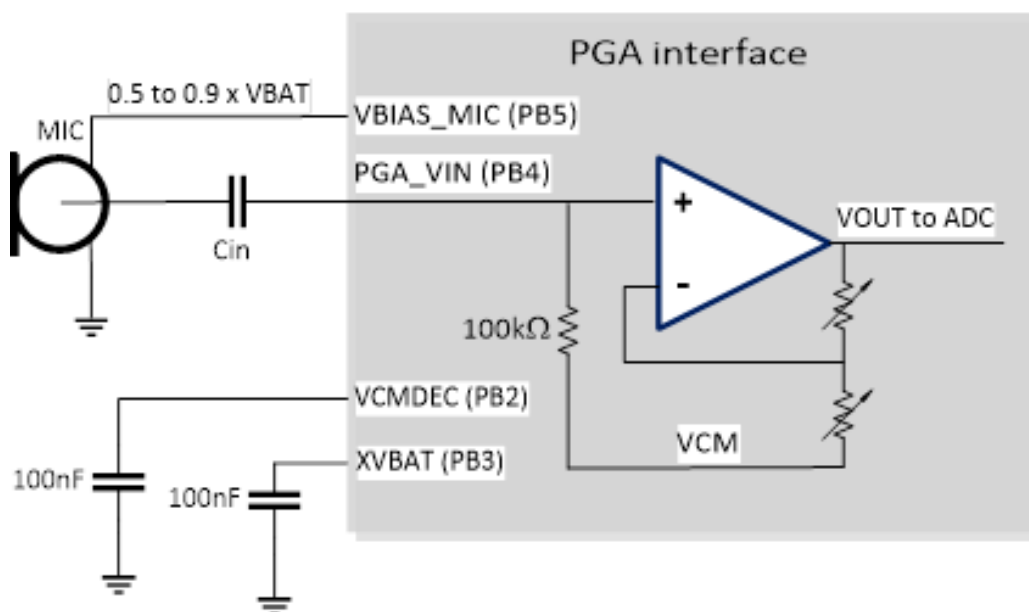

For $V_{BAT} < 2.7\text{ V}$, the IO booster needs to be activated to maintain linearity.

12.2.1 Programmable gain amplifier (PGA)

The input signal coming from the analog microphone is amplified with a programmable gain amplifier (PGA) (see [Figure 23. Microphone setup](#)) from 0 dB to 30 dB by step of 3 dB.

The signal is then filtered by a low-pass filter with -1 dB at 20 kHz.

The PGA output voltage is 1.2 V and is inverted versus the VIN_MIC input signal.

Figure 23. Microphone setup

VBIAS_MIC, whose function is independent of PGA_VIN, is used as the microphone power supply. In order to accommodate different microphone supply specifications with a battery that could vary between 1.7 V and 3.6 V, VBIAS_MIC voltage is adjustable as a ratio of VBAT, between 0.5 and 0.9. Refer to the section on PGA_CONF registers for details.

100 nF capacitors need to be connected to VCMDEC and XVBAT respectively to filter out the noise above 1 kHz. PGA_VIN has a typical input common-mode voltage, VCM, of 750 mV. In order to avoid DC conflicts which could cause saturation in the PGA, a coupling capacitor, Cin, needs to be connected between the microphone and PGA_VIN. The recommended value is 1 μF but one could use a lower value (see [Table 29. PGA parameters](#)). The smaller the capacitor, the quicker the start-up time but with the drawback of the input signal being attenuated. For example, with a Cin of 10 nF a 1 kHz signal would be attenuated by approximately 1 dB.

The PGA gain is adjustable between 0 dB and 30 dB in steps of 3 dB (see [Section 12.6.5 ADC PGA configuration register \(PGA_CONF\)](#)). In order to avoid distortion in the PGA, the gain setting would need to be adjusted in accordance with the microphone output peak voltage. Below are the PGA maximum output peak voltage values to be respected along with the formula for estimating the maximum PGA gain with respect to the microphone sensitivity, S₀.

Table 29. PGA parameters

Parameter	Symbol	Min.	Typ.	Units	Remarks
Cin	Cin	0.1	1	μF	1 μF is recommended
PGA Max Vout	MxVout	-6.8	-5.8	dBVpk	Typ. at 25 °C; Min. at 105 °C

Note: Maximum PGA gain in dB = MxVout – S₀ – 3 [N.B. Sensitivity for analog mics are in dBVrms]

Note: E.g. With the microphone sensitivity = -38 dB in a typical setting and no attenuation in the input signal: Maximum PGA gain = -5.8 + 38 – 3 = 29.2 dB.

Note: The usage of the PGA in analog audio mode implies connecting 3 external capacitors on PB2/PB3/PB4 I/Os. The user has to ensure that the analog switch is well configured to select the PGA external capacitor mode (see [Section 8.2.11 I/O analog switch control register \(GPIO_SWA_CTRL\)](#) for details) and then that those two pads are programmed in analog mode (see [Section 7.4.1 GPIO port mode register \(GPIOx_MODER\)](#) (x = A, B) for details) in this order. A filter needs to be added to the output of the decimation filter in order to filter out the DC level.

12.2.2 Temperature sensor subsystem

The temperature sensor can be used to measure the junction temperature (T_j) of the device. The temperature sensor is internally connected to the ADC input channels which are used to convert the sensor output voltage to a digital value.

The temperature sensor needs to be enabled through the PWRC_CR2.ENTS bit.

The temperature sensor measurement conversion is on the input range 0 to 1.2 V as the temperature range is:

- for minimum temperature = -40 °C, $V_{min} = 0.585$ V
- for maximum temperature = +125 °C, $V_{max} = 0.999$ V

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip-to-chip due to process variation. The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by ST during production. During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference. In this way the temperature can be calculated with this formula:

$$Temperature\ in\ Celsius = \frac{55}{(C85 - C30)} \cdot [C_{meas} - C30] + 30 \quad (1)$$

Where:

C85 is the temperature sensor calibration value acquired at 85 °C readable @0x10001E68.

C30 is the temperature sensor calibration value acquired at 30 °C readable @0x10001E60.

Cmeas is the actual temperature sensor output value converted by ADC.

Note: ADC gain calibration for VINPx range 1.2 V only must be applied. Offset calibration must be 0 (not used).

12.2.3 Battery sensor

The battery sensor can be used to measure the internal battery voltage of the device. The battery input is internally connected to the ADC input channels which are used to convert the sensor output voltage to a digital value.

The battery sensor range is up to 3.6 V.

The formula for ADC converted data after calibration is the following:

Code = Integer(4096/3.6 * VIN) [clamped at 4095]

As calibration points the VBAT is considered as single negative input with 3.6 V range.

12.2.4 ADC input mode conversion

The ADC is designed to deliver a digital value corresponding to the ratio between the analog power supply and the voltage applied on the converted channel. For most application use cases, it is necessary to convert this ratio into a voltage independent of VDDA.

The formula for ADC digital converted data after calibration and offset is the following:

- Single-ended input mode

Code = Integer(Slope * VIN) [clamped at 4095]

where Slope for single-ended input mode has the following value:

3.6 V mode: Slope = 4096/3.6 [calibrated gain = 1/3]

2.4 V mode: Slope = 4096/2.4 [calibrated gain = 1/2]

1.2 V mode: Slope = 4096/1.25 [calibrated gain = 0.96, gain clamped at 1]

- Differential input mode

Code = Integer(Slope * (VINP - VINN)) + 2048 [clamped at 4095]

where Slope for differential input mode has the following value:

3.6 V mode: Slope = 2048/3.6 [calibrated gain = 1/3]

2.4 V mode: Slope = 2048/2.4 [calibrated gain = 1/2]

1.2 V mode: Slope = 2048/1.25 [calibrated gain = 0.96, gain clamped at 1]

12.2.5 Calibration points

Calibration values are stored in the system memory for each device by ST during production. Each value consists of a 12-bit unsigned value for the gain and an 8-bit signed value for the offset as follows:

OFFSET[18:12] | GAIN[11:0]

These values can be written inside the registers COMP_x with x=1, 2, 3, 4 to apply a point to a particular ADC input. The COMP_SEL register allows a specific calibration point to be associated to one of the ADC inputs.

The offset value can be written inside the COMP_x register only if it fits in the 7-bit of register field, that means offset is in [-64, 63]. Otherwise, it can be removed by the output raw data manually as raw_value + offset.

The negative offset values need to be converted as:

offset | 0x80, if the bitfield BIT_INVERT_SN=1 (default value).

Below the list of the calibration points and their location in the system memory.

Table 30. Calibration points

Calibration point	Address location
VINPx - VINMx range 1.2 V	0x10001E00
VINMx range 1.2 V	0x10001E04
VINPx range 1.2 V	0x10001E08
VINPx - VINMx range 2.4 V	0x10001E0C
VINMx range 2.4 V	0x10001E10
VINPx range 2.4 V	0x10001E14
VINPx - VINMx range 3.6 V	0x10001E18
VINMx range 3.6 V	0x10001E1C
VINPx range 3.6 V	0x10001E20

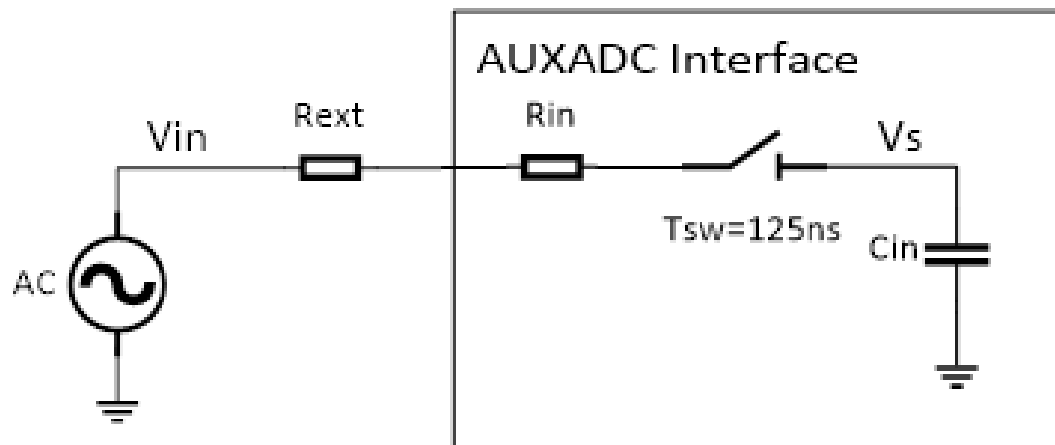

Note: Previous version of the calibration points has the offset in 7-bit signed. This version can be recognized as the user can read at address 0x10001EFC the value 0.

12.2.6 Steady-state input impedance

As the input nature of the ADC is a switched-capacitor, its steady-state input impedance is defined as the impedance seen in DC. It depends only on the analog sampling frequency, F_s , and the input capacitor, C_{in} : $Z_{in} = 1/(C_{in} \cdot F_s)$.

12.2.7 Input signal sampling transient response

As represented in [Figure 25. Effect of analog source resistance](#), the analog signal path consists of a series resistance (R_{ext}) between source and pin, the internal switch resistor (R_{in}) and the internal sampling capacitor (C_{in}). The charging of the capacitor is controlled by R_{in} . When there is R_{ext} in series, the effective value of charging of C_{in} is governed by $R_{in} + R_{ext}$. So the charging time constant becomes $(R_{in} + R_{ext}) \cdot C_{in}$ and the necessary time to reach a given accuracy is longer. The ADC has a fixed sampling time T_{sw} depending on ADC frequency which is $1/T_s$ as shown in [Figure 24. ADC sampling time \$T_{sw}\$ and sampling period \$T_s\$](#) .

Figure 24. ADC sampling time T_{sw} and sampling period T_s

Figure 25. Effect of analog source resistance

Knowing that: $R_{in}=550\ \Omega$, $C_{in}=4\ \text{pF}$, and imposing a maximum sampling error of 1/2 bits, we can determine the maximum input resistance as below:

$$\varepsilon = (V_s - V_{in}) / V_{in} = -e^{-(t/RC)}$$

$$\ln|\varepsilon| \leq t / (R_{ext} + R_{in}) * C_{in}$$

$$(R_{ext} + R_{in}) * C_{in} \leq t / \ln|\varepsilon|$$

$$(R_{ext} + R_{in}) * C_{in} \leq 125e-9 / \ln(122e-6)$$

$$(R_{ext} + R_{in}) * C_{in} \leq 14\ \text{ns}$$

$$R_{ext} \leq 14\ \text{ns} / 4\ \text{pF} - 550\ \Omega$$

$$R_{ext} \leq 2950\ \Omega$$

where:

$$|\varepsilon| \leq 1/2^{13}$$

$$|\varepsilon| \leq 122e-6$$

12.2.8 Decimation filter (DF)

The purpose of the decimation filter (DF) is to provide a way to reduce the incoming fixed rate sample to some fixed output data rates, while improving the overall noise performance (signal to noise ratio).

The decimation filter is used to process either the PDM data stream from a digital MEMS microphone or from the output of the 12-bit ADC, mainly targeting the audio sources of signal.

The input data rate of the decimation filter is:

- in analog audio / full mode: 1 Mbps

- in digital audio mode: the PDM clock rate itself (configured through PDM_RATE bit field of the DF_CONF register). The constraint is to fit the MEMS microphone range of possible frequencies (typically 1 to 3 MHz). The decimation filter is composed of two chained blocks:
 - a CIC filter capable to perform a wide range of decimation factors
 - a FIR filter performing the last stage of decimation and compensating the attenuation effect of the CIC filter.

The FIR filter has a fixed decimation rate of 3

Figure 26. Simplified decimation filter block diagram

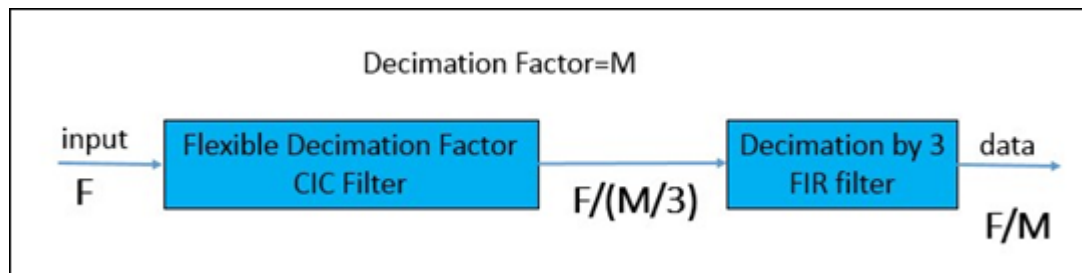

Table 31. Output data rate with ADC input at 1 MHz for analog mode and Table 32. CIC filter output frequency with digital microphone input list the decimation factors and the output frequencies according to the supported inputs (ADC or digital microphone).

The relationship between input data rate and output data rate is that the input data rate is:

- divided by DF_CIC_DEC_FACTOR
- then divided by 3
- divided by 2 if DF_CIC_DHF is set

Note: This divider by 2 is too noisy for digital audio scenario; to be kept for analog scenarios only.

- multiplied by 1.2 if DF_ITP1P2 is set

Table 31. Output data rate with ADC input at 1 MHz for analog mode

Target frequency	DF_CIC_DEC_FACTOR	DF_CIC_DHF (freq / 2)	DF_ITP1P2 (freq x 1.2)	Output frequency	Error
8 kHz	42	0	0	7.936 kHz	0.79 %
16 kHz	21	0	0	15.873 kHz	0.79 %
200 kHz ⁽¹⁾	2	0	1	200 kHz	0 %
44.1 kHz ⁽²⁾	14	1	0	44.444 kHz	0.78 %
48 kHz ⁽²⁾	7	0	0	47.619 kHz	0.79 %
22.05 kHz ⁽²⁾	15	0	0	22.222 kHz	0.78 %

1. The 200 kHz use-case is not supposed to be used for the analog audio scenario. It mainly targets sensor measurements.

2. This is a possible configuration but neither verified nor guaranteed (to be validated in lab).

Note: A constraint on the ratio between APB system clock (F_{PCLK}) and the output data rate (DR_{out}) must be respected:

- In analog audio mode and in full mode, the ratio to respect is $F_{PCLK} / DR_{out} \geq 6$.

Example: F_{PCLK} must be at least 2 MHz to have a $DR_{out} = 200$ kHz.

If the DMA is not used to get the data output by the decimation filter path, the CPU needs to be clocked at a frequency ratio high enough (taking into account bus matrix latency) to avoid missing samples.

Table 32. CIC filter output frequency with digital microphone input

Division ratio from 32 MHz clock	Digital microphone frequency	MCIC	Target frequency	Output frequency	Error
16	2 MHz	84	8 kHz	7.936 kHz	0.79 %
16	2 MHz	42	16 kHz	15.873 kHz	0.79 %
16	2 MHz	30	22.05 kHz	22.22 kHz	0.78 %
16	2 MHz	15	44.1 kHz	44.44 kHz	0.78 %
16	2 MHz	14	48 kHz	47.619 kHz	0.79 %

Table 33. Minimum decimation factor for the CIC / total versus pdm_rate provides the value of the allowable minimum decimation factor for the CIC filter and for the complete chain versus the pdm_rate input parameter.

Table 33. Minimum decimation factor for the CIC / total versus pdm_rate

pdm_rate	Decimation filter input rate	Minimum allowed decimation factor CIC / total
0	3.2 MHz	5 / 15
1	2.91 MHz	5 / 15
2	2.66 MHz	5 / 15
3	2.46 MHz	4 / 12
4	2.28 MHz	4 / 12
5	2.13 MHz	4 / 12
6	2.00 MHz	4 / 12
7	1.88 MHz	3 / 9
8	1.78 MHz	3 / 9
9	1.68 MHz	3 / 9
10	1.60 MHz	3 / 9
11	1.52 MHz	3 / 9
12	1.46 MHz	3 / 9
13	1.40 MHz	3 / 9
14	1.33 MHz	3 / 9
15	1.28 MHz	2 / 6

When the input of the decimation filter comes from 12-bit ADC, an unsigned-to-signed data conversion is possible through a configuration bit (DF_I_U2S bit in DF_CONF register).

The output of the decimation filter can also be converted from signed to unsigned through a configuration bit (DF_O_S2U bit in DF_CONF register) to be compatible with the down sampler output which is always signed.

The input PDM data is sampled either on the falling edge or the rising edge of the PDM clock. This is configurable through DF_MICRO_L_RN bit in the DF_CONF register. The PDM clock is generated by a division of the decimation filter clock (always 32 MHz) according to the targeted output frequency.

12.2.9 Down sampler (DS)

This down sampler is a simple averaging filter, which can divide the ADC frequency by 1 to 128 by power of 2. The goal is to handle multiple ADC samples and average them into a single data with increased data width ranging from 12-bit to 16-bit.

The down sampler increases the data precision but reduces the output data rate.

Note: *A constraint on the ratio between APB system clock (F_{PCLK}) and the output data rate (DR_{out}) must be respected:*

- In ADC mode, the ratio to respect is $F_{PCLK} / DR_{out} \geq 4$.

Example: F_{PCLK} must be at least 2 MHz to have a $DR_{out} = 500$ kHz.

If the DMA is not used to get the data output by the down sampler filter path, the CPU needs to be clocked at a frequency ratio high enough (taking into account bus matrix latency) to avoid missing samples.

12.3 Interrupts

There are 6 maskable interrupts generated by the ADC block. These interrupts are combined to produce one single interrupt output, which is the only interrupt line from the ADC to the CPU.

Table 34. ADC interrupt requests

Interrupt event	Event flag	Interrupt / flag clearing method	Interrupt enable control bit
Down sampler end of conversion	EODS_IRQ	Write 1 on EODS_IRQ bit	EODS_IRQ_ENA
Decimation filter end of conversion	EODF_IRQ	Write 1 on EODF_IRQ bit	EODF_IRQ_ENA
End of conversion sequence	EOS_IRQ	Write 1 on EOS_IRQ bit	EOS_IRQ_ENA
Analog watchdog event	AWD_IRQ	Write 1 on AWD_IRQ bit	AWD_IRQ_ENA
Down sampler overrun	OVR_DS_IRQ	Write 1 on OVR_DS_IRQ bit	OVR_DS_IRQ_ENA
Decimation filter overrun	OVR_DF_IRQ	Write 1 on OVR_DF_IRQ bit	OVR_DF_IRQ_ENA

12.4 DMA interface

The ADC has two DMA channels interface:

- one to get down sampler data output value (DS_DATAOUT register),
- one to get Decimation Filter data output value (DF_DATAOUT register)

The DMA feature is enabled by software through CONF register respectively by DMA_DS_ENA bit for down sampler data output and DMA_DF_ENA bit for decimation filter data output.

When DMA feature is disabled for one or both output, the data can be read by the CPU through the corresponding APB register.

12.5 ADC modes

Table 35. ADC mode summary provides an overview of the different supported modes.

Table 35. ADC mode summary

Mode	Input signal	DF or DS	Continuous or single	Possible concurrent mode
Analog audio	Analog microphone	DF	Continuous	Occasional
Digital audio	Digital GPIO (PDM_DATA)	DF	Continuous	ADC
ADC	<ul style="list-style-type: none"> 8 single external channels (or 4 when coupled as differential) VBAT Temperature sensor 	DS	Continuous or single	Digital audio
Full	<ul style="list-style-type: none"> 8 single external channels (or 4 when coupled as differential) VBAT Temperature sensor 	DF	Continuous	Occasional
Occasional	<ul style="list-style-type: none"> VBAT Temperature sensor 	DS	Single	<ul style="list-style-type: none"> Full Analog audio

12.5.1 Analog audio mode

Presentation

The Analog audio mode has the following characteristics:

- The input in the analog audio mode is the analog microphone signal
- The input signal is amplified with a programmable gain amplifier (PGA) from 0 dB to 30 dB
- The data path is from the analog audio PGA interface, the ADC and the decimation filter (down sampler not used in this mode)
- The converted data is output in the DF_DATAOUT register
- The analog audio mode conversion sequence is always in continuous mode.

Analog audio mode usage

This paragraph describes the process to use the analog audio mode:

- Program the PB2 and PB3 I/Os to connect the two external capacitors to the PGA analog block. This is done in two steps (keep the order):
 - first, program the PB2 and PB3 analog switch to select the PGA external capacitor mode by setting the GPIO_SWA_CTRL[1] bit in the SYSCFG block,
 - then, program the PB2 and PB3 I/Os to be in analog mode through the GPIOB_MODER[5:4] and GPIOB_MODER[7:6] bit field of the GPIOB block.
- Enable the LDO of the ADC by setting the ADC_LDO_ENA bit in the CTRL register.

Caution: This LDO enable bit must not be set when QFN32 devices are used because the VDDA pin used to supply the ADC LDO is not available on this package.

- Power on the ADC if not yet done by setting the ADC_ON_OFF bit in the CTRL register
- Program the wanted PGA gain through the PGA_GAIN bit field of the PGA_CONF register
- Set the analog bias voltage through the PGA_BIAS bit field of the PGA_CONF register
- Program the analog audio mode through the OP_MODE bit field in the CONF register
- Modify the data rate of the decimation filter if needed
- Program the continuous mode (mandatory in this mode) by setting the CONT bit in the CONF register
- Start the conversion by setting the START_CONV bit in CTRL register
- Each time a data is available at the output of the decimation filter, the data is stored in the DF_DATAOUT register and the EODF flag is set (as analog audio mode goes through the decimation filter)

- To get the converted values:
 - Either the DMA is enabled on DF data path (through DMA_DF_ENA bit in CONF register) and DMA copies the data in RAM at the end of each data conversion (via the APB bus)
 - Or the software has enabled the EODF_IRQ interrupt and is able to get the data from DF_DATAOUT register before a new converted data is generated.

Note: If the CPU does not manage to get the converted data before a new converted data is generated, the OVR_DF_IRQ flag is raised to inform a data has been lost. The software can program the hardware behavior in case of overrun through the OVR_DF_CFG bit in CONF register:

- *if 0, the previous data is kept, the new one is lost.*
- *if 1, the previous data is lost, the new one is kept.*
- The data conversion goes on until the software stops it by setting the STOP_OP_MODE bit in the CTRL register: in this case, the conversion stops immediately and on-going conversion data are issued.

12.5.2 ADC mode

Presentation

The ADC mode has the following characteristics:

- The input in the ADC mode can be the eight external channels and the two internal sources (VBAT and temperature sensor)
- The data path goes from the ADC to the down sampler (decimation filter is not used in this mode)
- The converted data is output in the DS_DATAOUT register
- The output data rates are in the range 4.4 ksp/s to 1 Msps
- The 12-bit converted data can be extended up to 16-bit data thanks to the down sampler. However, in this case, the output data rate is decreased
- A regular sequence of conversion can be executed in single or continuous mode
 - A regular sequence consists of chaining ADC conversions on any ADC input channel (except the analog microphone) and in any order.
 - A regular sequence can chain up to 16 conversions.
 - The source of the input for each conversion of the sequence is selected through SEQx bit field in SEQ_1 and SEQ_2 registers.
 - This regular sequence can be run once or repeated continuously by setting the CONT bit in CONF register.

ADC mode usage

This paragraph describes the process to use the ADC mode:

- Enable the LDO of the ADC by setting the ADC_LDO_ENA bit in the CTRL register

Note:

This LDO enable bit must not be set when QFN32 devices are used because the VDDA pin used to supply the ADC LDO is not available on this package.

- Power on the ADC if not yet done by setting the ADC_ON_OFF bit in the CTRL register
- Program the targeted data rate through SAMPLE_RATE and DS_CONF registers
- Program the input voltage selections through SWITCH register
- Program the COMP_1 to COMP_4 and the COMP_SEL registers
- Program the ADC mode through the OP_MODE bit field in the CONF register
- Program the targeted regular sequence (up to 16 chained conversions) through SEQ_1 and SEQ_2 registers
- Specify the length of the sequence in SEQ_LEN bit field in CONF (from 0 for one conversion to 0xF for sixteen conversions).

To have more than one conversion, ensure the bit SEQUENCE is well at 1 in CONF register.

- Program the CONT bit and the SEQ_LEN bit field in the CONF register, considering SEQUENCE bit is always set) depending on the wished sequence:
 - CONT = 0 and SEQ_LEN = 0 to have a single conversion on a single channel.
 - CONT = 0 and SEQ_LEN > 0 to have a single run of a sequence chaining several conversions on different channels/sources.
 - CONT = 1 and SEQ_LEN = 0 to have a continuous conversion of a single channel/source.
 - CONT = 1 and SEQ_LEN > 0 to have a continuous run of sequence chaining several conversions on different channels/sources.
- Launch the programmed regular sequence by setting the START_CONV bit in CTRL register
- Each time a data is available at the output of the down sampler, the data is stored in the DS_DATAOUT register and the EODS flag is set (as analog mode goes through the down sampler)
- To get the converted values:
 - Either the DMA is enabled on DS data path (through DMA_DS_ENA bit in CONF register) and DMA copies the converted data in RAM at the end of each data conversion
 - Or the software has enabled the EODS_IRQ interrupt and is able to get the data from DS_DATAOUT register before a new converted data is generated.

- Note:** *If the CPU does not manage to get the converted data before a new converted data is generated, the OVR_DS_IRQ flag is raised to inform a data has been lost. The software can program the hardware behavior in case of overrun through the OVR_DS_CFG bit in CONF register:*
- *if 0, the previous data is kept, the new one is lost.*
 - *if 1, the previous data is lost, the new one is kept.*
 - Each time the regular sequence is completed, the EOS_IRQ flag is raised (and may generate an interrupt if enabled)
 - If the sequence is a single sequence (SEQ_LEN=0), the ADC stops at the end of the sequence and does not restart until START_CONV bit is not set again
 - The data conversion goes on until the software stops it by setting the STOP_OP_MODE bit in the CTRL register: in this case, the conversion stops immediately and on-going conversion data are not issued.

12.5.3 Digital audio mode

Presentation

The digital audio mode aims to interconnect with an external digital MEMS microphone. The digital audio mode has the following characteristics:

- Only the decimation filter and the digital control resources are used
- The decimation filter interfaces with the external microphone with 2 GPIOs:
 - PDM_CLK: a clock output at programmable frequency through PDM_RATE[3:0] of the DF_CONF register (see [Section 12.6.2 ADC configuration register \(CONF\)](#)),
 - PDM_DATA: pulse density modulation input data.
- The converted data is output in the DF_DATAOUT register
- The digital audio mode conversion sequence is always in continuous mode.

Digital audio mode usage

This paragraph describes the process to use the digital audio mode:

- Program the PDM_CLK and PDM_DATA alternate functions on targeted IOs to have the digital microphone connected to the decimation filter
- Program the DF_MICRO_L_RN bit in the DF_CONF register to select the right or the left channel of the microphone
- Program the decimator rate through the DF_ITP1P2, DF_CIC_DHF and DF_CIC_DEC_FACTOR bit fields of the DF_CONF register
- Ensure the OP_MODE bit field in the CONF register is equal to 2
- As soon as the software sets the DIG_AUD_MODE bit in the CTRL register, the decimation filter starts sending the PDM_CLK and processing continuously the data received from the PDM_DATA input
- Each time a filtered data is available, the data is stored in the DF_DATAOUT register and the EODF_IRQ flag is raised (as digital audio mode goes through the decimation filter).

Note: *The first filtered data is available after a delay depending on the latency of the filter (according to the decimation factor) to guarantee the first issued value is correct.*

- To get the converted values:
 - Either the DMA is enabled on DF data path (through DMA_DF_ENA bit in CONF register) and DMA copies the converted data in RAM at the end of each data conversion
 - Or the software has enabled the EODF_IRQ interrupt and is able to get the data from DF_DATAOUT register before a new converted data is generated.

Note: *If the CPU does not manage to get the converted data before a new converted data is generated, the OVR_DF_IRQ flag is raised to inform a data has been lost.*

Note: *The software can program the hardware behavior in case of overrun through the OVR_DF_CFG bit in CONF register:*

- *if 0, the previous data is kept, the new one is lost.*
- *if 1, the previous data is lost, the new one is kept.*

- As soon as the software clears the DIG_AUD_MODE bit in the CTRL register, the conversion is stopped immediately and the on-going conversion is not completed.

12.5.4 Full mode

Presentation

The full mode is the same mode as the analog audio mode but with the other analog channels than the audio PGA interface.

The full mode has the following characteristics:

- The input in the full mode can be the eight external channels and the two internal sources (VBAT and temperature sensor)
- The data path is from the ADC through the decimation filter (down sampler not used in this mode)
- The converted data is output in the DF_DATAOUT register
- The full mode conversion sequence is always in continuous mode
- CONF.SEQ_LEN[3:0]=0x0 is the only supported configuration for this mode.

Full mode usage

This paragraph describes the process to use the full mode:

- Enable the LDO of the ADC by setting the ADC_LDO_ENA bit in the CTRL register

Note: This LDO enable bit must not be set when QFN32 devices are used because the VDDA pin used to supply the ADC LDO is not available on this package.

- Power on the ADC if not yet done by setting the ADC_ON_OFF bit in the CTRL register
- Program the full mode through the OP_MODE bit field in the CONF register
- Program the targeted data rate
- Program the continuous mode (mandatory in this mode) by setting the CONT bit in the CONF register
- Ensure CONF.SEQ_LEN[3:0]=0x0
- Start the conversion by setting the START_CONV bit in CTRL register
- Each time a conversion is completed, the converted data is stored in the DF_DATAOUT register and the EODF flag is set (as analog audio mode goes through the decimation filter)
- To get the converted values:
 - Either the DMA is enabled on DF data path (through DMA_DF_ENA bit in CONF register) and DMA copies the converted data in RAM at the end of each data conversion
 - Or the software has enabled the EODF_IRQ interrupt and is able to get the data from DF_DATAOUT register before a new converted data is generated.

Note: If the CPU does not manage to get the converted data before a new converted data is generated, the OVR_DF_IRQ flag is raised to inform a data has been lost.

Note: The software can program the hardware behavior in case of overrun through the OVR_DF_CFG bit in CONF register:

- if 0, the previous data is kept, the new one is lost.
- if 1, the previous data is lost, the new one is kept.
- The data conversion goes on until the software stops it by setting the STOP_OP_MODE bit in the CTRL register: in this case, the conversion stops immediately and on-going conversion data are not issued.

12.5.5 Occasional mode

Presentation

The occasional mode has the following characteristics:

- The occasional mode input is either the VBAT or the temperature sensor
- The data path is from the ADC through the down sampler
- The converted data is output in the DS_DATAOUT register
- The occasional mode is always a single conversion

- The occasional mode is only a complementary mode to analog AUDIO mode or full mode and cannot be activated alone
- The applied down sampler ratio is always 1 for this mode. The DS ratio programmed in the DS_RATIO bit field of the DS_RATIO register is not taken into account.

Occasional usage

This paragraph describes the process to use the occasional mode:

- Select the source to be converted during the occasional mode (VBAT or temperature sensor) through the OCM_SRC bit field in the OCM_CTRL register
- Set the OCM_ENA bit in the OCM_CTRL register to start the occasional conversion
- Once the single conversion is completed, the converted data is stored in the DS_DATAOUT register and the EODS flag is set (as occasional mode goes through the down sampler)
- To get the converted values:
 - Either the DMA is enabled on DS data path (through DMA_DS_ENA bit in CONF register) and DMA copies the converted data in RAM at the end of each data conversion
 - Or the software has enabled the EODS_IRQ interrupt and is able to get the data from DS_DATAOUT register before a new converted data is generated.

12.5.6

Concurrent functions

Some modes support having concurrent conversions:

- ADC mode and digital audio mode
- Analog audio mode and occasional mode
- Full mode and occasional mode.

In this case the data are available in DF_DATAOUT and/or in DS_DATAOUT registers, depending on the selected concurrent modes.

Note:

Audio analog mode, full mode and occasional mode use a common hardware resource (12-bit ADC block). Furthermore, the audio analog mode and the full mode are continuous. So when the occasional mode is used in concurrent mode, they lose one conversion. In this configuration, the hardware keeps the previous data on lost conversion.

12.6 ADC register description

12.6.22 ADC timers configuration register (TIMER_CONF)

Address offset: 0x54

Reset value: 0x0000 9628

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRECH_DELAY_SEL	VBIAS_PRECH_DELAY[7:0]								ADC_LDO_DELAY[7:0]							
															rw	rw								rw							

Bits 31:17	Reserved, must be kept at reset value.
Bit 16	PRECH_DELAY_SEL : Selects the time step PD_STEP for the VBIAS_PRECH_DELAY timer. – 0: PD_STEP = 4 us = (32 x 4) / 32 MHz – 1: PD_STEP = 4.096 ms = (32 x 4 x 1024) / 32 MHz
Bits 15:8	VBIAS_PRECH_DELAY[7:0] : Defines the duration of a waiting time starting at rising edge of PGA_EN signal and corresponding to the VBIAS precharge pulse duration. The delay is expressed in multiples of PD_STEP knowing PD_STEP is defined by the PRECH_DELAY_SEL bit value. The time unit is PD_STEP (4 us or 4.096 ms). With PRECH_DELAY_SEL=0, the maximum delay is 1.02 ms (255 x 4 us). With PRECH_DELAY_SEL=1, the maximum delay is 1044.48 ms (255 x 4.096 ms). Default value is 600 us (150 x 4 us).
Bits 7:0	ADC_LDO_DELAY[7:0] : Defines the duration of a waiting time to be inserted between the ADC_LDO enable and the ADC ON to let time to the LDO to stabilize before starting a conversion. The time unit is 4 us. Maximum delay is 1.02 ms (255 x 4 us). Default value is 40 = 160 us.

Refer to [Table 3. BlueNRG-LP memory map and peripheral register boundary addresses](#) for the register boundary addresses.

13 Random number generator (RNG)

The RNG is a random number generator based on a continuous analog noise that provides a 16-bit value to the host when read.

13.1 Features

- AHB slave peripheral
- Deliver 16-bit random number produced by an analog generator
- Minimum period of 1.25 us (corresponding to 20 RNGCLK cycles) between two consecutive random numbers. This is automatically managed by a pulling spacer counter that adds wait-state on the AHB bus when reading occurs too closely to the previous one
- Monitoring of the entropy of the RNG to flag abnormal behavior (generation of stable values or stable sequence of values)
- 2 clock domains:
 - RNGCLK: 16 MHz for the normalization and shifter (specific serial to 16-bit parallel conversion)
 - HCLK: AHB clock (16 MHz, 32 MHz or 64 MHz) for the AHB interface
- Can be disabled to reduce power consumption.

Power consumption and RNG:

The internal free-running oscillators are quite power consuming. It is possible to stop them when the RNG is not used

- After a PORESETn, the internal free-running oscillators are stopped by default to limit consumption
- When the RNG clock tree is enabled through the RCC after a PORESETn, the oscillators are automatically restarted
- If the SW enables the RNG clock tree through the RCC, it does not stop the internal oscillator. The SW has to first set the RNG_CR[2] = RNG_DIS to stop them.
- On the other side, the SW has to restart them by clearing the RNG_DIS bit once the RNG clock tree is re-enabled.

13.2 RNG register map

Refer to [Section 2.2.2 Memory map and register boundary addresses](#) for the register boundary addresses.

Note: *Despite RNG registers being addressed through AHB, only 32-bit accesses are allowed. Any 8-bit or 16-bit access generates an AHB error leading to a hard fault on Cortex-M0+.*

Table 37. RNG register list

1. These acronyms have the following meaning: RW = read and write; RO = read only.

13.3 RNG register description

RNG_CR

This register configures the RNG.

Table 38. RNG_CR register description

Address: RNG_BASE + 0x00				
Bit	Field name	Reset	R/W	Description
1:0	RESERVED	2'h0	RW	RESERVED
2	RNG_DIS	1'h0	RW	<p>RNG disable bit.</p> <p>This bit enables or disables the random number generator.</p> <ul style="list-style-type: none"> 0: RNG is enabled (default) 1: RNG is disabled. The internal free-running oscillators are put in power-down mode and the RNG clock is stopped at the input of the block.
3	TST_CLK	1'h0	RW	<p>RNG test clock bit.</p> <p>Writing this bit with 1b starts the logic that detects the presence of the RNG_CLK. Then wait (with a timeout of at least four RNGCLK cycles) for REVCLK = 1b in the RNG_SR register. If REVCLK = 0b after timeout elapsed, it means that RNGCLK is not present and reading RNG_VAL register triggers an AHB error response.</p> <p>For security reasons, software should check that the RNGCLK is present before reading random values.</p> <p>This bit is auto-cleared and always read as 0.</p>
31:4	RESERVED	28'h00000000	R	RESERVED

RNG_SR

This register provides status flags of the RNG.

Table 39. RNG_SR register description

Address: RNG_BASE + 0x04				
Bit	Field name	Reset	R/W	Description
0	RNGRDY	1'h0	R	<p>New random value ready.</p> <ul style="list-style-type: none"> 0: The RNG_VAL register value is not yet valid. If performing a read access to RNG_VAL, the host is on hold (by wait-states insertion on the AHB bus) until a random value is available. 1: The RNG_VAL register contains a valid random number. This bit remains at 0b when the RNG is disabled (RNGDIS bit = 1b in RNG_CR)
1	REVCLK	1'h0	R	<p>RNGCLK clock reveal bit.</p> <p>A write with 1b to bit TSTCLK in RNG_CR resets this bit. If the RNGCLK is present, this bit is 1b after four RNGCLK cycles after the end of the write to RNG_CR. If REVCLK = 0b after this period, it means the RNGCLK is not present and reading RNG_VAL triggers an AHB error response.</p>
2	FAULT	1'h0	RC_W1	<p>Fault reveal bit.</p> <p>This bit is set by hardware when a faulty sequence of bits occurs. The faulty sequences are:</p> <ul style="list-style-type: none"> sequence of more than 32 consecutive bits of samevalue (0b or 1b) sequence of more than 16 consecutive alternation of 0band 1b (010101...01b). <p>Writing this bit with 1b clear it. Writing with 0b has no effect.</p>
31:3	RESERVED	29'h00000000	R	RESERVED

RNG_VAL

This register delivers a 16-bit random value when read. After being read, this register delivers a new random value only after 20 cycles of RNGCLK. If the host performs a new read before the period has elapsed, the RNG inserts a wait-state on the AHB bus.

Table 40. RNG_VAL register description

Address: RNG_BASE + 0x08

14 Public key accelerator (PKA)

The public key accelerator is an AHB slave block dedicated to the computation of cryptographic public key primitives related to ECC (elliptic curve cryptography) using a predefined prime modulus and a predefined curve. The PKA core is clocked by the system clock divided by two and the PKA memory is clocked by system clock.

14.1 Features

The main features of the PKA block are:

- Elliptic curve Diffie-Hellman (ECDH) public-private key pair calculation accelerator
- Based on the Montgomery method for fast modular multiplications
- Built-in Montgomery domain inward and outward transformations
- AMBA AHB lite slave interface with a reduced command set
- Single port internal memory available for the system when the BlueNRG-LPPKA is not using it.

14.2 PKA registers map

The device communicates to the PKA via 32-bit-wide control registers accessible via the AMBA™ rev. 2.0 “AHB bus. These registers are listed in [Table 41. PKA register list](#) and are described in detail on the following pages. Refer to [Table 3. BlueNRG-LP memory map and peripheral register boundary addresses](#).

Table 41. PKA register list

Address offset	Name	RW ⁽¹⁾	Reset	Description
0x00	PKA_CSR	RW	0x00000002	Command and Status register. See Table 42. PKA_CSR register description .
0x04	PKA_ISR	RW	0x00000000	Interrupt register. See Table 43. PKA_ISR register description .
0x08	PKA_IEN	RW	0x00000000	Interrupt Enable register. See Table 44. PKA_ISR register description .

1. These acronyms have the following meaning: RW = read and write RC = read and write to clear.

14.3 PKA register description

Command and status register (PKA_CSR)

Table 42. PKA_CSR register description

Address: PKA_BASE + 0x00				
Bit	Field name	Reset	R/W	Description
0	GO	1'h0	RW	PKA start processing command. <ul style="list-style-type: none"> Writing 0 has no effect Writing 1 starts the encryption engine This bit must be written back to zero before the end of the calculation.
1	READY	1'h1	R	PKA readiness status. <ul style="list-style-type: none"> 0: The PKA is still computing 1: The PKA is ready to start a new calculation Caution: If READY bit is high, the PKA cannot be accessed through the AHB interface. The rising edge of the READY bit set the PROC_END flag in the PKA_ISR register.
6:2	RESERVED	5'h00	-	Reserved, must be kept at reset value.
7	SFT_RST	1'h0	RW	PKA software reset. <ul style="list-style-type: none"> Writing 0 clears the bit and releases the PKA block reset. Writing 1 resets the PKA block. The PKA RAM content is not changed. <i>Note: When the SFT_RST is set, the access to the PKA registers is not blocked, only the core is under reset.</i>
31:8	RESERVED	5'h00	-	Reserved, must be kept at reset value.

PKA interrupt status register PKA_ISR

The PKA_ISR register gives the interrupts status of the PKA block.

To clear a pending interrupt, it is necessary to chain two writings in the corresponding bit: write 1'b1 and then 1'b0.

Table 43. PKA_ISR register description

Address: PKA_BASE + 0x04				
Bit	Field name	Reset	R/W	Description
0	PROC_END	1'h0	RW	PKA process ending interrupt. When read: <ul style="list-style-type: none"> 0: No new event detected 1: The PKA process is ended (This bit is set to 1 when the PKA_CSR.READY bit rises.) When written: To clear the pending interrupt, the user must write this bit to 1 and clear it just after by writing 0. If the write 0 does not occur, the interrupt is generated on next event towards the CPU if enabled in PKA_IER but the flag is seen at 0 when the interrupt handler reads it in this register (as clear action is still active).
1	RESERVED	1'h0	-	Reserved, must be kept at reset value.
2	RAM_ERR	1'h0	RW	RAM read / write access error interrupt. When read: <ul style="list-style-type: none"> 0: All AHB read or write access to the PKA RAM occurred while the PKA was stopped 1: All the AHB read or write access to the PKA RAM occurred while the PKA was operating and using the internal RAM. Those read or write could not succeed as the PKA internal RAM is disconnected from the AHB bus when the PKA is operating (READY bit low). When written:

Address: PKA_BASE + 0x04				
Bit	Field name	Reset	R/W	Description
				To clear the pending interrupt, the user must write this bit to 1 and clear it just after by writing 0. If the write 0 does not occur, the interrupt is generated on next event towards the CPU if enabled in PKA_IER but the flag is seen at 0 when the interrupt handler reads it in this register (as clear action is still active).

Table 44. PKA_ISR register description

Address: PKA_BASE + 0x04				
Bit	Field name	Reset	R/W	Description
3	ADD_ERR	1'h0	RW	AHB Address error interrupt. When read: <ul style="list-style-type: none"> 0: All AHB read or write access to the PKA RAM occurred in a mapped address range 1: All AHB read or write access to the PKA RAM occurred in an unmapped address range When written: To clear the pending interrupt, the user must write this bit to 1 and clear it just after by writing 0. If the write 0 does not occur, the interrupt is generated on next event towards the CPU if enabled in PKA_IER but the flag is seen at 0 when the interrupt handler reads it in this register (as clear action is still active).
31:4	RESERVED	28'h0000000	-	Reserved, must be kept at reset value.

PKA interrupt enable register PKA_IEN

The PKA_IEN register allows enabling the PKA interrupts.

Table 45. PKA_IEN register description

Address: PKA_BASE + 0x08				
Bit	Field name	Reset	R/W	Description
0	READY_EN	1'h0	RW	READY interrupt enable. <ul style="list-style-type: none"> 0: READY interrupt is disabled 1: READY interrupt is enabled
1	RESERVED	1'h0	-	Reserved, must be kept at reset value.
2	RAMERR_EN	1'h0	RW	RAM access error interrupt enable. <ul style="list-style-type: none"> 0: RAM_ERR interrupt is disabled 1: RAM_ERR interrupt is enabled
3	ADDERR_EN	1'h0	RW	AHB Address error interrupt enable. <ul style="list-style-type: none"> 0: ADD_ERR interrupt is disabled 1: ADD_ERR interrupt is enabled
31:4	RESERVED	28'h0000000	-	Reserved, must be kept at reset value.

14.4 Programmer model

14.4.1 Basic sequence

The typical sequence to use the PKA block is the following:

1. Load input data into the PKA internal memory (PKA_RAM).
2. Assert the GO command by setting the GO bit in the PKA_CSR register.
3. Wait for READY bit setting (by polling READY bit in PKA_CSR register or through PROC_END interrupt).
4. Copy back elaboration results from PKA internal memory.

14.4.2 Data location in PKA_RAM

The input and output data have a specific location in PKA_RAM. The locations are specified in [Table 46. ECC scalar multiplication data location](#).

Table 46. ECC scalar multiplication data location

Parameter description	Mnemonic	Address (decimal)	Size (words)	PKA_RAM offset address
Input				
'k' of kP	ecc_addr_k	27	EOS ⁽¹⁾	0x6C
Initial point P, coordinates X,Y	ecc_addr_px ecc_addr_py	36	2*EOS ⁽¹⁾	0x90
		45		0xB4
Output				
Coordinates X,Y, of the results	ecc_addr_px ecc_addr_py	36	2*EOS ⁽¹⁾	0x90
		45		0xB4
Error	ecc_addr_kp_error	0	1	0x00

1. EOS:ECC operand size.

The error field returns one if the input point is not a valid point so does not satisfy the curve equation. In this case the computation is very short. If the error field is zero at the end of the calculation, then the result should be considered as valid. The maximum length of data is calculated with the following formula:

max. EOS = (max_ecc_size / word_size) + 1.

Example 1

If ECC P256 is used, an operand needs (256 / 32 + 1) words, so 9 words are needed by the PKA core. When loading an input that is represented on 256 bits = 8 words, an additional word is requested and has to be filled with zero.

15 Cyclic redundancy check calculation unit (CRC)

15.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the purpose of the functional safety standards, they offer a means of verifying the Flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

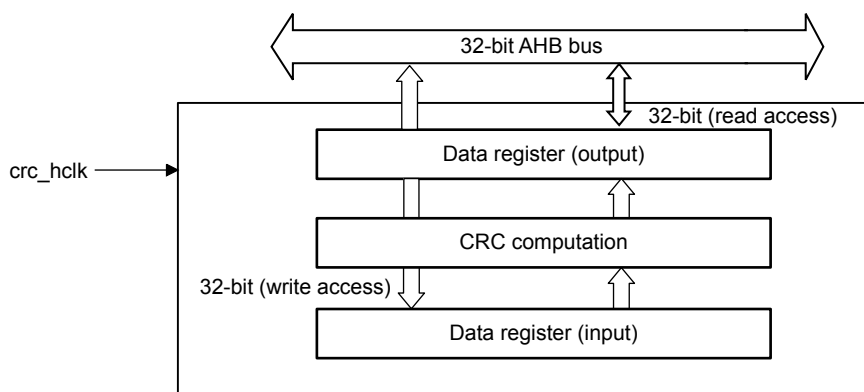

15.2 CRC main features

- Fully programmable polynomial with programmable size (7, 8, 16, 32-bits).
- Handles 8, 16, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/Odata.

15.3 CRC functional description

15.3.1 CRC block diagram

Figure 27. CRC calculation unit block diagram

15.3.2 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte-by-byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit access is allowed.

The duration of the computation depends on data width:

- 4 AHB clock cycles for 32-bit
- 2 AHB clock cycles for 16-bit
- 1 AHB clock cycles for 8-bit.

An input buffer allows a second data to be immediately written without waiting for any wait states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed, to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example: input data 0x1A2B3C4D is used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word.

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.

The operation is done at bit level: for example, output data 0x11223344 is converted into 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-the-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is on-going, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

15.4 CRC registers

15.4.1 Data register (CRC_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

16 Advanced-control timers (TIM1)

In this section, “TIMx” should be understood as “TIM1” since there is only one instance of this timer in the BlueNRG-LP device.

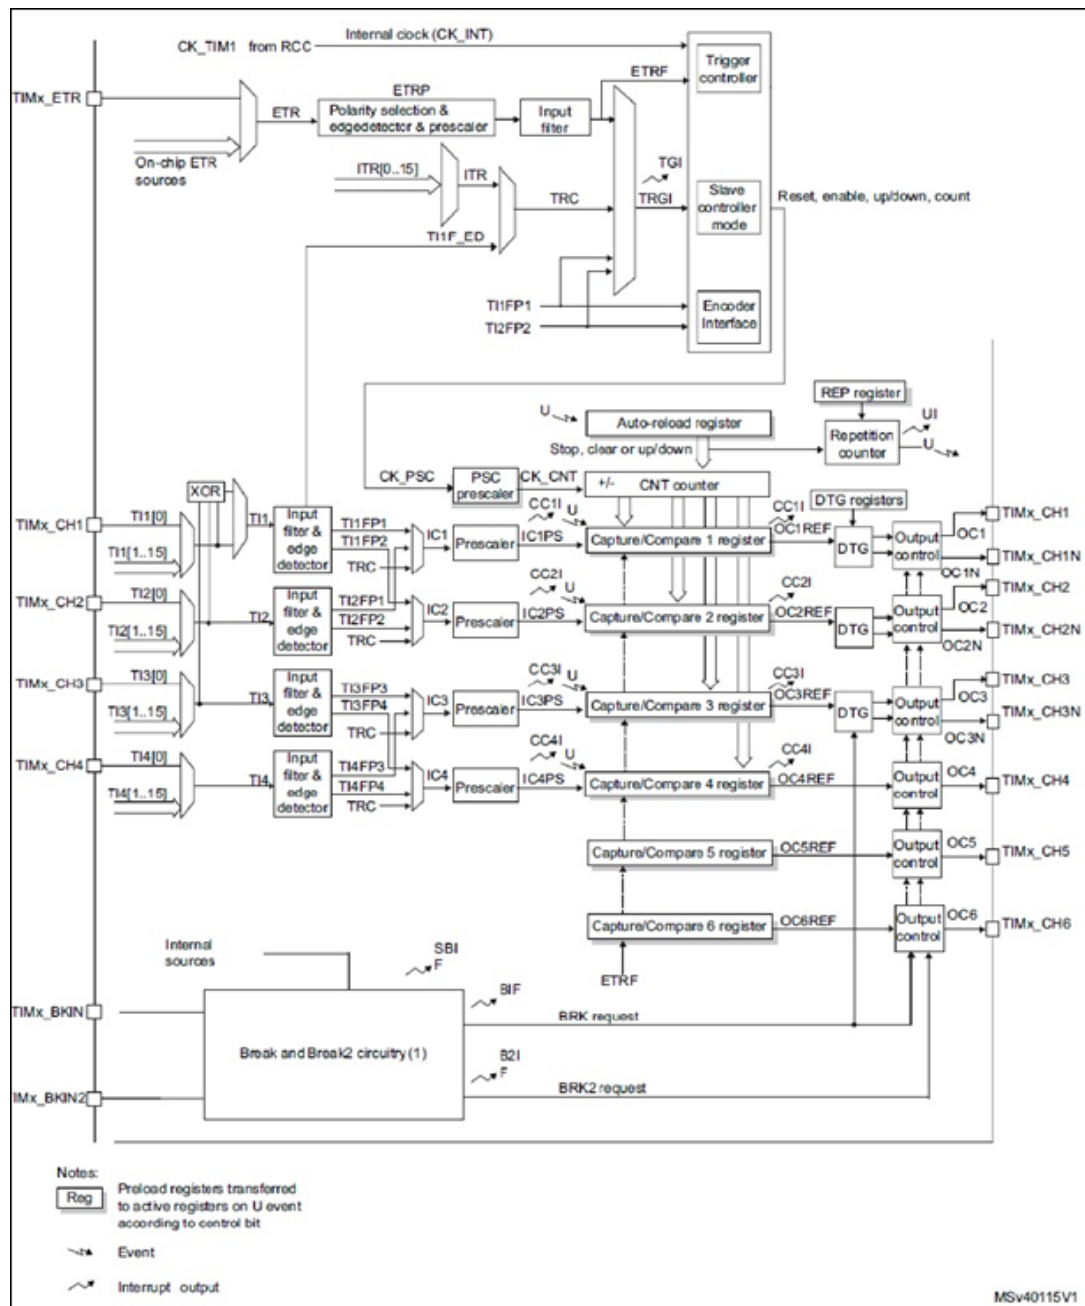

16.1 TIM1 introduction

The advanced-control timers (TIM1) consist of a 16-bit auto-reload counter driven by a programmable prescaler. It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with deadtime insertion). Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler on the timer input clock which is at 64 MHz.

16.2 TIM1 main features

TIM1 timer features include:

- 16-bit up, down, up/down auto-reload counter
- 16-bit programmable prescaler allowing dividing (also “on-the-fly”) the counter clock frequency either by any factor between 1 and 65536
- Up to 6 independent channels for:
 - Input capture (except channels 5 and 6)
 - Output compare
 - PWM generation (edge and center-aligned mode)
 - One-pulse mode output
- Complementary outputs with programmable deadtime
- Synchronization circuit to control the timer with external signals
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- 2 break inputs to put the timer output signals in a safe user selectable configuration
- Interrupt generation on the following events:
 - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
 - Trigger event (counter start, stop, initialization or count by internal/external trigger)
 - Input capture
 - Output compare
- Supports incremental (quadrature) encoder for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management.

Figure 28. Advanced-control timer block diagram

16.3 TIM1 functional description

16.3.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler. The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register(TIMx_CNT)
- Prescaler register(TIMx_PSC)
- Auto-reload register(TIMx_ARR)
- Repetition counter register(TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The contents of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when down-counting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on-the-fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 29. Counter timing diagram with prescaler division change from 1 to 2 and Figure 30. Counter timing diagram with prescaler division change from 1 to 4 give some examples of the counter behavior when the prescaler ratio is changed on-the-fly

Figure 29. Counter timing diagram with prescaler division change from 1 to 2

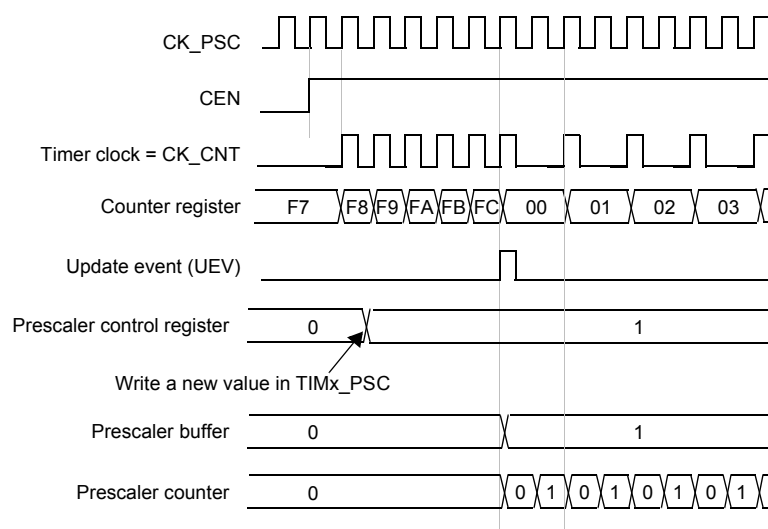

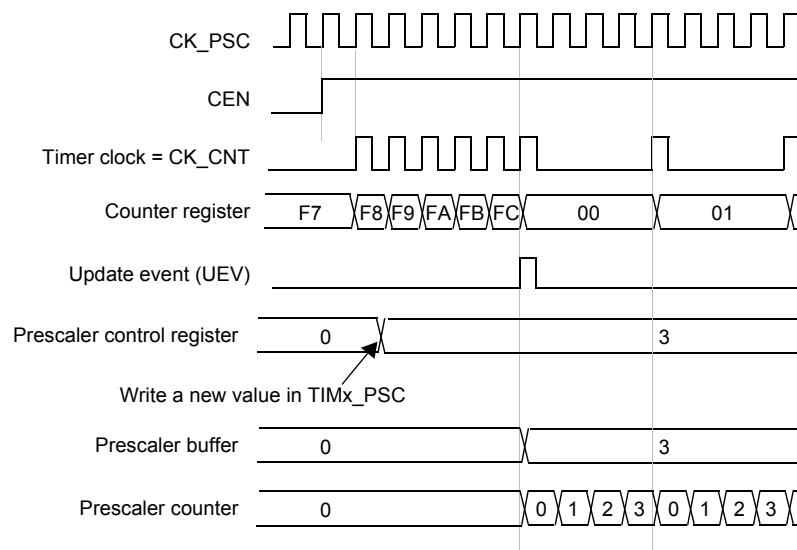

Figure 30. Counter timing diagram with prescaler division change from 1 to 4

16.3.2

Counter modes

Up-counting mode

In up-counting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after up-counting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Otherwise, the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

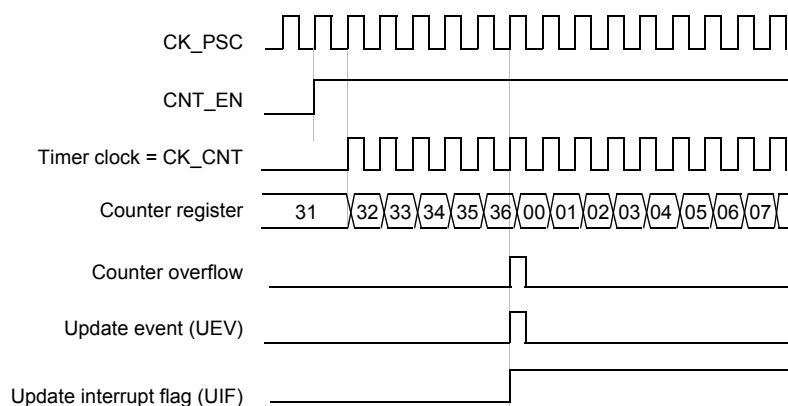

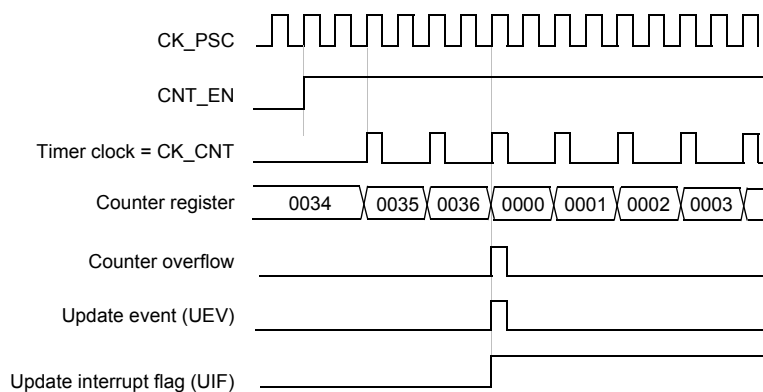

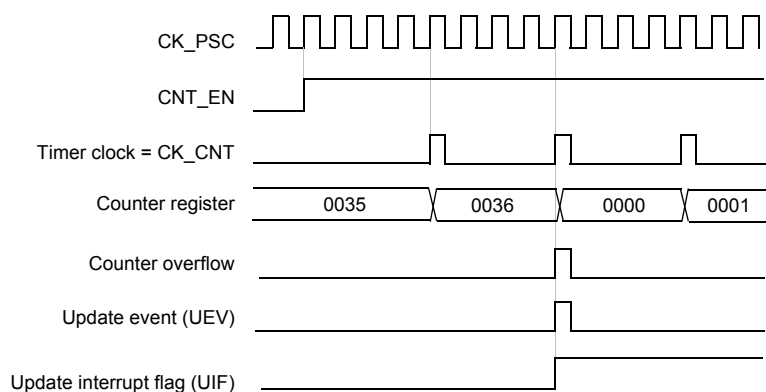

Figure 31. Counter timing diagram, internal clock divided by 1

Figure 33. Counter timing diagram, internal clock divided by 4

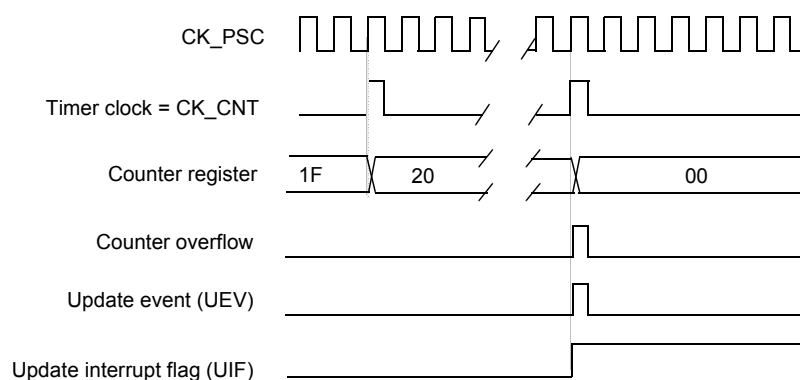

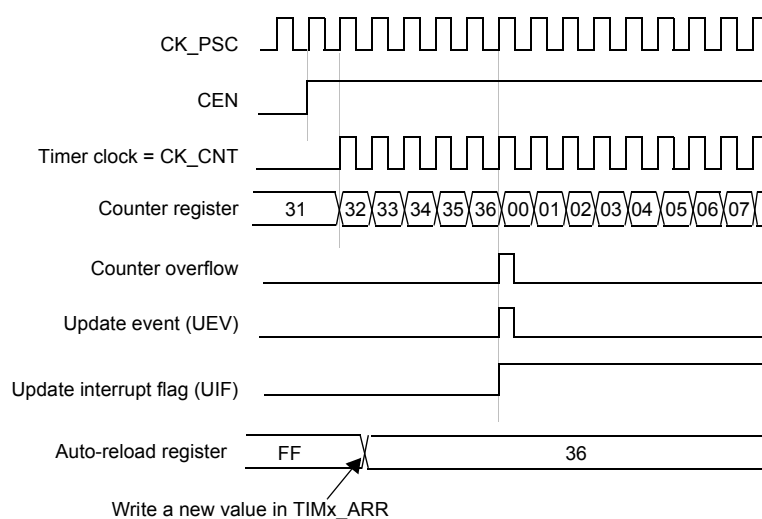

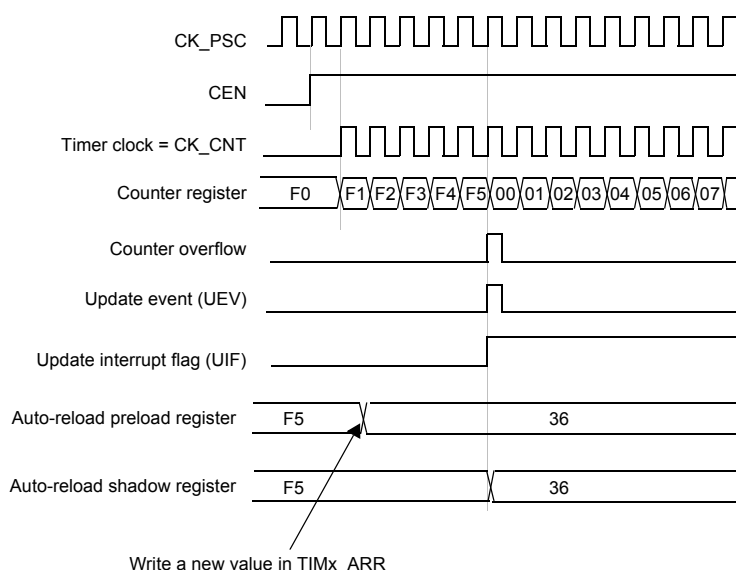

Figure 34. Counter timing diagram, internal clock divided by N

Figure 35. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)

Figure 36. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)

Down-counting mode

In down-counting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after down-counting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) +1. Otherwise, the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate does not change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

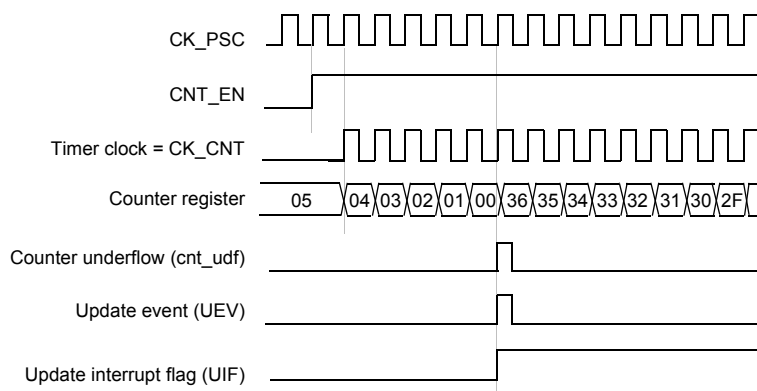

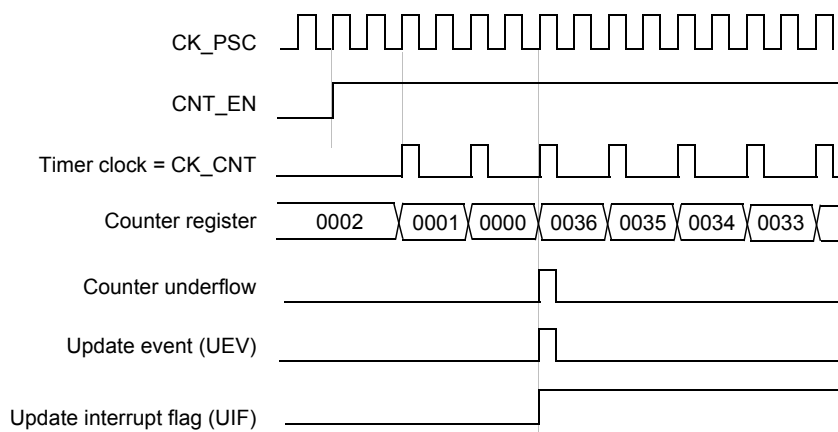

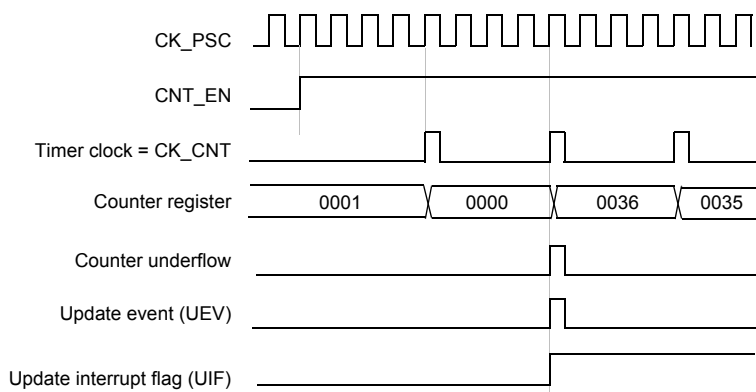

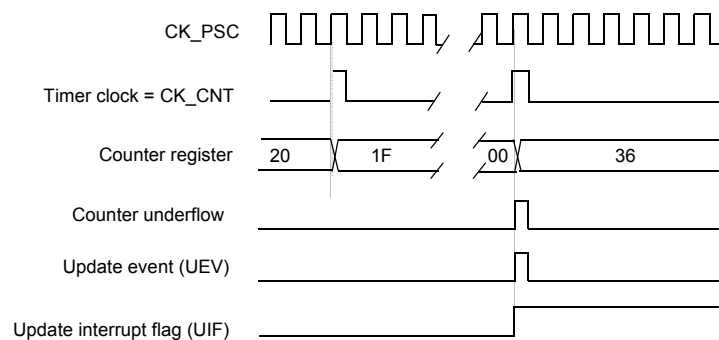

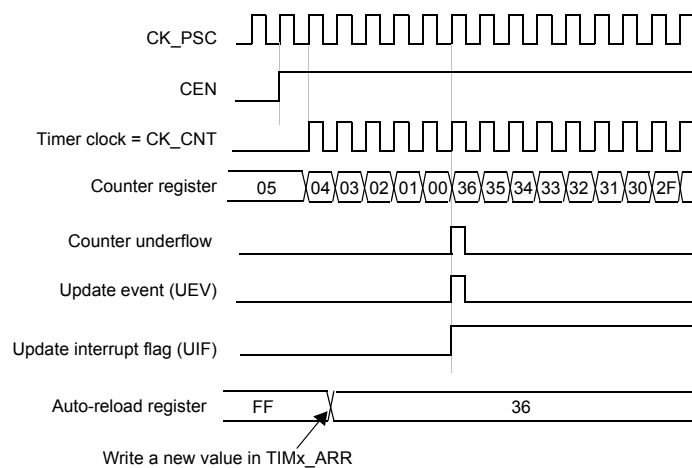

Figure 37. Counter timing diagram, internal clock divided by 1

Figure 38. Counter timing diagram, internal clock divided by 2

Figure 39. Counter timing diagram, internal clock divided by 4

Figure 40. Counter timing diagram, internal clock divided by N

Figure 41. Counter timing diagram, update event when repetition counter is not used

Center-aligned mode (up/down-counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register is not equal to '00'. The output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

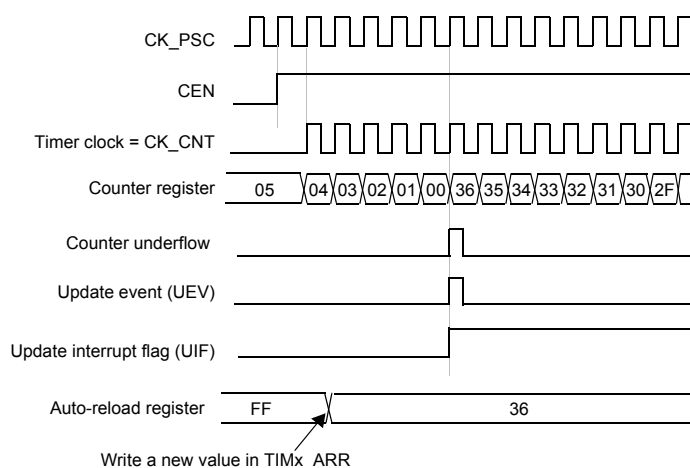

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates a UEV update event but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

Figure 42. Counter timing diagram, internal clock divided by 1, TIMx_ARR = 0x6

Note: Here, center-aligned mode 1 is used (for more details refer to [Section 16.4 TIM1 registers](#)).

Figure 46. Counter timing diagram, update event with ARPE=1 (counter underflow)

Figure 47. Counter timing diagram, update event with ARPE=1 (counter overflow)

16.3.3 Repetition counter

Section 16.3.1 Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:

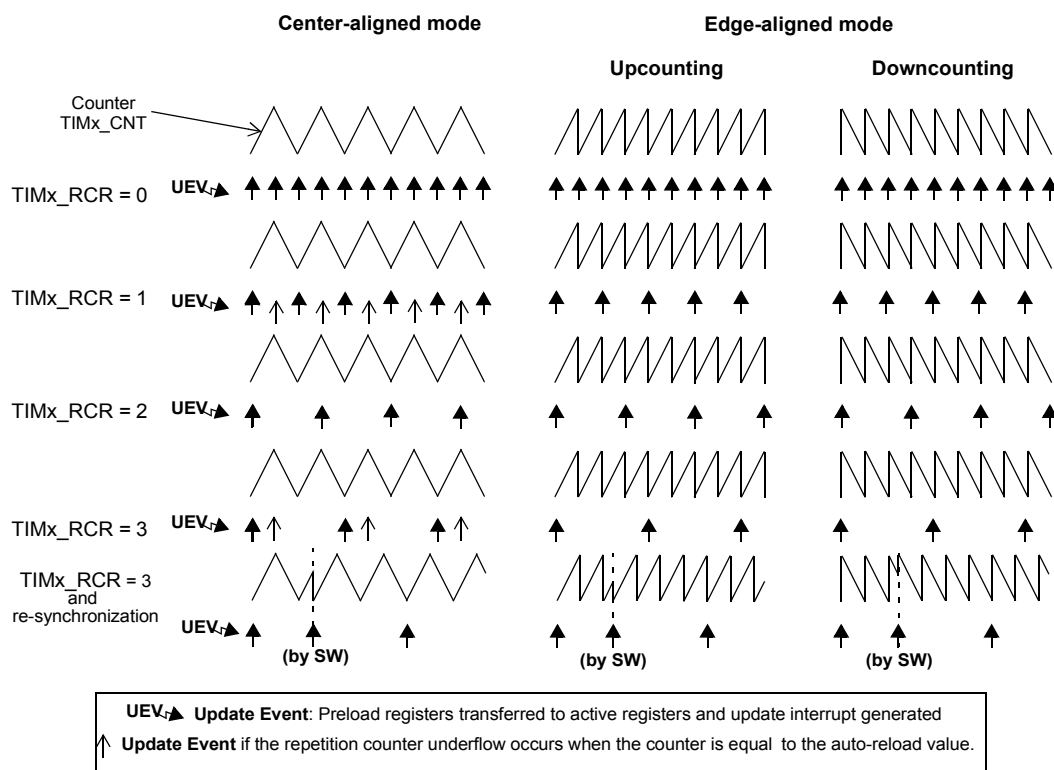

- At each counter overflow in up-counting mode
- At each counter underflow in down-counting mode
- At each counter overflow and at each counter underflow in center-aligned mode. Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is $2 \times T_{CK}$, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 48. Update rate examples depending on mode and TIMx_RCR register settings).

When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.

In center-aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the overflow. If the RCR was written after launching the counter, the UEV occurs on the underflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

Figure 48. Update rate examples depending on mode and TIMx_RCR register settings

16.3.4 External trigger input

The timer features an external trigger input ETR. It can be used as:

- External clock (external clock mode 2, see [Section 16.3.5](#))
- Trigger for the slave mode (see [Section 16.4 TIM1 registers](#))
- PWM reset input for cycle-by-cycle current regulation [Section 16.3.17 Clearing the OCxREF signal on an external event](#)).

Figure 49. External trigger input block below describes the ETR input conditioning. The input polarity is defined with the ETP bit in TIMx_SMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bit field and digitally filtered with the ETF[3:0] bit field.

Figure 49. External trigger input block

The ETR input comes from input pins (see [Table 7. GPIO alternate options AF3 - AF4](#) and [Table 8. I/O analog feature mapping](#)).

16.3.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1: external input pin

Note: Only channel 1 and channel 2 support the external clock mode 1.

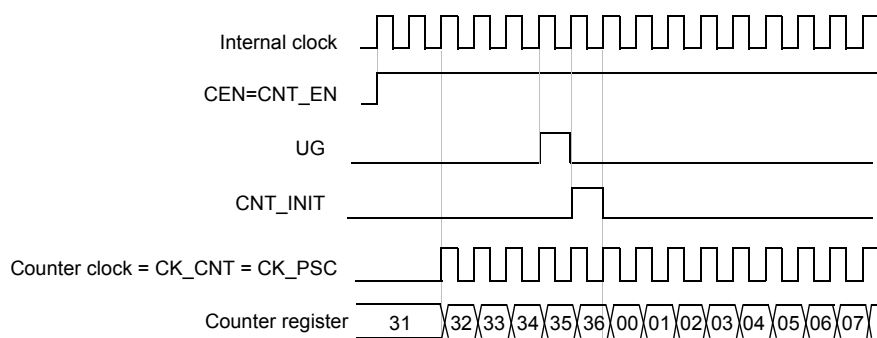

- External clock mode 2: external trigger input ETR
- Encoder mode.

Internal clock source (CK_INT)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

Figure 50. Control circuit in normal mode, internal clock divided by 1 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

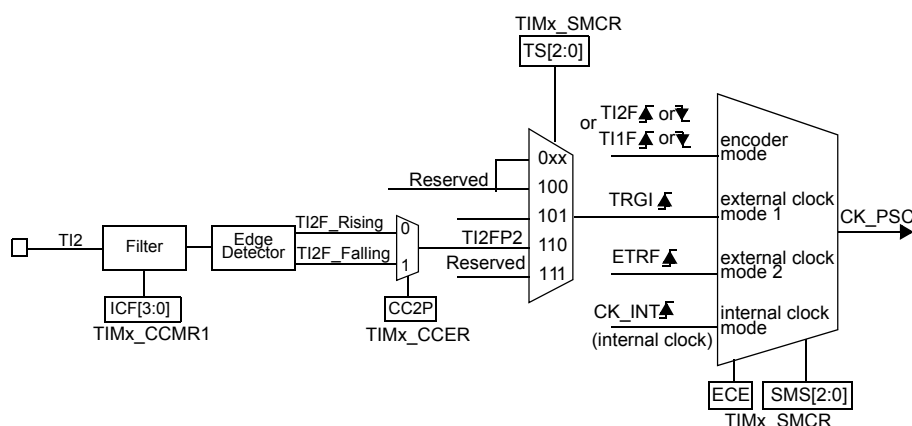

Figure 50. Control circuit in normal mode, internal clock divided by 1

External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 51. TI2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.

2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
4. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select TI2 as the trigger input source by writing TS=110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

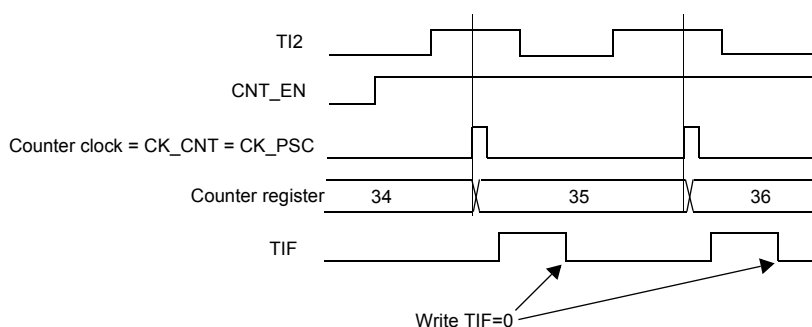

Note:

The capture prescaler is not used for triggering, so you do not need to configure it.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

Figure 52. Control circuit in external clock mode 1

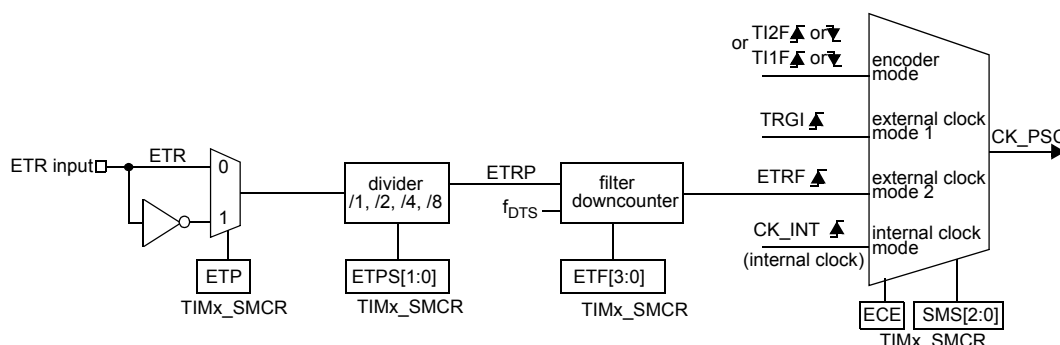

External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

Shown below in Figure 53. External trigger input block.

Figure 53. External trigger input block

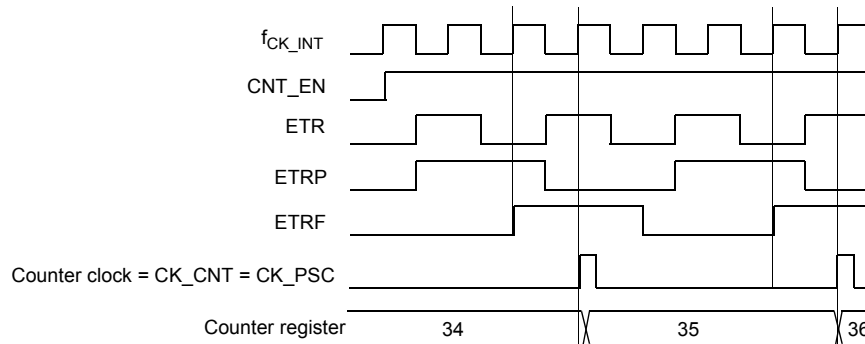

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register.
4. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

Figure 54. Control circuit in external clock mode 2

16.3.6

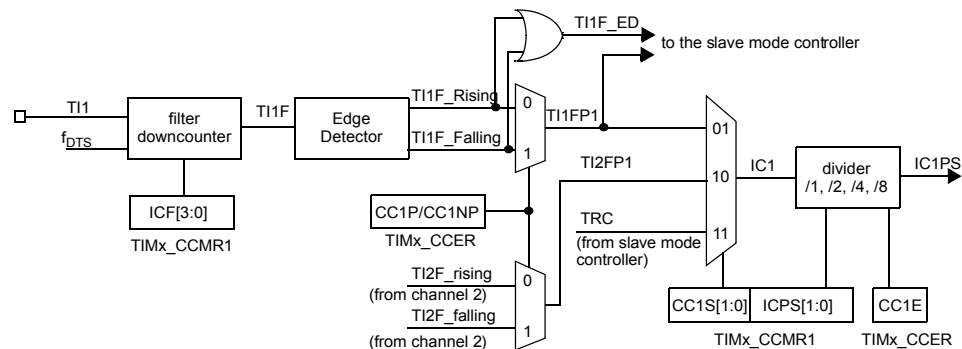

Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

Figure 55. Capture/compare channel (example: channel 1 input stage) to Figure 58. Output stage of capture/compare channel (channel 4) give an overview of one capture/compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 55. Capture/compare channel (example: channel 1 input stage)

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

Figure 56. Capture/compare channel 1 main circuit

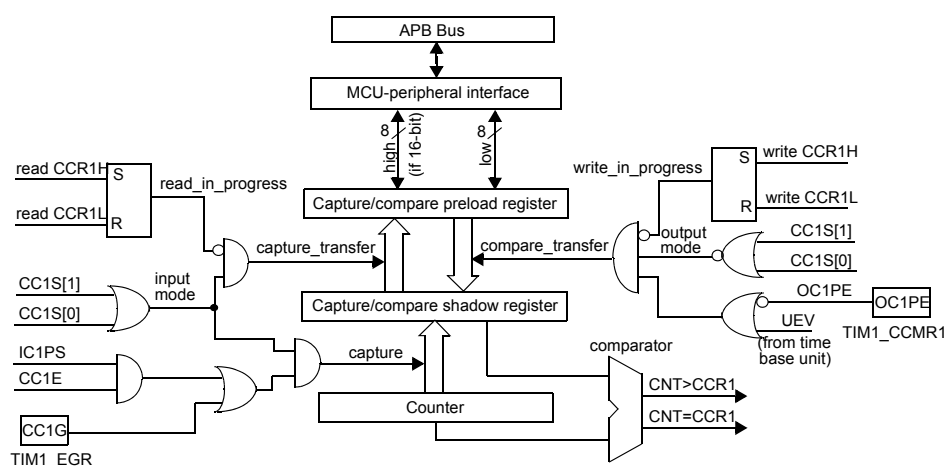

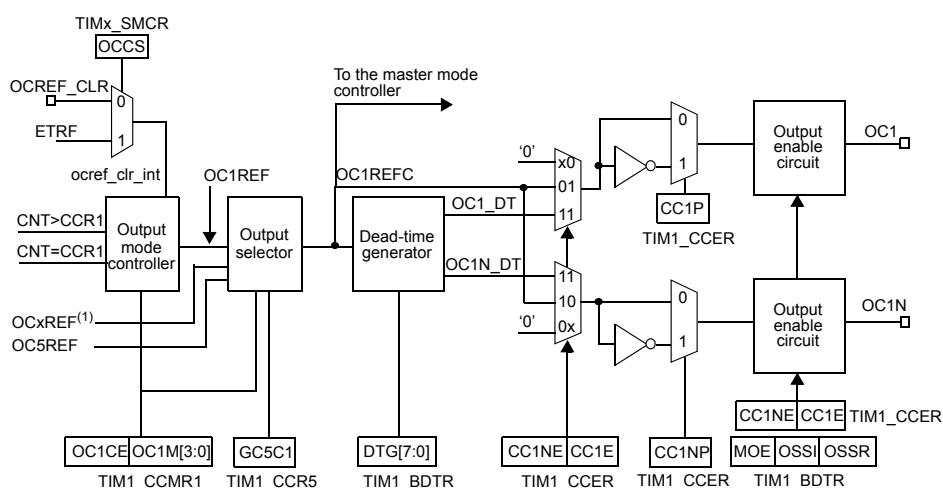

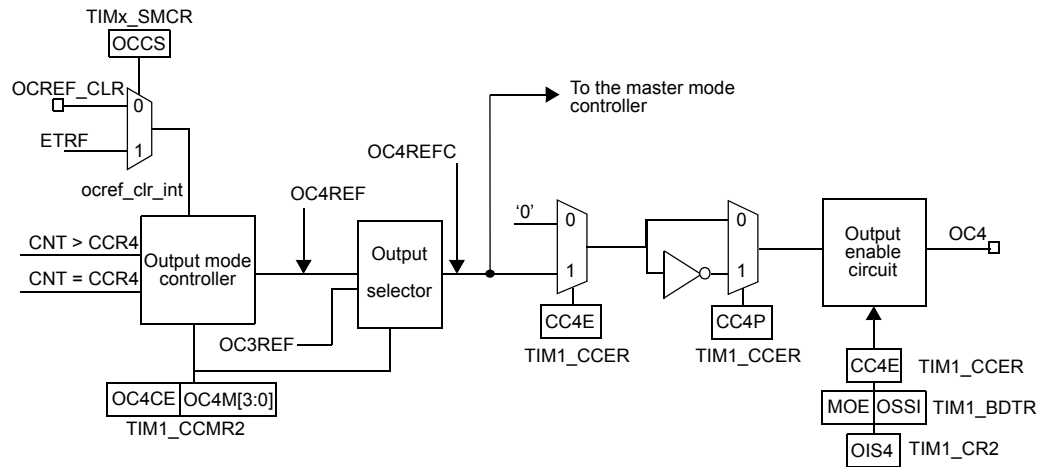

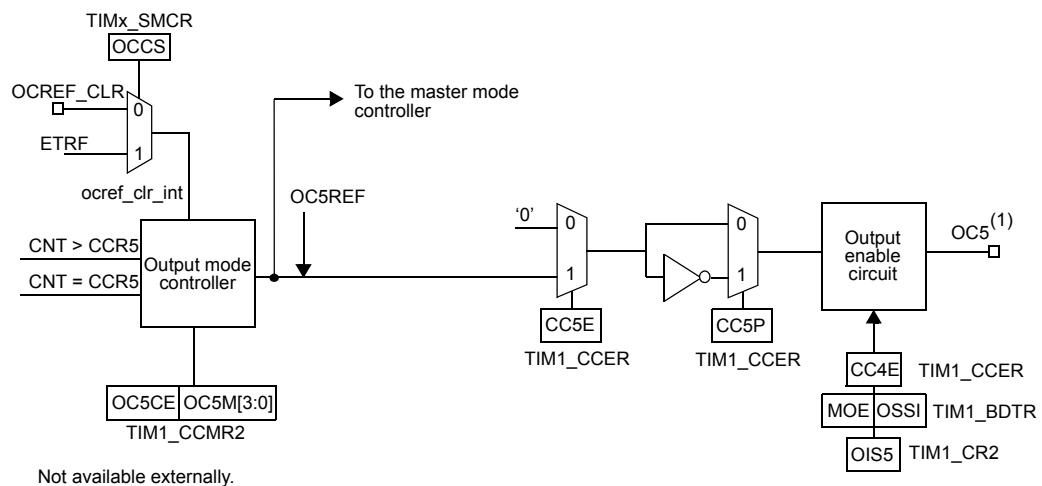

Figure 57. Output stage of capture/compare channel (channel 1, idem ch. 2 and 3)

Note: OCxREF, where x is the rank of the complementary channel.

Figure 58. Output stage of capture/compare channel (channel 4)

Figure 59. Output stage of capture/compare channel (channel 5, idem ch.6)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

16.3.7

Input capture mode

In input capture mode, the capture/compare registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the overcapture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when you write it to '0'.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.

- Program the input filter duration you need with respect to the signal you connect to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Imagine that, when toggling, the input signal is not stable during, at most, 5 internal clock cycles. A filter duration longer than these 5 clock cycles must be programmed. A transition on TI1 can be validated when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
- Select the edge of the active transition on the TI1 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

16.3.8 PWM input mode

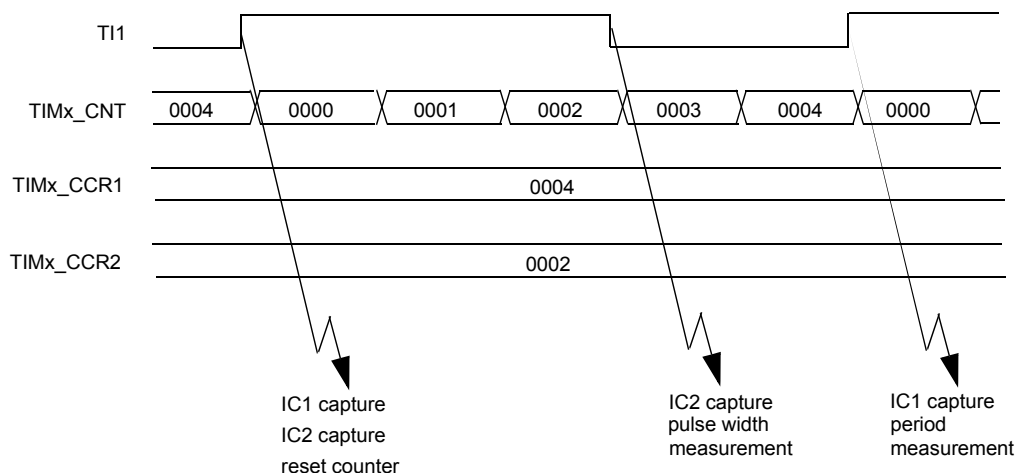

Note: Only channel 1 and channel 2 support this PWM input mode.

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input
- These 2 ICx signals are active on edges with opposite polarity
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, you can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to '0' (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP='10' (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx_CCER register.

Figure 60. PWM input mode timing

16.3.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCxREF/OCx) to its active level, you just need to write 0101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus, OCxREF is forced high (OCxREF is always active high) and OCx gets an opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 0100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt can be sent accordingly. This is described in the output compare mode section below.

16.3.10 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 6 can be output.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCRx register). The output pin can keep its level (OCxM=0000), be set active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in one-pulse mode).

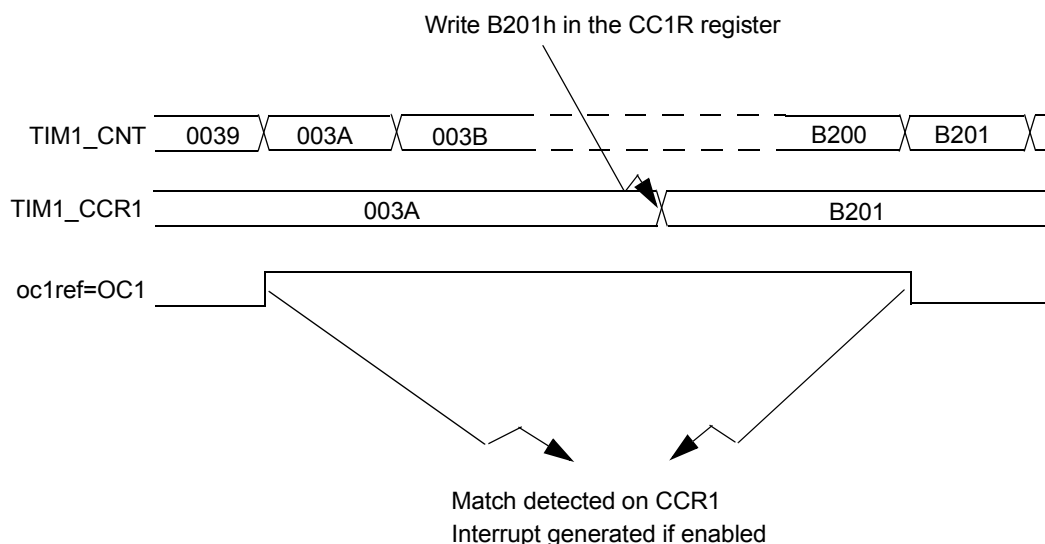

Procedure:

1. Select the counter clock (internal, external, prescaler)
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
 - a. Write OCxM = 0011 to toggle OCx output pin when CNT matches CCRx
 - b. Write OCxPE = 0 to disable preload register
 - c. Write CCxP = 0 to select active high polarity
 - d. Write CCxE = 1 to enable the output

5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', otherwise the TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 61. Output compare mode, toggle on OC1](#)

Figure 61. Output compare mode, toggle on OC1

16.3.11 PWM mode

Pulse width modulation mode allows you to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing '0110' (PWM mode 1) or '0111' (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. You must enable the corresponding preload register by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in up-counting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, you have to initialize all the registers by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether $TIMx_CCRx \leq TIMx_CNT$ or $TIMx_CNT \leq TIMx_CCRx$ (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.

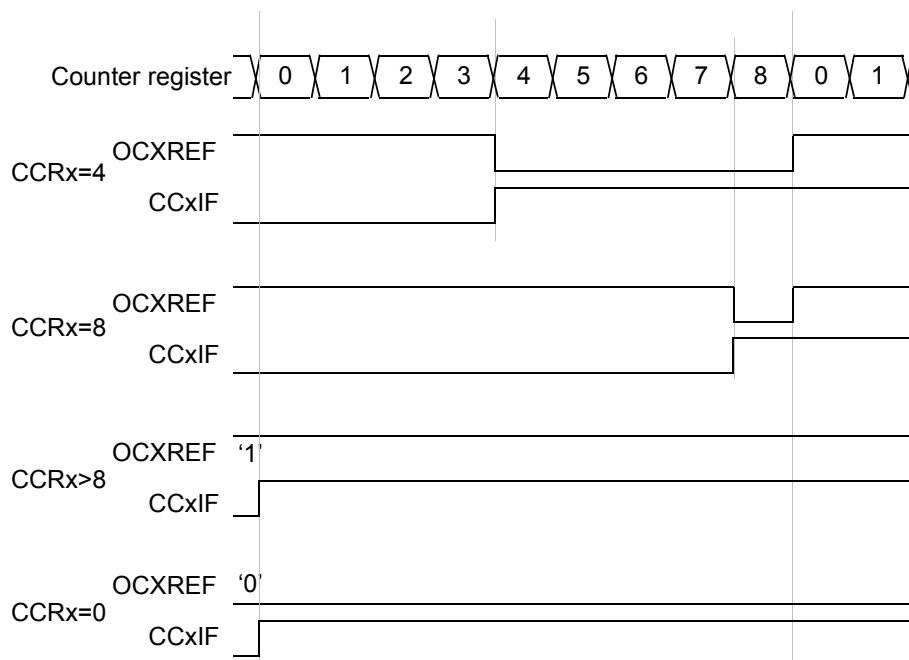

PWM edge-aligned mode

- Up-counting configuration

Up-counting is active when the DIR bit in the TIMx_CR1 register is low. Refer to [Section 16.3.2 Counter modes](#).

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as $TIMx_CNT < TIMx_CCRx$, otherwise it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxRef is held at '0'.

[Figure 62. Edge-aligned PWM waveforms \(ARR=8\)](#) shows some edge-aligned PWM waveforms in an example where $TIMx_ARR=8$.

Figure 62. Edge-aligned PWM waveforms (ARR=8)

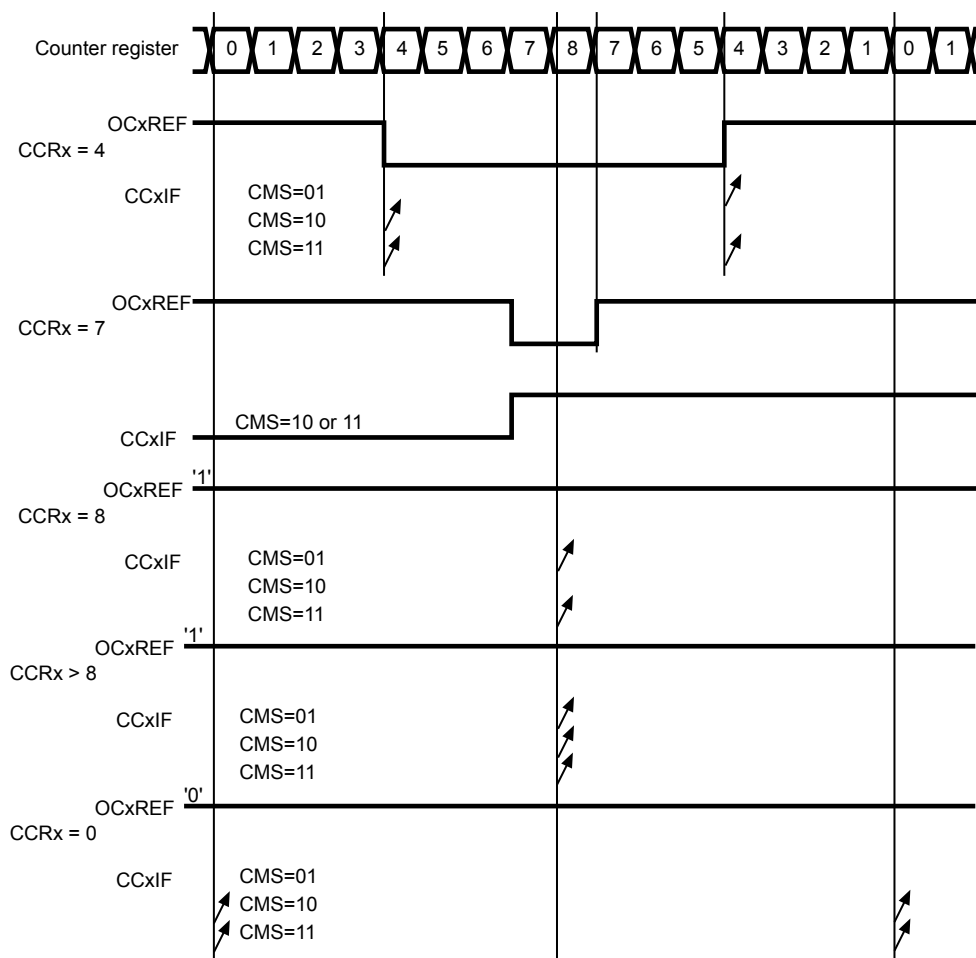

- Down-counting configuration
Down-counting is active when DIR bit in TIMx_CR1 register is high. Refer to [Section 16.3.2 Counter modes](#).
In PWM mode 1, the reference signal OCxRef is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then OCxREF is held at '1'. 0% PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from '00' (all the remaining configurations having the same effect on the OCxRef/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to [Section 16.3.2 Counter modes](#).

[Figure 63. Center-aligned PWM waveforms \(ARR=8\)](#) shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR=8
- PWM mode is the PWM mode 1
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Figure 63. Center-aligned PWM waveforms (ARR=8)

Hints on using center-aligned mode

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
 - The direction is not updated if you write a value in the counter that is greater than the auto-reload value (TIMx_CNT > TIMx_ARR). For example, if the counter was counting up, it continues to count up.
 - The direction is updated if you write 0 or write the TIMx_ARR value in the counter but no Update Event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

16.3.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase-shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx registers. One register controls the PWM during up-counting, the second during down-counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1110' (asymmetric PWM mode 1) or '1111' (asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

Note: *The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.*

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 1.

Figure 64. Generation of 2 phase-shifted PWM signals with 50% duty cycle represents an example of signals that can be generated using the asymmetric PWM mode (channels 1 to 4 are configured in asymmetric PWM mode 1). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.

Figure 64. Generation of 2 phase-shifted PWM signals with 50% duty cycle

16.3.13 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase-shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

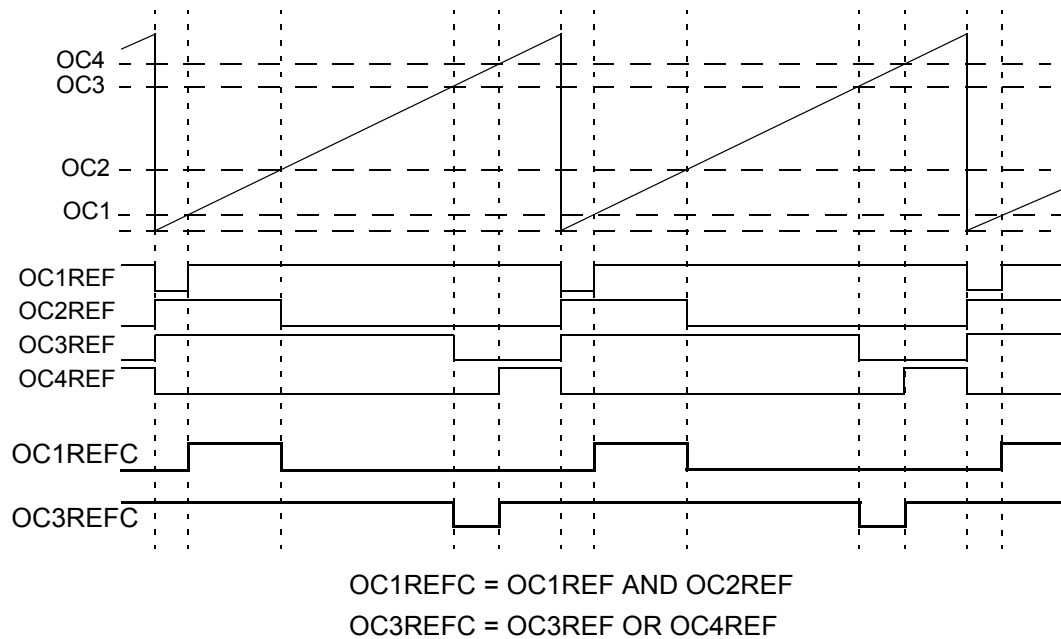

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1100' (combined PWM mode 1) or '1101' (combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in combined PWM mode 1 and the other in combined PWM mode 2).

Note: *The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.*

Figure 65. Combined PWM mode on channel 1 and 3 represents an example of signals that can be generated using the asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in combined PWM mode 2
- Channel 2 is configured in PWM mode 1
- Channel 3 is configured in combined PWM mode 2
- Channel 4 is configured in PWM mode 1.

Figure 65. Combined PWM mode on channel 1 and 3

16.3.14 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The OC5REF signal is used to define the resulting combined signal. The 3-bit GC5C[3:1] in the TIMx_CCR5 allows the selection on which reference signal the OC5REF is combined. The resulting signals, OCxREFC, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, OC1REFC is controlled by TIMx_CCR1 and TIMx_CCR5
- If GC5C2 is set, OC2REFC is controlled by TIMx_CCR2 and TIMx_CCR5
- If GC5C3 is set, OC3REFC is controlled by TIMx_CCR3 and TIMx_CCR5

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].

Figure 66. 3-phase combined PWM signals with multiple trigger pulses per period

16.3.15 Complementary outputs and deadtime insertion

The advanced-control timers (TIM1) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

Note: *This feature concerns channels 1 to 4 only.*

This time is generally known as the deadtime and you have to adjust it depending on the devices you have connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

You can select the polarity of the outputs (main output OCx or complementary OCxN) independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSS1 and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers.

Refer to [Table 50. Output control bits for complementary OCx and OCxN channels with break feature](#) for more details. In particular, the deadtime is activated when switching to the idle-state (MOE falling down to 0).

The deadtime insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit deadtime generator for each channel. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the deadtime generator and the reference signal OCxREF (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples).

Figure 67. Complementary output with deadtime insertion

Figure 68. Deadtime waveforms with delay greater than the negative pulse

Figure 69. Deadtime waveforms with delay greater than the positive pulse

The deadtime delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to [Section 16.4.18 TIM1 break and deadtime register \(TIMx_BDTR\)](#) for delay calculation.

Re-directing OCxREF to OCx or OCxN

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows you to send a specific waveform (such as PWM or static active level) on one output while the complementary remains in its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with deadtime.

Note: When OCxN is enabled (CCxE=0, CCxNE=1) only, it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

16.3.16 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the TIM1 timer. The break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break features two channels which gather the application fault from input pins. A break2 channel is able to force the outputs to an inactive state. The output enable signal and output levels during break depend on several control bits:

- the MOE bit in TIMx_BDTR register allows the outputs to be enabled/disabled by software and is reset in case of break or break2 event

- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shutdown level, either active or inactive. The OCx and OCxN outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to [Table 50. Output control bits for complementary OCx and OCxN channels with break feature](#) for more details.

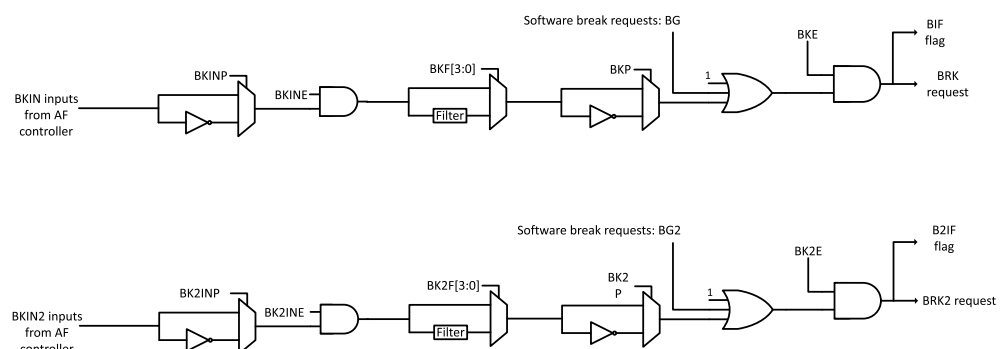

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions are globally enabled by setting the BKE and BKE2 bits in the TIMx_BDTR register. The break input global polarities can be selected by configuring the BKP and BKP2 bits in the TIMx_BDTR register. BKEx and BKPx can be modified at the same time. When the BKEx and BKPx bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait for 1 APB clock period to correctly read back the bit after the write operation.

Note: Since MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if you write MOE to 1 whereas it was low, you must insert a delay (dummy instruction) before reading it correctly. This is because you write the asynchronous signal and read the synchronous signal.

The break can be generated from multiple sources, which can be individually enabled and with programmable edge sensitivity, using the TIMx_AF1 and TIMx_AF2 registers.

Break events can also be generated by software using BG and B2G bits in the TIMx_EGR register. The software break generation using BG and BG2 is active whatever the BKE and the BKE2 enable bits values.

Figure 70. Break and break2 circuitry overview

Caution

An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail-safe clock mode must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on the one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature functions even if the MCU oscillator is off
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO controller) while the enable output remains high

- When complementary outputs are used:
 - The outputs are first put into an inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer
 - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 ck_tim clock cycles)
 - If OSSI=0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state) otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high
- The break status flag (BIF and B2IF bits in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Otherwise, MOE remains low until you write it to '1' again. In this case, it can be used for security and you can connect the break input to an alarm from power drivers, thermal sensors or any security components.

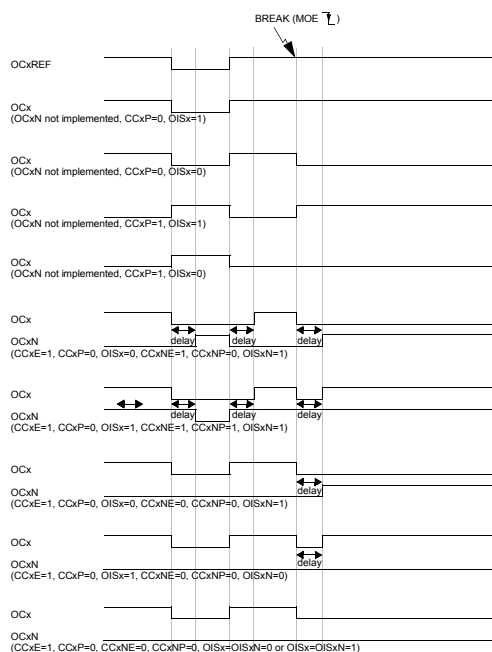

Note:

The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows you to freeze the configuration of several parameters (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). You can choose from 3 levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to [Section 16.4.18 TIM1 break and deadtime register \(TIMx_BDTR\)](#). The LOCK bits can be written only once after an MCU reset.

Figure 71. Various output behavior in response to a break event on BRK (OSSI = 1) shows an example of behavior of the outputs in response to a break.

Figure 71. Various output behavior in response to a break event on BRK (OSSI = 1)

The two break inputs have different behaviors on timer outputs:

- The BRKIN input can either disable (inactive state) or force the PWM outputs to a predefined safe state
- BRKIN2 can only disable (inactive state) the PWM outputs.

The BRKIN has a higher priority than BRKIN2 input, as described in Table 48. Behavior of timer outputs versus BRK/BK2inputs.

Note: BRKIN2 must only be used with $OSSR = OSSI = 1$.

Table 48. Behavior of timer outputs versus BRK/BK2inputs

BRKIN	BRKIN2	Timer outputs state	Typical use case	
			OCxN output (low-side switches)	OCx output (high-side switches)
Active	X	<ul style="list-style-type: none"> Inactive then forced output state (after a deadtime) Outputs disabled if $OSSI = 0$ (control taken over by GPIO logic) 	ON after deadtime insertion	OFF
Inactive	Active	Inactive	OFF	OFF

Figure 72. PWM output state following BRK and BRK2 pins assertion ($OSSI=1$) gives an example of OCx and OCxN output behavior in case of active signals on BRK and BRK2 inputs. In this case, both outputs have active high polarities ($CCxP = CCxNP = 0$ in TIMx_CCER register).

Figure 72. PWM output state following BRK and BRK2 pins assertion ($OSSI=1$)

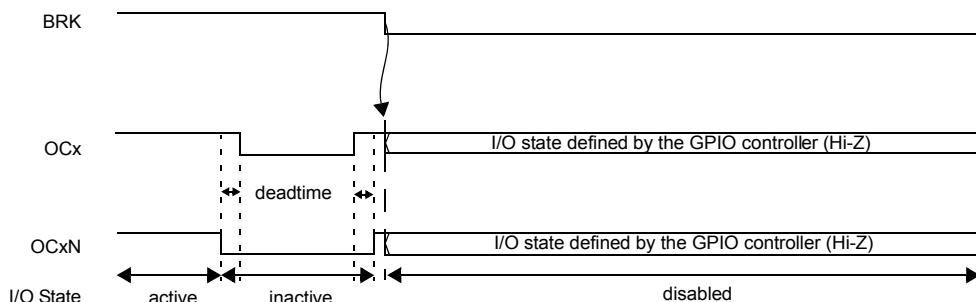

Figure 73. PWM output state following BRK assertion ($OSSI=0$)

16.3.17 Clearing the OCxREF signal on an external event

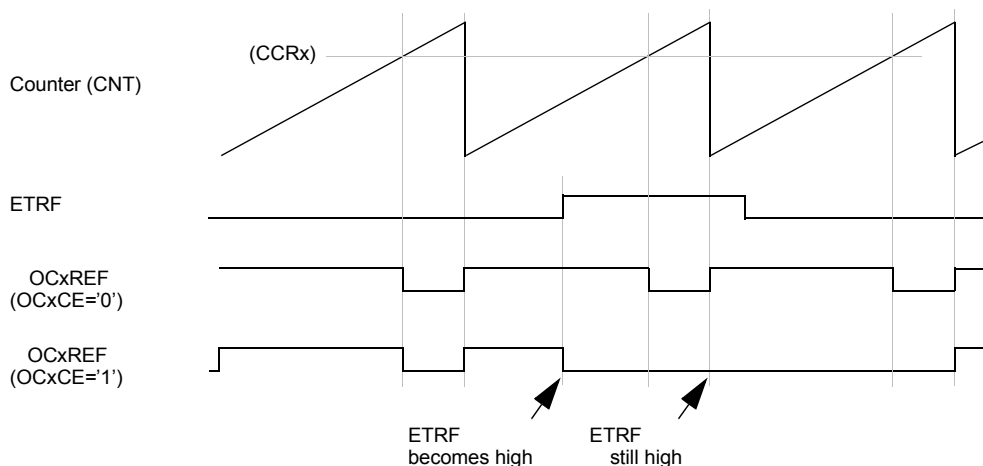

The OCxREF signal of a given channel can be cleared when a high level is applied on the ETRF input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1) if TIMx_SMCR.OCCS bit is set to 1.

This function can only be used in output compare and PWM modes. It does not work in forced mode.

1. The external trigger prescaler should be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to '00'.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to '0'.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the user needs.

Figure 74. Clearing TIMx OCxREF shows the behavior of the OCxREF signal when the ETRF input becomes high, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

Figure 74. Clearing TIMx OCxREF

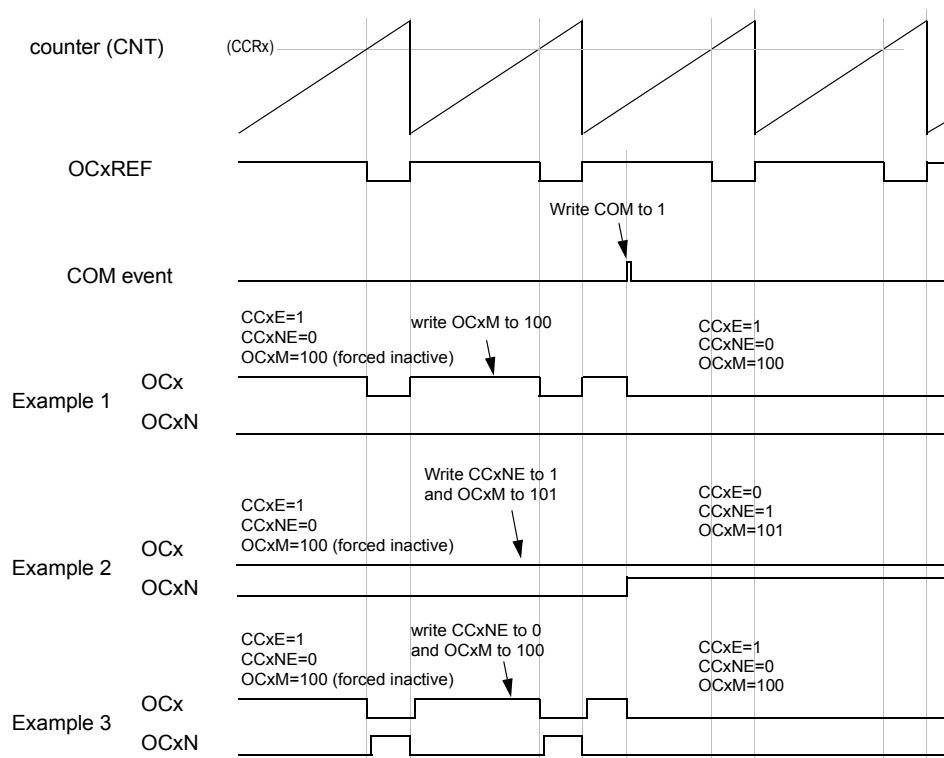

Note: In case of a PWM with a 100% duty cycle (if $CCR_x > ARR$), then OCxREF is enabled again at the next counter overflow.

16.3.17.1 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Therefore the user can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on TRGI rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register).

Figure 75. 6-step generation, COM example (OSSR=1) describes the behavior of the OCx and OCxN outputs when a COM event occurs, in 3 different examples of programmed configurations.

Figure 75. 6-step generation, COM example (OSSR=1)

16.3.18 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. You select one-pulse mode by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In up-counting: $CNT < CCRx \leq ARR$ (in particular, $0 < CCRx$)
- In down-counting: $CNT > CCRx$

Figure 76. Example of one-pulse mode

For example you may want to generate a positive pulse on OC1 with a length of t_{PULSE} and after a delay of t_{DELAY} as soon as a positive edge is detected on the TI2 input pin.

Let us use TI2FP2 as trigger 1:

- Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx_CCMR1 register
- TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS='110' in the TIMx_SMCR register
- TI2FP2 is used to start the counter by writing SMS to '110' in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The t_{DELAY} is defined by the value written in the TIMx_CCR1 register.
- The t_{PULSE} is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1)
- Assume that you want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this you enable PWM mode 2 by writing OC1M=111 in the TIMx_CCMR1 register. You can optionally enable the preload registers by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case you have to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for the external trigger event on TI2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

You only want 1 pulse (single mode), so you write '1' in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to '0', so the repetitive mode is selected.

Particular case: OCx fast enable:

In one-pulse mode, the edge detection on TIx input sets the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. Several clock cycles are needed for these operations. The minimum delay t_{DELAY} is the minimum we can get.

If you want to output a waveform with the minimum delay, you can set the OCxFE bit in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking into account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

16.3.19 Retriggerable one-pulse mode (OPM)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with non-retriggerable one-pulse mode described in [Section 16.3.18 One-pulse mode](#):

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed.

The timer must be in slave mode, with the bits SMS[3:0] = '1000' (combined reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to '1000' or '1001' for retriggerable OPM mode 1 or 2.

If the timer is configured in up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in down-counting mode, the ARR must be set to 0 (the CCRx register sets the pulse length).

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bits are not contiguous with the 3 least significant ones. In retriggerable one-pulse mode, the CCxIF flags are not significant.

Figure 77. Retriggerable one-pulse mode

16.3.20 Encoder interface mode

To select encoder interface mode write SMS='001' in the TIMx_SMCR register if the counter is counting on TI2 edges only, SMS='010' if it is counting on TI1 edges only and SMS='011' if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, you can program the input filter as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to a quadrature encoder. Refer to [Table 49. Counting direction versus encodersignals](#).

The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with the direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So you must configure TIMx_ARR before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and external clock mode 2 are not compatible and must not be selected together.

Note: The prescaler must be set to zero when encoder mode is enabled.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, it always represents the encoder position. The count direction corresponds to the rotation direction of the connected sensor. The table below summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

Table 49. Counting direction versus encodersignals

Active edge	Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1)	TI1FP1 signal		TI2FP2 signal	
		Rising	Falling	Rising	Falling
Counting on TI1 only	High	Down	Up	No Count	No count
	Low	Up	Down	No Count	No count
Counting on TI2 only	High	No count	No count	Up	Down
	Low	No count	No count	Down	Up
Counting on TI1 and TI2	High	Down	Up	Up	Down
	Low	Up	Down	Down	Up

A quadrature encoder can be connected directly to the MCU without any external interface logic. However, comparators are normally used to convert the encoder differential outputs to digital signals. This greatly increases noise immunity. The third encoder output, which indicates the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

Figure 78. Example of counter operation in encoder interface mode gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx_CCMR1 register, TI1FP1 mapped on TI1)
- CC2S='01' (TIMx_CCMR2 register, TI1FP2 mapped on TI2)
- CC1P='0' and CC1NP='0' (TIMx_CCER register, TI1FP1 non-inverted, TI1FP1=TI1)
- CC2P='0' and CC2NP='0' (TIMx_CCER register, TI1FP2 non-inverted, TI1FP2= TI2)
- SMS='011' (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN='1' (TIMx_CR1 register, counter enabled).

Figure 78. Example of counter operation in encoder interface mode

Figure 79. Example of encoder interface mode with TI1FP1 polarity inverted gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P='1').

Figure 79. Example of encoder interface mode with TI1FP1 polarity inverted

The timer, when configured in encoder interface mode, provides some information on the sensor current position. You can obtain the dynamic information (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode (not available in the BlueNRG-LP device). The output of the encoder, which indicates the mechanical zero, can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. You can do this by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer).

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter most significant bit is only accessible in write mode).

16.3.21 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag UIF into the timer counter register bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (update interrupt). There is no latency between the UIF and UIFCPY flags assertion.

16.3.22 Timer input XOR function

The TI1S bit, in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the two input pins TIMx_CH1 and TIMx_CH2. The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per [Figure 80. Measuring time interval between edges on 3 signals.](#)

Figure 80. Measuring time interval between edges on 3 signals

16.4 TIM1 registers

16.4.1 TIM1 control register 1 (TIMx_CR1)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	UIFREMAP	Res.	CKD[1:0]		ARPE	CMS[1:0]		DIR	OPM	URS	UDIS	CEN
				rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:12	Reserved, always read as 0.
Bit 11	UIFREMAP : UIF status bit remapping. 0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31. 1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.
Bits 10	Reserved, always read as 0.
Bits 9:8	CKD[1:0] : Clock division. This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and the deadtime and sampling clock (tDTS) used by the deadtime generators and the digital filters (ETR, Tlx). 00: $t_{DTS} = t_{CK_INT}$ 01: $t_{DTS} = 2 * t_{CK_INT}$ 10: $t_{DTS} = 4 * t_{CK_INT}$ 11: Reserved, do not program this value
Bit 7	ARPE : Auto-reload preload enable. 0: TIMx_ARR register is not buffered 1: TIMx_ARR register is buffered
Bits 6:5	CMS[1:0] : Center-aligned mode selection. 00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR). 01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down. 10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up. 11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down. Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1).
Bit 4	DIR : Direction 0: Counter used as up-counter 1: Counter used as down-counter Note: This bit is read only when the timer is configured in center-aligned mode or encoder mode.
Bit 3	OPM : One-pulse mode. 0: Counter is not stopped at update event 1: Counter stops counting to the next update event (clearing the bit CEN)
Bit 2	URS : Update request source.

	<p>This bit is set and cleared by software to select the UEV event sources.</p> <p>0: Any of the following events generates an update interrupt if enabled. These events can be:</p> <ul style="list-style-type: none"> Counter overflow/underflow Setting the UG bit Update the generation through the slave mode controller <p>1: Only counter overflow/underflow generates an update interrupt if enabled</p>
Bit 1	<p>UDIS: Update disable.</p> <p>This bit is set and cleared by software to enable/disable UEV event generation.</p> <p>0: UEV enabled. The update (UEV) event is generated by one of the following events:</p> <ul style="list-style-type: none"> Counter overflow/underflow Setting the UG bit Update generation through the slave mode controller buffered registers are then loaded with their preload values. <p>1: UEV disabled. The update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.</p>
Bit 0	<p>CEN: Counter enable.</p> <p>0: Counter disabled</p> <p>1: Counter enabled</p> <p>Note: The external clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.</p>

16.4.2 TIM1 control register 2 (TIMx_CR2)

Address offset: 0x04

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw	rw	rw	rw	rw	rw	rw	rw					rw		rw

Bits 31:19	Reserved, always read as 0.
Bit 18	OIS6 : Output idle state 6 (OC6 output). Refer to OIS1 bit.
Bit 17	Reserved, always read as 0.
Bit 16	OIS5 : Output idle state 5 (OC5 output). Refer to OIS1 bit.
Bit 15	Reserved, always read as 0.
Bit 14	OIS4 : Output idle state 4 (OC4 output). Refer to OIS1 bit.
Bit 13	OIS3N : Output idle state 3 (OC3N output). Refer to OIS1N bit.
Bit 12	OIS3 : Output idle state 3 (OC3 output). Refer to OIS1 bit.
Bit 11	OIS2N : Output idle state 2 (OC2N output). Refer to OIS1N bit.
Bit 10	OIS2 : Output idle state 2 (OC2 output). Refer to OIS1 bit.

Bit 9	OIS1N : Output idle state 1 (OC1N output). 0: OC1N=0 after a deadtime when MOE=0 1: OC1N=1 after a deadtime when MOE=0 Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 8	OIS1 : Output idle state 1 (OC1 output). 0: OC1=0 (after a deadtime if OC1N is implemented) when MOE=0 1: OC1=1 (after a deadtime if OC1N is implemented) when MOE=0 Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 7	TI1S : TI1 selection. 0: The TIMx_CH1 pin is connected to TI1 input 1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)
Bits 6:3	Reserved, always read as 0.
Bit 2	CCUS : Capture/compare control update selection. 0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only 1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI Note: This bit acts only on channels that have a complementary output.
Bit 1	Reserved, always read as 0.
Bit 0	CCPC : Capture/compare preloaded control. 0: CCxE, CCxNE and OCxM bits are not preloaded 1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit) Note: This bit acts only on channels that have a complementary output.

16.4.3 TIM1 slave mode control register (TIMx_SMCR)

Address offset: 0x08

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bit 31:17	Reserved, always read as 0.
Bit 16	SMS[3] : Slave mode selection - bit 3. Refer to SMS description - bits 2:0.
Bit 15	ETP : External trigger polarity. This bit selects whether ETR or $\overline{\text{ETR}}$ is used for trigger operations. 0: ETR is non-inverted, active at high level or rising edge

	1: ETR is inverted, active at low level or falling edge
Bit 14	<p>ECE: External clock enable.</p> <p>This bit enables external clock mode 2.</p> <p>0: External clock mode 2 disabled</p> <p>1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.</p> <p>Note: 1: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111).</p> <p>2: It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111).</p> <p>3: If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.</p>
Bits 13:12	<p>ETPS[1:0]: External trigger prescaler.</p> <p>External trigger signal ETRP frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.</p> <p>00: Prescaler OFF</p> <p>01: ETRP frequency divided by 2</p> <p>10: ETRP frequency divided by 4</p> <p>11: ETRP frequency divided by 8</p>
Bits 11:8	<p>ETF[3:0]: External trigger filter.</p> <p>This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:</p> <p>0000: No filter, sampling is done at fDTS 0001: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N=2</p> <p>0010: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N=4</p> <p>0011: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N=8</p> <p>0100: $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$, N=6</p> <p>0101: $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$, N=8</p> <p>0110: $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$, N=6</p> <p>0111: $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$, N=8</p> <p>1000: $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$, N=6</p> <p>1001: $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$, N=8</p> <p>1010: $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$, N=5</p> <p>1011: $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$, N=6</p> <p>1100: $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$, N=8</p> <p>1101: $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$, N=5</p> <p>1110: $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$, N=6</p> <p>1111: $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$, N=8</p>
Bit 7	Reserved, always read as 0.
Bits 6:4	<p>TS[2:0]: Trigger selection.</p> <p>This bit-field selects the trigger input to be used to synchronize the counter.</p> <p>101: Filtered timer input 1 (TI1FP1)</p> <p>110: Filtered timer input 2 (TI2FP2) others: Reserved</p> <p>Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.</p>
Bit 3	<p>OCCS: OCREF clear selection.</p> <p>This bit is used to select the OCREF clear source.</p>

	0: OCREF_CLR_INT is connected to the OCREF_CLR input (stuck at 0 so no effect) 1: OCREF_CLR_INT is connected to ETRF
Bits 2:0	<p>SMS: Slave mode selection.</p> <p>When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).</p> <p>0000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock</p> <p>0001: Encoder mode 1 - counter counts up/down on TI2FP2 edge depending on TI1FP1 level</p> <p>0010: Encoder mode 2 - counter counts up/down on TI1FP1 edge depending on TI2FP2 level</p> <p>0011: Encoder mode 3 - counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input</p> <p>0100: Reset mode - rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers</p> <p>0101: Gated mode - the counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.</p> <p>0110: Trigger mode - the counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.</p> <p>0111: External clock mode 1 - rising edges of the selected trigger (TRGI) clock the counter.</p> <p>1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.</p> <p>Codes above 1000: Reserved</p> <p>Note: The gated mode must not be used if TI1F_ED is selected as the trigger input (TS='100'). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.</p>

Bits 31:18	Reserved, always read as 0.
Bit 17	CC6IF : Compare 6 interrupt flag. Refer to CC1IF description (note: channel 6 can only be configured as output).
Bit 16	CC5IF : Compare 5 interrupt flag. Refer to CC1IF description (note: channel 5 can only be configured as output).
Bits 15:13	Reserved, always read as 0.
Bit 12	CC4OF : Capture/compare 4 overcapture flag. Refer to CC1OF description.
Bit 11	CC3OF : Capture/compare 3 overcapture flag. Refer to CC1OF description.
Bit 10	CC2OF : Capture/compare 2 overcapture flag. Refer to CC1OF description.
Bit 9	CC1OF : Capture/compare 1 overcapture flag. This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'. 0: No overcapture has been detected 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set
Bit 8	B2IF : Break 2 interrupt flag. This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active. 0: No break event occurred 1: An active level has been detected on the break 2 input. An interrupt is generated if BIE=1 in the TIMx_DIER register.
Bit 7	BIF : Break interrupt flag.

	<p>This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.</p> <p>0: No break event occurred</p> <p>1: An active level has been detected on the break input. An interrupt is generated if BIE = 1 in the TIMx_DIER register.</p>
Bit 6	<p>TIF: Trigger interrupt flag.</p> <p>This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.</p> <p>0: No trigger event occurred</p> <p>1: Trigger interrupt pending</p>
Bit 5	<p>COMIF: COM interrupt flag.</p> <p>This flag is set by hardware on COM event (when capture/compare control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.</p> <p>0: No COM event occurred</p> <p>1: COM interrupt pending</p>
Bit 4	CC4IF : Capture/compare 4 interrupt flag. Refer to CC1IF description.
Bit 3	CC3IF : Capture/compare 3 interrupt flag. Refer to CC1IF description.
Bit 2	CC2IF : Capture/compare 2 interrupt flag. Refer to CC1IF description.
Bit 1	<p>CC1IF: Capture/compare 1 interrupt flag.</p> <p>If channel CC1 is configured as output:</p> <p>This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx_CR1 register description). It is cleared by software.</p> <p>0: No match</p> <p>1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the contents of TIMx_CCR1 are greater than the contents of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode).</p> <p>If channel CC1 is configured as input:</p> <p>This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register.</p> <p>0: No input capture occurred</p> <p>1: The counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1 which matches the selected polarity)</p>
Bit 0	<p>UIF: Update interrupt flag.</p> <p>This bit is set by hardware on an update event. It is cleared by software.</p> <p>0: No update occurred</p> <p>1: Update interrupt pending. This bit is set by hardware when the registers are updated:</p> <ul style="list-style-type: none"> At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register. When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register. When CNT is reinitialized by a trigger event (refer to Section 16.4.3 TIM1 slave mode control register (TIMx_SMCR)), if URS=0 and UDIS=0 in the TIMx_CR1 register.

16.4.6 TIM1 event generation register (TIMx_EGR)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
----	----	----	----	----	----	---	---	---	---	---	---	---	---	---	---

							w	w	w	w	w	w	w	w	w

Bits 15:9	Reserved, always read as 0.
Bit 8	B2G : Break 2 generation. This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.
Bit 7	BG : Break generation. This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt can occur if enabled.
Bit 6	TG : Trigger generation. This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: The TIF flag is set in TIMx_SR register. Related interrupt can occur if enabled.
Bit 5	COMG : Capture/compare control update generation. This bit can be set by software, it is automatically cleared by hardware. 0: no action 1: When CCPC bit is set, it allows to update CCxE, CCxNE and OCxM bits Note: This bit acts only on channels having a complementary output.
Bit 4	CC4G : Capture/compare 4 generation. Refer to CC1G description.
Bit 3	CC3G : Capture/compare 3 generation. Refer to CC1G description.
Bit 2	CC2G : Capture/compare 2 generation. Refer to CC1G description.
Bit 1	CC1G : Capture/compare 1 generation. This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: A capture/compare event is generated on channel 1: If channel CC1 is configured as output: CC1IF flag is set, corresponding interrupt is sent if enabled. If channel CC1 is configured as input: The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.
Bit 0	UG : Update generation. This bit can be set by software, it is automatically cleared by hardware. 0: No action 1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (up-counting), else it takes the auto-reload. Value (TIMx_ARR) if DIR=1 (down-counting).

16.4.7

TIM1 capture/compare mode register 1 (TIMx_CCMR1)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So you must take care that the same bit can have a different meaning for the input stage and for the output stage.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Output compare mode:

Bits 31:25	Reserved, always read as 0.
Bit 24	OC2M[3] : Output compare 2 mode - bit 3
Bits 23:17	Reserved, always read as 0.
Bits 16	OC1M[3] : Output compare 1 mode - bit 3. Refer to OC1M description on bits 6:4.
Bit 15	OC2CE : Output compare 2 clear enable.
Bits 14:12	OC2M[2:0] : Output compare 2 mode.
Bit 11	OC2PE : Output compare 2 preload enable.
Bit 10	OC2FE : Output compare 2 fast enable.
Bits 9:8	CC2S[1:0] : Capture/compare 2 selection. This bit-field defines the direction of the channel (input/output) as well as the used input. 00: CC2 channel is configured as output 01: CC2 channel is configured as input, IC2 is mapped on TI2 10: CC2 channel is configured as input, IC2 is mapped on TI1 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register). Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).
Bit 7	OC1CE : Output compare 1 clear enable. 0: OC1 Ref is not affected by the ETRF input 1: OC1 Ref is cleared as soon as a high level is detected on ETRF input
Bits 6:4	OC1M : Output compare 1 mode. These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits. 0000: Frozen - the comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs (this mode is used to generate a timing base). 0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

	<p>0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).</p> <p>0011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.</p> <p>0100: Force inactive level - OC1REF is forced low.</p> <p>0101: Force active level - OC1REF is forced high.</p> <p>0110: PWM mode 1 - in up-counting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1, otherwise inactive. In down-counting, channel 1 is inactive (OC1REF='0') as long as TIMx_CNT>TIMx_CCR1, otherwise active (OC1REF='1').</p> <p>0111: PWM mode 2 - in up-counting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1, otherwise active. In down-counting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1, otherwise inactive.</p> <p>1000: Retriggerable OPM mode 1 - in up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels become active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels become inactive again at the next update.</p> <p>1001: Retriggerable OPM mode 2 - in up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels become inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels become active again at the next update.</p> <p>1010: Reserved</p> <p>1011: Reserved</p> <p>1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.</p> <p>1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.</p> <p>1110: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.</p> <p>1111: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.</p> <p>Note 1: These bits cannot be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).</p> <p>Note 2: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.</p> <p>Note 3: On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.</p>
Bit 3	<p>OC1PE: Output compare 1 preload enable</p> <p>0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken into account immediately.</p> <p>1: Preload register on TIMx_CCR1 enabled. Read/write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.</p> <p>Note 1: These bits cannot be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).</p> <p>Note 2: The PWM mode can be used without validating the preload register only in one-pulse mode (OPM bit set in TIMx_CR1 register). Otherwise the behavior is not guaranteed.</p>
Bit 2	<p>OC1FE: Output compare 1 fast enable</p> <p>This bit is used to accelerate the effect of an event on the trigger in input on the CC output.</p> <p>0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.</p> <p>1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.</p>
Bits 1:0	<p>CC1S: Capture/compare 1 selection.</p> <p>This bit-field defines the direction of the channel (input/output) as well as the used input.</p> <p>00: CC1 channel is configured as output</p>

	01: CC1 channel is configured as input, IC1 is mapped on TI1 10: CC1 channel is configured as input, IC1 is mapped on TI2 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register). Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).
--	---

Input capture mode

Bits 31:16	Reserved, always read as 0.
Bits 15:12	IC2F : Input capture 2 filter.
Bits 11:10	IC2PSC[1:0] : Input capture 2 prescaler.
Bits 9:8	CC2S : Capture/compare 2 selection. This bit-field defines the direction of the channel (input/output) as well as the used input. 00: CC2 channel is configured as output 01: CC2 channel is configured as input, IC2 is mapped on TI2 10: CC2 channel is configured as input, IC2 is mapped on TI1 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register). Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).
Bits 7:4	IC1F[3:0] : Input capture 1 filter. This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N events are needed to validate a transition on the output: 0000: No filter, sampling is done at f_{DTS} 0001: $f_{SAMPLING}=f_{CK_INT}$, N=2 0010: $f_{SAMPLING}=f_{CK_INT}$, N=4 0011: $f_{SAMPLING}=f_{CK_INT}$, N=8 0100: $f_{SAMPLING}=f_{DTS}/2$, N=6 0101: $f_{SAMPLING}=f_{DTS}/2$, N=8 0110: $f_{SAMPLING}=f_{DTS}/4$, N=6 0111: $f_{SAMPLING}=f_{DTS}/4$, N=8 1000: $f_{SAMPLING}=f_{DTS}/8$, N=6 1001: $f_{SAMPLING}=f_{DTS}/8$, N=8 1010: $f_{SAMPLING}=f_{DTS}/16$, N=5 1011: $f_{SAMPLING}=f_{DTS}/16$, N=6 1100: $f_{SAMPLING}=f_{DTS}/16$, N=8 1101: $f_{SAMPLING}=f_{DTS}/32$, N=5 1110: $f_{SAMPLING}=f_{DTS}/32$, N=6 1111: $f_{SAMPLING}=f_{DTS}/32$, N=8
Bits 3:2	IC1PSC : Input capture 1 prescaler. This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register). 00: No prescaler, capture is done each time an edge is detected on the capture input 01: Capture is done once every 2 events

	10: Capture is done once every 4 events 11: Capture is done once every 8 events
Bits 1:0	CC1S : Capture/compare 1 selection This bit-field defines the direction of the channel (input/output) as well as the used input. 00: CC1 channel is configured as output 01: CC1 channel is configured as input, IC1 is mapped on TI1 10: CC1 channel is configured as input, IC1 is mapped on TI2 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register). Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

16.4.8 TIM1 capture/compare mode register 2 (TIMx_CCMR2)

Address offset: 0x1C

Reset value: 0x0000

Refer to [Section 16.4.7 TIM1 capture/compare mode register 1 \(TIMx_CCMR1\)](#).

Output compare mode

Bits 31:25	Reserved, always read as 0.
Bit 24	OC4M[3] : Output compare 4 mode - bit 3
Bits 23:17	Reserved, always read as 0.
Bit 16	OC3M[3] : Output compare 3 mode - bit 3.
Bit 15	OC4CE : Output compare 4 clear enable.
Bits 14:12	OC4M : Output compare 4 mode.
Bit 11	OC4PE : Output compare 4 preload enable.
Bit 10	OC4FE : Output compare 4 fast enable.
Bits 9:8	CC4S : Capture/compare 4 selection. This bit-field defines the direction of the channel (input/output) as well as the used input. 00: CC4 channel is configured as output 01: CC4 channel is configured as input, IC4 is mapped on TI4 10: CC4 channel is configured as input, IC4 is mapped on TI3 11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register). Note: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx_CCER).
Bit 7	OC3CE : Output compare 3 clear enable.

Bits 6:4	OC3M : Output compare 3 mode.
Bit 3	OC3PE : Output compare 3 preload enable.
Bit 2	OC3FE : Output compare 3 fast enable.
Bits 1:0	CC3S : Capture/compare 3 selection. This bit-field defines the direction of the channel (input/output) as well as the used input. 00: CC3 channel is configured as output 01: CC3 channel is configured as input, IC3 is mapped on TI3 10: CC3 channel is configured as input, IC3 is mapped on TI4 11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register). Note: CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx_CCER).

Input capture mode

Bits 31:16	Reserved, always read as 0.
Bits 15:12	IC4F : Input capture 4 filter.
Bits 11:10	IC4PSC : Input capture 4 prescaler.
Bits 9:8	CC4S : Capture/compare 4 selection. This bit-field defines the direction of the channel (input/output) as well as the used input. 00: CC4 channel is configured as output 01: CC4 channel is configured as input, IC4 is mapped on TI4 10: CC4 channel is configured as input, IC4 is mapped on TI3 11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register). Note: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx_CCER).
Bits 7:4	IC3F : Input capture 3 filter.
Bits 3:2	IC3PSC : Input capture 3 prescaler.
Bits 1:0	CC3S : Capture/compare 3 selection. This bit-field defines the direction of the channel (input/output) as well as the used input. 00: CC3 channel is configured as output 01: CC3 channel is configured as input, IC3 is mapped on TI3 10: CC3 channel is configured as input, IC3 is mapped on TI4 11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register). Note: CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx_CCER).

	<p>00: Non-inverted/rising edge. The circuit is sensitive to TlxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TlxFP1 is not inverted (trigger operation in gated mode or encoder mode).</p> <p>01: Inverted/falling edge. The circuit is sensitive to TlxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TlxFP1 is inverted (trigger operation in gated mode or encoder mode).</p> <p>10: Reserved, do not use this configuration.</p> <p>11: Non-inverted/both edges/ The circuit is sensitive to both TlxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TlxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.</p> <p>Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).</p> <p>Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a commutation event is generated.</p>
Bit 0	<p>CC1E: Capture/compare 1 output enable.</p> <p>CC1 channel configured as output:</p> <p>0: Off - OC1 is not active. OC1 level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.</p> <p>1: On - OC1 signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits</p> <p>CC1 channel configured as input:</p> <p>This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.</p> <p>0: Capture disabled.</p> <p>1: Capture enabled.</p> <p>Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a commutation event is generated.</p>

Table 50. Output control bits for complementary OCx and OCxN channels with break feature

Control bits					Output states ⁽¹⁾	
MOE bit	OSSI bit	OSSR bit	CCxE bit	CCxNE bit	OCx output state	OCxN output state
1	X	X	0	0	Output disabled (not driven by the timer: Hi-Z) OCx=0, OCxN=0	
		0	0	1	Output disabled (not driven by the timer: Hi-Z) OCx=0	OCxREF + Polarity OCxN=OCxREF xor CCxNP
		0	1	0	OCxREF + polarity OCx=OCxREF xor CCxP	Output disabled (not driven by the timer: Hi-Z) OCxN=0
		X	1	1	OCREF + polarity + deadtime	Complementary to OCREF (not OCREF) + polarity + deadtime
		1	0	1	Off-state (output enabled with inactive state) OCx=CCxP	OCxREF + polarity OCxN=OCxREF xor CCxNP
		1	1	0	OCxREF + polarity OCx=OCxREF xor CCxP	Off-state (output enabled with inactive state) OCxN=CCxNP
0	0	X	X	X	Output disabled (not driven by the timer: Hi-Z) OCx=CCxP, OCxN=CCxNP	
	0		0			
	0		1	Off-state (output enabled with inactive state) Asynchronously: OCx=CCxP, OCxN=CCxNP (if BRKIN or BRKIN2 is triggered). Then (this is valid only if BRKIN is triggered), if the clock is present: OCx=OISx and OCxN=OISxN after a deadtime, assuming that OISx and OISxN do not correspond to OCx and OCxN both in active state (may cause a short-circuit when driving switches in half-bridge configuration). Note: BRKIN2 can only be used if OSSI = OSSR = 1		
	1		0			
	1		1			

1. When both outputs of a channel are not used (control taken over by GPIO), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary OCx and OCxN channels depends on the OCx and OCxN channel state and the GPIO registers.

16.4.10 TIM1 counter (TIMx_CNT)

Address offset: 0x24

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UIFCPY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r

CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31	UIFCPY: UIF copy This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in the TIMxCR1 is reset, bit 31 is reserved and read at 0.
Bits 30:16	Reserved, always read as 0.
Bits 15:0	CNT[15:0]: Counter value

16.4.11 TIM1 prescaler (TIMx_PSC)

Address offset: 0x28

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0	PSC[15:0]: Prescaler value The counter clock frequency (CK_CNT) is equal to $f_{CK_PSC} / (PSC[15:0] + 1)$. PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in "reset mode").
-----------	---

16.4.12 TIM1 auto-reload register (TIMx_ARR)

Address offset: 0x2C

Reset value: 0xFFFF

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0	ARR[15:0]: Prescaler value.
	ARR is the value to be loaded in the actual auto-reload register.
	Refer to Section 16.3.1 Time-base unit for more details about ARR update and behavior.
	The counter is blocked while the auto-reload value is null.

16.4.13 TIM1 repetition counter register (TIMx_RCR)

Address offset: 0x30

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REP[15:0]															
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW

Bits 15:0	REP[15:0]: Repetition counter value.
	These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enabled, as well as the update interrupt generation rate, if this interrupt is enabled.
	Each time the REP_CNT related down-counter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken into account until the next repetition update event.
	It means in PWM mode (REP+1) corresponds to: the number of PWM periods in edge-aligned mode the number of half PWM period in center-aligned mode

16.4.14 TIM1 capture/compare register 1 (TIMx_CCR1)

Address offset: 0x34

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1[15:0]															
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW

Bits 15:0	CCR1[15:0]: Capture/compare 1 value.
	If channel CC1 is configured as output: CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Otherwise the preload value is copied in the active capture/compare 1 register when an update event occurs.
	The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.
	If channel CC1 is configured as input: CCR1 is the counter value transferred by the last input capture 1 event (IC1).

16.4.15 TIM1 capture/compare register 2 (TIMx_CCR2)

Address offset: 0x38

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0	CCR2[15:0]: Capture/compare 2 value														
	If channel CC2 is configured as output:														
	CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).														
	It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Otherwise the preload value is copied in the active capture/compare 2 register when an update event occurs.														
	The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on OC2 output.														
	If channel CC2 is configured as input:														
	CCR2 is the counter value transferred by the last input capture 2 event (IC2).														

16.4.16 TIM1 capture/compare register 3 (TIMx_CCR3)

Address offset: 0x3C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0	CCR3[15:0]: Capture/compare value														
	If channel CC3 is configured as output:														
	CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).														
	It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC3PE). Otherwise the preload value is copied in the active capture/compare 3 register when an update event occurs.														
	The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on OC3 output.														
	If channel CC3 is configured as input:														
	CCR3 is the counter value transferred by the last input capture 3 event (IC3).														

16.4.17 TIM1 capture/compare register 4 (TIMx_CCR4)

Address offset: 0x40

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR4[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0	CCR4[15:0]: Capture/compare value
	If channel CC4 is configured as output:
	CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR4 register (bit OC4PE). Otherwise the preload value is copied in the active capture/compare 4 register when an update event occurs.
	The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC4 output.
	If channel CC4 is configured as input:
	CCR4 is the counter value transferred by the last input capture 4 event (IC4).

16.4.18 TIM1 break and deadtime register (TIMx_BDTR)

Address offset: 0x44

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	BK2P	BK2E	BK2F[3:0]				BKF[3:0]			
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOE	AOE	BKP	BKE	OSSR	OSSI	LOCK[1:0]		DTG[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Note: As the bits BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bits 31:26	Reserved.
Bit 25	BK2P: Break 2 polarity. 0: Break input BRK2 is active low 1: Break input BRK2 is active high Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bit 24	BK2E: Break 2 enable. This bit enables the complete break 2 protection (including all sources connected to bk_acth and BKIN sources). 0: Break2 function disabled 1: Break2 function enabled Note: The BRKIN2 must only be used with OSSR = OSSI = 1. Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bits 23:20	BK2F[3:0]: Break 2 filter. This bit-field defines the frequency used to sample BRK2 input and the length of the digital filter applied to BRK2. The digital filter is made of an event counter in which N events are needed to validate a transition on the output. Note:

	<p>0000: No filter, BRK2 acts asynchronously</p> <p>0001: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N=2</p> <p>0010: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N=4</p> <p>0011: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N=8</p> <p>0100: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/2$, N=6</p> <p>0101: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/2$, N=8</p> <p>0110: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/4$, N=6</p> <p>0111: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/4$, N=8</p> <p>1000: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/8$, N=6</p> <p>1001: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/8$, N=8</p> <p>1010: $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$, N=5</p> <p>1011: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/16$, N=6</p> <p>1100: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/16$, N=8</p> <p>1101: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/32$, N=5</p> <p>1110: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/32$, N=6</p> <p>1111: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}/32$, N=8</p> <p>Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).</p>
Bits 19:16	<p>BKF[3:0]: Break filter.</p> <p>This bit-field defines the frequency used to sample BRK input and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:</p> <p>0000: No filter, BRK acts asynchronously</p> <p>0001: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N=2</p> <p>0010: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N=4</p> <p>0011: $f_{\text{SAMPLING}} = f_{\text{CK_INT}}$, N=8</p> <p>0100: $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$, N=6</p> <p>0101: $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$, N=8</p> <p>0110: $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$, N=6</p> <p>0111: $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$, N=8</p> <p>1000: $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$, N=6</p> <p>1001: $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$, N=8</p> <p>1010: $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$, N=5</p> <p>1011: $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$, N=6</p> <p>1100: $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$, N=8</p> <p>1101: $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$, N=5</p> <p>1110: $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$, N=6</p> <p>1111: $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$, N=8</p> <p>This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).</p>
Bit 15	<p>MOE: Main output enable.</p> <p>This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (BRK or BRK2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.</p> <p>0: In response to a break 2 event. OC and OCN outputs are disabled</p> <p>In response to a break event or if MOE is written to.</p> <p>0: OC and OCN outputs are disabled or forced to idle state depending on the OSS1 bit.</p>

	<p>1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register). See OC/OCN enable description for more details (Section 16.4.9 TIM1 capture/compare enable register (TIMx_CCER)).</p>
Bit 14	<p>AOE: Automatic output enable. 0: MOE can be set only by software 1: MOE can be set by software or automatically at the next update event (if none of the break inputs BRK and BRK2 are active). Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).</p>
Bit 13	<p>BKP: Break polarity. 0: Break input BRK is active low 1: Break input BRK is active high Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.</p>
Bit 12	<p>BKE: Break enable. This bit enables the complete break protection (including all sources connected to bk_acth and BKIN sources). 0: Break function disabled. 1: Break function enabled. Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.</p>
Bit 11	<p>OSSR: Off-state selection for Run mode. This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer. See OC/OCN enable description for more details (Section 16.4.9 TIM1 capture/compare enable register (TIMx_CCER)). 0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state). 1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer). Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).</p>
Bit 10	<p>OSSI: Off-state selection for Idle mode. This bit is used when MOE=0 due to a break event or by a software write, on channels configured as outputs. See OC/OCN enable description for more details (Section 16.4.9 TIM1 capture/compare enable register (TIMx_CCER)). 0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state). 1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output. Note: This bit cannot be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).</p>
Bits 9:8	<p>LOCK[1:0]: Lock configuration. These bits offer a write protection against software errors. 00: LOCK OFF - No bit is write protected. 01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can be no longer written. 10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can be no longer written.</p>

	<p>11: LOCK level 3 = LOCK level 2 + CC control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can be no longer written.</p> <p>Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.</p>
Bits 7:0	<p>DTG[7:0]: Deadtime generator setup.</p> <p>This bit-field defines the duration of the deadtime inserted between the complementary outputs. DT matches this duration.</p> <p>DTG[7:5]=0xx => DT=DTG[7:0]x t_{dtg} with $t_{dtg}=t_{DTS}$. DTG[7:5]=10x => DT=(64+DTG[5:0])xt_{dtg} with $T_{dtg}=2xT_{DTS}$. DTG[7:5]=110 => DT=(32+DTG[4:0])xt_{dtg} with $T_{dtg}=8xT_{DTS}$. DTG[7:5]=111 => DT=(32+DTG[4:0])xt_{dtg} with $T_{dtg}=16xT_{DTS}$.</p> <p>Example if $T_{DTS} = 125\text{ ns}$ (8 MHz), deadtime possible values are:</p> <p>0 to 15875 ns by 125 ns steps, 16 us to 31750 ns by 250 ns steps, 32 us to 63us by 1 us steps, 64 us to 126 us by 2 us steps</p> <p>Note: This bit-field cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).</p>

16.4.19 TIM1 capture/compare mode register 3 (TIMx_CCMR3)

Address offset: 0x54

Reset value: 0x00000000

Refer to [Section 16.4.7 TIM1 capture/compare mode register 1 \(TIMx_CCMR1\)](#) about the configuration of channels 5 and 6.

17 Real-time clock (RTC)

17.1 Introduction

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupt.

The RTC also includes a periodic programmable wake-up flag with interrupt capability. The RTC provides an automatic wakeup to manage all low-power modes.

Two 32-bit registers contain the seconds, minutes, hours (12- or 24-hour format), day (day of week), date (day of month), month, and year, expressed in binary coded decimal format (BCD). The sub-seconds value is also available in binary format.

Compensations for 28-, 29- (leap year), 30-, and 31-day months are performed automatically. Daylight saving time compensation can also be performed.

Additional 32-bit registers contain the programmable alarm sub-seconds, seconds, minutes, hours, day, and date.

A digital calibration feature is available to compensate for any deviation in crystal oscillator accuracy.

After power-on reset, all RTC registers are protected against possible parasitic write accesses.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (run mode, low-power mode or under system reset).

Note: The RTC counter does not freeze when the CPU is halted by a debugger.

17.2 RTC main features

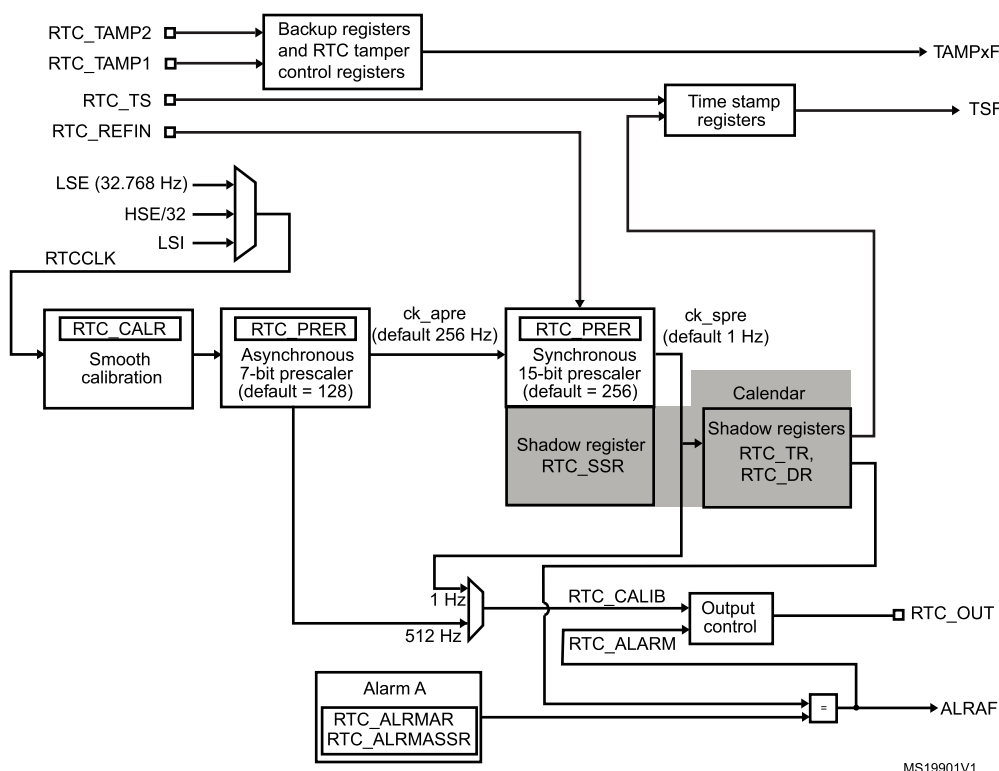

The RTC unit main features are the following (see [Figure 81. RTC block diagram](#)):

- Calendar with sub-seconds, seconds, minutes, hours (12 or 24 format), day (day of week), date (day of month), month, and year.
- Daylight saving compensation programmable by software
- Programmable alarm with interrupt function. The alarm can be triggered by any combination of the calendar fields
- Automatic wakeup unit generating a periodic flag that triggers an automatic wakeup interrupt
- Digital calibration circuit (periodic counter correction): 0.95 ppm accuracy, obtained in a calibration window of several seconds
- Maskable interrupts/events:
 - Alarm A
 - Wake-up interrupt.

17.3 RTC functional description

17.3.1 RTC block diagram

Figure 81. RTC block diagram

17.3.2 Clock and prescalers

The RTC clock source (RTCCLK) is selected through the clock controller among the LSE clock, the LSI oscillator clock, and the HSI_64M clock. For more information on the RTC clock source configuration, refer to [Section 6 Reset and clock controller \(RCC\)](#).

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see [Figure 81. RTC block diagram](#)):

- A 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register
- A 15-bit synchronous prescaler configured through the PREDIV_S bits of the RTC_PRER register.

Note: When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is 2^{22} . This corresponds to a maximum input frequency of around 4 MHz. f_{ck_apre} is given by the following formula:

$$f_{CK_APRE} = \frac{f_{RTCCLK}}{PREDIV A + 1} \quad (2)$$

The ck_apre clock is used to clock the binary RTC_SSR sub-seconds down-counter. When it reaches 0, RTC_SSR is reloaded with the content of PREDIV_S.

f_{ck_spre} is given by the following formula:

$$f_{CK_SPRE} = \frac{f_{RTCCLK}}{(PREDIV_S + 1) \times (PREDIV_A + 1)} \quad (3)$$

The ck_spre clock can be used either to update the calendar or as timebase for the 16-bit wake-up auto-reload timer. To obtain short timeout periods, the 16-bit wake-up auto-reload timer can also run with the RTCCLK divided by the programmable 4-bit asynchronous prescaler (see [Section 17.3.5 Periodic auto-wakeup](#)).

17.3.3 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC_SSR for the sub-seconds
- RTC_TR for the time
- RTC_DR for the date

Every two RTCCLK periods, the current calendar value is copied into the shadow registers, and the RSF bit of the RTC_ISR register is set (see [Section 17.6.4 RTC initialization and status register \(RTC_ISR\)](#)).

The copy is not performed in stop and standby mode. When exiting these modes, the shadow registers are updated after up to 2 RTCCLK periods.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the BYPSHAD control bit in the RTC_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC_SSR, RTC_TR or RTC_DR registers in BYPSHAD=0 mode, the frequency of the APB clock (f_{APB}) must be at least 7 times the frequency of the RTC clock (f_{RTCCLK}).

The shadow registers are reset by system reset.

17.3.4 Programmable alarm

The RTC unit provides programmable alarm: Alarm A. The programmable alarm function is enabled through the ALRAE bit in the RTC_CR register. The ALRAF is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC_ALRMASR and RTC_ALRMAR. Each calendar field can be independently selected through the MSKx bits of the RTC_ALRMAR register, and through the MASKSSx bits of the RTC_ALRMASR register. The alarm interrupt is enabled through the ALRAIE bit in the RTC_CR register.

Caution: If the seconds field is selected (MSK0 bit reset in RTC_ALRMAR), the synchronous prescaler division factor set in the RTC_PRER register must be at least 3 to ensure correct behavior.

Alarm A (if enabled by bits OSEL[0:1] in RTC_CR register) can be routed to the RTC_ALARM output. RTC_ALARM output polarity can be configured through bit POL in the RTC_CR register.

17.3.5 Periodic auto-wakeup

The periodic wake-up flag is generated by a 16-bit programmable auto-reload down-counter. The wake-up timer range can be extended to 17 bits.

The wake-up function is enabled through the WUTE bit in the RTC_CR register. The wake-up timer clock input can be:

- RTC clock (RTCCLK) divided by 2, 4, 8, or 16.
When RTCCLK is LSE (32.768 kHz), this allows the wake-up interrupt period to be configured from 122 μ s to 32 s, with a resolution down to 61 μ s.
- ck_spre (usually 1 Hz internal clock)
When ck_spre frequency is 1 Hz, this allows a wake-up time to be achieved from 1 s to around 36 hours with one-second resolution. This large programmable time range is divided in 2 parts:
 - from 1 s to 18 hours when WUCKSEL [2:1] = 10
 - and from around 18 h to 36 h when WUCKSEL[2:1] = 11. In this last case 216 is added to the 16-bit counter current value. When the initialization sequence is complete (see [Section 17.3.6 RTC initialization and configuration](#)), the timer starts counting down. When the wake-up function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC_ISR register, and the wake-up counter is automatically reloaded with its reload value (RTC_WUTR register value).

The WUTF flag must then be cleared by software.

When the periodic wake-up interrupt is enabled by setting the WUTIE bit in the RTC_CR2 register, it can exit the device from low-power modes.

The periodic wake-up flag can be routed to the RTC_ALARM output provided it has been enabled through bits OSEL[0:1] of the RTC_CR register. RTC_ALARM output polarity can be configured through the POL bit in the RTC_CR register.

System reset, as well as low-power mode (DEEPSLEEP) have no influence on the wake-up timer.

17.3.6 RTC initialization and configuration

RTC register access

The RTC registers are 32-bit registers. The APB interface introduces 2 wait-states in RTC register accesses except on read accesses to calendar shadow registers when BYPSHAD=0.

RTC register write protection

After power-on reset, all the RTC registers are write-protected. Writing to the RTC registers is enabled by writing a key into the write protection register, RTC_WPR.

The following steps are required to unlock the write protection on all the RTC registers except for RTC_ISR[13:8], and RTC_BKPxR.

1. Write '0xCA' into the RTC_WPR register.
2. Write '0x53' into the RTC_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC_ISR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.
2. Poll INITF bit in the RTC_ISR register. The initialization phase mode is entered when INITF is set to 1. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC_PRER register.
4. Load the initial time and date values in the shadow registers (RTC_TR and RTC_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC_CR register.
5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded and the counting restarts after 4 RTCCLK clock cycles.

When the initialization sequence is complete, the calendar starts counting.

Note: 1. After a system reset, the application can read the INITS flag in the RTC_ISR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its power-on reset default value (0x00).

Note: 2. To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC_ISR register.

Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

Programming the alarm

A similar procedure must be followed to program or update the programmable alarms.

1. Clear ALRAE in RTC_CR to disable Alarm A
2. Program the Alarm A registers (RTC_ALRMASSR/RTC_ALRMAR)
3. Set ALRAE in the RTC_CR register to enable alarm A again.

Programming the wake-up timer

The following sequence is required to configure or change the wake-up timer auto-reload value (WUT[15:0] in RTC_WUTR):

1. Clear WUTE in RTC_CR to disable the wake-up timer.
2. Poll WUTWF bit until it is set in RTC_ISR register to make sure the access to wake up auto-reload counter and to WUCKSEL[2:0] bits is allowed. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. Program the wake-up auto-reload value WUT[15:0], and the wake-up clock selection (WUCKSEL[2:0] bits in RTC_CR). Set WUTE in RTC_CR to enable the timer again. The wake-up timer restarts down-counting.

17.3.7 Reading the calendar

- When BYPSHAD control bit is cleared in the RTC_CR register:

To read the RTC calendar registers (RTC_SSR, RTC_TR and RTC_DR) properly, the APB1 clock frequency (fPCLK) must be equal to or greater than seven times the fRTCCLKRTC clock frequency. This ensures a secure behavior of the synchronization mechanism.

If the APB0 clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB0 clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in the RTC_ISR register each time the calendar registers are copied into the RTC_TR and RTC_DR shadow registers. The copy is performed every two RTCCLK cycles. To ensure consistency between the 3 values, reading either RTC_SSR or RTC_TR locks the values in the higher-order calendar shadow registers until RTC_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 2 RTCCLK periods: RSF must be cleared by software after the first calendar read, and then the software must wait until RSF is set before reading again the RTC_SSR, RTC_TR and RTC_DR registers.

After waking up from low-power mode (DEEPSLEEP), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC_SSR, RTC_TR and RTC_DR registers.

The RSF bit must be cleared after wakeup and not before entering low-power mode.

After a system reset, the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers. Indeed, a system reset resets the shadow registers to their default values.

After an initialization, the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

After synchronization (refer to [Section 17.3.9 RTC synchronization](#)): the software must await until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

- When the BYPSHAD control bit is set in the RTC_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting from low-power modes (STOP or Standby), since the shadow registers are not updated during these modes.

When the BYPSHAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCLK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCLK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.

Note: While BYPSHAD=1, instructions which read the calendar registers require one extra APB cycle to complete.

17.3.8 Resetting the RTC

The calendar shadow registers (RTC_SSR, RTC_TR and RTC_DR) and the RTC status register (RTC_ISR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a power-on reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC_CR), the prescaler register (RTC_PRER), the RTC calibration register (RTC_CALR), the RTC shift register (RTC_SHIFTR), the RTC backup registers (RTC_BKPxR), the wakeup timer register (RTC_WUTR), the Alarm A registers (RTC_ALRMASSR/RTC_ALRMAR).

In addition, the RTC keeps on running under system reset if the reset source is different from the power-on reset one. When a power-on reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.

17.3.9 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the sub-second field (RTC_SSR or RTC_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by “shifting” its clock by a fraction of a second using RTC_SHIFTR.

RTC_SSR contains the value of the synchronous prescaler counter. This allows to calculate the exact time being maintained by the RTC down to a resolution of $1 / (\text{PREDIV_S} + 1)$ seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value (PREDIV_S[14:0]). The maximum resolution allowed (30.52 μ s with a 32768 Hz clock) is obtained with PREDIV_S set to 0x7FFF.

However, increasing PREDIV_S means that PREDIV_A must be decreased in order to maintain the synchronous prescaler's output at 1 Hz. In this way, the frequency of the asynchronous prescaler's output increases, which may increase the RTC dynamic consumption.

The RTC can be finely adjusted using the RTC shift control register (RTC_SHIFTR). Writing to RTC_SHIFTR can shift (either delay or advance) the clock by up to a second with a resolution of $1 / (\text{PREDIV_S} + 1)$ seconds. The shift operation consists of adding the SUBFS[14:0] value to the synchronous prescaler counter SS[15:0]: this delays the clock. If at the same time the ADD1S bit is set, this results in adding one second and at the same time subtracting a fraction of a second, so this advances the clock.

Caution: Before initiating a shift operation, the user must check that SS[15] = 0 in order to ensure that no overflow occurs.

As soon as a shift operation is initiated by a write to the RTC_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.

17.3.10 RTC smooth digital calibration

The RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using a series of small adjustments (adding and/or subtracting individual RTCCLK pulses). These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

The smooth digital calibration is performed during a cycle of about 220 RTCCLK pulses, or 32 seconds when the input frequency is 32768 Hz. This cycle is maintained by a 20-bit counter, calib_cnt[19:0], clocked by RTCCLK.

The smooth calibration register (RTC_CALR) specifies the number of RTCCLK clock cycles to be masked during the 32-second cycle:

- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the 32-second cycle
- Setting CALM[1] to 1 causes two additional cycles to be masked
- Setting SMC[2] to 1 causes four additional cycles to be masked
- and so on up to SMC[8] set to 1 which causes 256 clocks to be masked

Note: CALM[8:0] (RTC_CALR) specifies the number of RTCCLK pulses to be masked during the 32-second cycle. Setting the bit CALM[0] to '1' causes exactly one pulse to be masked during the 32-second cycle at the moment when cal_cnt[19:0] is 0x80000; CALM[1]=1 causes two other cycles to be masked (when cal_cnt is 0x40000 and 0xC0000); SMC[2]=1 causes four other cycles to be masked (cal_cnt = 0x20000/0x60000/0xA0000/ 0xE0000); and so on up to SMC[8]=1 which causes 256 clocks to be masked (cal_cnt = 0xXX800).

While CALM allows the RTC frequency to be reduced by up to 487.1 ppm ($511/(220+511)$) with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm ($512/(220-512)$). Setting CALP to '1' effectively inserts an extra RTCCLK pulse every 211 RTCCLK cycles, which means that 512 clocks are added during every 32-second cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 RTCCLK cycles can be added during the 32-second cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency (FCAL) given the input frequency (FRTCCLK) is as follows:

$$F_{\text{CAL}} = F_{\text{RTCCLK}} \times [1 + (\text{CALP} \times 512 - \text{CALM}) / (2^{20} + \text{CALM} - \text{CALP} \times 512)]$$

Calibration when PREDIV_A < 3

The CALP bit can not be set to 1 when the asynchronous prescaler value (PREDIV_A bits in RTC_PRER register) is less than 3. If CALP was already set to 1 and PREDIV_A bits are set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

To perform a calibration with PREDIV_A less than 3, the synchronous prescaler value (PREDIV_S) should be reduced so that each second is accelerated by 8 RTCCLK clock cycles, which is equivalent to adding 256 clock cycles every 32 seconds. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each 32-second cycle using only the CALM bits.

With a nominal RTCCLK frequency of 32768 Hz, when PREDIV_A equals 1 (division factor of 2), PREDIV_S should be set to 16379 rather than 16383 (4 less). The only other interesting case is when PREDIV_A equals 0, PREDIV_S should be set to 32759 rather than 32767 (8 less).

If PREDIV_S is reduced in this way, the formula giving the effective frequency of the calibrated input clock is as follows:

$$F_{\text{CAL}} = F_{\text{RTCCLK}} \times [1 + (256 - \text{CALM}) / (2^{20} + \text{CALM} - 256)]$$

In this case, CALM[7:0] equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCLK is exactly 32768.00 Hz.

Note: *The case PREDIV_A=2 (asynchronous prescaler divides by 3) seems unlikely to be useful unless the nominal input frequency is a multiple of 3. For example, if RTCCLK is nominally 98304 Hz (32768 Hz x 3), setting PREDIV_S to 32759 rather than 32767 (8 less) would render the above formula valid.*

Verifying the RTC calibration

RTC precision is ensured by measuring the precise frequency of R_TCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 R_TCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.

However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.

Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 R_TCLK cycles over 32 seconds, due to the limitation of the calibration resolution).

- CALW16 bit of the RTC_CALR register can be set to 1 to force a 16-second calibration cycle period.

In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 R_TCLK cycles over 16 seconds). However, since the calibration resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when CALW16 is set to 1.

- CALW8 bit of the RTC_CALR register can be set to 1 to force a 8-second calibration cycle period.

In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 R_TCLK cycles over 8 s). The long term RTC precision is also reduced to 1.907 ppm: CALM[1:0] bits are stuck at 00 when CALW8 is set to 1.

Re-calibration on-the-fly

The calibration register (RTC_CALR) can be updated on-the-fly while RTC_ISR/INITF=0, by using the following process:

1. Poll the RTC_ISR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC_CALR, if necessary. RECALPF is then automatically set to 1.
3. Within three ck_apre cycles after the write operation to RTC_CALR, the new calibration settings take effect.

Note: *RECALPF then becomes '0' automatically. Note that RECALPF can stay at '1' for as long as 4 ck_apre cycles plus 2 system clock cycles after writing to RTC_CALR. During initialization mode (RTC_ISR/INIT=1), RECALPF can stay at '1' indefinitely.*

17.3.11 Calibration clock output

When the COE bit is set to 1 in the RTC_CR register, a reference clock is provided on the RTC_CALIB device output.

Note: *This RTC_CALIB information is output on the RTC_OUT I/O signal if the I/O is programmed with the associated AFx mode, see Section 5 Power controller (PWRC).*

If the COSEL bit in the RTC_CR register is reset and PREDIV_A = 0x7F, the RTC_CALIB frequency is $f_{\text{RTCCLK}}/64$. This corresponds to a calibration output at 512 Hz for an f_{RTCCLK} frequency at 32.768 kHz. The RTC_CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

When COSEL is set and “PREDIV_S+1” is a non-zero multiple of 256 (i.e: PREDIV_S[7:0] = 0xFF), the RTC_CALIB frequency is $f_{\text{RTCCLK}}/(256 * (\text{PREDIV_A}+1))$. This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV_A = 0x7F, PREDIV_S = 0xFF), with an RTCCLK frequency at 32.768 kHz.

17.3.12 Alarm output

The OSEL[1:0] control bits in the RTC_CR register are used to activate the alarm alternate function output RTC_ALARM, and to select the function which is output. These functions reflect the contents of the corresponding flags in the RTC_ISR register. The polarity of the output is determined by the POL control bit in RTC_CR so that the opposite of the selected flag bit is output when POL is set to 1.

Note: The RTC_ALARM is output on the RTC_OUT I/O signal if the I/O is programmed with the associated AFx mode, see [Section 5 Power controller \(PWRC\)](#).

Note: Once the RTC_ALARM output is enabled, it has priority over RTC_CALIB (COE bit must be kept cleared, which means the RTC_OUT I/O outputs the RTC_ALARM).

17.4 RTC low-power modes

The RTC is able to run in DEEPSLEEP mode and generate a wake-up event to wake the device through RTC alarm and RTC wake-up root cause.

Note: The software has to clear the RTC_ISR.WUTF flag in the RTC after a wakeup, otherwise it prevents from going into low-power again. The PWRC block only mirrors the RTC wake-up signal in its own wake-up flag register.

17.5 RTC interrupts

All RTC interrupts are combined and connected to the NVIC controller. Refer to [Section 2.3.2 Interrupts](#).

To enable the RTC alarm interrupt, the following sequence is required:

1. Configure and enable the RTC_ALARM IRQ channel in the NVIC
2. Configure the RTC to generate RTC alarms (alarm A)

To enable the wake-up timer interrupt, the following sequence is required:

1. Configure and enable the RTC IRQ channel in the NVIC
2. Configure the RTC to detect the WUT event

17.6 RTC registers

Refer to [Section 1.3 Acronyms](#) of the reference manual for a list of abbreviations used in register descriptions.
The peripheral registers can be accessed by words (32-bit).

17.6.1 RTC time register (RTC_TR)

The RTC_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to [Section 17.3.7 Reading the calendar](#).

This register is write protected. The write access procedure is described in [Section 17.3.6 RTC initialization and configuration](#).

Address offset: 0x00

Power-on reset value: 0x0000 0000

System reset: 0x0000 0000 when BYPSHAD = 0 . Not affected when BYPSHAD = 1.

Bits 31:25	Reserved, must be kept at reset value.
Bit 23	COE : Calibration output enable. This bit enables the RTC_CALIB output. 0: Calibration output disabled 1: Calibration output enabled
Bits 22:21	OSEL[1:0] : Output selection. These bits are used to select the flag to be routed to RTC_OUT output. 00: Output disabled

	01: Alarm A output enabled 10: 11: Wakeup output enabled
Bit 20	POL : Output polarity. This bit is used to configure the polarity of RTC_ALARM output. 0: The pin is high when ALRAF/WUTF is asserted (depending on OSEL[1:0]) 1: The pin is low when ALRAF/WUTF is asserted (depending on OSEL[1:0])
Bit 19	COSEL : Calibration output selection. When COE=1, this bit selects which signal is output on RTC_CALIB. 0: Calibration output is 512 Hz 1: Calibration output is 1 Hz These frequencies are valid for R_{TCCLK} at 32.768 kHz and prescalers at their default values (PREDIV_A=127 and PREDIV_S=255). Refer to Section 17.3.11 Calibration clock output .
Bit 18	BKP : Backup This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.
Bit 17	SUB1H : Subtract 1 hour (winter time change). When this bit is set outside initialization mode, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0. Setting this bit has no effect when current hour is 0. 0: No effect 1: Subtracts 1 hour to the current time. This can be used for winter time change.
Bit 16	ADD1H : Add 1 hour (summer time change). When this bit is set outside initialization mode, 1 hour is added to the calendar time. This bit is always read as 0. 0: No effect 1: Adds 1 hour to the current time. This can be used for summer time change.
Bit 15	Reserved, must be kept at reset value.
Bit 14	WUTIE : Wakeup timer interruptenable. 0: Wakeup timer interrupt disabled 1: Wakeup timer interrupt enabled
Bit 12	ALRAIE : Alarm A interrupt enable 0: Alarm A interrupt disabled 1: Alarm A interrupt enabled
Bit 11	Reserved, must be kept at reset value.
Bit 10	WUTE : Wakeup timer enable. 0: Wakeup timer disabled 1: Wakeup timer enabled
Bit 8	ALRAE : Alarm A enable. 0: Alarm A disabled 1: Alarm A enabled
Bit 7	Reserved, must be kept at reset value.
Bit 6	FMT : Hour format. 0: 24 hour/day format 1: AM/PM hour format
Bit 5	BYPHAD : Bypass the shadow registers.

	<p>0: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken by the shadow registers, which are updated once every two RTCCLK cycles</p> <p>1: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken directly by the calendar counters</p> <p>Note: If the frequency of the APB1 clock is less than seven times the frequency of RTCCLK, BYPSHAD must be set to '1'.</p>
Bit 4	Reserved, must be kept at reset value.
Bit 3	Reserved, must be kept at reset value.
Bits 2:0	<p>WUCKSEL[2:0]: Wake-up clock selection 000: RTC/16 clock is selected.</p> <p>001: RTC/8 clock is selected</p> <p>010: RTC/4 clock is selected</p> <p>011: RTC/2 clock is selected</p> <p>10x: ck_spre (usually 1 Hz) clock is selected</p> <p>11x: ck_spre (usually 1 Hz) clock is selected and 216 is added to the WUT counter value (see note below)</p>

Note:

1. Bits 7, 6 and 4 of this register can be written in initialization mode only ($RTC_ISR/INITF = 1$).
2. $WUT = \text{Wake-up unit counter value}$. $WUT = (0x0000 \text{ to } 0xFFFF) + 0x10000$ added when $WUCKSEL[2:1 = 11]$.
3. Bits 2 to 0 of this register can be written only when RTC_CR WUTE bit = 0 and RTC_ISR WUTWF bit = 1.
4. It is recommended not to change the hour during the calendar hour increment as it could mask the incrementation of the calendar hour.
5. $ADD1H$ and $SUB1H$ changes are effective in the next second.
6. This register is write protected. The write access procedure is described in [Section 17.6 RTC registers](#).

17.6.4 RTC initialization and status register (RTC_ISR)

This register is write protected (except for $RTC_ISR[-17:8]$ bits).

The write access procedure is described in [Section 17.6.3 RTC control register \(RTC_CR\)](#).

WUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16	Reserved, must be kept at reset value.
Bits 15:0	WUT[15:0] : Wake-up auto-reload value bits. When the wake-up timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck_wut cycles. The ck_wut period is selected through WUCKSEL[2:0] bits of the RTC_CR register. When WUCKSEL[2] = 1, the wake-up timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.

The first assertion of WUTF occurs (WUT+1) ck_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] = 011 (RTCCLK/2) is forbidden.

17.6.7 RTC alarm A register (RTC_ALRMAR)

This register can be written only when ALRAWF is set to 1 in RTC_ISR, or in initialization mode.

This register is write protected. The write access procedure is described in [Section 17.6 RTC registers](#).

Address offset: 0x1C

Power-on reset value: 0x0000 0000

System reset: not affected

Bits 6:4	ST[2:0]: Second tens in BCD format
Bits 3:0	SU[3:0]: Second units in BCD format

17.6.8 RTC write protection register (RTC_WPR)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8	Reserved, must be kept at reset value.
Bits 7:0	KEY[7:0]: Write protection key. This byte is written by software. Reading this byte always returns 0x00. Refer to Section 17.6 RTC registers for a description of how to unlock RTC register write protection.

17.6.9 RTC sub-second register (RTC_SSR)

Address offset: 0x28

Power-on reset value: 0x0000 0000

System reset: 0x0000 0000 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SS[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16	Reserved, must be kept at reset value.
Bits 15:0	SS: Sub-second value. SS[15:0] is the value in the synchronous prescaler counter. The fraction of a second is given by the formula below: $\text{Second fraction} = (\text{PREDIV_S} - \text{SS}) / (\text{PREDIV_S} + 1)$ Note: SS can be larger than PREDIV_S only after a shift operation. In that case, the correct time/date is one second less than as indicated by RTC_TR/RTC_DR.

17.6.10 RTC shift control register (RTC_SHIFTR)

This register is write protected. The write access procedure is described in [Section 17.6.8 RTC write protection register \(RTC_WPR\)](#).

Address offset: 0x2C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADD1S	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
w															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SUBFS[14:0]														
	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bit 31	<p>ADD1S: Add one second.</p> <p>0: No effect</p> <p>1: Add one second to the clock/calendar</p> <p>This bit is "write" only and is always "read" as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC_ISR).</p> <p>This function is intended to be used with SUBFS (see description below) in order to effectively add a fraction of a second to the clock in an atomic operation.</p>
Bits 31:15	Reserved, must be kept at reset value.
Bits 14:0	<p>SUBFS: Subtract a fraction of a second.</p> <p>These bits are "write" only and are always "read" as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC_ISR).</p> <p>The value which is written to SUBFS is added to the synchronous prescaler's counter. Since this counter counts down, this operation effectively subtracts from (delays) the clock by:</p> <p>Delay (seconds) = SUBFS / (PREDIV_S + 1)</p> <p>A fraction of a second can effectively be added to the clock (advancing the clock) when the ADD1S function is used in conjunction with SUBFS, effectively advancing the clock by :</p> <p>Advance (seconds) = (1 - (SUBFS / (PREDIV_S + 1))) .</p> <p>Note: Writing to SUBFS causes RSF to be cleared. Software can then wait until RSF=1 to be sure that the shadow registers have been updated with the shifted time.</p> <p>Refer to Section 17.3.9 RTC synchronization.</p>

17.6.11 RTC calibration register (RTC_CALR)

This register is "write" protected. The write access procedure is described in [Section 17.6.8 RTC write protection register \(RTC_WPR\)](#).

Address offset: 0x3C

Power-on reset value: 0x0000 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CALP	CALW8	CALW 16	Res.	Res.	Res.	Res.	CALM[8:0]								
rw	rw	rw					rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31:16	Reserved, must be kept at reset value.
Bit 15	CALP: Increase frequency of RTC by 488.5 ppm

	<p>0: No RTCCLK pulses are added</p> <p>1: One RTCCLK pulse is effectively inserted every 211 pulses (frequency increased by 488.5 ppm).</p> <p>This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. if the input frequency is 32768 Hz, the number of RTCCLK pulses added during a 32-second window is calculated as follows:</p> <p>$(512 * CALP) - CALM$.</p> <p>Refer to Section 17.3.10 RTC smooth digital calibration.</p>
Bit 14	<p>CALW8: Use an 8-second calibration cycle period.</p> <p>When CALW8 is set to '1', the 8-second calibration cycle period is selected.</p> <p>Note: CALM[1:0] are stuck at "00" when CALW8 = '1'. Refer to Section 17.3.10 RTC smooth digital calibration.</p>
Bit 13	<p>CALW16: Use a 16-second calibration cycle period.</p> <p>When CALW16 is set to '1', the 16-second calibration cycle period is selected. This bit must not be set to '1' if CALW8=1.</p> <p>Note: CALM[0] is stuck at '0' when CALW16 = '1'. Refer to Section 17.3.10 RTC smooth digital calibration.</p>
Bits 12:9	Reserved, must be kept at reset value.
Bits 8:0	<p>CALM[8:0]: Calibration minus</p> <p>The frequency of the calendar is reduced by masking CALM out of 2^{20} RTCCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.</p> <p>To increase the frequency of the calendar, this feature should be used in conjunction with CALP. See Section 17.3.10 RTC smooth digital calibration.</p>

17.6.12 RTC alarm A sub second register (RTC_ALRMASR)

This register can be written only when ALRAE is reset in RTC_CR register, or in initialization mode.

This register is "write" protected. The write access procedure is described in [Section 17.6.8 RTC write protection register \(RTC_WPR\)](#).

Address offset: 0x44

Power-on reset value: 0x0000 0000

System reset: not affected

18 Independent watchdog (IWDG)

18.1 Introduction

The devices feature an embedded watchdog peripheral which offers a combination of high safety level, timing accuracy and flexibility of use. The independent watchdog peripheral serves to detect and resolves malfunctions due to software failure, and to trigger system reset when the counter reaches a given timeout value.

The independent watchdog (IWDG) is clocked by its own dedicated low-speed clock (LSI) and thus remains active even if the main clock fails.

The IWDG is best suited to applications which require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints.

18.2 IWDG main features

- Free-running down-counter
- Clocked from an independent RC oscillator (can operate in standby and stop modes)
- Conditional Reset
 - Reset (if watchdog activated) when the down-counter value becomes less than 000h
 - Reset (if watchdog activated) if the down-counter is reloaded outside the window

18.3 IWDG functional description

Figure 82. Independent watchdog block diagram shows the functional blocks of the independent watchdog module.

When the independent watchdog is started by writing the value 0x0000 CCCC in the Key register (IWDG_KR), the counter starts counting down from the reset value of 0xFFFF. When it reaches the end of count value (0x000) a reset signal is generated (IWDG reset).

Whenever the key value 0x0000 AAAA is written in the IWDG_KR register, the IWDG_RLR value is reloaded in the counter and the watchdog reset is prevented.

18.3.1 Window option

The IWDG can also work as a window watchdog by setting the appropriate window in the IWDG_WINR register. If the reload operation is performed while the counter is greater than the value stored in the window register (IWDG_WINR), then a reset is provided.

The default value of the IWDG_WINR is 0x0000 0FFF, so if it is not updated, the window option is disabled.

As soon as the window value is changed, a reload operation is performed in order to reset the down-counter to the IWDG_RLR value and ease the cycle number calculation to generate the next reload.

Configuring the IWDG when the window option is enabled

1. Enable the IWDG by writing 0x0000 CCCC in the IWDG_KR register.
2. Enable register access by writing 0x0000 5555 in the IWDG_KR register.
3. Write the IWDG prescaler by programming IWDG_PR from 0 to 7.
4. Write the reload register(IWDG_RLR).
5. Wait for the registers to be updated (IWDG_SR = 0x00000000).
6. Write to the window register IWDG_WINR. This automatically refreshes the counter value IWDG_RLR.

Note: Writing the window value allows the counter value to be refreshed by the RLR when IWDG_SR is set to 0x0000 0000.

Configuring the IWDG when the window option is disabled.

When the window option it is not used, the IWDG can be configured as follows:

1. Enable register access by writing 0x0000 5555 in the IWDG_KR register.
2. Write the IWDG prescaler by programming IWDG_PR from 0 to 7.

3. Write the reload register (IWDG_RLR).
4. Wait for the registers to be updated (IWDG_SR = 0x00000000).
5. Refresh the counter value with IWDG_RLR (IWDG_KR = 0x0000AAAA).
6. Enable the IWDG by writing 0x0000 CCCC in the IWDG_KR.

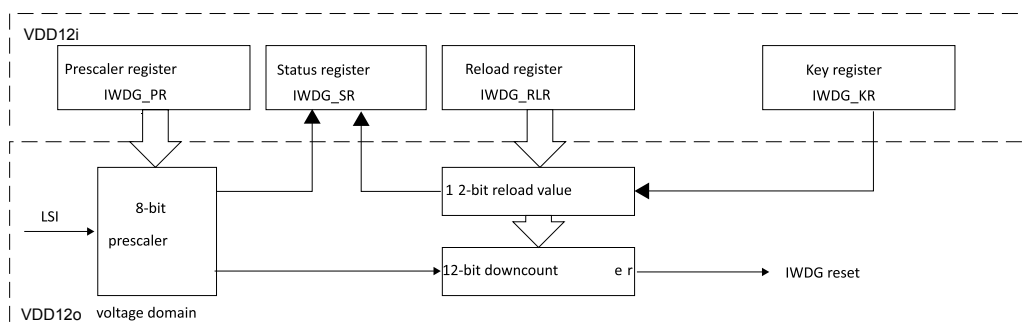

18.3.2 Register access protection

Write access to the IWDG_PR, IWDG_RLR and IWDG_WINR registers is protected. To modify them, you must first write the code 0x0000 5555 to the IWDG_KR register. A write access to this register with a different value breaks the sequence and register access is protected again. This implies that it is the case of the reload operation (writing 0x0000 AAAA). A status register is available to indicate that an update of the prescaler or the down-counter reload value or the window value is on-going.

18.3.3 Debug mode

No specific debug mode implemented in the BlueNRG-LP. The timer goes on counting even when the CPU is halted by the debugger.

Figure 82. Independent watchdog block diagram

Note: The watchdog is implemented in the VDD12o power domain that is still functional in DEEPSTOP mode.

18.4 IWDG registers

Refer to [Table 2. Acronyms](#) for a list of abbreviations used in register descriptions. The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

18.4.1 Key register (IWDG_KR)

Address offset: 0x00

Reset value: 0x0000 0000 (reset by standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16	Reserved, must be kept at reset value.
Bits 15:0	KEY[15:0]: Key value (write only, read 0x0000). These bits must be written by software at regular intervals with the key value 0xAAAA, otherwise the watchdog generates a reset when the counter reaches 0. Writing the key value 0x5555 enables access to the IWDG_PR, IWDG_RLR and IWDG_WINR registers (see Section 18.3.2 Register access protection). Writing the key value CCCCh starts the watchdog (except if the hardware watchdog option is selected).

18.4.2 Prescaler register (IWDG_PR)

Address offset: 0x04

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WVU	RVU	PVU
													r	r	r

Bits 31:3	Reserved, must be kept at reset value.
Bit 2	WVU: Watchdog counter window value update.

	<p>This bit is set by hardware to indicate that an update of the window value is on-going. It is reset by hardware when the reload value update operation is completed in the VDD12o voltage domain (takes up to 5 RC 40 kHzcycles).</p> <p>Window value can be updated only when WVU bit is reset. This bit is generated only if generic "window" = 1.</p>
Bit 1	<p>RVU: Watchdog counter reload value update.</p> <p>This bit is set by hardware to indicate that an update of the reload value is on-going. It is reset by hardware when the reload value update operation is completed in the VDD12o voltage domain (takes up to 5 RC 40 kHzcycles).</p> <p>Reload value can be updated only when RVU bit is reset.</p>
Bit 0	<p>PVU: Watchdog prescaler value update.</p> <p>This bit is set by hardware to indicate that an update of the prescaler value is on-going. It is reset by hardware when the prescaler update operation is completed in the VDD12o voltage domain (takes up to 5 RC 40 kHz cycles).</p> <p>Prescaler value can be updated only when PVU bit is reset.</p>

18.4.5 Window register (IWDG_WINR)

Address offset: 0x10

Reset value: 0x0000 0FFF (reset by standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	WIN[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12	Reserved, must be kept at reset value.
Bits 11:0	<p>WIN[11:0]: Watchdog counter window value.</p> <p>These bits are write access protected, see Section 18.3.2 Register access protection. These bits contain the high limit of the window value to be compared to the down-counter.</p> <p>To prevent a reset, the down-counter must be reloaded when its value is lower than the window register value and greater than 0x0.</p> <p>The WVU bit in the IWDG_SR register must be reset in order to be able to change the reload value.</p> <p>Note: Reading this register returns the reload value from the VDD12o voltage domain. This value may not be valid if a write operation to this register is on-going. For this reason the value read from this register is valid only when the WVU bit in the IWDG_SR register is reset.</p>

Note: *If several reload, prescaler, or window values are used by the application, it is mandatory to wait for the RVU bit to be reset before changing the reload value, to wait for the PVU bit to be reset before changing the prescaler value, and to wait for the WVU bit to be reset before changing the window value. However, after updating the prescaler and/or the reload/window value it is not necessary to wait for RVU or PVU or WVU to be reset before continuing code execution except in case of low-power mode entry.*

18.5 IWDG register map

The following table gives the IWDG register map and reset values.

Table 53. IWDG register map

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Section 2.2.2 Memory map and register boundary addresses](#) for the register boundary addresses.

19 Inter-integrated circuit (I2C) interface

19.1 Introduction

The I²C (inter-integrated circuit) bus interface handles communications between the microcontroller and the serial I²C bus. It provides multimaster capability, and controls all I²C bus-specific sequencing, protocol, arbitration and timing. It supports standard-mode (Sm), fast-mode (Fm) and fast-mode plus (Fm+).

It is also SMBus (system management bus) and PMBus (power management bus) compatible.

DMA can be used to reduce CPU overload.

19.2 I2C main features

- I²C bus specification rev 03 compatibility:
 - Slave and master modes
 - Multi master capability
 - Standard-mode (up to 100 kHz)
 - Fast-mode (up to 400 kHz)
 - Fast-mode plus (up to 1 MHz)
 - 7-bit and 10-bit addressing mode
 - Multiple 7-bit slave addresses (2 addresses, 1 with configurable mask)
 - All 7-bit addresses acknowledge mode
 - General call
 - Programmable setup and hold times
 - Easy to use event management
 - Optional clock stretching
 - Software reset
- 1-byte buffer with DMA capability
- Programmable analog and digital noise filters.

The following additional features are also available depending on the product implementation (see [Section 19.3 I2C implementation](#)):

- SMBus specification rev 2.0 compatibility:
 - Hardware PEC (packet error checking) generation and verification with ACK control
 - Command and data acknowledge control
 - Address resolution protocol (ARP) support
 - Host and device support
 - SMBus alert
 - Timeouts and idle condition detection
- PMBus rev 1.1 standard compatibility
- Independent clock: a choice of independent clock sources allowing the I²C communication speed to be independent from the PCLK reprogramming.

Note: *For the fast-mode plus mode, it is strongly recommended to use I²C pins mentioned as open-drain capable (embedding a 10ns/50ns filter).*

19.3 I2C implementation

This manual describes the full set of features implemented in I2C1 and I2C2.

Table 54. BlueNRG-LP I²C implementation

I ² C features ⁽¹⁾	I2C1	I2C2
7-bit addressing mode	X	X
10-bit addressing mode	X	X
Standard-mode (up to 100 kbit/s)	X	X
Fast-mode (up to 400 kbit/s)	X	X
Fast-mode plus with 20 mA output drive I/Os (up to 1 Mbit/s)	X	X
Independent clock	X	X
SMBus	X	X

1. X=supported

19.4 I2C functional description

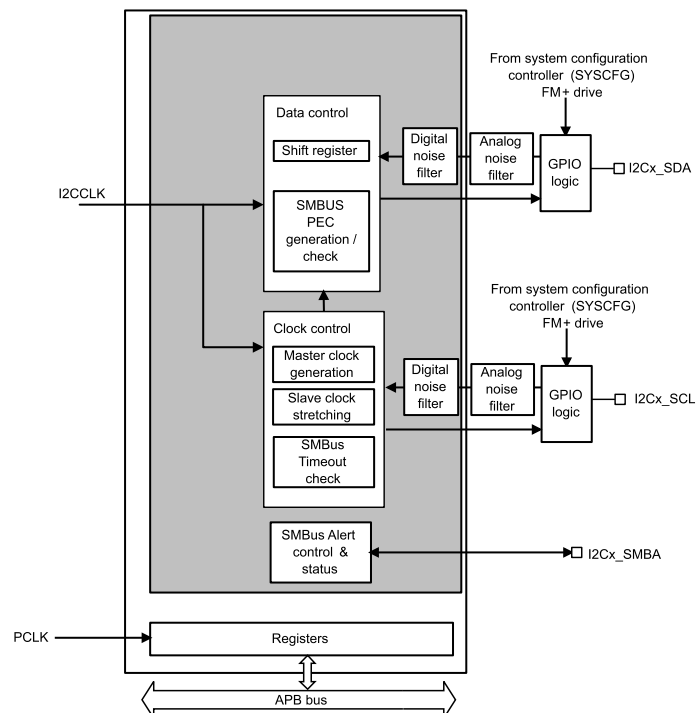

In addition to receiving and transmitting data, this interface converts it from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The interface is connected to the I²C bus by a data pin (SDA) and by a clock pin (SCL). It can be connected with a standard (up to 100 kHz), fast-mode (up to 400 kHz) or fast-mode plus (up to 1 MHz) I²C bus.

This interface can also be connected to an SMBus with the data pin (SDA) and clock pin (SCL).

If SMBus feature is supported: the additional optional SMBus alert pin (SMBA) is also available.

19.4.1 I2C block diagram

The block diagram of the I²C interface is shown below.

Figure 83. I²C block diagram

The I²C is clocked by an independent clock source which allows the I²C to operate independently from the PCLK frequency.

This independent clock source is a fixed 16-MHz clock. Refer to [Section 6 Reset and clock controller \(RCC\)](#) for more details.

I²C I/Os supports 20 mA output current drive for fast-mode plus operation. This is enabled by setting the driving capability control bits for SCL and SDA in [Section 8.2.3 I2C Fast-Mode Plus pin capability control register \(I2C_FMP_CTRL\)](#).

19.4.2 I2C clock requirements

The I²C kernel is clocked by I2CCLK.

The I2CCLK period t_{I2CCLK} must respect the following conditions:

$$t_{I2CCLK} < (t_{LOW} - t_{filters}) / 4 \text{ and } t_{I2CCLK} < t_{HIGH}$$

with:

t_{LOW} : SCL low time and t_{HIGH} : SCL high time

$t_{filters}$: when enabled, sum of the delays brought by the analog filter and by the digital filter. Analog filter delay is maximum 260 ns. Digital filter delay is $DNF \times t_{I2CCLK}$.

The PCLK clock period t_{PCLK} must respect the following condition: $t_{PCLK} < 4/3 t_{SCL}$

with t_{SCL} : SCL period.

19.4.3 Mode selection

The interface can operate in one of the four following modes:

- Slave transmitter
- Slave receiver
- Master transmitter
- Master receiver

By default, it operates in slave mode. The interface automatically switches from slave to master when it generates a START condition, and from master to slave if an arbitration loss or a STOP generation occurs, allowing multimaster capability.

Communication flow

In master mode, the I²C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a START condition and ends with a STOP condition. Both START and STOP conditions are generated in master mode by software.

In slave mode, the interface is capable of recognizing its own addresses (7 or 10-bit), and the general call address. The general call address detection can be enabled or disabled by software. The reserved SMBus addresses can also be enabled by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first byte(s) following the START condition contain the address (one in 7-bit mode, two in 10-bit mode). The address is always transmitted in master mode.

A 9th clock pulse follows the 8 clock cycles of a byte transfer, during which the receiver must send an acknowledge bit to the transmitter. Refer to the following figure.

Figure 84. I²C bus protocol

Acknowledge can be enabled or disabled by software. The I²C interface addresses can be selected by software.

19.4.4 I2C initialization

Enabling and disabling the peripheral

The I²C peripheral clock must be configured and enabled in the clock controller (refer to [Section 6 Reset and clock controller \(RCC\)](#)).

Then the I²C can be enabled by setting the PE bit in the I2C_CR1 register. When the I²C is disabled (PE=0), the I²C performs a software reset. Refer to [Section 19.4.5 Software reset](#) for more details.

Noise filters

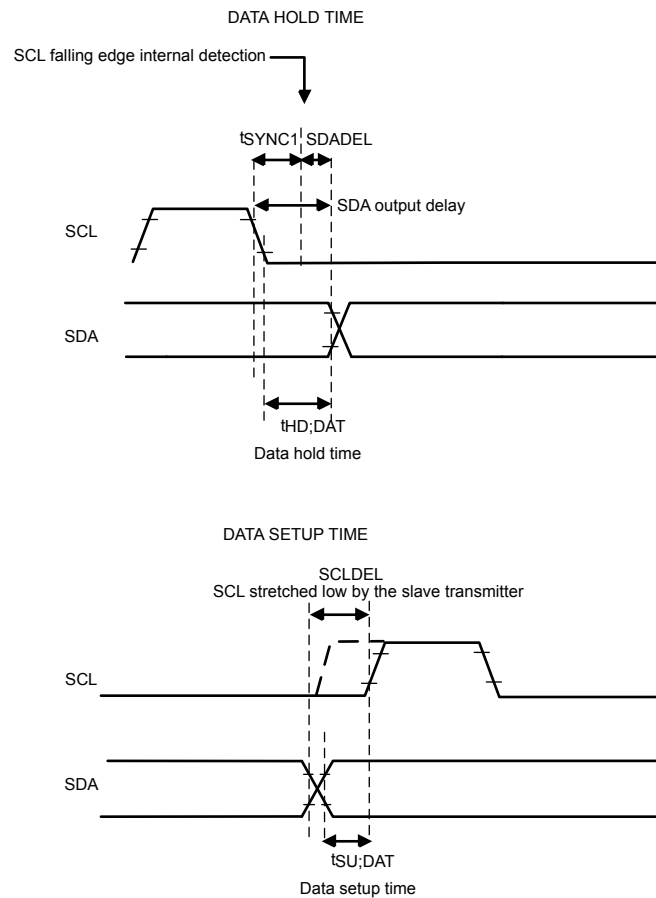

Before you enable the I²C peripheral by setting the PE bit in the I2C_CR1 register, you must configure the noise filters, if needed. By default, an analog noise filter is present on the SDA and SCL inputs. This analog filter is compliant with the I²C specification which requires the suppression of spikes with a pulse width up to 50 ns in fast-mode and fast-mode plus. You can disable this analog filter by setting the ANFOFF bit, and/or select a digital filter by configuring the DNF[3:0] bit in the I2C_CR1 register.

When the digital filter is enabled, the level of the SCL or the SDA line is internally changed only if it remains stable for more than DNF x I2CCLK periods. This allows spikes to be suppressed with a programmable length of 1 to 15 I2CCLK periods.

Caution: Changing the filter configuration is not allowed when the I²C is enabled.

I²C timings

The timings must be configured in order to guarantee a correct data hold and set-up time, used in master and slave modes. This is done by programming the PRESC[3:0], SCLDEL[3:0] and SDADEL[3:0] bits in the I2C_TIMINGR register.

Figure 85. Setup and hold timings

- When the SCL falling edge is internally detected, a delay is inserted before sending SDA output. This delay is

$$t_{SDADEL} = SDADEL \times t_{PRESC} + t_{I2CCLK} \text{ where } t_{PRESC} = (PRESC + 1) \times t_{I2CCLK}$$

t_{SDADEL} and impacts the hold time $t_{HD;DAT}$.

The total SDA output delay is:

$$t_{SYNC1} + \{[SDADEL \times (PRESC + 1) + 1] \times t_{I2CCLK}\}$$

t_{SYNC1} duration depends on these parameters:

- SCL falling slope
- When enabled, input delay t_{SYNC1} brought by the analog filter: $t_{AF(min)} < t_{AF} < t_{AF(max)}$ ns.
- When enabled, input delay brought by the digital filter: $t_{DNF} = DNF \times t_{I2CCLK}$
- Delay due to SCL synchronization to I2CCLK clock (2 to 3 I2CCLK periods)

In order to bridge the undefined region of the SCL falling edge, you must program SDADEL in such a way that:

$$\{t_{f(max)} + t_{HD;DAT(min)} - t_{AF(min)} - [(DNF + 3) \times t_{I2CCLK}]\} / \{(PRESC + 1) \times t_{I2CCLK}\} \leq SDADEL$$

$$SDADEL \leq \{t_{HD;DAT(max)} - t_{AF(max)} - [(DNF + 4) \times t_{I2CCLK}]\} / \{(PRESC + 1) \times t_{I2CCLK}\}$$

Note:

$t_{AF(min)}$ / $t_{AF(max)}$ are part of the equation only when the analog filter is enabled. Refer to device datasheet for t_{AF} values.

The maximum $t_{HD;DAT}$ could be 3.45 μ s, 0.9 μ s and 0.45 μ s for standard-mode, fast-mode and fast-mode plus, but must be less than the maximum of $t_{VD;DAT}$ by a transition time. This maximum must only be met if the device does not stretch the LOW period (t_{LOW}) of the SCL signal. If the clock stretches the SCL, the data must be validated by the set-up time before it releases the clock.

The SDA rising edge is usually the worst case, so in this case the previous equation becomes:

$$SDADEL \leq \{t_{VD;DAT(max)} - t_{r(max)} - 260 \text{ ns} - [(DNF+4) \times t_{I2CCLK}]\} / \{(PRESC + 1) \times t_{I2CCLK}\}.$$

Note:

This condition can be violated when NOSTRETCH=0, because the device stretches SCL low to guarantee the set-up time, according to the SCLDEL value.

Refer to [Table 55. I²C-SMBUS specification data setup and hold times](#) for t_r , t_r , $t_{HD;DAT}$ and $t_{VD;DAT}$ standard values.

- After sending SDA output, SCL line is kept at low level during the set-up time. This set-up time is $t_{SCLDEL} = (SCLDEL+1) \times t_{PRESC}$ where $t_{PRESC} = (PRESC+1) \times t_{I2CCLK}$. t_{SCLDEL} impacts the set-up time $t_{SU;DAT}$.

In order to bridge the undefined region of the SDA transition (rising edge usually worst case), you must program SCLDEL in such a way that:

$$\{[t_{r(max)} + t_{SU;DAT(min)}] / [(PRESC+1)] \times t_{I2CCLK}\} - 1 \leq SCLDEL$$

Refer to [Table 55. I²C-SMBUS specification data setup and hold times](#) for t_r and $t_{SU;DAT}$ standard values.

The SDA and SCL transition time values to be used are the ones in the application. Using the maximum values from the standard increases the constraints for the SDADEL and SCLDEL calculation, but ensures the feature whatever the application.

Table 55. I²C-SMBUS specification data setup and hold times

Symbol	Parameter	Standard-mode (Sm)		Fast-mode (Fm)		Fast-mode Plus (Fm+)		SMBUS		Unit
		Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	
$t_{HD;DAT}$	Data hold time	0	-	0	-	0	-	0.3	-	μs
$t_{VD;DAT}$	Data valid time	-	3.45	-	0.9	-	0.45	-	-	
$t_{SU;DAT}$	Data set-up time	250	-	100	-	50	-	250	-	ns
t_r	Rise time of both SDA and SCL signals	-	1000	-	300	-	120	-	1000	
t_f	Fall time of both SDA and SCL signals	-	300	-	300	-	120	-	300	

Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0] and SCLL[7:0] bits in the I2C_TIMINGR register.

- When the SCL falling edge is internally detected, a delay is inserted before releasing the SCL output. This delay is $t_{SCLL} = (SCLL+1) \times t_{PRESC}$ where $t_{PRESC} = (PRESC+1) \times t_{I2CCLK}$.

t_{SCLL} impacts the SCL low time t_{LOW} .

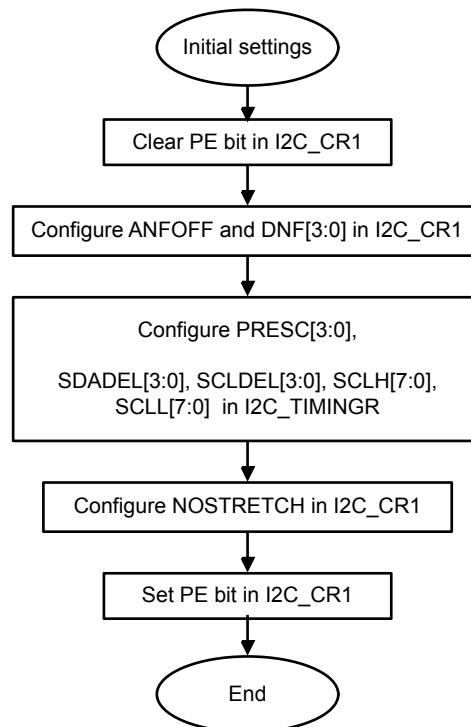

- When the SCL rising edge is internally detected, a delay is inserted before forcing the SCL output to low level. This delay is $t_{SCLH} = (SCLH+1) \times t_{PRESC}$ where $t_{PRESC} = (PRESC+1) \times t_{I2CCLK}$. t_{SCLH} and impacts the SCL high time t_{HIGH} .

Refer to [Section 19.4.8 I2C master mode](#) for more details.

Caution: Changing the timing configuration is not allowed when the I²C is enabled.

The I²C slave NOSTRETCH mode must also be configured before enabling the peripheral.

Caution: Changing the NOSTRETCH configuration is not allowed when the I²C is enabled.

Figure 86. I²C initialization flowchart

19.4.5 Software reset

A software reset can be performed by clearing the PE bit in the I2C_CR1 register. In that case I²C lines SCL and SDA are released. Internal state machines are reset and communication control bits, as well as status bits come back to their reset value. The configuration registers are not impacted.

Here is the list of impacted register bits:

1. I2C_CR2 register: START, STOP, NACK
2. I2C_ISR register: BUSY, TXE, TXIS, RXNE, ADDR, NACKF, TCR, TC, STOPF, BERR, ARLO, OVR

and in addition when the SMBus feature is supported:

1. I2C_CR2 register: PECBYTE
2. I2C_ISR register: PECERR, TIMEOUT, ALERT

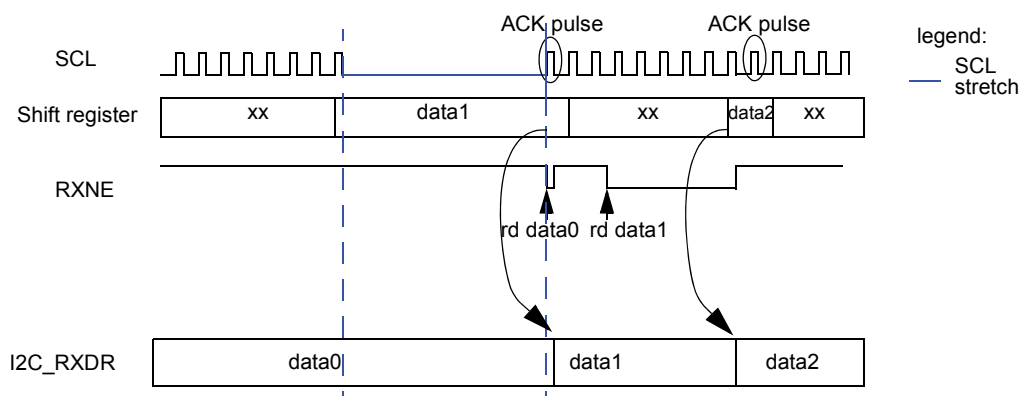

PE must be kept low during at least 3 APB clock cycles in order to perform the software reset. This is ensured by writing the following software sequence: - Write PE=0 - Check PE=0 - Write PE=1.

19.4.6 Data transfer

The data transfer is managed through transmit and receive data registers and a shift register.

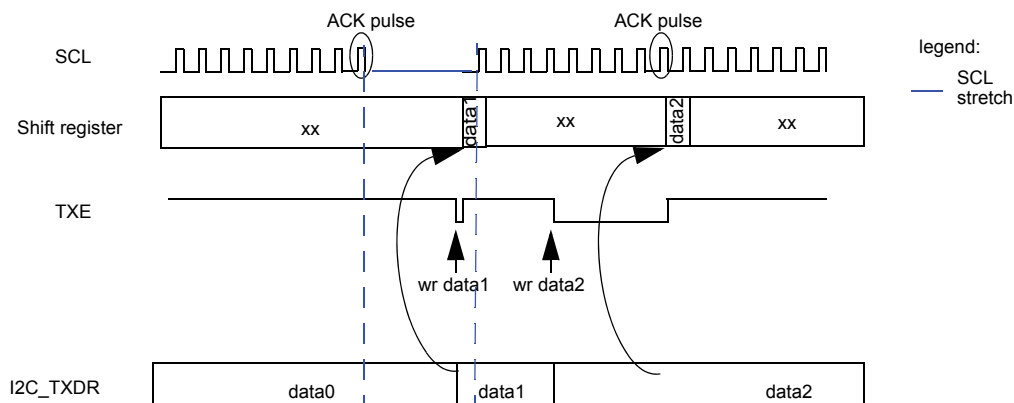

Reception

The SDA input fills the shift register. After the 8th SCL pulse (when the complete data byte is received), the shift register is copied into the I2C_RXDR register if it is empty (RXNE=0). If RXNE=1, meaning that the previous received data byte has not yet been read, the SCL line is stretched low until I2C_RXDR is read. The stretch is inserted between the 8th and 9th SCL pulse (before the acknowledge pulse).

Figure 87. Data reception

Transmission

If the I2C_TXDR register is not empty (TXE=0), its content is copied into the shift register after the 9th SCL pulse (the acknowledge pulse). Then the shift register content is shifted out on the SDA line. If TXE=1, meaning that no data is written yet in I2C_TXDR, SCL line is stretched low until I2C_TXDR is written. The stretch is done after the 9th SCL pulse.

Figure 88. Data transmission

Hardware transfer management

The I²C has a byte counter embedded in hardware in order to manage byte transfer and to close the communication in various modes such as:

- NACK, STOP and ReSTART generation in master mode
- ACK control in slave receiver mode
- PEC generation/checking when SMBus feature is supported

The byte counter is always used in master mode. By default it is disabled in slave mode, but it can be enabled by software by setting the SBC (slave byte control) bit in the I2C_CR2 register.

The number of bytes to be transferred is programmed in the NBYTES[7:0] bit field in the I2C_CR2 register. If the number of bytes to be transferred (NBYTES) is greater than 255, or if a receiver wants to control the acknowledge value of a received data byte, the reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this mode, TCR flag is set when the number of bytes programmed in NBYTES has been transferred, and an interrupt is generated if TCIE is set. SCL is stretched as long as TCR flag is set. TCR is cleared by software when NBYTES is written to a non-zero value.

When the NBYTES counter is reloaded with the last number of bytes, RELOAD bit must be cleared.

When RELOAD=0 in master mode, the counter can be used in 2 modes:

- **Automatic end mode** (AUTOEND = '1' in the I2C_CR2 register). In this mode, the master automatically sends a STOP condition once the number of bytes programmed in the NBYTES[7:0] bit field has been transferred.
- **Software end mode** (AUTOEND = '0' in the I2C_CR2 register). In this mode, software action is expected once the number of bytes programmed in the NBYTES[7:0] bit field has been transferred; the TC flag is set and an interrupt is generated if the TCIE bit is set. The SCL signal is stretched as long as the TC flag is set. The TC flag is cleared by software when the START or STOP bit is set in the I2C_CR2 register. This mode must be used when the master wants to send a RESTART condition.

Caution: The AUTOEND bit has no effect when the RELOAD bit is set.

Table 56. I2C configurable table

Function	SBC bit	RELOAD bit	AUTOEND bit
Master Tx/Rx NBYTES + STOP	x	0	1
Master Tx/Rx + NBYTES + RESTART	x	0	0
Slave Tx/Rx all received bytes ACKed	0	x	x
Slave Rx with ACK control	1	1	x

19.4.7

I2C slave mode

I2C slave initialization

In order to work in slave mode, you must enable at least one slave address. Two registers, I2C_OAR1 and I2C_OAR2, are available in order to program the slave own addresses OA1 and OA2.

- OA1 can be configured either in 7-bit mode (by default) or in 10-bit addressing mode by setting the OA1MODE bit in the I2C_OAR1 register.
OA1 is enabled by setting the OA1EN bit in the I2C_OAR1 register.
- If additional slave addresses are required, you can configure the 2nd slave address OA2. Up to 7 OA2 LSB can be masked by configuring the OA2MSK[2:0] bits in the I2C_OAR2 register. Therefore for OA2MSK configured from 1 to 6, only OA2[7:2], OA2[7:3], OA2[7:4], OA2[7:5], OA2[7:6] or OA2[7] are compared with the received address. As soon as OA2MSK is not equal to 0, the address comparator for OA2 excludes the I2C reserved addresses (0000 XXX and 1111 XXX), which are not acknowledged. If OA2MSK=7, all received 7-bit addresses are acknowledged (except reserved addresses). OA2 is always a 7-bit address.
These reserved addresses can be acknowledged if they are enabled by the specific enable bit, if they are programmed in the I2C_OAR1 or I2C_OAR2 register with OA2MSK=0.
OA2 is enabled by setting the OA2EN bit in the I2C_OAR2 register.
- The general call address is enabled by setting the GCEN bit in the I2C_CR1 register.

When the I2C is selected by one of its enabled addresses, the ADDR interrupt status flag is set, and an interrupt is generated if the ADDRIE bit is set.

By default, the slave uses its clock stretching capability, which means that it stretches the SCL signal at low level when needed, in order to perform software actions. If the master does not support clock stretching, the I2C must be configured with NOSTRETCH=1 in the I2C_CR1 register.

After receiving an ADDR interrupt, if several addresses are enabled you must read the ADDCODE[6:0] bits in the I2C_ISR register in order to check which address matched. DIR flag must also be checked in order to know the transfer direction.

Slave clock stretching (NOSTRETCH = 0)

In default mode, the I²C slave stretches the SCL clock in the following situations:

- When the ADDR flag is set: the received address matches with one of the enabled slave addresses. This stretch is released when the ADDR flag is cleared by software setting the ADDRCONF bit.
- In transmission, if the previous data transmission is completed and no new data is written in I2C_TXDR register, or if the first data byte is not written when the ADDR flag is cleared (TXE=1). This stretch is released when the data is written to the I2C_TXDR register.
- In reception when the I2C_RXDR register is not read yet and a new data reception is completed. This stretch is released when I2C_RXDR is read.
- When TCR = 1 in Slave Byte Control mode, reload mode (SBC=1 and RELOAD=1), meaning that the last data byte has been transferred. This stretch is released when then TCR is cleared by writing a non-zero value in the NBYTES[7:0] field.
- After SCL falling edge detection, the I²C stretches SCL low during $[(SDADEL+SCLDEL+1) \times (PRESC+1) + 1] \times t_{I2CCCLK}$.

Slave without clock stretching (NOSTRETCH = 1)

When NOSTRETCH = 1 in the I2C_CR1 register, the I²C slave does not stretch the SCL signal.

- The SCL clock is not stretched while the ADDR flag is set.
- In transmission, the data must be written in the I2C_TXDR register before the first SCL pulse corresponding to its transfer occurs. If not, an underrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. The OVR flag is also set when the first data transmission starts and the STOPF bit is still set (has not been cleared). Therefore, if you clear the STOPF flag of the previous transfer only after writing the first data to be transmitted in the next transfer, you ensure that the OVR status is provided, even for the first data to be transmitted.
- In reception, the data must be read from the I2C_RXDR register before the 9th SCL pulse (ACK pulse) of the next data byte occurs. If not an overrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Slave byte control mode

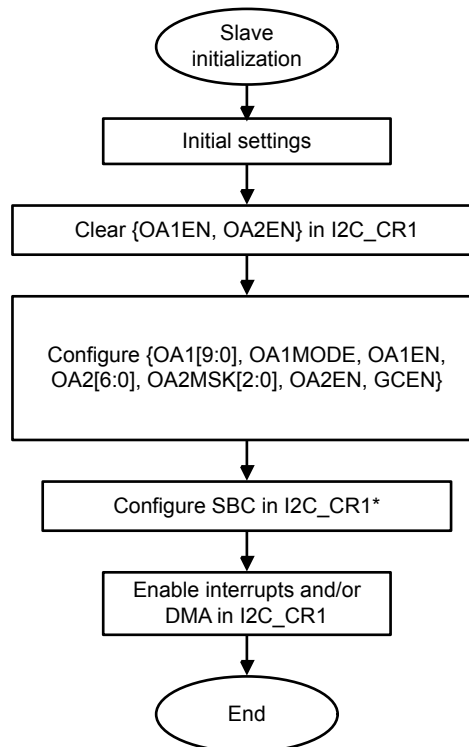

In order to allow byte ACK control in slave reception mode, slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. This is required to be compliant with SMBus standards.

Reload mode must be selected in order to allow byte ACK control in slave reception mode (RELOAD=1). To get control of each byte, NBYTES must be initialized to 0x1 in the ADDR interrupt subroutine, and reloaded to 0x1 after each received byte. When the byte is received, the TCR bit is set, stretching the SCL signal low between the 8th and 9th SCL pulses. You can read the data from the I2C_RXDR register, and then decide to acknowledge it or not by configuring the ACK bit in the I2C_CR2 register. The SCL stretch is released by programming NBYTES to a non-zero value: the acknowledge or not- acknowledge is sent and the next byte can be received.

NBYTES can be loaded with a value greater than 0x1, and in this case, the reception flow is continuous during NBYTES data reception.

Note: The SBC bit must be configured when the I²C is disabled, or when the slave is not addressed, or when ADDR=1. The RELOAD bit value can be changed when ADDR=1, or when TCR=1.

Caution: Slave byte control mode is not compatible with NOSTRETCH mode. Setting SBC when NOSTRETCH=1 is not allowed.

Figure 89. Slave initialization flowchart

*SBC must be set to support SMBus features

Slave transmitter

A transmit interrupt status (TXIS) is generated when the I2C_TXDR register becomes empty. An interrupt is generated if the TXIE bit is set in the I2C_CR1 register.

The TXIS bit is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

When a NACK is received, the NACKF bit is set in the I2C_ISR register and an interrupt is generated if the NACKIE bit is set in the I2C_CR1 register. The slave automatically releases the SCL and SDA lines in order to let the master perform a STOP or a RESTART condition. The TXIS bit is not set when a NACK is received.

When a STOP is received and the STOPIE bit is set in the I2C_CR1 register, the STOPF flag is set in the I2C_ISR register and an interrupt is generated. In most applications, the SBC bit is usually programmed to '0'. In this case, If TXE = 0 when the slave address is received (ADDR=1), you can choose either to send the content of the I2C_TXDR register as the first data byte, or to flush the I2C_TXDR register by setting the TXE bit in order to program a new data byte.

In slave byte control mode (SBC=1), the number of bytes to be transmitted must be programmed in NBYTES in the address match interrupt subroutine (ADDR=1). In this case, the number of TXIS events during the transfer corresponds to the value programmed in NBYTES.

Caution: When NOSTRETCH=1, the SCL clock is not stretched while the ADDR flag is set, so you cannot flush the I2C_TXDR register content in the ADDR subroutine, in order to program the first data byte. The first data byte to be sent must be previously programmed in the I2C_TXDR register:

- This data can be the data written in the last TXIS event of the previous transmission message

- If this data byte is not the one to be sent, the I2C_TXDR register can be flushed by setting the TXE bit in order to program a new data byte. The STOPF bit must be cleared only after these actions, in order to guarantee that they are executed before the first data transmission starts, following the address acknowledge.

If STOPF is still set when the first data transmission starts, an underrun error is generated (the OVR flag is set).

If you need a TXIS event, (Transmit Interrupt or Transmit DMA request), you must set the TXIS bit in addition to the TXE bit, in order to generate a TXIS event.

Figure 90. Transfer sequence flowchart for I2C slave transmitter, NOSTRETCH=0

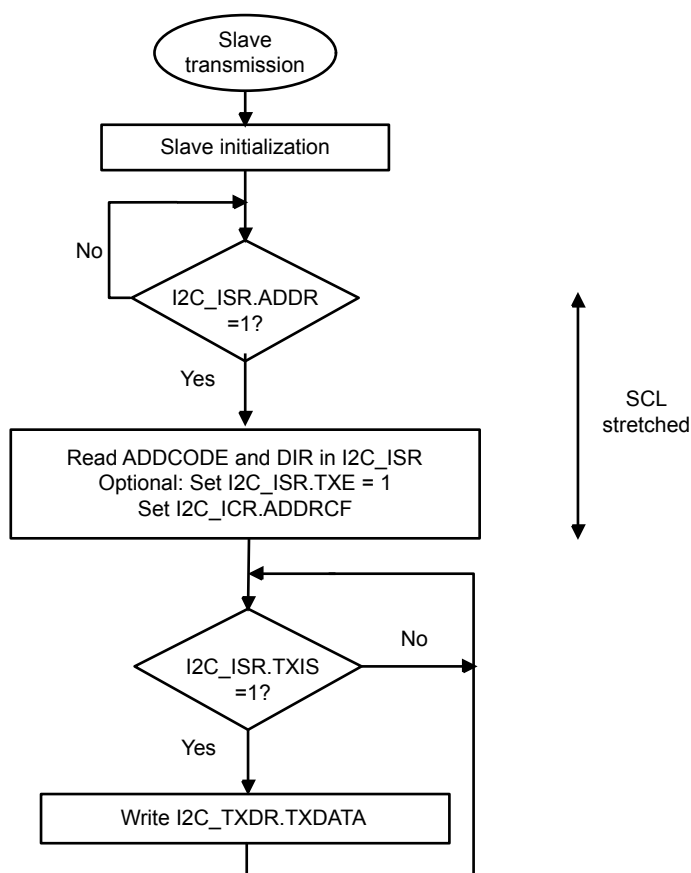

Figure 91. Transfer sequence flowchart for I2C slave transmitter, NOSTRETCH=1

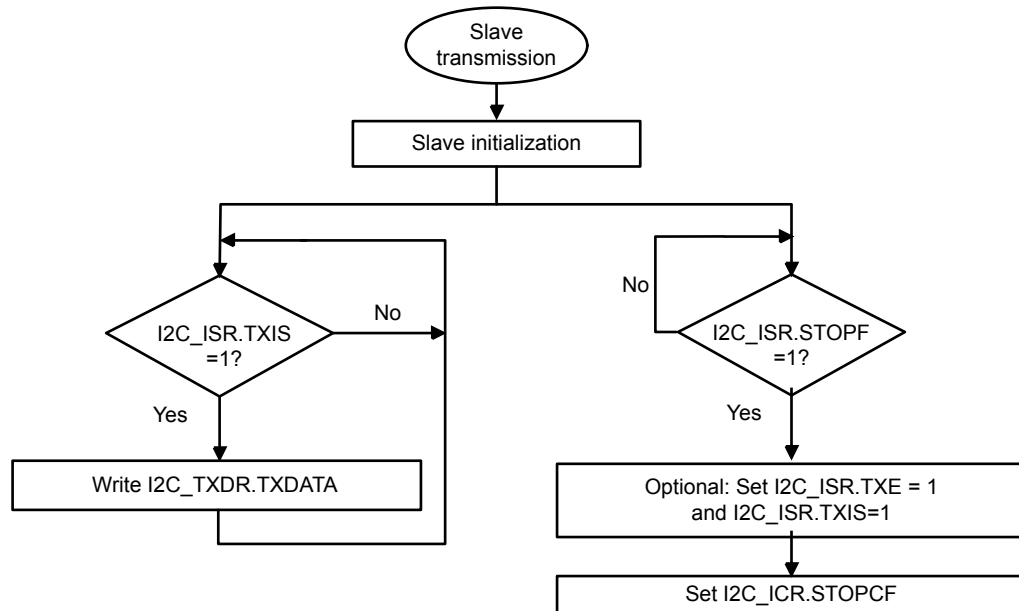

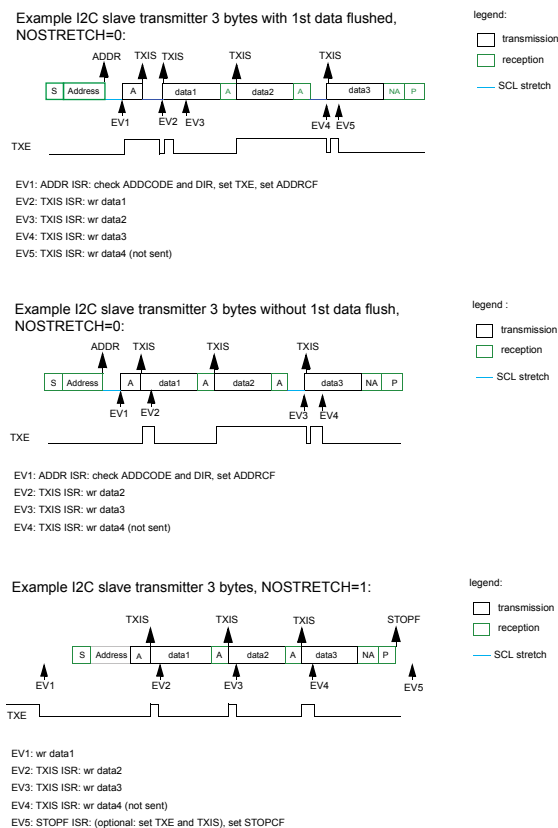

Figure 92. Transfer bus diagram for I2C slave transmitter

Slave receiver

RXNE is set in I2C_ISR when the I2C_RXDR is full, and generates an interrupt if RXIE is set in I2C_CR1. RXNE is cleared when I2C_RXDR is read.

When a STOP is received and STOPIE is set in I2C_CR1, STOPF is set in I2C_ISR and an interrupt is generated.

19.4.8 I2C master mode

I2C master initialization

Before enabling the peripheral, the I²C master clock must be configured by setting the SCLH and SCLL bits in the I2C_TIMINGR register.

A clock synchronization mechanism is implemented in order to support multi-master environment and slave clock stretching.

In order to allow clock synchronization:

- The low level of the clock is counted using the SCLL counter, starting from the SCL low level internal detection.
- The high level of the clock is counted using the SCLH counter, starting from the SCL high level internal detection.

The I²C detects its own SCL low level after a t_{SYNC1} delay depending on the SCL falling edge, SCL input noise filters (analog + digital) and SCL synchronization to the I2CxCLK clock. The I²C releases SCL to high level once the SCLL counter reaches the value programmed in the SCLL[7:0] bits in the I2C_TIMINGR register.

The I²C detects its own SCL high level after a t_{SYNC2} delay depending on the SCL rising edge, SCL input noise filters (analog + digital) and SCL synchronization to I2CxCLK clock. The I²C ties SCL to low level once the SCLH counter reaches the value programmed in the SCLH[7:0] bits in the I2C_TIMINGR register.

Consequently the master clock period is:

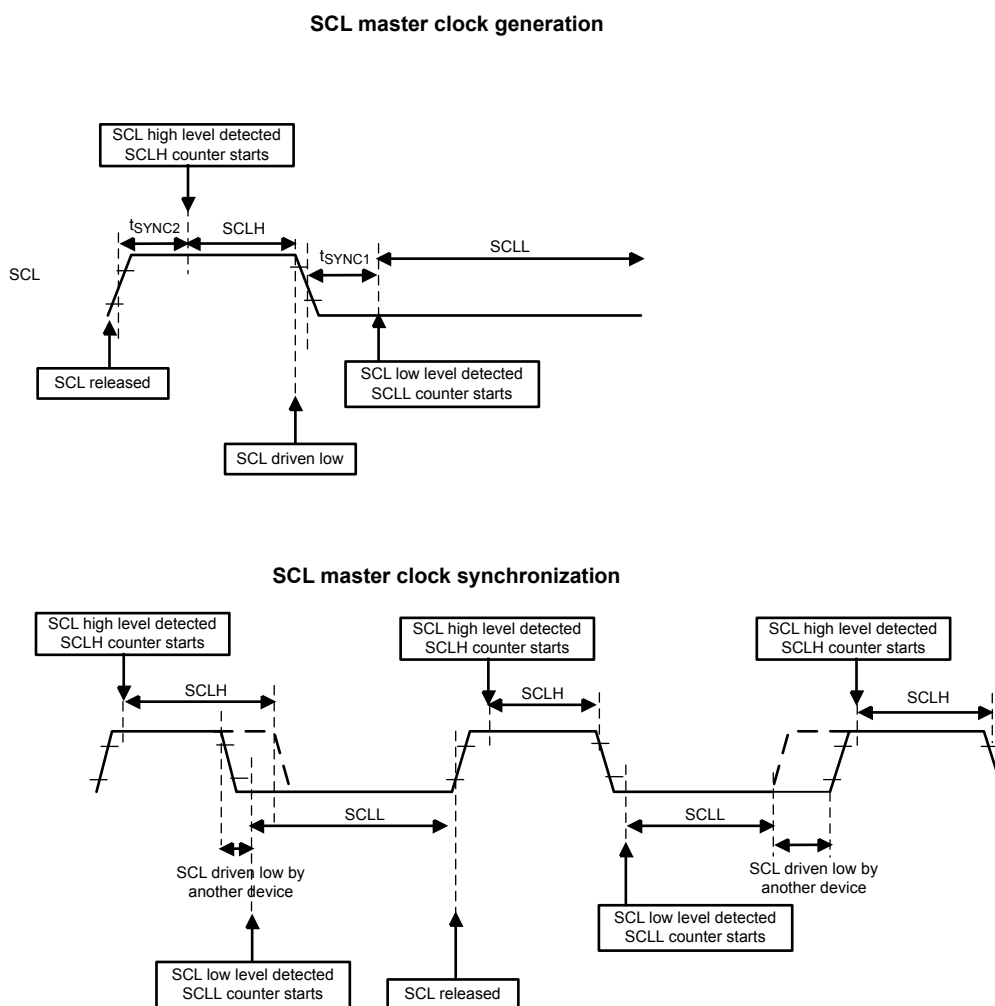

$$t_{\text{SCL}} = t_{\text{SYNC1}} + t_{\text{SYNC2}} + \{[(\text{SCLH}+1) + (\text{SCLL}+1)] \times (\text{PRESC}+1) \times t_{\text{I2CCLK}}\}$$

The duration of t_{SYNC1} depends on these parameters:

- SCL falling slope
- When enabled, input delay induced by the analog filter
- When enabled, input delay induced by the digital filter: $\text{DNF} \times t_{\text{I2CCLK}}$
- Delay due to SCL synchronization with I2CCLK clock (2 to 3 I2CCLK periods).

The duration of t_{SYNC2} depends on these parameters:

- SCL rising slope
- When enabled, input delay induced by the analog filter
- When enabled, input delay induced by the digital filter: $\text{DNF} \times t_{\text{I2CCLK}}$
- Delay due to SCL synchronization with I2CCLK clock (2 to 3 I2CCLK periods).

Figure 96. Master clock generation

Caution: In order to be I²C or SMBus compliant, the master clock must respect the timings given below:

Table 57. I²C-SMBUS specification clock timings

Symbol	Parameter	Standard- mode (Sm)		Fast-mode (Fm)		Fast-mode Plus (Fm+)		SMBUS		Unit
		Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	
f_{SCL}	SCL clock frequency		100		400		1000		100	kHz
$t_{HD:STA}$	Hold time (repeated) START condition	4.0	-	0.6		0.26	-	4.0	-	μs
$t_{SU:STA}$	Set-up time for a repeated START condition	4.7	-	0.6		0.26	-	4.7	-	μs
$t_{SU:STO}$	Set-up time for STOP condition	4.0	-	0.6		0.26	-	4.0	-	μs
t_{BUF}	Bus free time between a STOP and START condition	4.7	-	1.3		0.5	-	4.7	-	μs
t_{LOW}	Low period of the SCL clock	4.7	-	1.3		0.5	-	4.7	-	μs

Symbol	Parameter	Standard- mode (Sm)		Fast-mode (Fm)		Fast-mode Plus (Fm+)		SMBUS		Unit
		Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	
t_{HIGH}	Period of the SCL clock	4.0	-	0.6		0.26	-	4.0	50	μs
t_r	Rise time of both SDA and SCL signals	-	1000	-	300		120	-	1000	ns
t_f	Fall time of both SDA and SCL signals	-	300	-	300		120	-	300	ns

Note: *SCLL is also used to generate the t_{BUF} and $t_{\text{SU:STA}}$ timings.*

SCLH is also used to generate the $t_{\text{HD:STA}}$ and $t_{\text{SU:STO}}$ timings.

Refer to [Section 19.4.9 I2C_TIMINGR register configuration examples](#) for examples of I2C_TIMINGR settings vs. I2CCLK frequency.

Master communication initialization (address phase)

In order to initiate the communication, you must program the following parameters for the addressed slave in the I2C_CR2 register:

- Addressing mode (7-bit or 10-bit): ADD10
- Slave address to be sent: SADD[9:0]
- Transfer direction: RD_WRN
- In case of 10-bit address read: HEAD10R bit. HEAD10R must be configured to indicate if the complete address sequence must be sent, or only the header in case of a direction change.
- The number of bytes to be transferred: NBYTES[7:0]. If the number of bytes is equal to or greater than 255 bytes, NBYTES[7:0] must initially be filled with 0xFF.

You must then set the START bit in the I2C_CR2 register. Changing all the above bits is not allowed when START bit is set.

Then the master automatically sends the START condition followed by the slave address as soon as it detects that the bus is free (BUSY = 0) and after a delay of t_{BUF} .

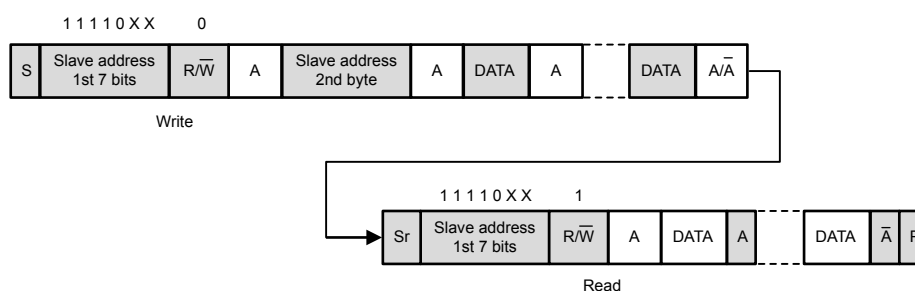

In case of an arbitration loss, the master automatically switches back to slave mode and can acknowledge its own address if it is addressed as a slave.

Note: *The START bit is reset by hardware when the slave address has been sent on the bus, whatever the received acknowledge value. The START bit is also reset by hardware if an arbitration loss occurs. If the I²C is addressed as a slave (ADDR=1) while the START bit is set, the I²C switches to slave mode and the START bit is cleared when the ADDRCONF bit is set.*

Note: *The same procedure is applied for a repeated start condition. In this case BUSY=1.*

Figure 97. Master initialization flowchart

Initialization of a master receiver addressing a 10-bit address slave

- If the slave address is in 10-bit format, you can choose to send the complete read sequence by clearing the HEAD10R bit in the I2C_CR2 register. In this case the master automatically sends the following complete sequence after the START bit is set: (Re)Start + Slave address 10-bit header Write + Slave address 2nd byte + REstart + Slave address 10-bit header Read
- If the master addresses a 10-bit address slave, transmits data to this slave and then reads data from the same slave, a master transmission flow must be done first. Then a repeated start is set with the 10 bit slave address configured with HEAD10R=1. In this case the master sends this sequence: ReStart + Slave address 10-bit header Read.

Figure 98. 10-bit address read access with HEAD10R=1

Master transmitter

In the case of a write transfer, the TXIS flag is set after each byte transmission, after the 9th SCL pulse when an ACK is received.

A TXIS event generates an interrupt if the TXIE bit is set in the I2C_CR1 register. The flag is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

The number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0]. If the total number of data bytes to be sent is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

The TXIS flag is not set when a NACK is received.

- When RELOAD=0 and NBYTES data have been transferred:
 - In automatic end mode (AUTOEND=1), a STOP is automatically sent.
 - In software end mode (AUTOEND=0), the TC flag is set and the SCL line is stretched low in order to perform software actions:
 A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition is sent on the bus.
 A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.
- If a NACK is received: the TXIS flag is not set, and a STOP condition is automatically sent after the NACK reception. the NACKF flag is set in the I2C_ISR register, and an interrupt is generated if the NACKIE bit is set.

Figure 99. Transfer sequence flowchart for I2C master transmitter for N 255 bytes

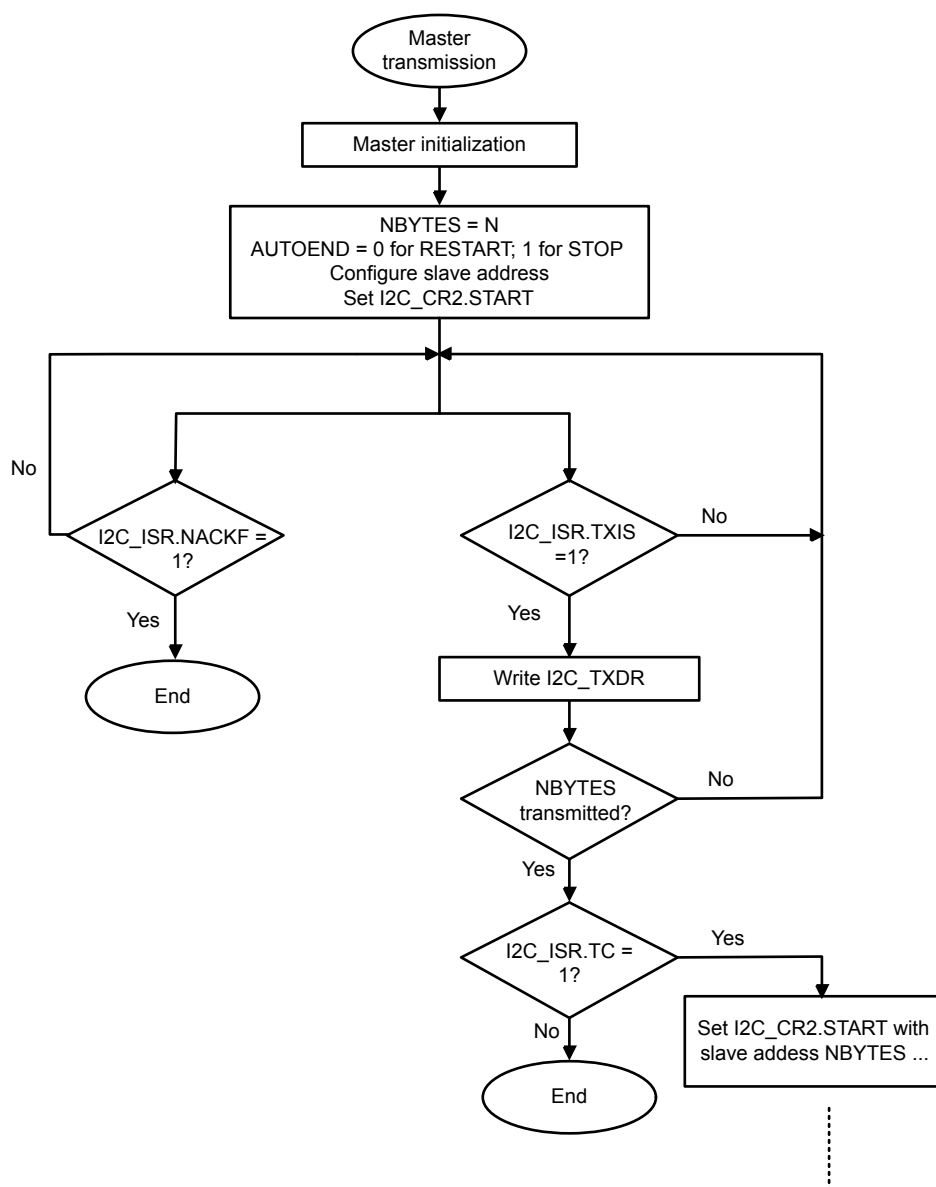

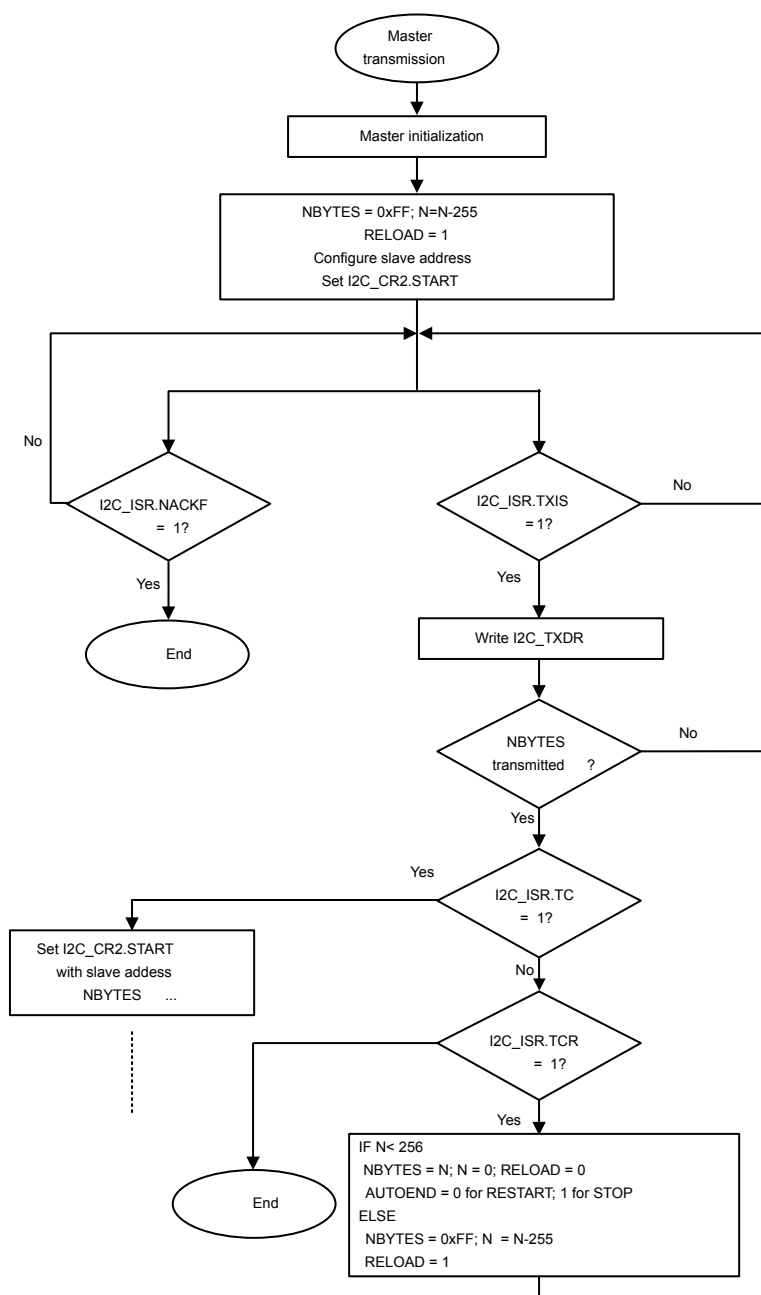

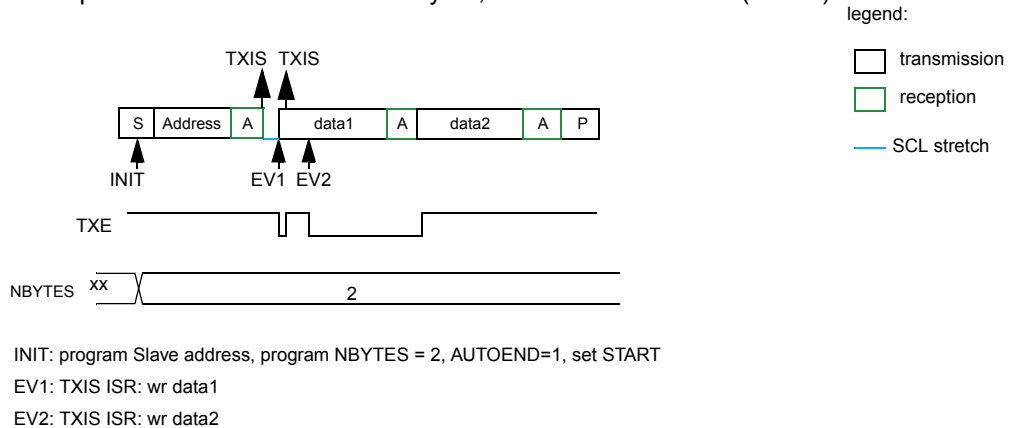

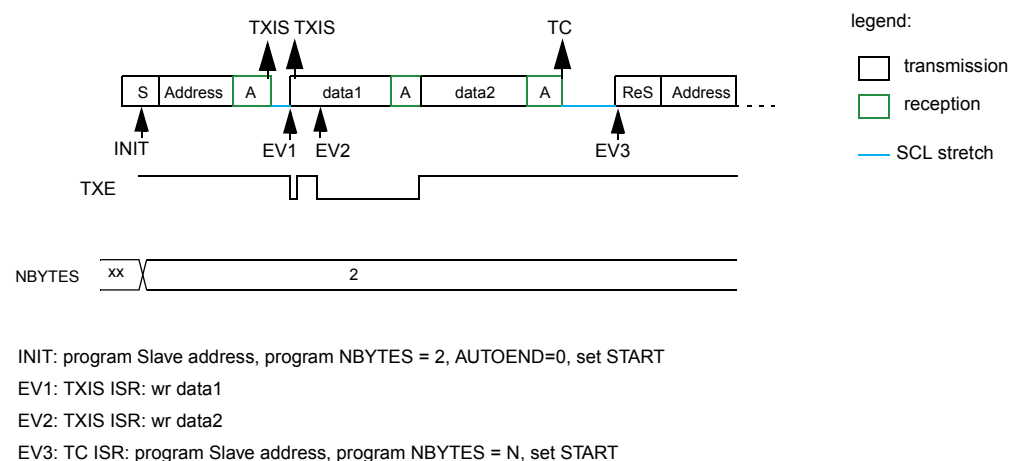

Figure 100. Transfer sequence flowchart for I2C master transmitter for N>255 bytes

Figure 101. Transfer bus diagrams for I2C master transmitter
Example I2C master transmitter 2 bytes, automatic end mode (STOP)

Example I2C master transmitter 2 bytes, software end mode (RESTART)

Master receiver

In the case of a read transfer, the RXNE flag is set after each byte reception, after the 8th SCL pulse. An RXNE event generates an interrupt if the RXIE bit is set in the I2C_CR1 register. The flag is cleared when I2C_RXDR is read.

If the total number of data bytes to be received is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES[7:0] data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

- When RELOAD=0 and NBYTES[7:0] data have been transferred:
 - In automatic end mode (AUTOEND=1), a NACK and a STOP are automatically sent after the last received byte
 - In software end mode (AUTOEND=0), a NACK is automatically sent after the last received byte, the TC flag is set and the SCL line is stretched low in order to allow software actions:
 A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition, followed by slave address, are sent on the bus.
 A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

19.4.9 I2C_TIMINGR register configuration examples

The tables below provide examples of how to program the I2C_TIMINGR to obtain timings compliant with the I²C specifications.

Table 58. Examples of timings settings for $f_{I2CCLK} = 16 \text{ MHz}$

Parameter	Standard-mode (Sm)		Fast-mode (Fm)	Fast-mode Plus (Fm+)
	10 kHz	100 kHz	400 kHz	1000 kHz
PRESC	3	3	1	0
SCLL	0xC7	0x13	0x9	0x4
t _{SCLL}	200 x 250 ns = 50 μs	20 x 250 ns = 5.0 μs	10 x 125 ns = 1250 ns	5 x 62.5 ns = 312.5 ns
SCLH	0xC3	0xF	0x3	0x2
t _{SCLH}	196 x 250 ns = 49 μs	16 x 250 ns = 4.0 μs	4 x 125 ns = 500 ns	3 x 62.5 ns = 187.5 ns
t _{SCL} ⁽¹⁾	~100 μs ⁽²⁾	~10 μs ⁽²⁾	~2500 ns ⁽³⁾	~1000 ns ⁽⁴⁾

Parameter	Standard-mode (Sm)		Fast-mode (Fm)	Fast-mode Plus (Fm+)
	10 kHz	100 kHz	400 kHz	1000 kHz
SDADEL	0x2	0x2	0x2	0x0
t _{SDADEL}	2 x 250 ns = 500 ns	2 x 250 ns = 500 ns	2 x 125 ns = 250 ns	0 ns
SCLDEL	0x4	0x4	0x3	0x2
t _{SCLDEL}	5 x 250 ns = 1250 ns	5 x 250 ns = 1250 ns	4 x 125 ns = 500 ns	3 x 62.5 ns = 187.5 ns

1. SCL period t_{SCL} is greater than $t_{SCLL} + t_{SCLH}$ due to SCL internal detection delay. Values provided for t_{SCL} are examples only.
2. $t_{SYNC1} + t_{SYNC2}$ minimum value is $4 \times t_{I2CCCLK} = 250$ ns. Example with $t_{SYNC1} + t_{SYNC2} = 1000$ ns
3. $t_{SYNC1} + t_{SYNC2}$ minimum value is $4 \times t_{I2CCCLK} = 250$ ns. Example with $t_{SYNC1} + t_{SYNC2} = 750$ ns
4. $t_{SYNC1} + t_{SYNC2}$ minimum value is $4 \times t_{I2CCCLK} = 250$ ns. Example with $t_{SYNC1} + t_{SYNC2} = 500$ ns

19.4.10 SMBus specific features

This section is relevant only when SMBus feature is supported. Please refer to [Section 19.3 I2C implementation](#).

Introduction

The system management bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on I²C principles of operation. SMBus provides a control bus for system and power management related tasks.

This peripheral is compatible with the SMBUS specification rev 2.0 (<http://smbus.org>).

The system management bus specification refers to three types of devices.

- A slave is a device that receives or responds to a command
- A master is a device that issues commands, generates the clocks and terminates the transfer
- A host is a specialized master that provides the main interface to the system's CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

This peripheral can be configured as master or slave device, and also as a host.

SMBUS is based on I²C specification rev 2.1.

Bus protocols

There are eleven possible command protocols for any given device. A device may use any or all of the eleven protocols to communicate. The protocols are Quick Command, Send Byte, Receive Byte, Write Byte, Write Word, Read Byte, Read Word, Process Call, Block Read, Block Write and Block Write-Block Read Process Call. These protocols should be implemented by the user software.

For more details of these protocols, refer to SMBus specification version 2.0 (<http://smbus.org>).

Address resolution protocol (ARP)

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. In order to provide a mechanism to isolate each device for the purpose of address assignment each device must implement a unique device identifier (UDID). This 128-bit number is implemented by software.

This peripheral supports the address resolution protocol (ARP). The SMBus Device Default Address (0b1100 001) is enabled by setting the SMBDEN bit in the I2C_CR1 register. The ARP commands should be implemented by the user software.

Arbitration is also performed in slave mode for ARP support.

For more details of the SMBus Address Resolution Protocol, refer to SMBus specification version 2.0 (<http://smbus.org>).

Received command and data acknowledge control

An SMBus receiver must be able to NACK each received command or data. In order to allow the ACK control in slave mode, the Slave Byte Control mode must be enabled by setting SBC bit in I2C_CR1 register.

Host Notify protocol

This peripheral supports the Host Notify protocol by setting the SMBHEN bit in the I2C_CR1 register. In this case the host acknowledges the SMBus Host address (0b0001 000).

When this protocol is used, the device acts as a master and the host as a slave.

SMBus alert

The SMBus ALERT optional signal is supported. A slave-only device can signal the host through the SMBALERT# pin that it wants to talk. The host processes the interrupt and simultaneously accesses all SMBALERT# devices through the Alert Response Address (0b0001 100). Only the device(s) which pulled SMBALERT# low acknowledges the Alert Response Address.

When configured as a slave device (SMBHEN=0), the SMBA pin is pulled low by setting the ALERTEN bit in the I2C_CR1 register. The Alert Response Address is enabled at the same time.

When configured as a host (SMBHEN=1), the ALERT flag is set in the I2C_ISR register when a falling edge is detected on the SMBA pin and ALERTEN=1. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. When ALERTEN=0, the ALERT line is considered high even if the external SMBA pin is low.

If the SMBus ALERT pin is not needed, the SMBA pin can be used as a standard GPIO if ALERTEN=0.

Packet error checking

A packet error checking mechanism has been introduced in the SMBus specification to improve reliability and communication robustness. Packet Error Checking is implemented by appending a Packet Error Code (PEC) at the end of each message transfer. The PEC is calculated by using the $C(x) = x^8 + x^2 + x + 1$ CRC-8 polynomial on all the message bytes (including addresses and read/write bits).

The peripheral embeds a hardware PEC calculator and allows a non Acknowledge to be sent automatically when the received byte does not match with the hardware calculated PEC.

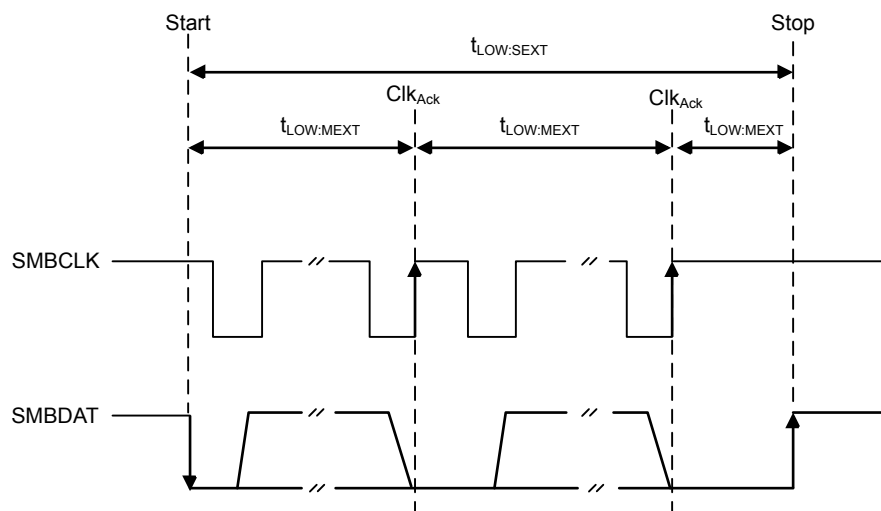

Timeouts

This peripheral embeds hardware timers in order to be compliant with the 3 timeouts defined in SMBus specification version 2.0.

Table 59. SMBus timeout specifications

Symbol	Parameter	Limits		Unit
		Min.	Max.	
t_{TIMEOUT}	Detect clock low timeout	25	35	ms
$t_{\text{LOW:SEXT}}^{(1)}$	Cumulative clock low extend time (slave device)		25	ms
$t_{\text{LOW:MEXT}}^{(2)}$	Cumulative clock low extend time (master device)		10	ms

- $t_{\text{LOW:SEXT}}$ is the cumulative time a given slave device is allowed to extend the clock cycles in one message from the initial START to the STOP. It is possible that, another slave device or the master also extends the clock causing the combined clock low extend time to be greater than $t_{\text{LOW:SEXT}}$. Therefore, this parameter is measured with the slave device as the sole target of a full-speed master.
- $t_{\text{LOW:MEXT}}$ is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master also extends the clock causing the combined clock low time to be greater than $t_{\text{LOW:MEXT}}$ on a given byte. Therefore, this parameter is measured with a full speed slave device as the sole target of the master.

Figure 105. Timeout intervals for $t_{\text{LOW:SEXT}}$, $t_{\text{LOW:MEXT}}$

Bus idle detection

A master can assume that the bus is free if it detects that the clock and data signals have been high for t_{IDLE} greater than $t_{\text{HIGH, MAX}}$. (Refer to [Table 57. I²C-SMBUS specification clock timings](#)).

This timing parameter covers the condition where a master has been dynamically added to the bus and may not have detected a state transition on the SMBCLK or SMBDAT lines. In this case, the master must wait long enough to ensure that a transfer is not currently in progress. The peripheral supports a hardware bus idle detection.

19.4.11 SMBus initialization

This section is relevant only when SMBus feature is supported. Please refer to [Section 19.3 I²C implementation](#).

In addition to I²C initialization, some other specific initializations must be done in order to perform SMBus communication:

Received command and data acknowledge control (slave mode)

An SMBus receiver must be able to NACK each received command or data. In order to allow ACK control in slave mode, the slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. Refer to [Section 19.4.7 I²C slave mode "slave bite control mode"](#) for more details.

Specific address (slave mode)

The specific SMBus addresses should be enabled if needed.

- The SMBus Device Default address (0b1100 001) is enabled by setting the SMBDEN bit in the I2C_CR1 register
- The SMBus Host address (0b0001 000) is enabled by setting the SMBHEN bit in the I2C_CR1 register.
- The Alert Response Address (0b0001100) is enabled by setting the ALERTEN bit in the I2C_CR1 register.

Packet error checking

PEC calculation is enabled by setting the PECEN bit in the I2C_CR1 register. Then the PEC transfer is managed with the help of a hardware byte counter: NBYTES[7:0] in the I2C_CR2 register. The PECEN bit must be configured before enabling the I²C.

The PEC transfer is managed with the hardware byte counter, so the SBC bit must be set when interfacing the SMBus in slave mode. The PEC is transferred after NBYTES-1 data have been transferred when the PECBYTE bit is set and the RELOAD bit is cleared. If RELOAD is set, PECBYTE has no effect.

Caution: Changing the PECEN configuration is not allowed when the I²C is enabled.

Table 60. SMBUS with PEC configuration

Mode	SBC bit	RELOAD bit	AUTOEND bit	PECBYTE bit
Master Tx/Rx NBYTES + PEC+ STOP	x	0	1	1
Master Tx/Rx NBYTES + PEC + ReSTART	x	0	0	1
Slave Tx/Rx with PEC	1	0	x	1

Timeout detection

The timeout detection is enabled by setting the TIMOUTEN and TEXTEN bits in the I2C_TIMEOUTR register. The timers must be programmed in such a way that they detect a timeout before the maximum time given in the SMBus specification version 2.0.

- $t_{\text{TIMEOUTcheck}}$

In order to enable the t_{TIMEOUT} check, the 12-bit TIMEOUTA[11:0] bits must be programmed with the timer reload value in order to check the t_{TIMEOUT} parameter. The TIDLE bit must be configured to '0' in order to detect the SCL low level timeout.

Then the timer is enabled by setting the TIMOUTEN in the I2C_TIMEOUTR register.

If SCL is tied low for a time greater than $(\text{TIMEOUTA}+1) \times 2048 \times t_{\text{I2CCLK}}$, the TIMEOUT flag is set in the I2C_ISR register.

Refer to [Table 61. Examples of TIMEOUTA settings \(max. \$t_{\text{TIMEOUT}} = 25\$ ms\)](#).

Caution: Changing the TIMEOUTA[11:0] bits and TIDLE bit configuration is not allowed when the TIMOUTEN bit is set.

- $t_{\text{LOW:SEXT}}$ and $t_{\text{LOW:MEXT}}$ check

Depending on whether the peripheral is configured as a master or as a slave, the 12-bit TIMEOUTB timer must be configured in order to check $t_{\text{LOW:SEXT}}$ for a slave and $t_{\text{LOW:MEXT}}$ for a master. As the standard specifies only a maximum, you can choose the same value for both.

Then the timer is enabled by setting the TEXTEN bit in the I2C_TIMEOUTR register.

If the SMBus peripheral performs a cumulative SCL stretch for a time greater than $(\text{TIMEOUTB}+1) \times 2048 \times t_{\text{I2CCLK}}$, the timeout interval, the TIMEOUT flag is set in the I2C_ISR register.

Refer to [Table 62. Example of TIMEOUTB settings](#).

Caution: Changing the TIMEOUTB configuration is not allowed when the TEXTEN bit is set.

Bus idle detection

In order to enable the t_{IDLE} check, the 12-bit TIMEOUTA[11:0] field must be programmed with the timer reload value in order to obtain the t_{IDLE} parameter. The TIDLE bit must be configured to '1' in order to detect both SCL and SDA high level timeout.

Then the timer is enabled by setting the TIMOUTEN bit in the I2C_TIMEOUTR register.

If both the SCL and SDA lines remain high for a time greater than $(\text{TIMEOUTA}+1) \times 4 \times t_{\text{I2CCLK}}$, the TIMEOUT flag is set in the I2C_ISR register.

Refer to [Table 63. Examples of TIMEOUTA settings \(max. \$t_{\text{IDLE}} = 50\$ \$\mu\$ s\)](#).

Caution: Changing the TIMEOUTA and TIDLE configuration is not allowed when the TIMOUTEN is set.

19.4.12
SMBus: I2C_TIMEOUTR register configuration examples

This section is relevant only when SMBus feature is supported. Please refer to [Section 19.3 I2C implementation](#).

- Configuring the maximum duration of t_{TIMEOUT} to 25 ms:

Table 61. Examples of TIMEOUTA settings (max. $t_{\text{TIMEOUT}} = 25$ ms)

f_{I2CCLK}	TIMEOUTA[11:0]bits	TIDLE bit	TIMEOUTEN bit	t_{TIMEOUT}
16 MHz	0xC3	0	1	$196 \times 2048 \times 62.5 \text{ ns} = 25 \text{ ms}$

- Configuring the maximum duration of $t_{\text{LOW:SEXT}}$ and $t_{\text{LOW:MEXT}}$ to 8 ms:

Table 62. Example of TIMEOUTB settings

f_{I2CCLK}	TIMEOUTB[11:0]bits	TEXTEN bit	$t_{LOW:EXT}$
16 MHz	0xC3	0	$196 \times 2048 \times 62.5 \text{ ns} = 8 \text{ ms}$

- Configuring the maximum duration of t_{IDLE} to 50 μs :

Table 63. Examples of TIMEOUTA settings (max. $t_{IDLE} = 50 \mu\text{s}$)

f_{I2CCLK}	TIMEOUTA[11:0]bits	TIDLE bit	TIMEOUTEN bit	t_{IDLE}
16 MHz	0xC7	0	1	$200 \times 4 \times 62.5 \text{ ns} = 50 \mu\text{s}$

19.4.13 SMBus slave mode

This section is relevant only when SMBus feature is supported. Please refer to [Section 19.3 I2C implementation](#).

In addition to I²C slave transfer management (refer to [Section 19.4.7 I2C slave mode](#)) some additional software flowcharts are provided to support SMBus.

SMBus slave transmitter

When the IP is used in SMBus, SBC must be programmed to '1' in order to allow the PEC transmission at the end of the programmed number of data bytes. When the PECBYTE bit is set, the number of bytes programmed in NBYTES[7:0] includes the PEC transmission. In that case the total number of TXIS interrupts is NBYTES-1 and the content of the I2C_PECR register is automatically transmitted if the master requests an extra byte after the NBYTES-1 data transfer.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 106. Transfer sequence flowchart for SMBus slave transmitter N bytes + PEC

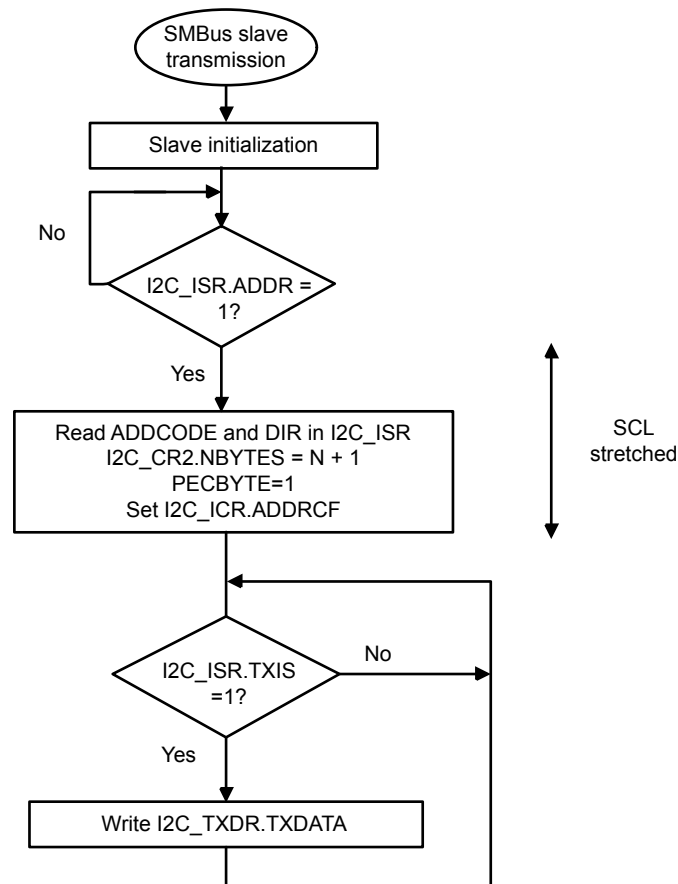

Figure 107. Transfer bus diagrams for SMBus slave transmitter (SBC=1)

Example SMBus slave transmitter 2 bytes + PEC,

EV1: ADDR ISR: check ADDCODE, program NBYTES=3, set PECBYTE, set ADDRCONF
EV2: TXIS ISR: wr data1
EV3: TXIS ISR: wr data2

SMBus slave receiver

When the I²C is used in SMBus mode, SBC must be programmed to '1' in order to allow the PEC checking at the end of the programmed number of data bytes. In order to allow the ACK control of each byte, the reload mode must be selected (RELOAD=1).

Refer to [Section 19.4.7 I2C slave mode "slave bite control mode"](#) for more details.

In order to check the PEC byte, the RELOAD bit must be cleared and the PECBYTE bit must be set. In this case, after NBYTES-1 data have been received, the next received byte is compared with the internal I2C_PECR register content. A NACK is automatically generated if the comparison does not match, and an ACK is automatically generated if the comparison matches, whatever the ACK bit value. Once the PEC byte is received, it is copied into the I2C_RXDR register like any other data, and the RXNE flag is set.

In the case of a PEC mismatch, the PECERR flag is set and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

If no ACK software control is needed, you can program PECBYTE=1 and, in the same write operation, program NBYTES with the number of bytes to be received in a continuous flow. After NBYTES-1 are received, the next received byte is checked as being the PEC.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 108. Transfer sequence flowchart for SMBus slave receiver N bytes + PEC

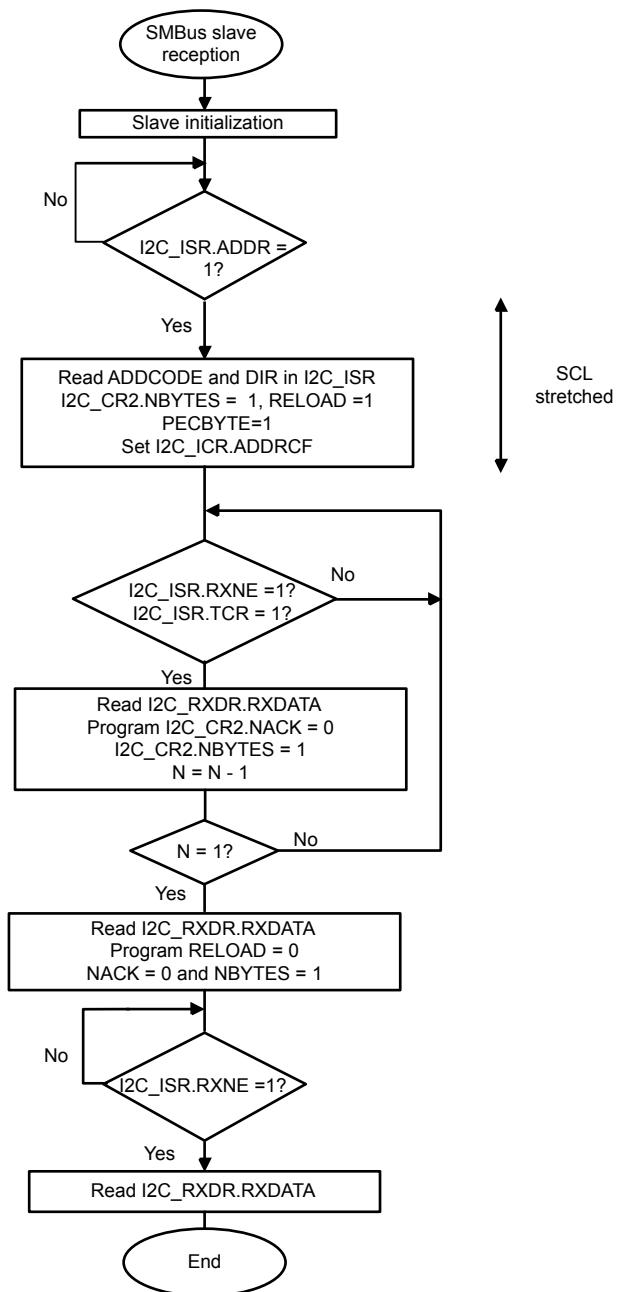

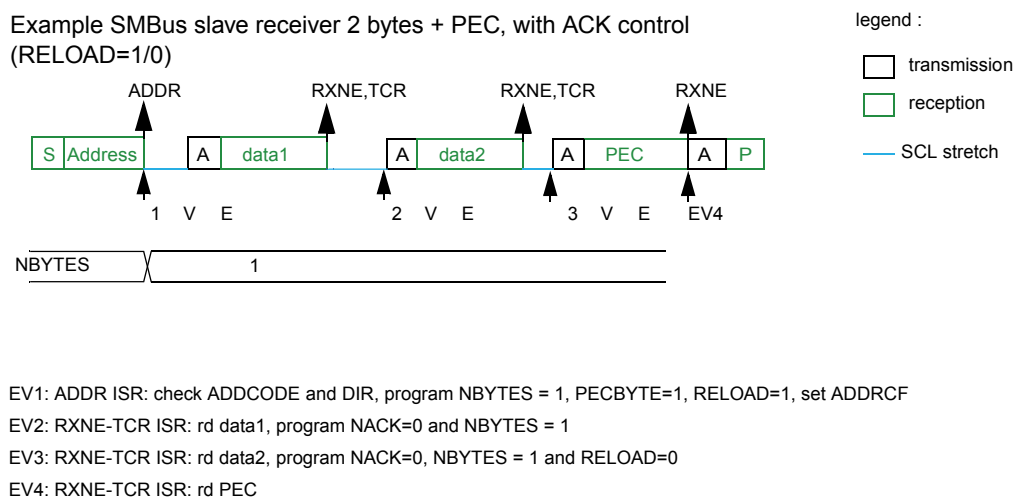

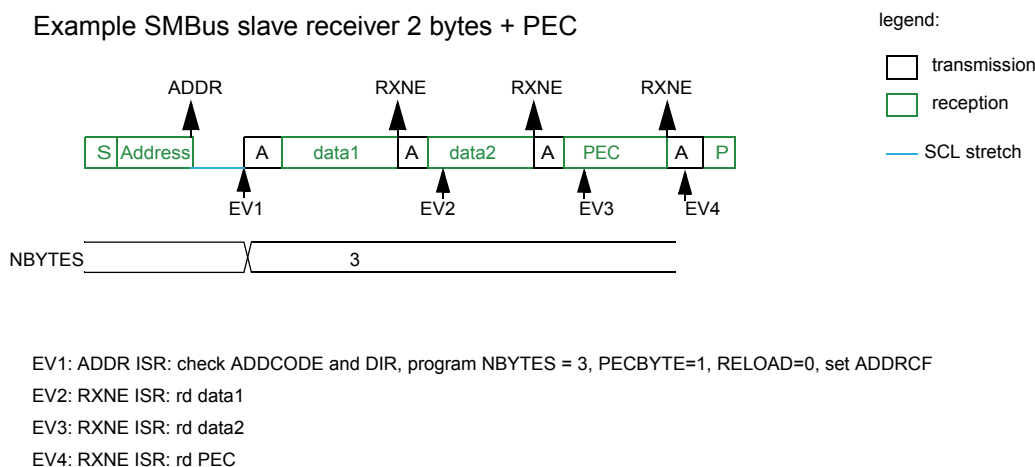

Figure 109. Bus transfer diagrams for SMBus slave receiver (SBC=1)

This section is relevant only when SMBus feature is supported. Please refer to [Section 19.3 I2C implementation](#).

In addition to I²C master transfer management (refer to [Section 19.4.8 I2C master mode](#)) some additional software flowcharts are provided to support SMBus.

SMBus master transmitter

When the SMBus master wants to transmit the PEC, the PECBYTE bit must be set and the number of bytes must be programmed in the NBYTES[7:0] field, before setting the START bit. In this case the total number of TXIS interrupts is NBYTES-1. So if the PECBYTE bit is set when NBYTES=0x1, the content of the I2C_PECR register is automatically transmitted.

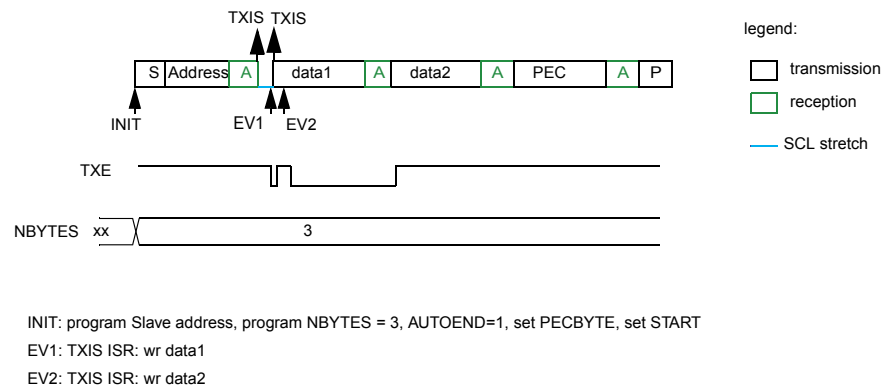

If the SMBus master wants to send a STOP condition after the PEC, automatic end mode should be selected (AUTOEND=1). In this case, the STOP condition automatically follows the PEC transmission.

When the SMBus master wants to send a RESTART condition after the PEC, software mode must be selected (AUTOEND=0). In this case, once NBYTES-1 have been transmitted, the I2C_PECR register content is transmitted and the TC flag is set after the PEC transmission, stretching the SCL line low. The RESTART condition must be programmed in the TC interrupt subroutine.

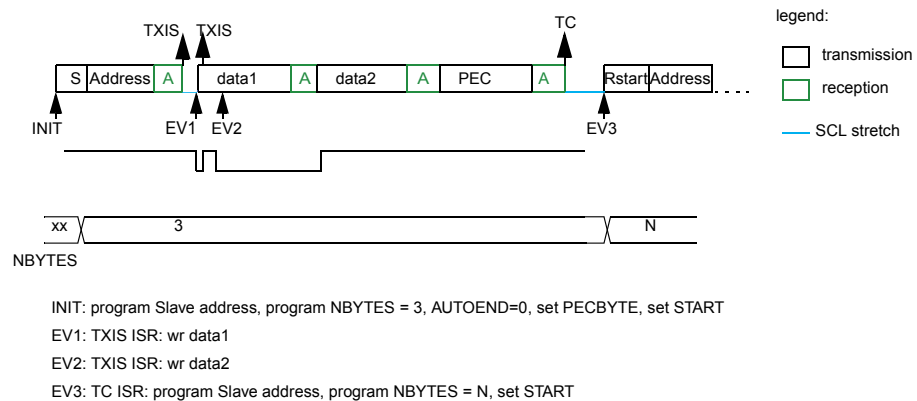

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 110. Bus transfer diagrams for SMBus master transmitter

Example SMBus master transmitter 2 bytes + PEC, automatic end mode (STOP)

Example SMBus master transmitter 2 bytes + PEC, software end mode (RESTART)

SMBus master receiver

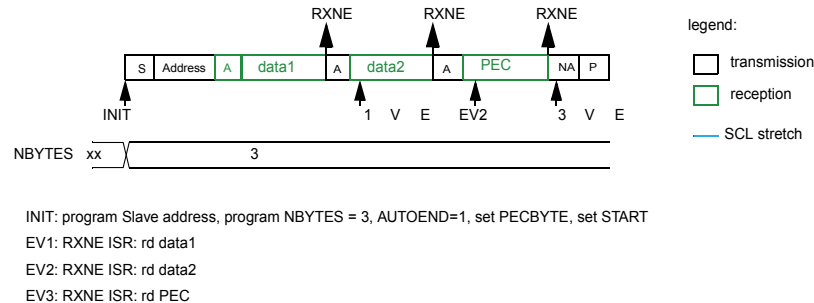

When the SMBus master wants to receive the PEC followed by a STOP at the end of the transfer, automatic end mode can be selected (AUTOEND=1). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES-1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. A NACK response is given to the PEC byte, followed by a STOP condition.

When the SMBus master receiver wants to receive the PEC byte followed by a RESTART condition at the end of the transfer, software mode must be selected (AUTOEND=0). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES-1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. The TC flag is set after the PEC byte reception, stretching the SCL line low. The RESTART condition can be programmed in the TC interrupt subroutine.

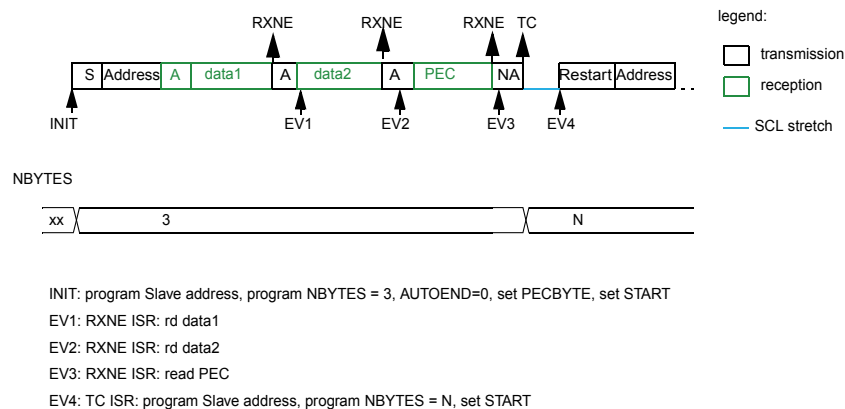

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 111. Bus transfer diagrams for SMBus master receiver

Example SMBus master receiver 2 bytes + PEC, automatic end mode (STOP)

Example SMBus master receiver 2 bytes + PEC, software end mode (RESTART)

19.4.14 Error conditions

The following are error conditions which may cause communication to fail.

Bus error (BERR)

A bus error is detected when a START or a STOP condition is detected and is not located after a multiple of 9 SCL clock pulses. A START or a STOP condition is detected when an SDA edge occurs while SCL is high.

The bus error flag is set only if the I²C is involved in the transfer as master or addressed slave (i.e not during the address phase in slave mode).

In case of a misplaced START or RESTART detection in slave mode, the I²C enters address recognition state like for a correct START condition.

When a bus error is detected, the BERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Arbitration loss (ARLO)

An arbitration loss is detected when a high level is sent on the SDA line, but a low level is sampled on the SCL rising edge.

- In master mode, arbitration loss is detected during the address phase, data phase and data acknowledge phase. In this case, the SDA and SCL lines are released, the START control bit is cleared by hardware and the master switches automatically to slave mode.
- In slave mode, arbitration loss is detected during data phase and data acknowledge phase. In this case, the transfer is stopped, and the SCL and SDA lines are released.

When an arbitration loss is detected, the ARLO flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Overrun/underrun error (OVR)

An overrun or underrun error is detected in slave mode when NOSTRETCH=1 and:

- In reception when a new byte is received and the RXDR register has not been read yet. The new received byte is lost, and a NACK is automatically sent as a response to the new byte.
- In transmission:
 - When STOPF=1 and the first data byte should be sent. The content of the I2C_TXDR register is sent if TXE=0, 0xFF if not.
 - When a new byte should be sent and the I2C_TXDR register has not been written yet, 0xFF is sent.

When an overrun or underrun error is detected, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Packet Error Checking Error (PECERR)

This section is relevant only when the SMBus feature is supported. Please refer to [Section 19.3 I2C implementation](#).

A PEC error is detected when the received PEC byte does not match with the I2C_PECR register content. A NACK is automatically sent after the wrong PEC reception.

When a PEC error is detected, the PECERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Timeout Error (TIMEOUT)

This section is relevant only when the SMBus feature is supported. Please refer to [Section 19.3 I2C implementation](#).

A timeout error occurs for any of these conditions:

- TIDLE=0 and SCL remained low for the time defined in the TIMEOUTA[11:0] bits: this is used to detect a SMBus timeout
- TIDLE=1 and both SDA and SCL remained high for the time defined in the TIMEOUTA [11:0] bits: this is used to detect a bus idle condition
- Master cumulative clock low extend time reached the time defined in the TIMEOUTB[11:0] bits (SMBus tLOW:MEXTparameter)
- Slave cumulative clock low extend time reached the time defined in TIMEOUTB[11:0] bits (SMBus tLOW:SEXTparameter).

When a timeout violation is detected in master mode, a STOP condition is automatically sent.

When a timeout violation is detected in slave mode, SDA and SCL lines are automatically released.

When a timeout error is detected, the TIMEOUT flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Alert (ALERT)

This section is relevant only when the SMBus feature is supported. Please refer to [Section 19.3 I2C implementation](#).

The ALERT flag is set when the I²C interface is configured as a host (SMBHEN=1), the alert pin detection is enabled (ALERTEN=1) and a falling edge is detected on the SMBA pin. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

19.4.15 DMA requests

Transmission using DMA

DMA (Direct Memory Access) can be enabled for transmission by setting the TXDMAEN bit in the I2C_CR1 register. Data is loaded from an SRAM area configured using the DMA peripheral (see [Section 10 DMA controller \(DMA\)](#)) to the I2C_TXDR register whenever the TXIS bit is set.

Only the data are transferred with DMA.

- In master mode: the initialization, the slave address, direction, number of bytes and START bit are programmed by software (the transmitted slave address cannot be transferred with DMA). When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.

- In slave mode:
 - With NOSTRETCH=0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in ADDR interrupt subroutine, before clearing ADDR
 - With NOSTRETCH=1, the DMA must be initialized before the address match event.
- For instances supporting SMBus: the PEC transfer is managed with NBYTES counter.

Refer to [Section 19.4.13 SMBus slave mode](#) "SMBus Slave transmitter" and "SMBus Master transmitter" for more details.

Note: If DMA is used for transmission, the TXIE bit does not need to be enabled.

Reception using DMA

DMA (direct memory access) can be enabled for reception by setting the RXDMAEN bit in the I2C_CR1 register. Data is loaded from the I2C_RXDR register to an SRAM area configured using the DMA peripheral (refer to [Section 10 DMA controller \(DMA\)](#)) whenever the RXNE bit is set. Only the data (including PEC) are transferred with DMA.

- In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software. When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.
- In slave mode with NOSTRETCH=0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in the ADDR interrupt subroutine, before clearing the ADDR flag.
- If SMBus is supported (see [Section 19.3 I2C implementation](#)): the PEC transfer is managed with the NBYTES counter.

Note: If DMA is used for reception, the RXIE bit does not need to be enabled.

19.5 I2C interrupts

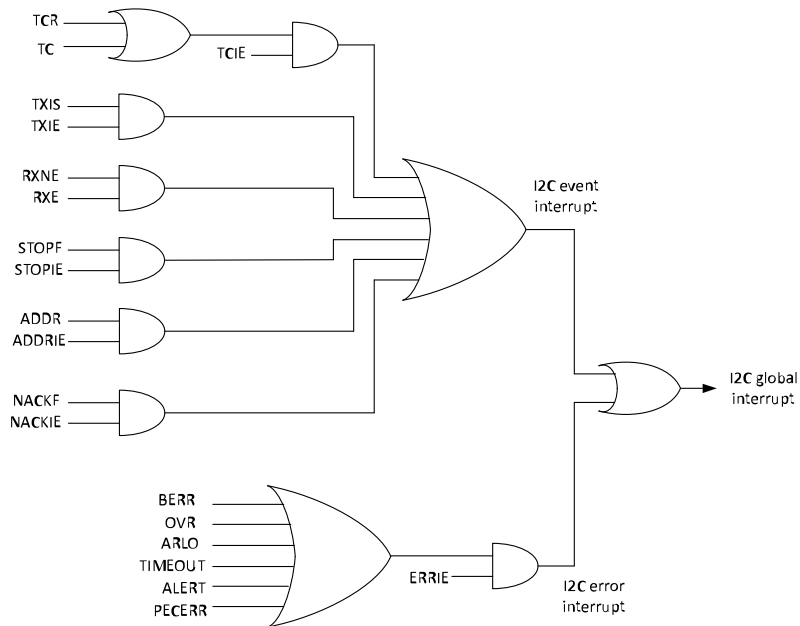

The table below gives the list of I²C interrupt requests.

Table 64. I²C interrupt requests

Interrupt event	Event flag	Event flag/interrupt clearing method	Interrupt enable control bit
Receive buffer not empty	RXNE	Read I2C_RXDR register	RXIE
Transmit buffer interrupt status	TXIS	Write I2C_TXDR register	TXIE
Stop detection interrupt flag	STOPF	Write STOPCF=1	STOPIE
Transfer complete reload	TCR	Write I2C_CR2 with NBYTES[7:0] ' 0	TCIE
Transfer complete	TC	Write START=1 or STOP=1	
Address matched	ADDR	Write ADDRCONF=1	ADDRIE
NACK reception	NACKF	Write NACKCF=1	NACKIE
Bus error	BERR	Write BERRCF=1	ERRIE
Arbitration loss	ARLO	Write ARLOCF=1	
Overrun/underrun	OVR	Write OVRCONF=1	
PEC error	PECERR	Write PECERRCF=1	
Timeout/t _{LOW} error	TIMEOUT	Write TIMEOUTCF=1	
SMBus alert	ALERT	Write ALERTCF=1	

Depending on the product implementation, all these interrupt events can either share the same interrupt vector (I²C global interrupt), or be grouped into 2 interrupt vectors (I²C event interrupt and I²C error interrupt). In order to enable the I²C interrupts, the following sequence is required:

- Configure and enable the I²C IRQ channel in the NVIC
- Configure the I²C to generate interrupts

Figure 112. I²C interrupt mapping diagram

19.6 I2C registers

Refer to [Section 1.3 Acronyms](#) for a list of abbreviations used in register descriptions. The peripheral registers are accessed by words (32-bit).

19.6.1 Control register 1 (I2C_CR1)

Address offset: 0x00 Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access to this register is on-going. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to $2 \times \text{PCLK1} + 6 \times \text{I2CCCLK}$.

Bit 13	<p>START: Start generation.</p> <p>This bit is set by software, and cleared by hardware after the Start followed by the address sequence is sent, by an arbitration loss, by a timeout error detection, or when PE = 0. It can also be cleared by software by writing '1' to the ADDRCF bit in the I2C_ICR register.</p> <p>0: No start generation</p> <p>1: Restart/start generation:</p> <ul style="list-style-type: none"> If the I²C is already in master mode with AUTOEND = 0, setting this bit generates a Repeated Start condition when RELOAD = 0, after the end of the NBYTES transfer. Otherwise, setting this bit generates a START condition once the bus is free. <p>Note: Writing '0' to this bit has no effect.</p> <p>The START bit can be set even if the bus is BUSY or I²C is in slave mode. This bit has no effect when RELOAD is set.</p>
Bit 12	<p>HEAD10R: 10-bit address header only read direction (master receiver mode).</p> <p>0: The master sends the complete 10 bit slave address read sequence: start + 2 bytes 10-bit address in write direction + restart + 1st 7 bits of the 10-bit address in read direction</p> <p>1: The master only sends the 1st 7 bits of the 10-bit address, followed by Read direction</p> <p>Note: Changing this bit when the START bit is set is not allowed.</p>
Bit 11	<p>ADD10: 10-bit addressing mode (master mode).</p> <p>0: The master operates in 7-bit addressing mode</p> <p>1: The master operates in 10-bit addressing mode</p> <p>Note: Changing this bit when the START bit is set is not allowed.</p>
Bit 10	<p>RD_WRN: Transfer direction (master mode).</p> <p>0: Master requests a write transfer</p> <p>1: Master requests a read transfer</p> <p>Note: Changing this bit when the START bit is set is not allowed.</p>
Bits 9:8	<p>SADD[9:8]: Slave address bit 9:8 (master mode).</p> <p>In 7-bit addressing mode (ADD10 = 0): These bits are don't care</p> <p>In 10-bit addressing mode (ADD10 = 1):</p> <p>These bits should be written with bits 9:8 of the slave address to be sent</p> <p>Note: Changing these bits when the START bit is set is not allowed.</p>
Bits 7:1	<p>SADD[7:1]: Slave address bit 7:1 (master mode).</p> <p>In 7-bit addressing mode (ADD10 = 0):</p> <p>These bits should be written with the 7-bit slave address to be sent</p> <p>In 10-bit addressing mode (ADD10 = 1):</p> <p>These bits should be written with bits 7:1 of the slave address to be sent</p> <p>Note: Changing these bits when the START bit is set is not allowed.</p>
Bit 0	<p>SADD0: Slave address bit 0 (master mode). In 7-bit addressing mode (ADD10 = 0): This bit is don't care</p>

	In 10-bit addressing mode (ADD10 = 1): This bit should be written with bit 0 of the slave address to be sent Note: Changing these bits when the START bit is set is not allowed.
--	---

19.6.3 Own address 1 register (I2C_OAR1)

Address offset: 0x08

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access to this register is on-going. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to $2 \times \text{PCLK1} + 6 \times \text{I2CCCLK}$.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

OA1EN	Res.	Res.	Res.	Res.	OA1 MODE	OA1[9:8]	OA1[7:1]							OA1[0]	
rw					rw	rw	rw							rw	

Bits 31:16	Reserved, must be kept at reset value.
Bit 15	OA1EN : Own address 1 enable. 0: Own address 1 disabled. The received slave address OA1 is NACKed. 1: Own address 1 enabled. The received slave address OA1 is ACKed.
Bits 14:11	Reserved, must be kept at reset value.
Bit 10	OA1MODE Own address 1 10-bit mode. 0: Own address 1 is a 7-bit address 1: Own address 1 is a 10-bit address Note: This bit can be written only when OA1EN=0.
Bits 9:8	OA1[9:8] : Interface address. 7-bit addressing mode: do not care 10-bit addressing mode: bits 9:8 of address Note: These bits can be written only when OA1EN=0.
Bits 7:1	OA1[7:1] : Interface address bits 7:1 of address. Note: These bits can be written only when OA1EN=0.
Bit 0	OA1[0] : Interface address. 7-bit addressing mode: do not care 10-bit addressing mode: bit 0 of address Note: This bit can be written only when OA1EN=0.

19.6.4 Own address 2 register (I2C_OAR2)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access to this register is on-going. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to $2 \times \text{PCLK1} + 6 \times \text{I2CCCLK}$.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OA2EN	Res.	Res.	Res.	Res.	OA2MSK[2:0]			OA2[7:1]							Res.
rw					rw			rw							

Bits 31:16	Reserved, must be kept at reset value.
Bit 15	OA2EN : Own address 2 enable. 0: Own address 2 disabled. The received slave address OA2 is NACKed. 1: Own address 2 enabled. The received slave address OA2 is ACKed.
Bits 14:11	Reserved, must be kept at reset value.
Bits 10:8	OA2MSK[2:0] : Own Address 2 masks. 000: No mask 001: OA2[1] is masked and don't care. Only OA2[7:2] are compared. 010: OA2[2:1] are masked and don't care. Only OA2[7:3] are compared. 011: OA2[3:1] are masked and don't care. Only OA2[7:4] are compared. 100: OA2[4:1] are masked and don't care. Only OA2[7:5] are compared. 101: OA2[5:1] are masked and don't care. Only OA2[7:6] are compared. 110: OA2[6:1] are masked and don't care. Only OA2[7] is compared. 111: OA2[7:1] are masked and don't care. No comparison is done, and all (except reserved) 7-bit received addresses are acknowledged. Note: These bits can be written only when OA2EN=0. As soon as OA2MSK is not equal to 0, the reserved I ² C addresses (0b0000xxx and 0b1111xxx) are not acknowledged even if the comparison matches.
Bits 7:1	OA2[7:1] : Interface address bits 7:1 of address. Note: These bits can be written only when OA2EN=0.
Bit 0	Reserved, must be kept at reset value.

19.6.5 Timing register (I2C_TIMINGR)

Address offset: 0x10

Reset value: 0x0000 0000

Access: no wait states

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PRESC[3:0]				Res.	Res.	Res.	Res.	SCLDEL[3:0]				SDADEL[3:0]			
rw								rw				rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SCLH[7:0]								SCLL[7:0]							
rw								rw							

Bits 31:28	PRESC[3:0] : Timing prescaler. This field is used to prescale I2CCLK in order to generate the clock period t_{PRESC} used for data setup and hold counters and for SCL high and low level counters. $t_{\text{PRESC}} = (\text{PRESC} + 1) \times t_{\text{I2CCLK}}$
------------	--

Bits 27:24	Reserved, must be kept at reset value.
Bits 23:20	SCLDEL[3:0] : Data setup time. This field is used to generate a delay t_{SCLDEL} between SDA edge and SCL rising edge in transmission mode. $t_{SCLDEL} = (SCLDEL+1) \times t_{PRESC}$ Note: t_{SCLDEL} is used to generate $t_{SU:DAT}$ timing.
Bits 19:16	SDADEL[3:0] : Data hold time. This field is used to generate the delay t_{SDADEL} between SCL falling edge SDA edge in transmission mode. $t_{SDADEL} = SDADEL \times t_{PRESC}$ Note: SDADEL is used to generate $t_{HD:DAT}$ timing.
Bits 15:8	SCLH[7:0] : SCL high period (master mode). This field is used to generate the SCL high period in master mode. $t_{SCLH} = (SCLH+1) \times t_{PRESC}$. Note: SCLH is also used to generate $t_{SU:STO}$ and $t_{HD:STA}$ timing.
Bits 7:0	SCLL[7:0] : SCL low period (master mode). This field is used to generate the SCL low period in master mode. $t_{SCLL} = (SCLL+1) \times t_{PRESC}$. Note: SCLL is also used to generate t_{BUF} and $t_{SU:STA}$ timings.

Note: This register must be configured when the I²C is disabled ($PE = 0$).

19.6.6 Timeout register (I2C_TIMEOUTR)

Address offset: 0x14

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access to this register is on-going. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to $2 \times PCLK1 + 6 \times I2CCCLK$.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TEXTEN	Res.	Res.	Res.	TIMEOUTB [11:0]											
rw				rw											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMOUTEN	Res.	Res.	TIDLE	TIMEOUTA [11:0]											
rw			rw	rw											

Bit 31	TEXTEN : Extended clock timeout enable. 0: Extended clock timeout detection is disabled 1: Extended clock timeout detection is enabled. When a cumulative SCL stretch for more than $t_{LOW:EXT}$ is done by the I ² C interface, a timeout error is detected (TIMEOUT=1).
Bits 30:28	Reserved, must be kept at reset value.
Bits 27:16	TIMEOUTB[11:0] : Bus timeout B. This field is used to configure the cumulative clock extension timeout: In master mode, the master cumulative clock low extend time ($t_{LOW:MEXT}$) is detected in slave mode, the slave cumulative clock low extend time ($t_{LOW:SEXT}$) is detected $t_{LOW:EXT} = (TIMEOUTB+1) \times 2048 \times t_{I2CCCLK}$. Note: These bits can be written only when TEXTEN=0.
Bit 15	TIMOUTEN : Clock timeout enable.

	0: SCL timeout detection is disabled 1: SCL timeout detection is enabled: when SCL is low for more than t_{TIMEOUT} (TIDLE=0) or high for more than t_{IDLE} (TIDLE=1), a timeout error is detected (TIMEOUT=1)
Bits 14:13	Reserved, must be kept at reset value.
Bit 12	TIDLE : Idle clock timeout detection. 0: TIMEOUTA is used to detect SCL low timeout 1: TIMEOUTA is used to detect both SCL and SDA high timeout (bus idle condition) Note: This bit can be written only when TIMOUTEN=0.
Bits 11:0	TIMEOUTA[11:0] : Bus timeout A. This field is used to configure: <ul style="list-style-type: none"> The SCL low timeout condition t_{TIMEOUT} when TIDLE=0 $t_{\text{TIMEOUT}} = (\text{TIMEOUTA}+1) \times 2048 \times t_{\text{I2CCLK}}$ The bus idle condition (both SCL and SDA high) when TIDLE=1 $t_{\text{IDLE}} = (\text{TIMEOUTA}+1) \times 4 \times t_{\text{I2CCLK}}$ Note: These bits can be written only when TIMOUTEN=0.

Note: *If the SMBus feature is not supported, this register is reserved and forced by hardware to “0x00000000”. Please refer to [Section 19.3 I2C implementation](#).*

19.6.7 Interrupt and status register (I2C_ISR)

Address offset: 0x18

Reset value: 0x0000 0001

Access: no wait states

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ADDCODE[6:0]							DIR
								r							r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BUSY	Res.	ALERT	TIME OUT	PEC ERR	OVR	ARLO	BERR	TCR	TC	STOPF	NACKF	ADDR	RXNE	TXIS	TXE
r		r	r	r	r	r	r	r	r	r	r	r	r	rs	rs

Bits 31:24	Reserved, must be kept at reset value.
Bits 23:17	ADDCODE[6:0] : Address match code (slave mode). These bits are updated with the received address when an address match event occurs (ADDR = 1). In the case of a 10-bit address, ADDCODE provides the 10-bit header followed by the 2 MSBs of the address.
Bit 16	DIR : Transfer direction (slave mode). This flag is updated when an address match event occurs (ADDR=1). 0: Write transfer, slave enters receiver mode 1: Read transfer, slave enters transmitter mode
Bit 15	BUSY : Bus busy. This flag indicates that a communication is in progress on the bus. It is set by hardware when a START condition is detected. It is cleared by hardware when a stop condition is detected, or when PE=0.
Bit 14	Reserved, must be kept at reset value.
Bit 13	ALERT : SMBus alert. This flag is set by hardware when SMBHEN=1 (SMBus host configuration), ALERTEN=1 and an SMBALERT event (falling edge) is detected on SMBA pin. It is cleared by software by setting the ALERTCF bit. Note: This bit is cleared by hardware when PE=0.

	<p>If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 19.3 I2C implementation.</p>
Bit 12	<p>TIMEOUT: Timeout or t_{LOW} detection flag.</p> <p>This flag is set by hardware when a timeout or extended clock timeout occurred. It is cleared by software by setting the TIMEOUTCF bit.</p> <p>Note: This bit is cleared by hardware when PE=0.</p> <p>If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 19.3 I2C implementation.</p>
Bit 11	<p>PECERR: PEC error in reception.</p> <p>This flag is set by hardware when the received PEC does not match with the PEC register content. A NACK is automatically sent after the wrong PEC reception. It is cleared by software by setting the PECCF bit.</p> <p>Note: This bit is cleared by hardware when PE=0.</p> <p>If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 19.3 I2C implementation.</p>
Bit 10	<p>OVR: Overrun/underrun (slave mode).</p> <p>This flag is set by hardware in slave mode with NOSTRETCH=1, when an overrun/underrun error occurs. It is cleared by software by setting the OVRCF bit.</p> <p>Note: This bit is cleared by hardware when PE=0.</p>
Bit 9	<p>ARLO: Arbitration loss.</p> <p>This flag is set by hardware in case of arbitration loss. It is cleared by software by setting the ARLOCF bit.</p> <p>Note: This bit is cleared by hardware when PE=0.</p>
Bit 8	<p>BERR: Bus error.</p> <p>This flag is set by hardware when a misplaced Start or Stop condition is detected whereas the peripheral is involved in the transfer. The flag is not set during the address phase in slave mode. It is cleared by software by setting BERRCF bit.</p> <p>Note: This bit is cleared by hardware when PE=0.</p>
Bit 7	<p>TCR: Transfer complete reload.</p> <p>This flag is set by hardware when RELOAD=1 and NBYTES data have been transferred. It is cleared by software when NBYTES is written to a non-zero value.</p> <p>Note: This bit is cleared by hardware when PE=0.</p> <p>This flag is only for master mode, or for slave mode when the SBC bit is set.</p>
Bit 6	<p>TC: Transfer complete (master mode).</p> <p>This flag is set by hardware when RELOAD=0, AUTOEND=0 and NBYTES data have been transferred. It is cleared by software when START bit or STOP bit is set.</p> <p>Note: This bit is cleared by hardware when PE=0.</p>
Bit 5	<p>STOPF: Stop detection flag.</p> <p>This flag is set by hardware when a stop condition is detected on the bus and the peripheral is involved in this transfer:</p> <ul style="list-style-type: none"> • either as a master, provided that the STOP condition is generated by the peripheral. • or as a slave, provided that the peripheral has been addressed previously during this transfer. <p>It is cleared by software by setting the STOPCF bit.</p> <p>Note: This bit is cleared by hardware when PE=0.</p>
Bit 4	<p>NACKF: Not acknowledge received flag.</p> <p>This flag is set by hardware when a NACK is received after a byte transmission. It is cleared by software by setting the NACKCF bit.</p> <p>Note: This bit is cleared by hardware when PE=0.</p>
Bit 3	<p>ADDR: Address matched (slave mode).</p> <p>This bit is set by hardware as soon as the received slave address matched with one of the enabled slave addresses. It is cleared by software by setting ADDRCF bit.</p>

	Note: This bit is cleared by hardware when PE=0.
Bit 2	RXNE : Receive data register not empty (receivers). This bit is set by hardware when the received data is copied into the I2C_RXDR register, and is ready to be read. It is cleared when I2C_RXDR is read. Note: This bit is cleared by hardware when PE=0.
Bit 1	TXIS : Transmit interrupt status (transmitters). This bit is set by hardware when the I2C_TXDR register is empty and the data to be transmitted must be written in the I2C_TXDR register. It is cleared when the next data to be sent is written in the I2C_TXDR register. This bit can be written to '1' by software when NOSTRETCH=1 only, in order to generate a TXIS event (interrupt if TXIE=1 or DMA request if TXDMAEN=1). Note: This bit is cleared by hardware when PE=0.
Bit 0	TXE : Transmit data register empty (transmitters). This bit is set by hardware when the I2C_TXDR register is empty. It is cleared when the next data to be sent is written in the I2C_TXDR register. This bit can be written to '1' by software in order to flush the transmit data register I2C_TXDR. Note: This bit is set by hardware when PE=0.

19.6.8 Interrupt clear register (I2C_ICR)

Address offset: 0x1C

Reset value: 0x0000 0000

Access: no wait states

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

		w	w	w	w	w	w			w	w	w			

Bits 31:14	Reserved, must be kept at reset value.
Bit 13	ALERTCF : Alert flag clear. Writing 1 to this bit clears the ALERT flag in the I2C_ISR register. Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 19.3 I2C implementation .
Bit 12	TIMOUTCF : Timeout detection flag clear. Writing 1 to this bit clears the TIMEOUT flag in the I2C_ISR register. Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 19.3 I2C implementation .
Bit 11	PECCF : PEC Error flag clear. Writing 1 to this bit clears the PECERR flag in the I2C_ISR register. Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 19.3 I2C implementation .
Bit 10	OVRCF : Overrun/underrun flag clear. Writing 1 to this bit clears the OVR flag in the I2C_ISR register.
Bit 9	ARLOCF : Arbitration loss flag clear.

	Writing 1 to this bit clears the ARLO flag in the I2C_ISR register.
Bit 8	BERRCF : Bus error flag clear. Writing 1 to this bit clears the BERRF flag in the I2C_ISR register.
Bits 7:6	Reserved, must be kept at reset value.
Bit 5	STOPCF : Stop detection flag clear. Writing 1 to this bit clears the STOPF flag in the I2C_ISR register.
Bit 4	NACKCF : Not acknowledge flag clear. Writing 1 to this bit clears the ACKF flag in I2C_ISR register.
Bit 3	ADDRCF : Address matched flag clear. Writing 1 to this bit clears the ADDR flag in the I2C_ISR register. Writing 1 to this bit also clears the START bit in the I2C_CR2 register.
Bits 2:0	Reserved, must be kept at reset value.

19.6.9

PEC register (I2C_PECR)

Address offset: 0x20

Reset value: 0x0000 0000

Access: no wait states

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

20 Universal synchronous asynchronous receiver transmitter (USART)

20.1 USART introduction

The universal synchronous asynchronous receiver transmitter (USART) offers a flexible means of full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The USART offers a very wide range of baud rates using a fractional baud rate generator.

It supports synchronous one-way communication and half-duplex single-wire communication. It also supports the LIN (local interconnection network), smartcard protocol and IrDA (infrared data association) SIR ENDEC specifications, and modem operations (CTS/RTS). It also supports multiprocessor communications.

High speed data communication is possible by using the DMA (direct memory access) for multi-buffer configuration.

20.2 USART main features

- Full-duplex asynchronous communication
- NRZ standard format (mark/space)
- Configurable oversampling method by 16 or 8 to give flexibility between speed and clock tolerance
- Baud rate generator systems
- Two internal FIFOs for transmit and receive data, that can be enabled/disabled by software. FIFOs come with status flags for FIFOs states
- A common programmable transmit and receive baud rate of up to 2 Mbit/s with the clock frequency at 16 MHz and oversampling is by 8
- Dual clock domain with a dedicated kernel clock allowing baud rate programming independent from the PCLK reprogramming
- Auto baud rate detection
- Programmable data word length (7 or 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Synchronous master/slave mode and clock output/input for synchronous communications
- SPI slave transmission underrun error flag
- Single-wire half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
- Communication control/error detection flags
- Parity control:
 - Transmits parity bit
 - Checks parity of received data byte
- Interrupt sources with flags
- Multi processor communications
- Wakeup from mute mode (by idle line detection or address mark detection)

20.3 USART extended features

- LIN master synchronous break send capability and LIN slave break detection capability
 - 13-bit break generation and 10/11 bit break detection when USART is hardware configured for LIN
- IrDA SIR encoder decoder supporting 3/16 bit duration for normal mode
- Smartcard mode
 - Supports the T=0 and T=1 asynchronous protocols for smartcards as defined in the ISO/IEC 7816-3 standard
 - 0.5 and 1.5 stop bits for smartcard operation
- Support for Modbus communication
 - Timeout feature
 - CR/LF character recognition

20.4 USART implementation

Table 66. USART/LPUART features describes the USART and LPUART implementation on the BlueNRG-LP device.

Table 66. USART/LPUART features

USART modes/features ⁽¹⁾	USART	LPUART
Hardware flow control for modem	X	X
Continuous communication using DMA	X	X
Multiprocessor communication	X	X

20.5 USART functional description

Any USART bidirectional communication requires a minimum of two pins: receive data in (RX) and transmit data out (TX):

- **RX:** receive data input
This is the serial data input. Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.
- **TX:** Transmit data output
When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In single-wire and smartcard modes, this I/O is used to transmit and receive the data.

Serial data are transmitted and received through these pins in normal USART mode. The frames are comprised of:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (7, 8 or 9 bits) least significant bit first
- 0.5, 1, 1.5, 2 stop bits indicating that the frame is complete
- The USART interface uses a baud rate generator
- A status register(USART_ISR)
- Receive and transmit data registers (USART_RDR, USART_TDR). When FIFO mode is enabled, writing into USART_TDR adds one data to the transmit FIFO; and reading from USART_RDR removes one data from the receive FIFO
- A baud rate register(USART_BRR)
- A guardtime register (USART_GTPR) in case of smartcard mode.

Refer to [Section 20.7 USART registers](#) for the definitions of each bit.

The following pin is required to interface in synchronous mode and smartcard mode:

- **SCLK:** This pin acts as clock output in synchronous master and smartcard modes. It acts as clock input in synchronous slave mode. In synchronous master mode, this pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel, data can be received synchronously on RX. This can be used to control peripherals that have shift registers (e.g. LCD drivers). The clock phase and polarity are software programmable.

In smartcard mode, SCLK output can provide the clock to the smartcard.

- **NSS:** This pin acts as slave select input in synronous slave mode.

The following pins are required in RS232 hardware flow control mode:

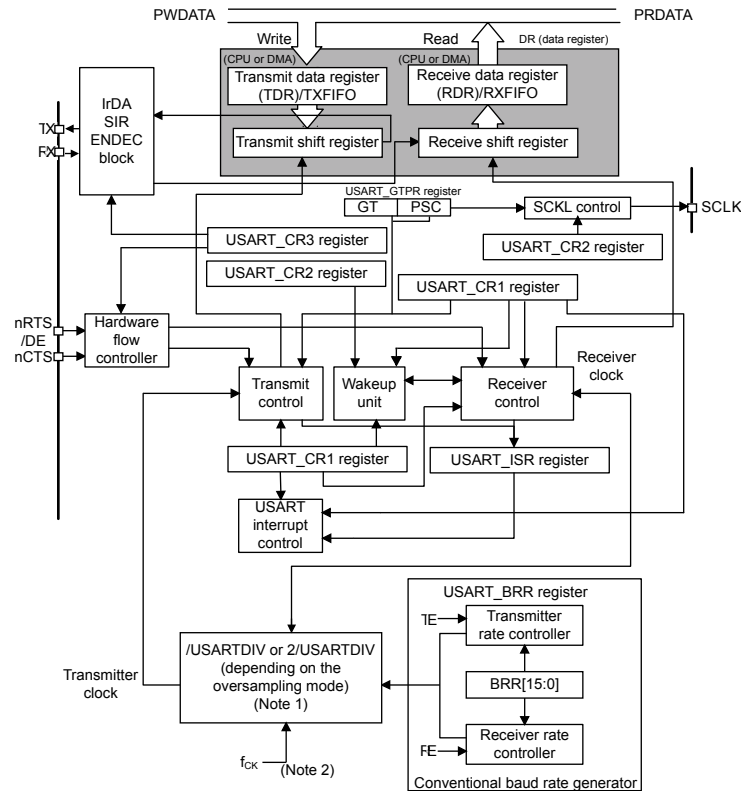

- **nCTS:** Clear to send blocks the data transmission at the end of the current transfer when high
- **nRTS:** Request to send indicates that the USART is ready to receive data (when low).

The following pin is required in RS485 hardware control mode:

- **DE:** driver enable activates the transmission mode of the external transceiver.

Note: DE and nRTS share the same pin.

Note: NSS and nCTS share the same pin.

Figure 113. USART block diagram

Note: For details on coding USARTDIV in the USARTx_BRR register, please refer to [Section 20.5.5 Baud rate generation](#).

Note: f_{CK} is 16 MHz.

20.5.1 USART character description

The word length can be selected as being either 7 or 8 or 9 bits by programming the M bits (M0: bit 12 and M1: bit 28) in the USART_CR1 register (see [Figure 114. Word length programming](#)).

- 7-bit character length: M[1:0] = 10
- 8-bit character length: M[1:0] = 00
- 9-bit character length: M[1:0] = 01

Note: In 7-bits data length mode, the smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

In default configuration, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

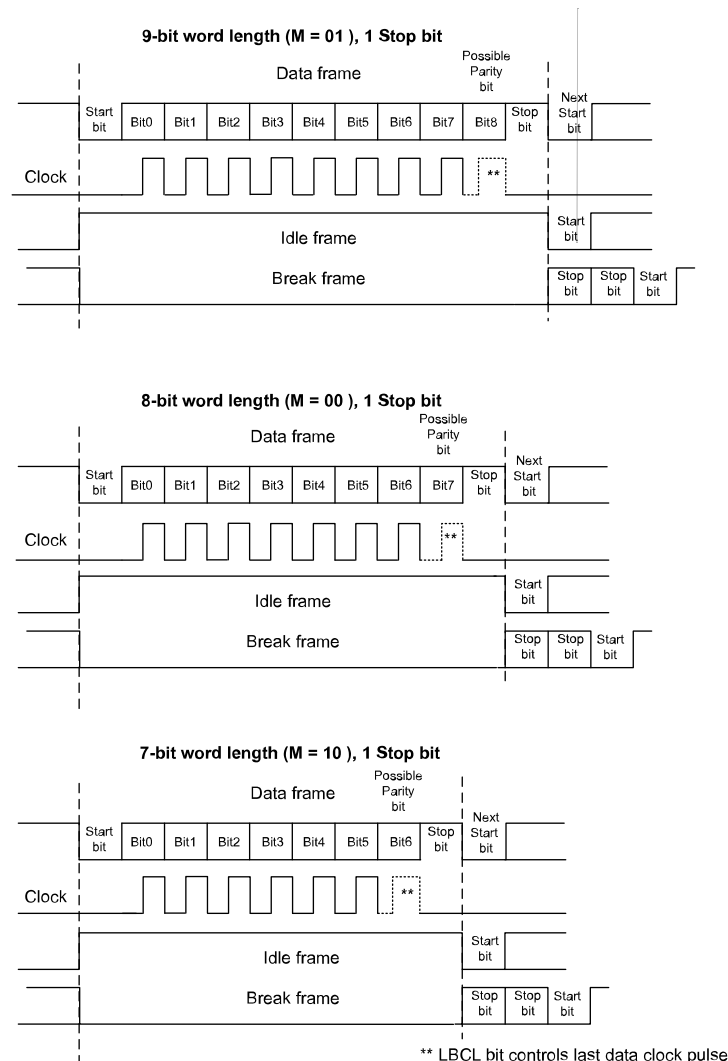

These values can be inverted, separately for each signal, through polarity configuration control.

An **Idle character** is interpreted as an entire frame of “1”s. (The number of “1”s includes the number of stop bits).

A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator, the clock for each is generated when the enable bit is set respectively for the transmitter and receiver.

The details of each block is given below.

Figure 114. Word length programming

20.5.2 FIFOs and thresholds

The USART can operate in FIFO mode, with the FIFO buffers having a depth of 16 bytes (8 bytes TX, 8 bytes RX).

The USART comes with a transmit FIFO (TXFIFO) and a receive FIFO (RXFIFO). The FIFO mode is enabled by setting the bit 29 FIFOEN in the USARTx_CR1 register.

The FIFO mode is supported only on UART, SPI and smartcard modes.

Being 9 bits the maximum data word length, the TXFIFO is 9-bits wide. However the RXFIFO is by default 12-bits wide. This is due to the fact that the receiver does not only put the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

Note: *The received data is stored in the RXFIFO with its flags. But If you read RDR, you read just the data. The status flags are available in the USART_ISR register.*

It is possible to define the TXFIFO and RXFIFO levels at which the Tx and RX interrupt are triggered. These thresholds are programmed through bit fields RXFTCFG and TXFTCFG in USARTx_CR3 control register.

In this case:

- The receive interrupt is generated when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields

- The transmit interrupt is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bit fields.

RXFIFO threshold

The RXFIFO threshold is configured using the RXFTCFG bits fields in the USARTx_CR3 register.

When the number of received data is equal to the programmed RXFTCFG, the flag RXFT in the USART_ISR register is set.

Having RXFT flag set means that there are RXFTCFG data received: 1 data in USARTx_RDR and (RXFTCFG - 1) data in the RXFIFO. So, when the RXFTCFG is programmed to «101», the RXFT flag is set when 8 data are received: 7 data in the RXFIFO and 1 data in the USARTx_RDR. Consequently, the 9th received data do not set the overrun flag.

20.5.3

Transmitter

The transmitter can send data words of either 7 or 8 or 9 bits depending on the M bit status. The transmit enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin and the corresponding clock pulses are output on the SCLK pin.

Character transmission

During an USART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the USARTx_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register.

When FIFO mode is enabled, data written to the transmit data register USART_TDR, is queued in the TXFIFO.

Every character is preceded by a start bit which is a logic level low for one bit period. The character is terminated by a configurable number of stop bits.

The following stop bits are supported by USART: 0.5, 1, 1.5 and 2 stop bits.

Note:

The TE bit must be set before writing the data to be transmitted to the USART_TDR. The TE bit should not be reset during transmission of data. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters get frozen. The current data being transmitted are lost. An idle frame is sent after the TE bit is enabled.

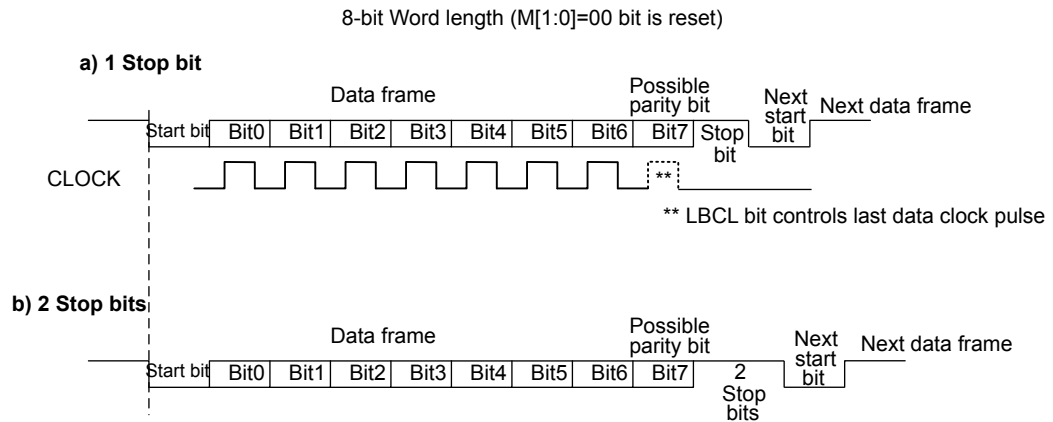

Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in control register 2, bits 13,12.

- 1 stop bit: this is the default value of number of stop bits
- 2 stop bits: this is supported by normal USART, single-wire and modem modes
- 1.5 stop bits: to be used in smartcard mode.

An idle frame transmission includes the stop bits.

A break transmission is 10 low bits (when M[1:0] = 00) or 11 low bits (when M[1:0] = 01) or 9 low bits (when M[1:0] = 10) followed by 2 stop bits (see [Figure 115. Configurable stop bits](#)). It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

Figure 115. Configurable stop bits

Character transmission procedure

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the USART_BRR register.
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAT) in USART_CR3 if multi-buffer communication is to take place. Configure the DMA register as explained in multi-buffer communication.
6. Set the TE bit in USART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART_TDR register. Repeat this for each data to be transmitted in case of single buffer.
 - a. When FIFO mode is disabled, writing a data in the USART_TDR clears the TXE flag.
 - b. When FIFO mode is enabled, writing a data in the USART_TDR adds one data to the TXFIFO and write operations in the USART_TDR are made when TXFNF flag is set. This flag remains set until the TXFIFO is full.
8. After writing the last data into the USART_TDR register, wait until TC=1.
 - When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
 - When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.

Single byte communication

- When FIFO mode is disabled:

clearing the TXE flag is always performed by a write to the transmit data register. The TXE flag is set by hardware and it indicates:

- the data has been moved from the USARTx_TDR register to the shift register and the data transmission has started
- the USARTx_TDR register is empty
- the next data can be written in the USARTx_TDR register without overwriting the previous data.

This flag generates an interrupt if the TXEIE bit is set.

When a transmission is taking place, a write instruction to the USARTx_TDR register stores the data in the TDR register and which is copied in the shift register at the end of the current transmission.

When no transmission is taking place, a write instruction to the USARTx_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

- When FIFO mode is enabled, the TXFNF (TXFIFO not full) flag is set by hardware and it indicates:
 - the TXFIFO is not full
 - the USART_TDR register is empty
 - the next data can be written in the USART_TDR register without overwriting the previous data. When a transmission is taking place, a write operation to the USART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO into the shift register at the end of the current transmission.

When the TXFIFO is not full, the TXFNF flag stays at 1 even after a write in USART_TDR. It is cleared when the TXFIFO is full.

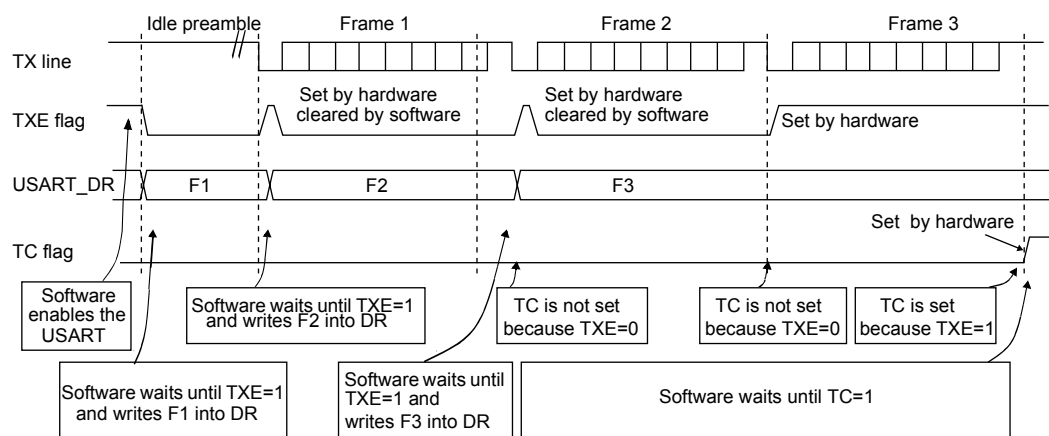

This flag generates an interrupt if the TXFNFIE bit is set.

Alternatively, interrupts can be generated and data can be written into FIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed trigger level.

If a frame is transmitted (after the stop bit) and the TXE flag (TXFE in case of FIFO mode) is set, the TC flag goes high. An interrupt is generated if the TCIE bit is set in the USART_CR1 register.

After writing the last data in the USART_TDR register, it is mandatory to wait for TC=1 before disabling the USART or causing the microcontroller to enter the low-power mode (see [Figure 116. TC/TXE behavior when transmitting](#)).

Figure 116. TC/TXE behavior when transmitting

Note: When FIFO management is enabled, the TXFNF flag is used for data transmission.

Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bit (see [Figure 114. Word length programming](#)).

If a '1' is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The USART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

Idle characters

Setting the TE bit drives the USART to send an idle frame before the first data frame.

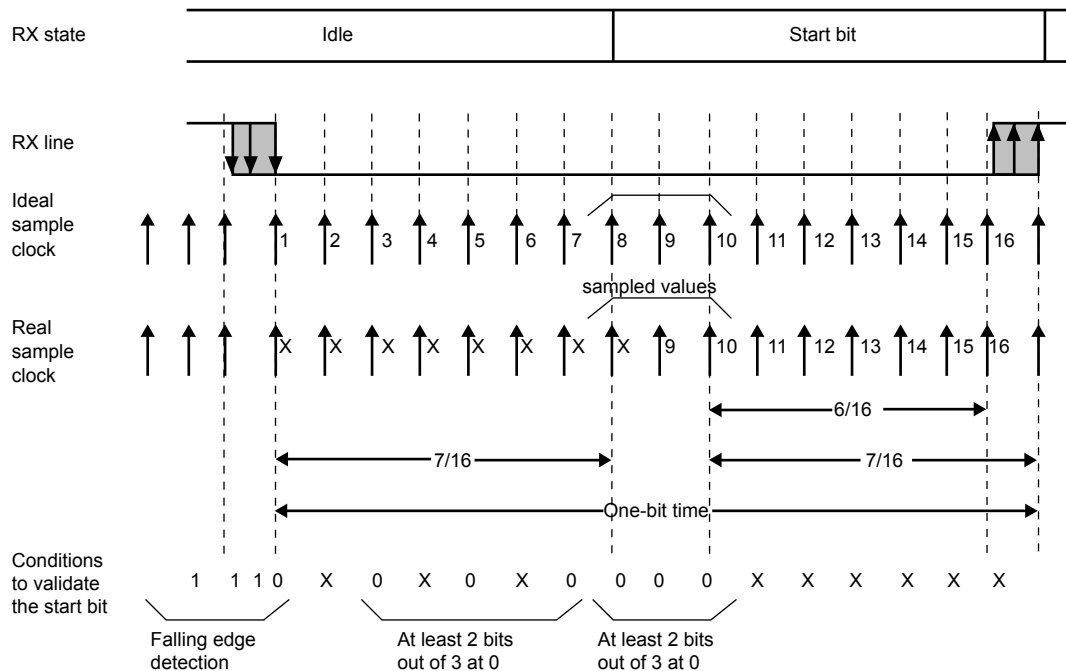

20.5.4

Receiver

The USART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the USART_CR1 register.

Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8. In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0X 0X 0 X 0X 0.

Figure 117. Start bit detection when oversampling by 16 or 8

Note: *If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.*

The start bit is confirmed (RXNE flag set, interrupt generated if RXNEIE=1 (RXFNE flag set, interrupt generated if RXFNEIE=1 if FIFO mode is enabled) if the 3 sampled bits are at 0 (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at 0 and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at 0).

The start bit is validated but the NF noise flag is set if,

1. for both samplings, 2 out of the 3 sampled bits are at 0 (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits)
- or
2. for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at 0.

If neither conditions, 1 or 2, are met, the start detection aborts and the receiver returns to the idle state (no flag is set).

Character reception

During a USART reception, data shifts in least significant bit first (default configuration) through the RX pin.

Character reception procedure

1. Program the M bits in USART_CR1 to define the word length
2. Select the desired baud rate using the baud rate register USART_BRR
3. Program the number of stop bits in USART_CR2
4. Enable the USART by writing the UE bit in USART_CR1 register to 1
5. Select DMA enable (DMAR) in USART_CR3 if multi-buffer communication is to take place. Configure the DMA register as explained in multi-buffer communication
6. Set the RE bit USART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received

- When FIFO mode is disabled, the RXNE bit is set indicating that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags)

- When FIFO is enabled, the RXFNE bit is set indicating that the RXFIFO is not empty. A read of the USART_RDR gets the oldest entry in the RXFIFO. When a data is received, it is stored in the RXFIFO, with error bits associated with that data
- An interrupt is generated if the RXNEIE (RXFNEIE in case of FIFO mode) bit is set
- The error flags can be set if a frame error, noise, parity or an overrun error has been detected during reception
- In multi-buffer communication:
 - When FIFO mode is disabled, the RXNE is set after every byte received and is cleared by the DMA read of the receive data register.
 - When FIFO mode is enabled, the RXFNE is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. DMA request is triggered by RXFIFO if not empty, i.e. there is data in the RXFIFO to be read.
- In single buffer mode,
 - When FIFO mode is disabled: clearing the RXNE flag is performed by a software read to the USARTx_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USARTx_RQR register. The RXNE flag must be cleared before the end of the reception of the next character to avoid an overrun error.
 - When FIFO mode is enabled, the RXFNE is set when the RXFIFO is not empty. After every read of the USART_RDR, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set. Alternatively, interrupts can be generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

Break character

When a break character is received, the USART handles it as a framing error.

Idle character

When an idle frame is detected, there is the same procedure as for a received data character plus an interrupt if the IDLEIE bit is set.

Overrun error

- FIFO mode disabled:

An overrun error occurs when a character is received when RXNE has not been reset. Data cannot be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte received. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:

1. The ORE bit is set.
2. The RDR content is not lost. The previous data is available when a read to USARTx_RDR is performed.
3. The shift register is overwritten. After that point, any data received during overrun is lost.
4. An interrupt is generated if either the RXNEIE bit is set or EIE bit is set.

- FIFO mode enabled

An overrun error occurs when the shift register is ready to be transferred when the receive FIFO is full. Data can not be transferred from the shift register to the USARTx_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty. An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:

1. The ORE bit is set.
2. The first entry in the RXFIFO is not lost. It is available when a read to USART_RDR is performed.
3. The shift register is overwritten. After that point, any data received during overrun is lost.
4. An interrupt is generated if either the RXFNEIE bit is set or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the USARTx_ICR register.

Note: The ORE bit, when set, indicates that at least 1 data has been lost. When the FIFO mode is disabled, there are two possibilities

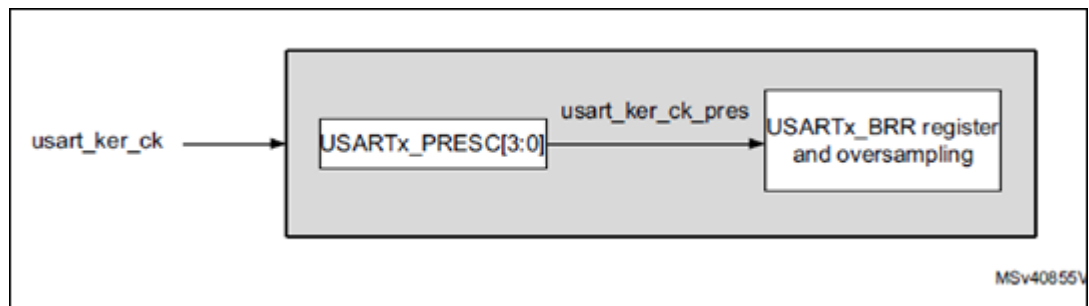

- if $RXNE=1$, then the last valid data is stored in the receive register RDR and can be read
- if $RXNE=0$, then it means that the last valid data has already been read and thus there is nothing to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.

Selecting the clock source and the proper oversampling method

The clock source frequency is f_{CK} (16 MHz).

The f_{CK} can be divided by a programmable factor in the USARTx_PRESC register.

Figure 118. usart_ker_ck clock divider block diagram

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver implements different user-configurable oversampling techniques (except in synchronous mode) for data recovery by discriminating between valid incoming data and noise. This allows a trade off between the maximum communication speed and noise/clock inaccuracy immunity.

The oversampling method can be selected by programming the OVER8 bit in the USART_CR1 register and can be either 16 or 8 times the baud rate clock (Figure 119. Data sampling when oversampling by 16 and Figure 120. Data sampling when oversampling by 8).

Depending on the application:

- Select oversampling by 8 ($OVER8=1$) to achieve higher speed (up to $f_{CKPRES}/8$). In this case the maximum receiver tolerance to clock deviation is reduced (refer to Section 20.5.6 Tolerance of the USART receiver to clock deviation).
- Select oversampling by 16 ($OVER8=0$) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum $f_{CKPRES}/16$.

where f_{CKPRES} is the USART input clock divided by a prescaler.

Programming the ONEBIT bit in the USART_CR3 register selects the method used to evaluate the logic level. There are two options:

- The majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NF bit is set
- A single sample in the center of the received bit

Depending on the application:

- select the three samples' majority vote method ($ONEBIT=0$) when operating in a noisy environment and reject the data when a noise is detected (refer to Figure 68. Deadtime waveforms with delay greater than the negative pulse because this indicates that a glitch occurred during the sampling).
- select the single sample method ($ONEBIT=1$) when the line is noise-free to increase the receiver's tolerance to clock deviations (see Section 20.5.6 Tolerance of the USART receiver to clock deviation). In this case the NF bit is never set.

When noise is detected in a frame:

- The NF bit is set at the rising edge of the RXNE bit (RXFNE in case of FIFO mode enabled)
- The invalid data is transferred from the Shift register to the USART_RDR register

- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case of FIFO mode enabled) which itself generates an interrupt. In case of multi-buffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The NF bit is reset by setting NFCF bit in the ICR register.

Note: Noise error is not supported in SPI mode.

Note: Oversampling by 8 is not available in the smartcard, IrDA and LIN modes. In those modes, the OVER8 bit is forced to '0' by hardware.

Figure 119. Data sampling when oversampling by 16

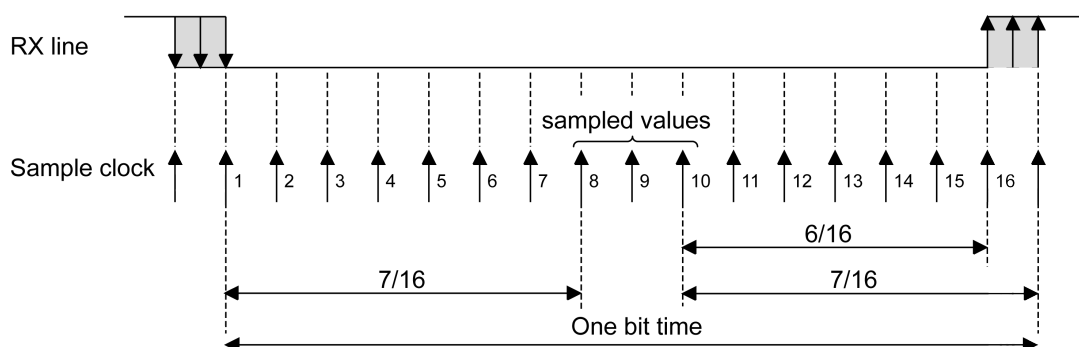

Figure 120. Data sampling when oversampling by 8

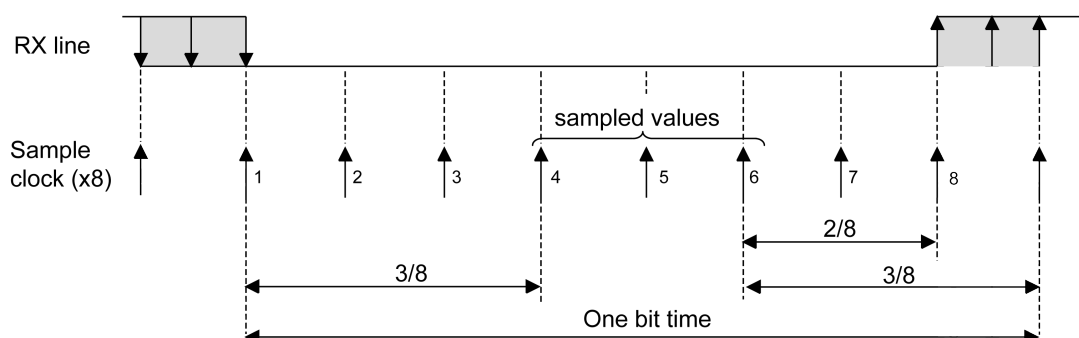

Table 67. Noise detection from sampled data

Sampled value	NE status	Received bit value
000	0	0
001	1	0
010	1	0
011	1	1
100	1	0
101	1	1
110	1	1
111	0	1

Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:

- The FE bit is set by hardware

- The invalid data is transferred from the shift register to the USART_RDR register (RXFIFO in case FIFO mode is enabled)
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case FIFO mode is enabled) which itself generates an interrupt. In case of multi-buffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The FE bit is reset by writing 1 to the FECF in the USART_ICR register.

Note: Framing error is not supported in SPI mode.

Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of control register 2 - it can be either 1 or 2 in normal mode and 0.5 or 1.5 in smartcard mode.

- **0.5 stop bit (reception in smartcard mode):** No sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.
- **1 stop bit:** Sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- **1.5 stop bits (smartcard mode):** When transmitting in smartcard mode, the device must check that the data is correctly sent. Thus the receiver block must be enabled (RE=1 in the USART_CR1 register) and the stop bit is checked to test if the smartcard has detected a parity error. In the event of a parity error, the smartcard forces the data signal low during the sampling - NACK signal -, which is flagged as a framing error. Then, the FE flag is set with the RXNE (RXFNE in case FIFO mode is enabled) at the end of the 1.5 stop bit. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bit can be decomposed into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through. Refer to [Section 20.5.14 Receiver timeout](#) for more details.
- **2 stop bits:** Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. If a framing error is detected during the first stop bit the framing error flag is set. The second stop bit is not checked for framing error. The RXNE (RXFNE in case FIFO mode is enabled) flag is set at the end of the first stop bit.

20.5.5

Baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the same value as programmed in the USART_BRR register.

The equation below is baud rate for standard USART (SPI mode included) (OVER8= 0 or 1).

In case of oversampling by 16, the equation is:

$$Tx/Rx_{baud} = \frac{f_{CKPRES}}{USARTDIV} \quad (4)$$

In case of oversampling by 8, the equation is:

$$Tx/Rx_{baud} = \frac{2 \times f_{CKPRES}}{USARTDIV} \quad (5)$$

The equation below is baud rate in Smartcard, LIN and IrDA modes (OVER8= 0):

$$Tx/Rx_{baud} = \frac{f_{CKPRES}}{USARTDIV} \quad (6)$$

f_{ckpres} is the USART clock which is the USART input clock divided by a prescaler configured in the USART_PRESC register.

USARTDIV is an unsigned fixed point number that is coded on the USART_BRR register.

- When OVER8 = 0, BRR = USARTDIV
- When OVER8 = 1
 - BRR[2:0] = USARTDIV[3:0] shifted 1 bit to the right
 - BRR[3] must be kept cleared
 - BRR[15:4] = USARTDIV[15:4]

Note: The baud counters are updated to the new value in the baud registers after a write operation to USART_BRR. Hence the baud rate register value should not be changed during communication. In case of oversampling by 16 and 8, USARTDIV must be greater than or equal to 16d.

How to derive USARTDIV from USART_BRR register values

Example 1

To obtain 9600 baud with $f_{CKPRES} = 8$ MHz.

- In case of oversampling by 16:
USARTDIV = 8 000 000/9600
BRR = USARTDIV = 833d = 0341h
- In case of oversampling by 8:
USARTDIV = 2 * 8 000 000/9600
USARTDIV = 1666,66 (1667d = 683h)
BRR[3:0] = 3h >>1 = 1h
BRR = 0x681

20.5.6 Tolerance of the USART receiver to clock deviation

The asynchronous receiver of the USART works correctly only if the total clock system deviation is less than the tolerance of the USART receiver. The causes which contribute to the total deviation are:

- DTRA: Deviation due to the transmitter error (which also includes the deviation of the transmitter's local oscillator)
 - DQUANT: Error due to the baud rate quantization of the receiver
 - DREC: Deviation of the receiver local oscillator
 - DTCL: Deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)
- DTRA + DQUANT + DREC + DTCL < USART receiver tolerance.

The USART receiver can receive data correctly at up to the maximum tolerated deviation specified in [Table 68. Tolerance of the USART receiver when BRR \[3:0\] = 0000 \(high-density devices\)](#) and [Table 69. Tolerance of the USART receiver when BRR\[3:0\] is different from 0000 \(high-density devices\)](#), depending on the following choices:

- 9-, 10- or 11-bit character length defined by the M bits in the USART_CR1 register
- Oversampling by 8 or 16 defined by the OVER8 bit in the USART_CR1 register
- Bits BRR[3:0] of USART_BRR register are equal to or different from 0000
- Use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART_CR3 register.

Table 68. Tolerance of the USART receiver when BRR [3:0] = 0000 (high-density devices)

M bits	OVER8 bit = 0		OVER8 bit = 1	
	ONEBIT=0	ONEBIT=1	ONEBIT=0	ONEBIT=1
00	3.75%	4.375%	2.50%	3.75%
01	3.41%	3.97%	2.27%	3.41%
10	4.16	4.86	2.77	4.16

Table 69. Tolerance of the USART receiver when BRR[3:0] is different from 0000 (high-density devices)

M bits	OVER8 bit = 0		OVER8 bit = 1	
	ONEBIT=0	ONEBIT=1	ONEBIT=0	ONEBIT=1
00	3.33%	3.88%	2%	3%
01	3.03%	3.53%	1.82%	2.73%
10	3.7	4.31	2.22	3.33

Note:

The data specified in [Table 68. Tolerance of the USART receiver when BRR \[3:0\] = 0000 \(high-density devices\)](#) and [Table 69. Tolerance of the USART receiver when BRR\[3:0\] is different from 0000 \(high-density devices\)](#) may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = 00 (11-bit times when M = 01 or 9-bit times when M = 10).

20.5.7 Auto baud rate detection

The USART is able to detect and automatically set the USART_BRR register value based on the reception of one character. Automatic baud rate detection is useful under two circumstances:

- The communication speed of the system is not known in advance
- The system is using a relatively low accuracy clock source and this mechanism allows the correct baud rate to be obtained without measuring the clock deviation.

The clock source frequency must be compatible with the expected communication speed (when oversampling by 16, the baud rate is between $f_{CK}/65535$ and $f_{CK}/16$. When oversampling by 8, the baud rate is between $f_{CK}/65535$ and $f_{CK}/8$).

Before activating the auto baud rate detection, the auto baud rate detection mode must be chosen. There are four modes based on different character patterns.

The modes can be chosen through the ABRMOD[1:0] field in the USART_CR2 register. In these auto baud rate modes, the baud rate is measured several times during the synchronization data reception and each measurement is compared to the previous one.

These modes are:

- **Mode 0:** Any character starting with a bit at 1.
In this case the USART measures the duration of the start bit (falling edge to rising edge).
- **Mode 1:** Any character starting with a 10xx bit pattern.
In this case, the USART measures the duration of the start and of the 1st data bit.
The measurement is done falling edge to falling edge, ensuring better accuracy in the case of slow signal slopes.
- **Mode 2:** A 0x7F character frame (it may be a 0x7F character in LSB first mode or a 0xFE in MSB first mode).
In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 6 (based on the measurement done from falling edge to falling edge: BR6). Bit0 to Bit6 are sampled at BRs while further bits of the character are sampled at BR6.
- **Mode 3:** A 0x55 character frame.
In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit0 (based on the measurement done from falling edge to falling edge: BR0), and finally at the end of bit6 (BR6). Bit0 is sampled at BRs, Bit1 to Bit6 are sampled at BR0, and further bits of the character are sampled at BR6. In parallel, another check is performed for each intermediate transition of RX line. An error is generated if the transitions on RX are not sufficiently synchronized with the receiver (the receiver being based on the baud rate calculated on bit 0).

Prior to activating auto baud rate detection, the USART_BRR register must be initialized by writing a non-zero baud rate value.

The automatic baud rate detection is activated by setting the ABREN bit in the USART_CR2 register. The USART then waits for the first character on the RX line. The auto baud rate operation completion is indicated by the setting of the ABRF flag in the USART_ISR register. If the line is noisy, the correct baud rate detection cannot be guaranteed. In this case the BRR value may be corrupted and the ABRE error flag is set. This also happens if the communication speed is not compatible with the automatic baud rate detection range (bit duration not between 16 and 65536 clock periods (oversampling by 16) and not between 8 and 65536 clock periods (oversampling by 8)).

The auto baud rate detection can be re-launched later by resetting the ABRF flag (by writing a 0).

When FIFO management is disabled, in case of auto baud rate error, the ABRE flag is set with RXNE and FE.

When FIFO management is enabled, in case of auto baud rate error, the ABRE flag is set with RXFNE and FE.

In case FIFO mode is enabled, the auto baud rate detection should be made using the data on the first RXFIFO location. So, prior to launching the auto baud rate detection, the user should make sure that the RXFIFO is empty using the RXFNE flag in the USARTx_ISR register.

Note: The BRR value may be corrupted if the USART is disabled (UE=0) during an auto baud rate operation.

20.5.8 Multiprocessor communication

It is possible to perform multiprocessor communication with the USART (with several USARTs connected in a network). For instance one of the USARTs can be the master, its TX output connected to the RX inputs of the other USARTs. The others are slaves, their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipients should actively receive the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non addressed devices may be placed in mute mode by means of the muting function. In order to use the mute mode feature, the MME bit must be set in the USARTx_CR1 register.

Note: *When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two UCLK cycles) otherwise mute mode might remain active.*

In mute mode:

- None of the reception status bits can be set
- All the receive interrupts are inhibited
- The RWU bit in USART_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the USART_RQR register, under certain conditions.

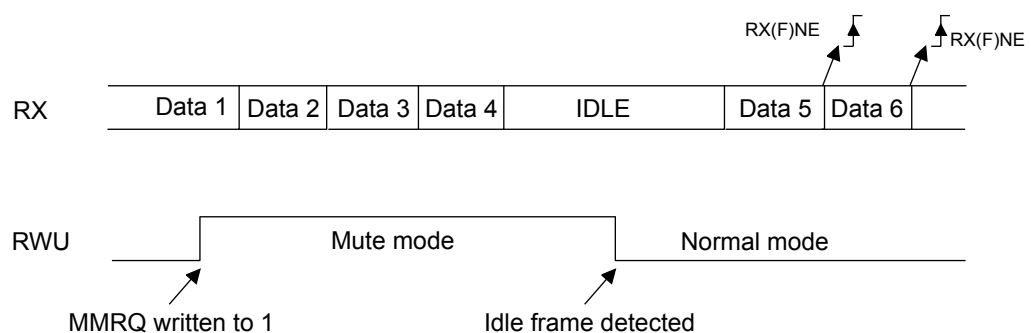

The USART can enter or exit from mute mode using one of two methods, depending on the WAKE bit in the USART_CR1 register:

- Idle Line detection if the WAKE bit is reset
- Address Mark detection if the WAKE bit is set.

Idle line detection (WAKE=0)

The USART enters mute mode when the MMRQ bit is written to 1 and the RWU is automatically set. It wakes up when an idle frame is detected. Then the RWU bit is cleared by hardware but the IDLE bit is not set in the USART_ISR register. An example of mute mode behavior using Idle line detection is given in [Figure 121. Mute mode using Idle line detection](#).

Figure 121. Mute mode using Idle line detection

Note: *If the MMRQ is set while the IDLE character has already elapsed, mute mode is not entered (RWU is not set).*

Note: *If the USART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).*

4-bit/7-bit address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a '1' otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART_CR2 register.

Note: *In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.*

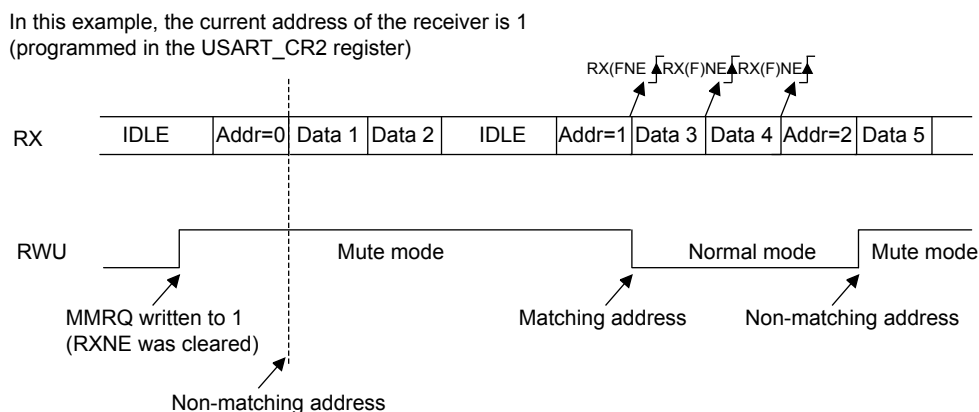

The USART enters mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the USART enters mute mode. When FIFO management is enabled, the software should ensure that there is at least one empty location in the RXFIFO before entering mute mode.

The USART also enters mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case. The USART exits from mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: *When FIFO management is enabled, when MMRQ is set while the receiver is sampling the last bit of data, these data may be received before entering mute mode.*

An example of mute mode behavior using address mark detection is given in [Figure 122. Mute mode using address mark detection](#).

Figure 122. Mute mode using address mark detection

20.5.9 Modbus communication

The USART offers basic support for the implementation of Modbus/RTU and Modbus/ASCII protocols. Modbus/RTU is a half-duplex, block transfer protocol. The control part of the protocol (address recognition, block integrity control and command interpretation) must be implemented in software.

The USART offers basic support for the end of the block detection, without software overhead or other resources.

Modbus/RTU

In this mode, the end of one block is recognized by a “silence” (idle line) for more than 2 character times. This function is implemented through the programmable timeout function.

The timeout function and interrupt must be activated, through the RTOEN bit in the USART_CR2 register and the RTOIE in the USART_CR1 register. The value corresponding to a timeout of 2 character times (for example 22 x bit time) must be programmed in the RTO register. When the receive line is idle for this duration, after the last stop bit is received, an interrupt is generated, informing the software that the current block reception is completed.

Modbus/ASCII

In this mode, the end of a block is recognized by a specific (CR/LF) character sequence. The USART manages this mechanism using the character match function. By programming the LF ASCII code in the ADD[7:0] field and by activating the character match interrupt (CMIE=1), the software is informed when an LF has been received and can check the CR/LF in the DMA buffer.

20.5.10 Parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART_CR1 register. Depending on the frame length defined by the M bits, the possible USART frame formats are as listed in [Table 70. Frame formats](#).

Table 70. Frame formats

M bits	PCE bit	USART frame ⁽¹⁾
00	0	SB 8-bit data STB
00	1	SB 7-bit data PB STB
01	0	SB 9-bit data STB
01	1	SB 8-bit data PB STB
10	0	SB 7-bit data STB
10	1	SB 6-bit data PB STB

1. *Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).*

Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit is 0 if even parity is selected (PS bit in USART_CR1 = 0).

Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit is 1 if odd parity is selected (PS bit in USART_CR1 = 1).

Parity checking in reception

If the parity check fails, the PE flag is set in the USART_ISR register and an interrupt is generated if PEIE is set in the USART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the USART_ICR register.

Parity generation in transmission

If the PCE bit is set in USART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1”s if even parity is selected (PS=0) or an odd number of “1”s if odd parity is selected (PS=1)).

20.5.11 LIN (local interconnection network) mode

This section is relevant only when LIN mode is supported. Please refer to [Section 20.4 USART implementation](#).

The LIN mode is selected by setting the LINEN bit in the USART_CR2 register. In LIN mode, the following bits must be kept cleared:

- CLKEN in the USART_CR2 register
- STOP[1:0], SCEN, HDSEL and IREN in the USART_CR3 register.

LIN transmission

The procedure explained in [Section 20.5.2 FIFOs and thresholds](#) has to be applied for LIN Master transmission. It must be the same as for normal USART transmission with the following differences:

- Clear the M bit to configure 8-bit word length
- Set the LINEN bit to enter LIN mode. In this case, setting the SBKRQ bit sends 13'0 bits as a break character. Then 2 bits of value '1' are sent to allow the next start detection.

LIN reception

When LIN mode is enabled, the break detection circuit is activated. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during idle state or during a frame.

When the receiver is enabled (RE=1 in USART_CR1), the circuit looks at the RX input for a start signal. The method to detect start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART_CR2) or 11 (when LBDL=1 in USART_CR2) consecutive bits are detected as '0', and are followed by a delimiter character, the LBDIE flag is set in USART_ISR. If the LBDIE bit=1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a '1' is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN=0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN=1), as soon as a framing error occurs (i.e. stop bit detected at '0', which is the case for any break frame), the receiver stops until the break detection circuit receives either a '1', if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown in Figure 123. Break detection in LIN mode (11-bit break length - LBDL bit is set).

Examples of break frames are given:

Figure 123. Break detection in LIN mode (11-bit break length - LBDL bit is set)

Case 1: break signal not long enough => break discarded, LBDF is not set

Case 2: break signal just long enough => break detected, LBDF is set

Case 3: break signal long enough => break detected, LBDF is set

Figure 124. Break detection in LIN mode vs. framing error detection

Case 1: break occurring after an Idle

Case 2: break occurring while data is being received

20.5.12 USART synchronous mode

Master mode

The synchronous master mode is selected by writing the CLKEN bit in the USART_CR2 register to 1. In synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in master mode. The SCLK pin is the output of the USART transmitter clock. No clock pulses are sent to the SCLK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART_CR2 register, clock pulses are, or are not, generated during the last valid data bit (address mark). The CPOL bit in the USART_CR2 register is used to select the clock polarity, and the CPHA bit in the USART_CR2 register is used to select the phase of the external clock (see [Figure 125. USART example of synchronous master transmission](#) and [Figure 126. USART data clock timing diagram M=0](#)).

During the idle state, preamble and send break, the external SCLK clock is not activated.

In synchronous master mode the USART transmitter works exactly like in asynchronous mode. But as SCLK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In this mode the USART receiver works in a different manner compared to the asynchronous mode. If RE=1, the data is sampled on SCLK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A setup and a hold time must be respected (which depends on the baud rate: 1/16 bit time).

Note: *In master mode, the SCLK pin works in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE=1) and data is being transmitted (the data register USART_DR written). This means that it is not possible to receive synchronous data without transmitting data.*

Figure 125. USART example of synchronous master transmission

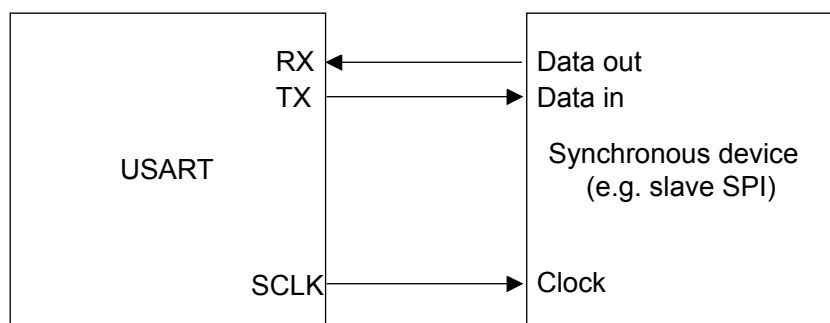

Figure 126. USART data clock timing diagram M=0

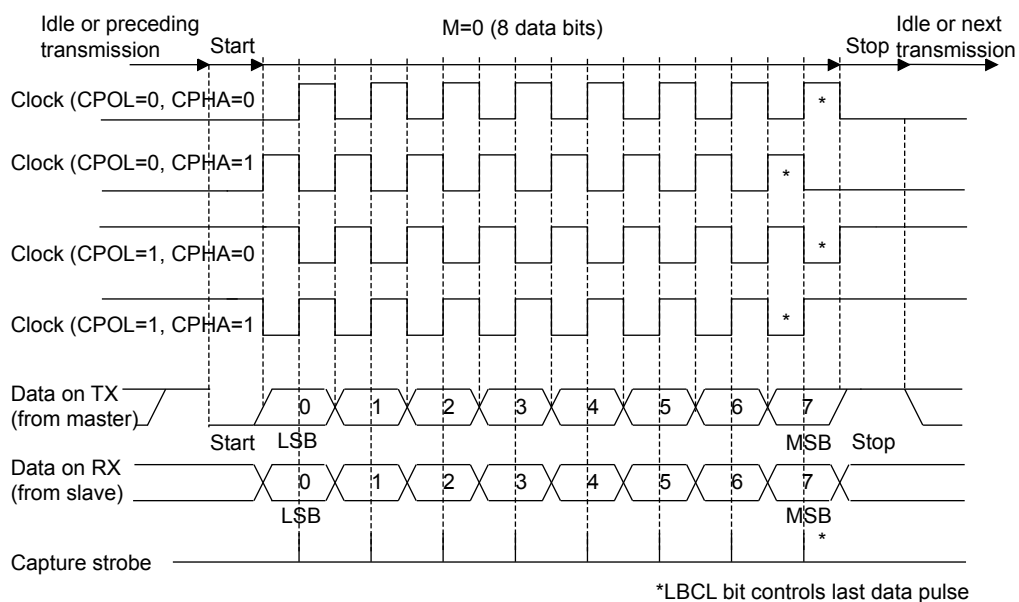

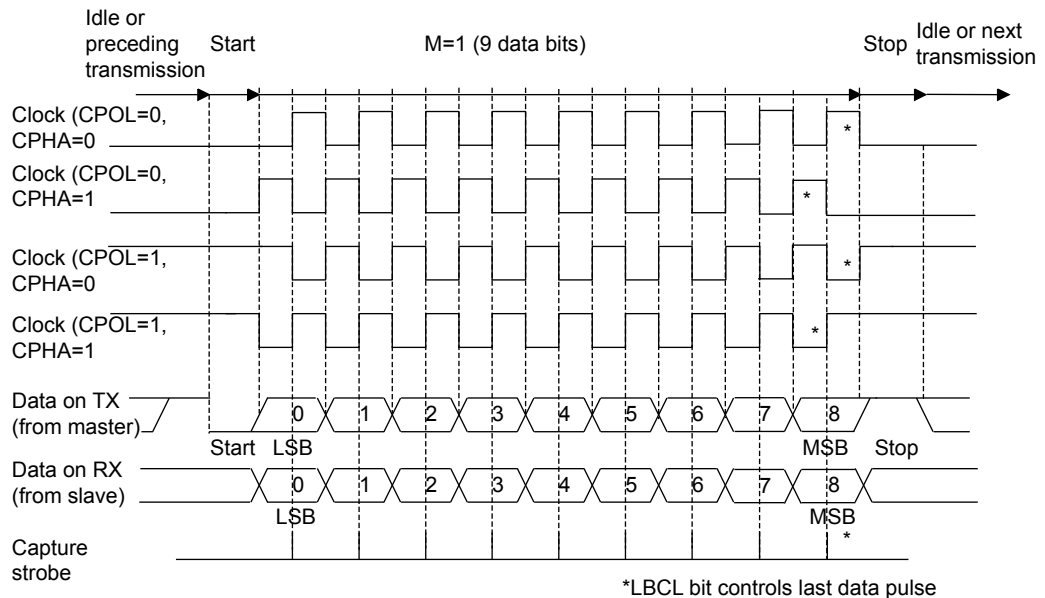

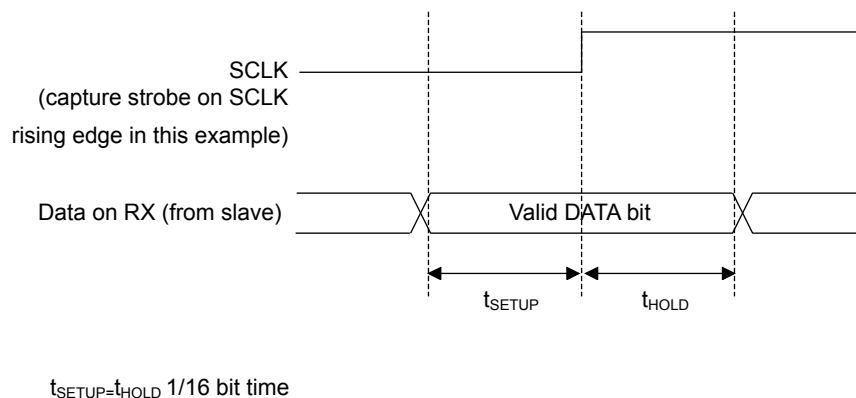

Figure 127. USART data clock timing diagram (M bits = 01)

Figure 128. RX data setup/hold time

Slave mode

The synchronous slave mode is selected by writing the SLVEN bit in the USART_CR2 register to 1. In synchronous slave mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in slave mode. The SCLK pin is the input of the USART in slave mode.

Note: When the peripheral is used in SPI slave mode, the peripheral clock source (fck_pres) must be greater than 3xSCLK input clock.

The CPOL bit in the USART_CR2 register is used to select the clock polarity, and the CPHA bit in the USART_CR2 register is used to select the phase of the external clock (see Figure 125. USART example of synchronous master transmission, Figure 126. USART data clock timing diagram M=0 and Figure 127. USART data clock timing diagram (M bits = 01)).

In slave transmission mode, an underrun error flag is available. This flag is set when the first clock for data transmission appears while the software has not yet loaded any value into USARTx_TDR.

The slave supports the hardware and software NSS management.

Slave select (NSS) pin management

Hardware or software slave select management can be set using the DIS_NSS bit in the USART_CR2 register.

- Software NSS management (DIS_NSS =1)
SPI slave is always selected and NSS input pin is ignored. The external NSS pin remains free for other application uses.
- Hardware NSS management (DIS_NSS =0)
The SPI slave selection depends on NSS input pin. The slave is selected when NSS is low and deselected when NSS high.

Note: The LBCL (used only on SPI master mode), CPOL and CPHA bits have to be selected when the USART is disabled (UE=0) to ensure that the clock pulses function correctly.

Note: When in SPI slave mode, the USART must be enabled before the master starts communication (or between frames while the clock is stable). Otherwise, if the USART slave is enabled while the master is in the middle of a frame, it becomes desynchronized with the master. The data register of the slave needs to be ready before the first edge of the communication clock or before the end of the on-going communication, otherwise SPI slave transmits zeros.

SPI slave underrun error

When an underrun error occurs, the SPI slave sends the last data until the underrun error flag is cleared in software.

The underrun flag is set at the beginning of the frame.

The underrun error flag is cleared by setting bit UDRCF in the USART_ICR register.

In underrun condition, it is allowed to write the TDR register. Clearing the underrun error would allow sending the new data.

If an underrun error occurred and there is no new data written in TDR, then the TC flag is set at the end of the frame.

Note: An underrun error may occur if the data is written in the USARTx_TDR too close to the first SCLK transmission edge. To avoid this underrun error, the USART_TDR should be written 3 UCLK cycles before the first SCLK edge.

20.5.13 Single-wire half-duplex communication

Single-wire half-duplex mode is selected by setting the HDSEL bit in the USART_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register
- SCEN and IREN bits in the USART_CR3 register.

The USART can be configured to follow a single-wire half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and full-duplex communication is made with a control bit HDSEL in USART_CR3.

As soon as HDSEL is written to 1:

- The TX and RX lines are internally connected
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal USART mode. Any conflicts on the line must be managed by software (by the use of a centralized arbiter, for instance). In particular, the transmission is never blocked by hardware and continues as soon as data are written in the data register while the TE bit is set.

Note: As the TX line and the RX lines are connected together, all the transmitted data are stored in the RX FIFO as the data received from an external device. The software has to take care to discard its "own" information after a transmit phase. In half-duplex mode, it is always wise to read back the transmitted data to check if they are correct as there is no hardware protection against possible collision between nodes. If the software does not want to have the RX FIFO storing the transmitted value then it has to disable the receiver part while transmitting (by clearing the RE bit in USART_CR1 register).

20.5.14 Receiver timeout

The receiver timeout feature is enabled by setting the RTOEN bit in the USART_CR2 control register. The timeout duration is programmed using the RTO bit fields in the USARTx_RTOR register.

The receiver timeout counter starts counting

- From the end of the stop bit in case STOP = 00 and STOP = 11
- From the end of the second stop bit in case STOP = 10
- From the beginning of the stop bit in case STOP = 01.

When the timeout duration has elapsed, the RTOF flag in the USARTx_ISR register is set and a timeout is generated if RTOIE bit in USARTx_CR1 register is set.

20.5.15 Smartcard mode

This section is relevant only when smartcard mode is supported. Please refer to [Section 20.4 USART implementation](#).

Smartcard mode is selected by setting the SCEN bit in the USART_CR3 register. In Smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register
- HDSEL and IREN bits in the USART_CR3 register.

The CLKEN bit may be set in order to provide a clock to the Smartcard.

The Smartcard interface is designed to support asynchronous protocol Smartcards as defined in the ISO 7816-3 standard. Both T=0 (character mode) and T=1 (block mode) are supported.

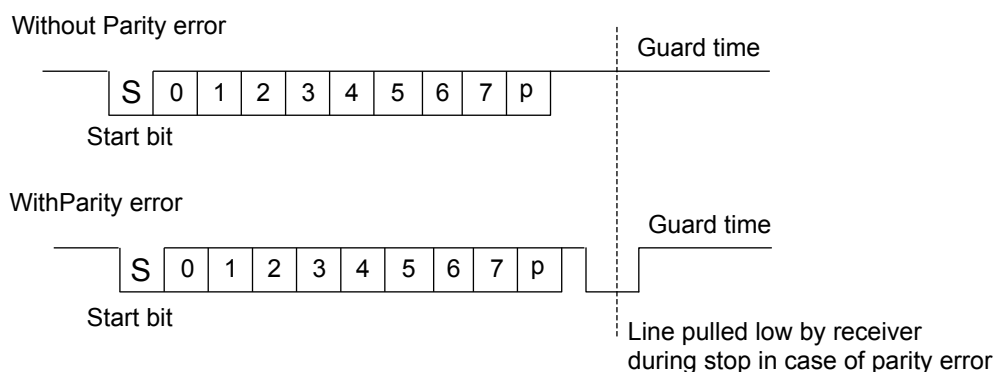

The USART should be configured as:

- 8-bit plus parity: where M=1 and PCE=1 in the USART_CR1 register
- 1.5 stop bits when transmitting and receiving data: where STOP=11 in the USART_CR2 register. It is also possible to choose the 0.5 stop bit for receiving.

In T=0 (character) mode, the parity error is indicated at the end of each character during the Guard Time period.

[Figure 129. ISO 7816-3 asynchronous protocol](#) shows examples of what can be seen on the data line with and without parity error.

Figure 129. ISO 7816-3 asynchronous protocol

When connected to a Smartcard, the TX output of the USART drives a bidirectional line that is also driven by the Smartcard. The TX pin must be configured as open drain.

Smartcard mode implements a single-wire half-duplex communication protocol.

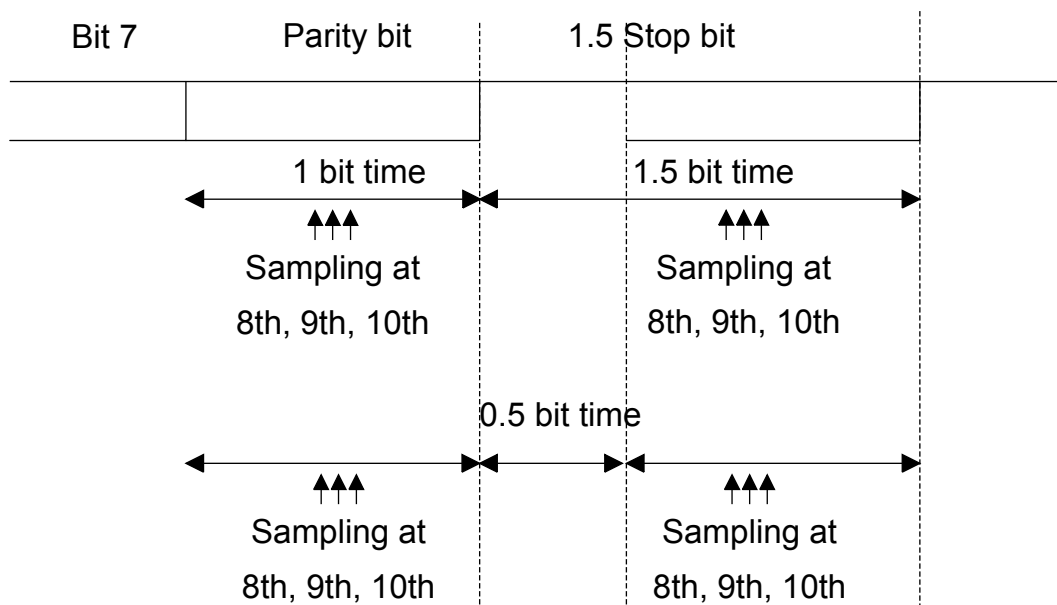

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In a normal operation a full transmit shift register starts shifting on the next baud clock edge. In Smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.

- In transmission, if the Smartcard detects a parity error, it signals this condition to the USART by driving the line low (NACK). This NACK signal (pulling transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The USART can handle automatic re-sending of data according to the protocol. The number of retries is programmed in the SCARCNT bit field. If the USART continues receiving the NACK after the programmed number of retries, it stops transmitting and signals the error as a framing error. The TXE bit (TXFNF bit in case FIFO mode is enabled) may be set using the TXFRQ bit in the USART_RQR register.
- Smartcard auto-retry in transmission: a delay of 2.5 baud periods is inserted between the NACK detection by the USART and the start bit of the repeated character. The TC bit is set immediately at the end of reception of the last repeated character (no Guard Time). If the software wants to repeat it again, it must ensure the minimum 2 baud periods required by the standard.
- If a parity error is detected during reception of a frame programmed with a 1.5 stop bit period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the Smartcard that the data transmitted to the USART has not been correctly received. A parity error is NACKed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted (to be used in T=1 mode). If the received character is erroneous, the RXNE (RXFNE in case FIFO mode is enabled)/receive DMA request is not activated. According to the protocol specification, the Smartcard must resend the same character. If the received character is still erroneous after the maximum number of retries specified in the SCARCNT bit field, the USART stops transmitting the NACK and signals the error as a parity error.
- Smartcard auto-retry in reception: the BUSY flag remains set if the USART NACKs the card but the card does not repeat the character.
- In transmission, the USART inserts the Guard Time (as programmed in the Guard Time register) between two successive characters. As the Guard Time is measured after the stop bit of the previous character, the GT[7:0] register must be programmed to the desired CGT (Character Guard Time, as defined by the 7816-3 specification) minus 12 (the duration of one character).
- The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In Smartcard mode an empty transmit shift register triggers the Guard Time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the Guard Time counter reaches the programmed value TC is asserted high. The TCBGT flag can be used to detect the end of data transfer without waiting for Guard Time completion. This flag is set just after the end of frame transmission and if no NACK has been received from the card.
- The de-assertion of TC flag is unaffected by Smart card mode.
- If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK is not detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.
- On the receiver side, if a parity error is detected and a NACK is transmitted the receiver does not detect the NACK as a start bit.

Note: *A break character is not significant in smartcard mode. A 0x00 data with a framing error is treated as data and not as a break.*

Note: *No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.*

Figure 130. Parity error detection using 1.5 stop bits details how the NACK signal is sampled by the USART. In this example the USART is transmitting data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.

Figure 130. Parity error detection using 1.5 stop bits

The USART can provide a clock to the Smartcard through the SCLK output. In Smartcard mode, SCLK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the prescaler register USART_. SCLK frequency can be programmed from $f_{CKPRES}/2$ to $f_{CKPRES}/62$, where f_{CKPRES} is the peripheral input clock divided by a programmed prescaler.

Block mode (T=1)

In T=1 (block) mode, the parity error transmission can be deactivated by clearing the NACK bit in the UART_CR3 register.

When requesting a read from the Smartcard, in block mode, the software must program the RTOR register to the BWT (block wait time) - 11 value. If no answer is received from the card before the expiration of this period, a timeout interrupt is generated. If the first character is received before the expiration of the period, it is signaled by the RXNE/RXFNE interrupt.

Note: *The RXNE/RXFNE interrupt must be enabled even when using the USART in DMA mode to read from the Smartcard in block mode. In parallel, the DMA must be enabled only after the first received byte.*

After the reception of the first character (RXNE/RXFNE interrupt), the RTO register must be programmed to the CWT (character wait time) - 11 value, in order to allow the automatic check of the maximum wait time between two consecutive characters. This time is expressed in baudtime units. If the Smartcard does not send a new character in less than the CWT period after the end of the previous character, the USART signals this to the software through the RTOF flag and interrupt (when RTOIE bit is set).

Note: *As in the Smartcard protocol definition, the BWT/CWT values should be defined from the beginning (start bit) of the last character. The RTO register must be programmed to BWT - 11 or CWT - 11, respectively, taking into account the length of the last character itself.*

A block length counter is used to count all the characters received by the USART. This counter is reset when the USART is transmitting. The length of the block is communicated by the Smartcard in the third byte of the block (prologue field). This value must be programmed to the BLEN field in the USART_RTOR register. When using DMA mode, before the start of the block, this register field must be programmed to the minimum value (0x0). With this value, an interrupt is generated after the 4th received character. The software must read the LEN field (third byte), its value must be read from the receive buffer.

In interrupt driven receive mode, the length of the block may be checked by software or by programming the BLEN value. However, before the start of the block, the maximum value of BLEN (0xFF) may be programmed. The real value is programmed after the reception of the third character.

If the block is using the LRC longitudinal redundancy check (1 epilogue byte), the $BLN=LEN$. If the block is using the CRC mechanism (2 epilog bytes), $BLN=LEN+1$ must be programmed. The total block length (including prologue, epilogue and information fields) equals $BLN+4$. The end of the block is signaled to the software through the EOB flag and interrupt (when EOBI bit is set). In case of an error in the block length, the end of the block is signaled by the RTO interrupt (character wait time overflow).

Note: *The error checking code (LRC/CRC) must be computed/verified by software.*

Direct and inverse convention

The Smartcard protocol defines two conventions: direct and inverse.

The direct convention is defined as: LSB first, logical bit value of 1 corresponds to a H state of the line and parity is even. In order to use this convention, the following control bits must be programmed: $MSBFIRST=0$, $DATAINV=0$ (default values).

The inverse convention is defined as: MSB first, logical bit value 1 corresponds to an L state on the signal line and parity is even. In order to use this convention, the following control bits must be programmed: $MSBFIRST=1$, $DATAINV=1$.

Note: *When logical data values are inverted (0=H, 1=L), the parity bit is also inverted in the same way.*

In order to recognize the card convention, the card sends the initial character, TS, as the first character of the ATR (answer to reset) frame. The two possible patterns for the TS are: LHH LLL LLH and LHH LHH LLH.

- (H) LHH LLL LLH sets up the inverse convention: state L encodes value 1 and moment 2 conveys the most significant bit (MSB first). When decoded by inverse convention, the conveyed byte is equal to '3F'.
- (H) LHH LHH LLH sets up the direct convention: state H encodes value 1 and moment 2 conveys the least significant bit (LSB first). When decoded by direct convention, the conveyed byte is equal to '3B'.

Character parity is correct when there is an even number of bits set to 1 in the nine moments 2 to 10.

As the USART does not know which convention is used by the card, it needs to be able to recognize either pattern and act accordingly. The pattern recognition is not done in hardware, but through a software sequence. Moreover, supposing that the USART is configured in direct convention (default) and the card answers with the inverse convention, TS = LHH LLL LLH => the USART received character is '03' and the parity is odd.

Therefore, two methods are available for TS pattern recognition:

Method 1

The USART is programmed in standard Smartcard mode/direct convention. In this case, the TS pattern reception generates a parity error interrupt and error signal to the card.

- The parity error interrupt informs the software that the card did not answer correctly in direct convention. Software then reprograms the USART for inverse convention
- In response to the error signal, the card retries the same TS character, and it is correctly received this time, by the reprogrammed USART.

Alternatively, in answer to the parity error interrupt, the software may decide to reprogram the USART and also to generate a new reset command to the card, then wait again for the TS.

Method 2

The USART is programmed in 9-bit/no-parity mode, no bit inversion. In this mode it receives either of the two TS patterns as:

- (H) LHH LLL LLH = 0x103 -> inverse convention to be chosen
- (H) LHH LHH LLH = 0x13B -> direct convention to be chosen.

The software checks the received character against these two patterns and, if either of them match, then programs the USART accordingly for the next character reception.

If neither of the two are recognized, a card reset may be generated in order to restart the negotiation.

20.5.16 IrDA SIR ENDEC block

This section is relevant only when IrDA mode is supported. Please refer to [Section 20.4 USART implementation](#). IrDA mode is selected by setting the IREN bit in the USART_CR3 register. In IrDA mode, the following bits must be kept cleared:

- LINEN, STOP and CLKEN bits in the USART_CR2 register
- SCEN and HDSEL bits in the USART_CR3 register.

The IrDA SIR physical layer specifies use of a return to zero, inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see [Figure 131. IrDA SIR ENDEC - block diagram](#)).

The SIR transmit encoder modulates the non-return-to-zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only the bit rates up to 115.2 Kbps for the SIR ENDEC. In normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to the USART. The decoder input is normally high (marking state) in the idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.

- IrDA is a half-duplex communication protocol. If the transmitter is busy (when the USART is sending data to the IrDA encoder), any data on the IrDA receive line is ignored by the IrDA decoder and if the receiver is busy (when the USART is receiving decoded data from the USART), data on the TX from the USART to IrDA is not encoded. While receiving data, transmission should be avoided as the data to be transmitted could be corrupted.
- A 0 is transmitted as a high pulse and a 1 is transmitted as a 0. The width of the pulse is specified as 3/16th of the selected bit period in normal mode (see [Figure 132. IrDA data modulation \(3/16\) - normal mode](#)).
- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.
- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.
- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.
- The IrDA specification requires the acceptance of pulses greater than 1.41 μ s. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the USART_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than 2 periods are accepted as a pulse. The IrDA encoder/decoder does not work when PSC=0.
- The receiver can communicate with a low-power transmitter.
- In IrDA mode, the STOP bits in the USART_CR2 register must be configured to "1 stop bit".

IrDA low-power mode

Transmitter

In low-power mode the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz. Generally, this value is 1.8432 MHz ($1.42 \text{ MHz} < \text{PSC} < 2.12 \text{ MHz}$). A low-power mode programmable divisor divides the system clock to achieve this value.

Receiver:

Receiving in low-power mode is similar to receiving in normal mode. For glitch detection the USART should discard pulses of duration shorter than 1/PSC. A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power baud clock (PSC value in the USART_GTPR).

Note: A pulse of width less than two and greater than one PSC period(s) may or may not be rejected.

Note: The receiver set-up time should be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half-duplex protocol).

Figure 131. IrDA SIR ENDEC - block diagram

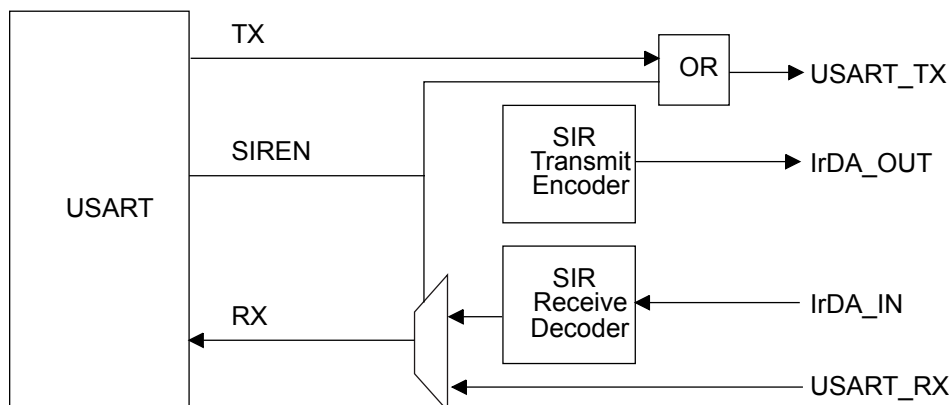

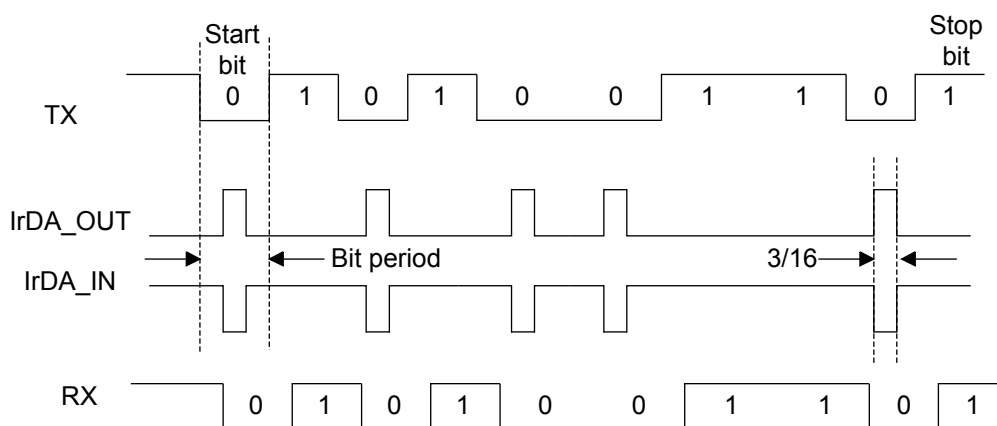

Figure 132. IrDA data modulation (3/16) - normal mode

20.5.17 Continuous communication using DMA

The USART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

Note:

Please refer to [Section 20.4 USART implementation](#) to determine if the DMA mode is supported. If DMA is not supported, use the USART as explained in [Section 20.5.4 Receiver](#). To perform continuous communication, when FIFO is disabled, you can clear the TXE/RXNE flags in the USART_ISR register.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the USART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to [Section 10 DMA controller \(DMA\)](#)) to the USART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

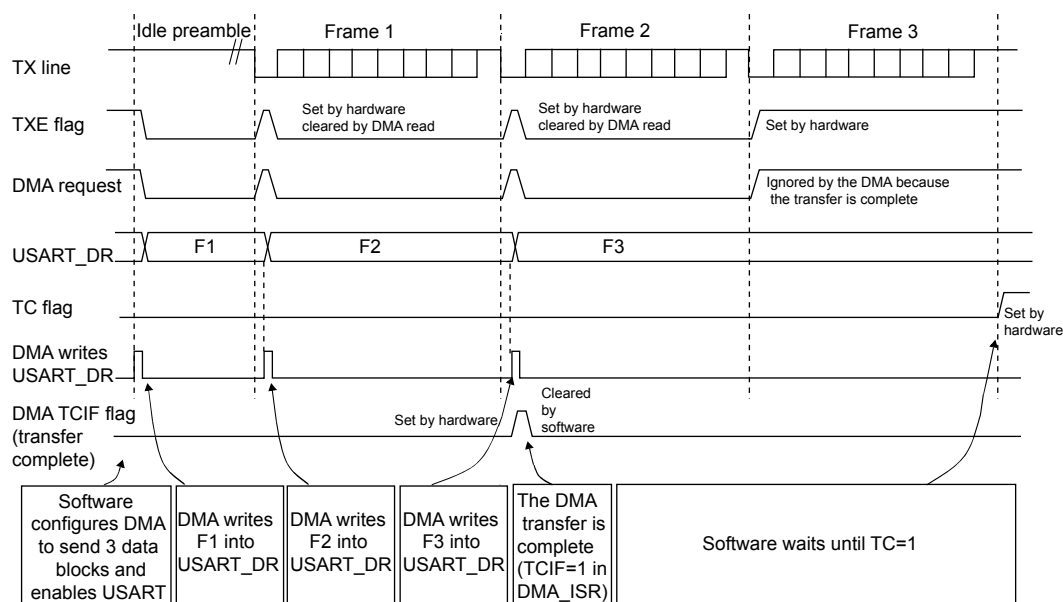

1. Write the USART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data are moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the USART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.

4. Configure the channel priority in the DMA register.
5. Configure DMA interrupt generation after half/ full transfer as required by the application.
6. Clear the TC flag in the USART_ISR register by setting the TCCF bit in the USART_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the USART communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or entering Stop mode. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

Figure 133. Transmission using DMA

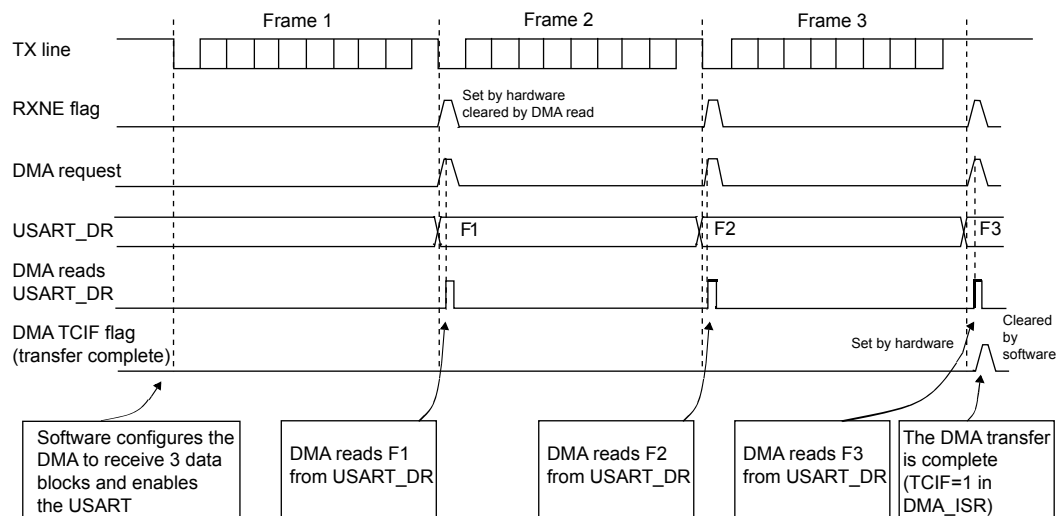

Note: When FIFO management is enabled, the DMA request is triggered by transmit FIFO not full (i.e. $TXFNF = 1$).

Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in USART_CR3 register. Data is loaded from the USART_RDR register to an SRAM area configured using the DMA peripheral (refer to [Section 10 DMA controller \(DMA\)](#)) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from USART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

Figure 134. Reception using DMA

Note: When FIFO management is enabled, the DMA request is triggered by ReceiveFIFO not empty (i.e. RXFNE = 1).

Error flagging and interrupt generation in multi-buffer communication

In multi-buffer communication if any error occurs during the transaction the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

20.5.18 RS232 hardware flow control and RS485 driver enable

It is possible to control the serial data flow between 2 devices by using the nCTS input and the nRTS output. Figure 135. Hardware flow control between 2 USARTs shows how to connect 2 devices in this mode.

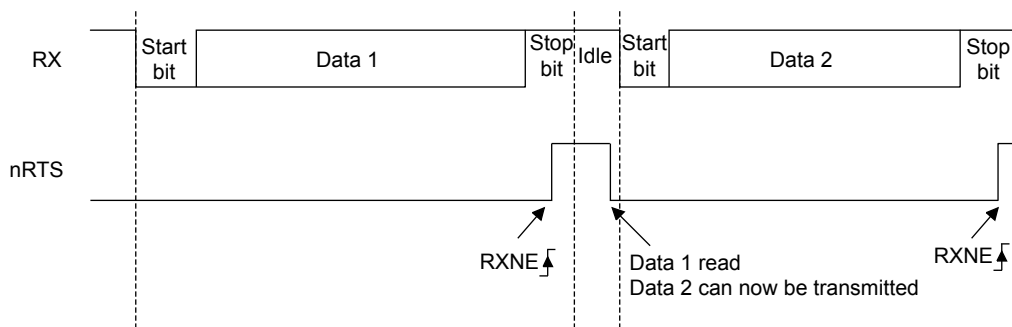

Figure 135. Hardware flow control between 2 USARTs

RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the USART_CR3 register).

RS232 RTS flow control

If the RTS flow control is enabled (RTSE=1), then nRTS is asserted (tied low) as long as the USART receiver is ready to receive new data. When the receive register is full, nRTS is deasserted, indicating that the transmission is expected to stop at the end of the current frame. [Figure 136. RS232 RTS flow control](#) shows an example of communication with RTS flow control enabled.

Figure 136. RS232 RTS flow control

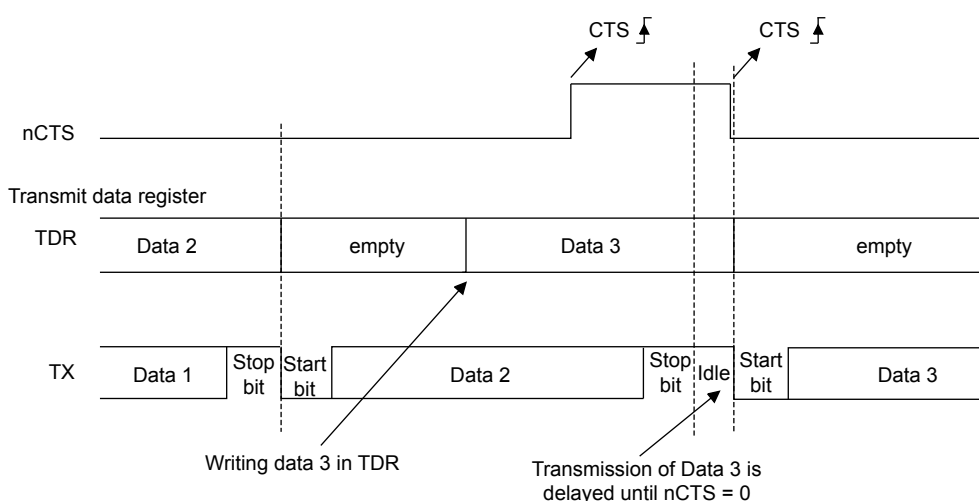

Note: When FIFO mode is enabled, nRTS is de-asserted only when RXFIFO is full.

RS232 CTS flow control

If the CTS flow control is enabled (CTSE=1), then the transmitter checks the nCTS input before transmitting the next frame. If nCTS is asserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE=0), otherwise the transmission does not occur. When nCTS is deasserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE=1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART_CR3 register is set. [Figure 137. RS232 CTS flow control](#) shows an example of communication with CTS flow control enabled.

Figure 137. RS232 CTS flow control

Note: For correct behavior, nCTS must be asserted at least 3 USART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

RS485 driver enable

The driver enable feature is enabled by setting bit DEM in the USART_CR3 control register. This allows the user to activate the external transceiver control, through the DE (driver enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the START bit. It is programmed using the DEAT [4:0] bit fields in the USART_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bit fields in the USART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the USART_CR3 control register.

In USART, the DEAT and DEDT are expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

20.6 USART interrupts

Table 71. USART interrupt requests

Interrupt event	Event flag	Enable control bit
Transmit data register empty	TXE	TXEIE
Transmit FIFO not full	TXFNF	TXFNFIE
Transmit FIFO empty	TXFE	TXFEIE
CTS interrupt	CTSIF	CTSIE
Transmission complete	TC	TCIE
Transmission complete before Guard Time	TCBGT	TCBGTIE
Receive data register not empty (data ready to be read)	RXNE	RXNEIE
Receive FIFO not empty	RXFNE	RXFNEIE
Receive FIFO full	RXFF	RXFFIE
Overrun error detected	ORE	RXNEIE/RXF- NEIE
Idle line detected	IDLE	IDLEIE
Parity error	PE	PEIE
LIN break	LBDF	LBDIE
Noise flag, overrun error and framing error in multi-buffer communication	NF or ORE or FE	EIE
Character match	CMF	CMIE
Receiver timeout error	RTOF	RTOIE
End of block	EOBF	EOBIE
SPI slave underrun error	UDR	EIE

These events generate an interrupt if the corresponding enable control bit is set.

20.7 USART registers

Refer to [Section 1.3 Acronyms](#) for a list of abbreviations used in register descriptions.

20.7.1 Control register 1 (USARTx_CR1)

Address offset: 0x00

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RXFFI E	TXFEIE	FIFOE N	M1	EOBIE	RTOIE	DEAT[4:0]					DEDT[4:0]				
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OVER8	CMIE	MME	M0	WAKE	PCE	PS	PEIE	TXEIE/ TXFNFI E	TCIE	RXNEIE /RXFNEIE	IDLEIE	TE	RE	Res.	UE
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw

Bit 31	RXFFIE : RXFIFO full interrupt enable. This bit is set and cleared by software. 0: Interrupt is inhibited 1: A USART interrupt is generated when RXFF=1 in the USART_ISR register Note: When FIFO mode is disabled, this bit is reserved and must be kept at reset value.
Bit 30	TXFEIE : TXFIFO empty interrupt enable. This bit is set and cleared by software. 0: Interrupt is inhibited 1: A USART interrupt is generated when TXFE=1 in the USART_ISR register Note: When FIFO mode is disabled, this bit is reserved and must be kept at reset value.
Bit 29	FIFOEN : FIFO mode enable. This bit is set and cleared by software. 0: FIFO mode is disabled 1: FIFO mode is enabled This bit field can only be written when the USART is disabled (UE=0). Note: FIFO mode can be used on standard UART communication, in SPI master/slave mode and in smartcard modes only. It must not be enabled in IrDA and LIN modes.
Bit 28	M1 : Word length. This bit, with bit 12 (M0) determines the word length. It is set or cleared by software. M[1:0] = 00: 1 Start bit, 8 data bits, n Stop bit M[1:0] = 01: 1 Start bit, 9 data bits, n Stop bit M[1:0] = 10: 1 Start bit, 7 Data bits, n Stop bit This bit can only be written when the USART is disabled (UE=0). Note: In 7-bits data length mode, the smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.
Bit 27	EOBIE : End of block interrupt enable. This bit is set and cleared by software. 0: Interrupt is inhibited 1: A USART interrupt is generated when the EOB flag is set in the USART_ISR register Note: If the USART does not support Smartcard mode, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation .
Bit 26	RTOIE : Receiver timeout interrupt enable. This bit is set and cleared by software.

	<p>0: Interrupt is inhibited</p> <p>1: A USART interrupt is generated when the RTOF bit is set in the USART_ISR register</p> <p>Note: If the USART does not support the Receiver timeout feature, this bit is reserved and forced by hardware to '0'. Section 20.4 USART implementation.</p>
Bits 25:21	<p>DEAT[4:0]: Driver enable assertion time.</p> <p>This 5-bit value defines the time between the activation of the DE (driver enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p> <p>Note: If the driver enable feature is not supported, this bit is reserved and must be kept cleared.</p> <p>Please refer to Section 20.4 USART implementation.</p>
Bits 20:16	<p>DEDT[4:0]: Driver enable deassertion time.</p> <p>This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (driver enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).</p> <p>If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p> <p>Note: If the driver enable feature is not supported, this bit is reserved and must be kept cleared. Please refer to Section 20.4 USART implementation.</p>
Bit 15	<p>OVER8: Oversampling mode.</p> <p>0: Oversampling by 16</p> <p>1: Oversampling by 8</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: In LIN, IrDA and Smartcard modes, this bit must be kept cleared.</p>
Bit 14	<p>CMIE: Character match interrupt enable. This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited</p> <p>1: A USART interrupt is generated when the CMF bit is set in the USART_ISR register</p>
Bit 13	<p>MME: Mute mode enable.</p> <p>This bit activates the mute mode function of the USART. When set, the USART can switch between the active and mute modes, as defined by the WAKE bit. It is set and cleared by software.</p> <p>0: Receiver in active mode permanently</p> <p>1: Receiver can switch between mute mode and active mode</p>
Bit 12	<p>M0: Word length.</p> <p>This bit, with bit 28 (M1) determines the word length. It is set or cleared by software.</p> <p>See bit 28 (M1) description.</p> <p>This bit can only be written when the USART is disabled (UE=0).</p>
Bit 11	<p>WAKE: Receiver wake-up method.</p> <p>This bit determines the USART wake-up method from mute mode. It is set or cleared by software.</p> <p>0: Idle line</p> <p>1: Address mark</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p>
Bit 10	<p>PCE: Parity control enable.</p> <p>This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).</p> <p>0: Parity control disabled</p> <p>1: Parity control enabled</p>

	This bit field can only be written when the USART is disabled (UE=0).
Bit 9	<p>PS: Parity selection.</p> <p>This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.</p> <p>0: Even parity 1: Odd parity</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p>
Bit 8	<p>PEIE: PE interrupt enable.</p> <p>This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited 1: A USART interrupt is generated whenever PE=1 in the USART_ISR register</p>
Bit 7	<p>TXEIE/TXFNFIE: Transmit data register empty/TXFIFO not full interrupt enable.</p> <p>This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited 1: A USART interrupt is generated whenever TXE/TXFNF=1 in the USART_ISR register</p>
Bit 6	<p>TCIE: Transmission complete interrupt enable. This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited 1: A USART interrupt is generated whenever TC=1 in the USART_ISR register</p>
Bit 5	<p>RXNEIE/RXFNEIE: Receive data register not empty/RXFIFO not empty interrupt enable.</p> <p>This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited 1: A USART interrupt is generated whenever ORE=1 or RXNE/RXFNE=1 in the USART_ISR register</p>
Bit 4	<p>IDLEIE: IDLE interrupt enable.</p> <p>This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited 1: A USART interrupt is generated whenever IDLE=1 in the USART_ISR register</p>
Bit 3	<p>TE: Transmitter enable.</p> <p>This bit enables the transmitter. It is set and cleared by software.</p> <p>0: Transmitter is disabled 1: Transmitter is enabled</p> <p>Note: During transmission, a “0” pulse on the TE bit (“0” followed by “1”) sends a preamble (idleline) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.</p> <p>In Smartcard mode, when TE is set there is a 1 bit-time delay before the transmission starts.</p>
Bit 2	<p>RE: Receiver enable.</p> <p>This bit enables the receiver. It is set and cleared by software.</p> <p>0: Receiver is disabled 1: Receiver is enabled and begins searching for a start bit</p>
Bit 1	Reserved, must be kept at reset value.
Bit 0	<p>UE: USART enable.</p> <p>When this bit is cleared, the USART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the USART is kept, but all the status flags in the USART_ISR are reset. This bit is set and cleared by software.</p> <p>0: USART prescaler and outputs disabled, low-power mode 1: USART enabled</p> <p>Note: In order to go into low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.</p>

	<p>The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.</p> <p>Note: In Smartcard mode, (SCEN = 1), the SCLK is always available when CLKEN = 1, regardless of the UE bit value.</p>
--	--

20.7.2 Control register 2 (USARTx_CR2)

Address offset: 0x04

Bits 31:28	<p>ADD[7:4]: Address of the USART node.</p> <p>This bit-field gives the address of the USART node or a character code to be recognized.</p> <p>This is used in multiprocessor communication during Mute mode or Stop mode for wakeup with 7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. It may also be used for character detection during normal reception, Mute mode inactive (for example, end of block detection in ModBus protocol). In this case, the whole received character (8-bit) is compared to the ADD[7:0] value and CMF flag is set on match.</p> <p>This bit field can only be written when reception is disabled (RE=0) or the USART is disabled (UE=0).</p>
Bits 27:24	<p>ADD[3:0]: Address of the USART node.</p> <p>This bit-field gives the address of the USART node or a character code to be recognized.</p> <p>This is used in multiprocessor communication during Mute mode or Stop mode, for wakeup with address mark detection.</p> <p>This bit field can only be written when reception is disabled (RE=0) or the USART is disabled (UE=0).</p>
Bit 23	<p>RTOEN: Receiver timeout enable.</p> <p>This bit is set and cleared by software. 0: Receiver timeout feature disabled 1: Receiver timeout feature enabled</p> <p>When this feature is enabled, the RTOF flag in the USART_ISR register is set if the RX line is idle (no reception) for the duration programmed in the RTOR (receiver timeout register).</p> <p>Note: If the USART does not support the Receiver timeout feature, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>
Bit 22:21	<p>ABRMOD[1:0]: Auto baud rate mode.</p> <p>These bits are set and cleared by software.</p> <p>00: Measurement of the start bit is used to detect the baud rate</p> <p>01: Falling edge to falling edge measurement (the received frame must start with a single bit = 1 -> Frame = Start10xxxxxx)</p> <p>10: 0x7F frame detection</p> <p>11: 0x55 frame detection</p> <p>This bit field can only be written when ABREN=0 or the USART is disabled (UE=0).</p> <p>Note: If DATAINV=1 and/or MSBFIRST=1 the patterns must be the same on the line, for example 0xAA for MSBFIRST).</p> <p>If the USART does not support the auto baud rate feature, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>
Bit 20	<p>ABREN: Auto baud rate enable.</p>

	<p>This bit is set and cleared by software. 0: Auto baud rate detection is disabled 1: Auto baud rate detection is enabled</p> <p>Note: If the USART does not support the auto baud rate feature, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>
Bit 19	<p>MSBFIRST: Most significant bit first.</p> <p>This bit is set and cleared by software.</p> <p>0: Data is transmitted/received with data bit 0 first, following the start bit</p> <p>1: Data is transmitted/received with the MSB (bit 7/8) first, following the start bit. This bit field can only be written when the USART is disabled (UE=0).</p>
Bit 18	<p>DATAINV: Binary data inversion.</p> <p>This bit is set and cleared by software.</p> <p>0: Logical data from the data register are sent/received in positive/direct logic. (1=H, 0=L)</p> <p>1: Logical data from the data register are sent/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p>
Bit 17	<p>TXINV: TX pin active level inversion. This bit is set and cleared by software.</p> <p>0: TX pin signal works using the standard logic levels (VDD=1/idle, Gnd=0/mark)</p> <p>1: TX pin signal values are inverted. (VDD=0/mark, Gnd=1/idle). This allows the use of an external inverter on the TX line.</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p>
Bit 16	<p>RXINV: RX pin active level inversion. This bit is set and cleared by software.</p> <p>0: RX pin signal works using the standard logic levels (VDD=1/idle, Gnd=0/mark)</p> <p>1: RX pin signal values are inverted. (VDD=0/mark, Gnd=1/idle). This allows the use of an external inverter on the RX line.</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p>
Bit 15	<p>SWAP: Swap TX/RX pins.</p> <p>This bit is set and cleared by software.</p> <p>0: TX/RX pins are used as defined in standard pinout</p> <p>1: The TX and RX pins functions are swapped. This helps to work in the case of a cross-wired connection to another UART.</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p>
Bit 14	<p>LINEN: LIN mode enable.</p> <p>This bit is set and cleared by software.</p> <p>0: LIN mode disabled</p> <p>1: LIN mode enabled</p> <p>The LIN mode enables the capability to send LIN Synch Breaks (13 low bits) using the SBKRQ bit in the USART_CR1 register, and to detect LIN Sync breaks.</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p> <p>Note: If the USART does not support LIN mode, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>
Bits 13:12	<p>STOP[1:0]: STOP bits.</p> <p>These bits are used for programming the stop bits.</p> <p>00: 1 stop bit</p> <p>01: 0.5 stop bit</p> <p>10: 2 stop bits</p> <p>11: 1.5 stop bits</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p>
Bit 11	<p>CLKEN: Clock enable.</p>

	<p>This bit allows the user to enable the SCLK pin.</p> <p>0: SCLK pin disabled 1: SCLK pin enabled</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: If neither synchronous mode nor Smartcard mode is supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p> <p>Note: In Smartcard mode, in order to provide correctly the SCLK clock to the smartcard, the steps below must be respected:</p> <ul style="list-style-type: none"> • UE=0 • SCEN=1 • GTPR configuration • CLKEN=1 • UE=1
Bit 10	<p>CPOL: Clock polarity.</p> <p>This bit allows the user to select the polarity of the clock output on the SCLK pin in synchronous mode. It works in conjunction with the CPHA bit to produce the desired clock/data relationship.</p> <p>0: Steady low value on SCLK pin outside transmission window 1: Steady high value on SCLK pin outside transmission window</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: If synchronous mode is not supported, this bit is reserved and forced by hardware to '0'.</p> <p>Please refer to Section 20.4 USART implementation.</p>
Bit 9	<p>CPHA: Clock phase.</p> <p>This bit is used to select the phase of the clock output on the SCLK pin in synchronous mode. It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see Figure 119. Data sampling when oversampling by 16 and Figure 120. Data sampling when oversampling by 8).</p> <p>0: The first clock transition is the first data capture edge 1: The second clock transition is the first data capture edge</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: If synchronous mode is not supported, this bit is reserved and forced by hardware to '0'.</p> <p>Please refer to Section 20.4 USART implementation.</p>
Bit 8	<p>LBCL: Last bit clock pulse.</p> <p>This bit is used to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the SCLK pin in synchronous mode.</p> <p>0: The clock pulse of the last data bit is not output to the SCLK pin 1: The clock pulse of the last data bit is output to the SCLK pin</p> <p>Caution: The last bit is the 7th or 8th or 9th data bit transmitted depending on the 7 or 8 or 9 bit format selected by the M bit in the USART_CR1 register.</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: If synchronous mode is not supported, this bit is reserved and forced by hardware to '0'.</p> <p>Please refer to Section 20.4 USART implementation.</p>
Bit 7	Reserved, must be kept at reset value.
Bit 6	<p>LBDIE: LIN break detection interrupt enable.</p> <p>Break interrupt mask (break detection using break delimiter).</p> <p>0: Interrupt is inhibited 1: An interrupt is generated whenever LBDF=1 in the USART_ISR register</p> <p>Note: If LIN mode is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>
Bit 5	<p>LBDL: LIN break detection length.</p> <p>This bit is for selection between 11 bit or 10 bit break detection.</p>

	0: 10-bit break detection 1: 11-bit break detection This bit can only be written when the USART is disabled (UE=0). Note: If LIN mode is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation .
Bit 4	ADD7 : 7-bit address detection/4-bit address detection. This bit is for selection between 4-bit address detection or 7-bit address detection. 0: 4-bit address detection. 1: 7-bit address detection (in 8-bit data mode) This bit can only be written when the USART is disabled (UE=0). Note: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.
Bit 3	DIS_NSS When the DIS_NSS bit is set, the NSS pin input is ignored. 0: SPI slave selection depends on NSS input pin 1: SPI slave is always selected and NSS input pin is ignored Note: When SPI slave mode is not supported, this bit is reserved and must be kept at reset value.
Bit 2	Reserved, must be kept at reset value.
Bit 1	Reserved, must be kept at reset value.
Bit 0	SLVEN : Synchronous slave mode enable. When the SLVEN bit is set, the synchronous slave mode is enabled. 0: Slave mode disabled 1: Slave mode enabled Note: When SPI slave mode is not supported, this bit is reserved and must be kept at reset value.

Note: The CPOL, CPHA and LBCL bits should not be written while the transmitter is enabled.

20.7.3 Control register 3 (USARTx_CR3)

Address offset: 0x08

Reset value: 0x0000

Bit28	RXFTIE : RXFIFO threshold interrupt enable. This bit is set and cleared by software.

	<p>0: Interrupt is inhibited</p> <p>1: A USART interrupt is generated when Receive FIFO reaches the threshold programmed in RXFTCFG</p>
Bits 27:25	<p>RXFTCFG: Receive FIFO threshold configuration.</p> <p>000: Receive FIFO reaches 1/8 of its depth</p> <p>001: Receive FIFO reaches 1/4 of its depth</p> <p>010: Receive FIFO reaches 1/2 of its depth</p> <p>011: Receive FIFO reaches 3/4 of its depth</p> <p>100: Receive FIFO reaches 7/8 of its depth</p> <p>101: Receive FIFO becomes full</p> <p>Remaining combinations: Reserved.</p>
Bit 24	<p>TCBGTIE: Transmission complete before Guard Time, interrupt enable.</p> <p>This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited</p> <p>1: A USART interrupt is generated whenever TCBGT=1 in the USARTx_ISR register</p> <p>Note: If the USART does not support the Smartcard mode, this bit is reserved and forced by hardware to '0'.</p>
Bit 23	<p>TXFTIE: TXFIFO threshold interrupt enable.</p> <p>This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited</p> <p>1: A USART interrupt is generated when TXFIFO reaches the threshold programmed in TXFTCFG</p>
Bits 22:20	<p>Reserved, must be kept at reset value.</p>
Bit 19:17	<p>SCARCNT[2:0]: Smartcard auto-retry count.</p> <p>This bit-field specifies the number of retries in transmit and receive, in Smartcard mode. In transmission mode, it specifies the number of automatic retransmission retries, before generating a transmission error (FE bit set).</p> <p>In reception mode, it specifies the number of erroneous reception trials, before generating a reception error (RXNE/RXFNE and PE bits set).</p> <p>This bit field must be programmed only when the USART is disabled (UE=0).</p> <p>When the USART is enabled (UE=1), this bit field may only be written to 0x0, in order to stop retransmission.</p> <p>0x0: Retransmission disabled - No automatic retransmission in transmit mode</p> <p>0x1 to 0x7: Number of automatic retransmission attempts (before signaling error)</p> <p>Note: If Smartcard mode is not supported, this bit is reserved and forced by hardware to '0'.</p> <p>Refer to Section 20.4 USART implementation.</p>
Bit 16	<p>Reserved, must be kept at reset value.</p>
Bit 15	<p>DEP: Driver enable polarity selection.</p> <p>0: DE signal is active high</p> <p>1: DE signal is active low</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: If the driver enable feature is not supported, this bit is reserved and must be kept cleared. Refer to Section 20.4 USART implementation.</p>
Bit 14	<p>DEM: Driver enable mode.</p> <p>This bit allows the user to activate the external transceiver control, through the DE signal.</p> <p>0: DE function is disabled</p> <p>1: DE function is enabled. The DE signal is output on the RTS pin.</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: If the driver enable feature is not supported, this bit is reserved and must be kept cleared.</p> <p>Section 20.4 USART implementation.</p>

Bit 13	<p>DDRE: DMA disable on reception error.</p> <p>0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data are transferred (used for Smartcard mode).</p> <p>1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR=0) or clear RXNE (RXFNE in case FIFO mode is enabled) before clearing the error flag.</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: The reception errors are: parity error, framing error or noise error.</p>
Bit 12	<p>OVRDIS: Overrun disable.</p> <p>This bit is used to disable the receive overrun detection.</p> <p>0: Overrun error flag, ORE, is set when received data is not read before receiving new data</p> <p>1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the USART_RDR register. When FIFO mode is enabled, the RXFIFO is bypassed and data are written directly in USARTx_RDR register. Even when FIFO management is enabled, the RXNE flag is to be used.</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: This control bit allows checking the communication flow w/o reading the data.</p>
Bit 11	<p>ONEBIT: One sample bit method enable.</p> <p>This bit allows the user to select the sample method. When the one sample bit method is selected the noise detection flag (NF) is disabled.</p> <p>0: Three sample bit method</p> <p>1: One sample bit method</p> <p>This bit can only be written when the USART is disabled (UE=0).</p>
Bit 10	<p>CTSIE: CTS interrupt enable.</p> <p>0: Interrupt is inhibited</p> <p>1: An interrupt is generated whenever CTSIF=1 in the USART_ISR register</p> <p>Note: If the hardware flow control feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 20.4 USART implementation.</p>
Bit 9	<p>CTSE: CTS enable.</p> <p>0: CTS hardware flow control disabled</p> <p>1: CTS mode enabled, data are only transmitted when the nCTS input is asserted (tied to 0). If the nCTS input is deasserted while data is being transmitted, then the transmission is completed before stopping. If data are written into the data register while nCTS is asserted, the transmission is postponed until nCTS is asserted.</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: If the hardware flow control feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 20.4 USART implementation.</p>
Bit 8	<p>RTSE: RTS enable.</p> <p>0: RTS hardware flow control disabled</p> <p>1: RTS output enabled, data are only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The nRTS output is asserted (pulled to 0) when data can be received.</p> <p>This bit can only be written when the USART is disabled (UE=0).</p> <p>Note: If the hardware flow control feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 20.4 USART implementation.</p>
Bit 7	<p>DMAT: DMA enable transmitter. This bit is set/reset by software.</p> <p>1: DMA mode is enabled for transmission</p> <p>0: DMA mode is disabled for transmission</p>
Bit 6	<p>DMAR: DMA enable receiver. This bit is set/reset by software.</p> <p>1: DMA mode is enabled for reception</p>

	0: DMA mode is disabled for reception
Bit 5	<p>SCEN: Smartcard mode enable. This bit is used for enabling Smartcard mode.</p> <p>0: Smartcard mode disabled 1: Smartcard mode enabled</p> <p>This bit field can only be written when the USART is disabled (UE=0). Note: If the USART does not support Smartcard mode, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>
Bit 4	<p>NACK: Smartcard NACK enable.</p> <p>0: NACK transmission in case of parity error is disabled 1: NACK transmission during parity error is enabled</p> <p>This bit field can only be written when the USART is disabled (UE=0). Note: If the USART does not support Smartcard mode, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>
Bit 3	<p>HDSEL: Half-duplex selection. Selection of single-wire half-duplex mode.</p> <p>0: Half-duplex mode is not selected 1: Half-duplex mode is selected</p> <p>This bit can only be written when the USART is disabled (UE=0).</p>
Bit 2	<p>IRLP: IrDA low-power.</p> <p>This bit is used for selecting between normal and low-power IrDA modes.</p> <p>0: Normal mode 1: Low-power mode</p> <p>This bit can only be written when the USART is disabled (UE=0). Note: If IrDA mode is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation</p>
Bit 1	<p>IREN: IrDA mode enable.</p> <p>This bit is set and cleared by software.</p> <p>0: IrDA disabled 1: IrDA enabled</p> <p>This bit can only be written when the USART is disabled (UE=0). Note: If IrDA mode is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>
Bit 0	<p>EIE: Error interrupt enable.</p> <p>Error interrupt enable bit is required to enable interrupt generation in case of a framing error, overrun error noise flag or SPI slave underrun error (FE=1 or ORE=1 or NF=1 or UDR = 1 in the USART_ISR register).</p> <p>0: Interrupt is inhibited 1: An interrupt is generated when FE=1 or ORE=1 or NF=1 or UDR = 1 (in SPI slave mode) in the USART_ISR register</p>

20.7.4

Baud rate register (USARTx_BRR)

This register can only be written when the USART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

BRR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16	Reserved, must be kept at reset value.
Bits 15:4	BRR[15:4] BRR[15:4] = USARTDIV[15:4]
Bits 3:0	BRR[3:0] When OVER8 = 0, BRR[3:0] = USARTDIV[3:0]. When OVER8 = 1: BRR[2:0] = USARTDIV[3:0] shifted 1 bit to the right. BRR[3] must be kept cleared.

20.7.5 Guard Time and prescaler register (USARTx_GTPR)

Address offset: 0x10

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GT[7:0]								PSC[7:0]							
rw								rw							

Bits 31:16	Reserved, must be kept at reset value.
Bits 15:8	GT[7:0]: Guard Time value. This bit-field is used to program the Guard Time value in terms of number of baud clock periods. This is used in smartcard mode. The transmission complete flag is set after this Guard Time value. This bit field can only be written when the USART is disabled (UE=0). Note: If smartcard mode is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 20.4 USART implementation .
Bits 7:0	PSC[7:0]: Prescaler value. In IrDA Low-power and normal IrDA mode: PSC[7:0] = IrDA Normal and Low-Power Baud Rate Used for programming the prescaler for dividing the USART source clock to achieve the low-power frequency: The source clock is divided by the value given in the register (8 significant bits): 00000000: Reserved - do not program this value 00000001: Divides the source clock by 1 00000010: Divides the source clock by 2

...	<p>In Smartcard mode:</p> <p>PSC[4:0]: Prescaler value</p> <p>Used for programming the prescaler for dividing the USART source clock to provide the Smartcard clock.</p> <p>The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency:</p> <p>00000: Reserved - do not program this value</p> <p>00001: Divides the source clock by 2</p> <p>00010: Divides the source clock by 4</p> <p>00011: Divides the source clock by 6</p> <p>...</p> <p>This bit field can only be written when the USART is disabled (UE=0).</p> <p>Note: Bits [7:5] must be kept cleared if Smartcard mode is used.</p> <p>This bit field is reserved and forced by hardware to '0' when the Smartcard and IrDA modes are not supported. Refer to Section 20.4 USART implementation.</p>
-----	---

20.7.6 Receiver timeout register (USARTx_RTOR)

Address offset: 0x14

Reset value: 0x0000

BLEN[7:0]								RTO[23:16]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24	<p>BLEN[7:0]: Block length.</p> <p>This bit-field gives the block length in Smartcard T=1 Reception. Its value equals the number of information characters + the length of the epilogue field (1-LEC/2-CRC) - 1.</p> <p>Examples:</p> <p>BLEN = 0 -> 0 information characters + LEC</p> <p>BLEN = 1 -> 0 information characters + CRC</p> <p>BLEN = 255 -> 254 information characters + CRC (total 256 characters)</p> <p>In Smartcard mode, the Block length counter is reset when TXE=0 (TXFE=0 in case FIFO mode is enabled).</p> <p>This bit-field can be used also in other modes. In this case, the Block length counter is reset when RE=0 (receiver disabled) and/or when the EOBCF bit is written to 1.</p> <p>Note: This value can be programmed after the start of the block reception (using the data from the LEN character in the prologue field). It must be programmed only once per received block.</p>
Bits 23:0	<p>RTO[23:0]: Receiver timeout value.</p> <p>This bit-field gives the Receiver timeout value in terms of number of baud clocks.</p> <p>In standard mode, the RTOF flag is set if, after the last received character, no new start bit is detected for more than the RTO value.</p> <p>In Smartcard mode, this value is used to implement the CWT and BWT. See Smartcard section for more details. In the standard, the CWT/BWT measurement is done starting from the start bit of the last received character.</p> <p>Note: This value must only be programmed once per received character.</p>

Note: *RTOR can be written on the fly. If the new value is lower than or equal to the counter, the RTOF flag is set. This register is reserved and forced by hardware to “0x00000000” when the receiver timeout feature is not supported. Please refer to [Section 20.4 USART implementation](#).*

20.7.7 Request register (USARTx_RQR)

Address offset: 0x18

Reset value: 0x0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TXFRQ	RXFRQ	MMRQ	SBKRQ	ABRRQ
											w_r0	w_r0	w_r0	w_r0	w_r0

Bits 31:5	Reserved, must be kept at reset value.
Bit 4	<p>TXFRQ: Transmit data flush request.</p> <p>When FIFO mode is disabled, writing 1 to this bit sets the TXE flag.</p> <p>This allows the transmit data to be discarded. This bit must be used only in Smartcard mode, when data has not been sent due to errors (NACK) and the FE flag is active in the USART_ISR register. If the USART does not support Smartcard mode, this bit is reserved and forced by hardware to '0'.</p> <p>When FIFO is enabled, TXFRQ bit is set to flush the whole FIFO. This sets the flag TXFE (transmit FIFO empty, bit 23 in the USART_ISR register). Flushing the transmit FIFO is supported in both UART and Smartcard modes.</p> <p>Note: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data is written in the data register.</p>
Bit 3	<p>RXFRQ: Receive data flush request.</p> <p>Writing 1 to this bit empties the entire receive FIFO, i.e. clears the bit RXFNE.</p> <p>This allows the received data to be discarded without reading them, and avoid an overrun condition.</p>
Bit 2	<p>MMRQ: Mute mode request.</p> <p>Writing 1 to this bit puts the USART in mute mode and resets the RWU flag.</p>
Bit 1	<p>SBKRQ: Send break request.</p> <p>Writing 1 to this bit sets the SBKF flag and requests to send a BREAK on the line, as soon as the transmit machine is available.</p> <p>Note: In the case the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.</p>
Bit 0	<p>ABRRQ: Auto baud rate request.</p> <p>Writing 1 to this bit resets the ABRF flag in the USART_ISR and requests an automatic baud rate measurement on the next received data frame.</p> <p>Note: If the USART does not support the auto baud rate feature, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>

20.7.8 Interrupt and status register (USARTx_ISR)

Address offset: 0x1C

Reset value: 0x00C0 (in case FIFO disabled).

Reset value: 0x2800C0 (in case FIFO/Smartcard mode enabled).

Reset value: 0x0800C0 (in case FIFO enabled/Smartcard mode disabled).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TXFT	RXFT	TCBGT	RXFF	TXFE	RE ACK	TE ACK	Res.	RWU	SBKF	CMF	BUSY
				r	r	r	r	r	r	r		r	r	r	r

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28	Reserved, must be kept at reset value.
Bit 27	<p>TXFT: TXFIFO threshold flag.</p> <p>This bit is set by hardware when the TXFIFO reaches the programmed threshold in TXFTCFG in USARTx_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit = 1 (bit 31) in the USART_CR3 register.</p> <p>0: TXFIFO doesn't reach the programmed threshold 1: TXFIFO reached the programmed threshold</p>
Bit 26	<p>RXFT: RXFIFO threshold flag.</p> <p>This bit is set by hardware when the programmed threshold in RXFTCFG in USARTx_CR3 register is reached. This means that there are (RXFTCFG - 1) data in the Receive FIFO and one data in the USART_RDR register. An interrupt is generated if the RXFTIE bit = 1 (bit 27) in the USART_CR3 register.</p> <p>0: Receive FIFO does not reach the programmed threshold 1: Receive FIFO reached the programmed threshold</p> <p>Note: When the RXFTCFG threshold is configured to «101», RXFT flag is set if 16 data are available, i.e. 15 data in the RXFIFO and 1 data in the USARTx_RDR. Consequently, the 17th received data do not cause an overrun error. The overrun error occurs after receiving the 18th data.</p>
Bit 25	<p>TCBGT: Transmission complete before Guard Time flag.</p> <p>This bit indicates when the last data written in the USART_TDR has been transmitted correctly out of the shift register .</p> <p>It is set by hardware in Smartcard mode, if the transmission of a frame containing data is complete and if there is no NACK from the smartcard. An interrupt is generated if TCBGTIE=1 in the USART_CR3 register. It is cleared by software, writing 1 to the TCBGTIE in the USART_ICR register or by a write to the USART_TDR register.</p> <p>0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card) 1: Transmission is complete successfully (before Guard Time completion and there is no NACK from the smart card).</p> <p>Note: If the USART does not support the Smartcard mode, this bit is reserved and forced by hardware to '0'. If the USART supports the Smartcard mode and the Smartcard mode is enabled, the TCBGT reset value is "1".</p>
Bit 24	<p>RXFF: RXFIFO full.</p> <p>This bit is set by hardware when RXFIFO is full.</p> <p>An interrupt is generated if the RXFFIE bit = 1 in the USART_CR1 register.</p> <p>0: RXFIFO is not full 1: RXFIFO is full</p>
Bit 23	<p>TXFE: TXFIFO empty.</p> <p>This bit is set by hardware when TXFIFO is Empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the USART_RQR register.</p> <p>An interrupt is generated if the TXFEIE bit = 1 (bit 30) in the USART_CR1 register.</p> <p>0: TXFIFO is not empty 1: TXFIFO is empty</p>
Bit 22	<p>REACK: Receive enable acknowledge flag.</p> <p>This bit is set/reset by hardware, when the receive enable value is taken into account by the USART.</p>

	<p>It can be used to verify that the USART is ready for reception before entering stop mode.</p> <p>Note: If the USART does not support the wakeup from Stop feature, this bit is reserved and forced by hardware to '0'.</p>
Bit 21	<p>TEACK: transmit enable acknowledge flag.</p> <p>This bit is set/reset by hardware, when the transmit enable value is taken into account by the USART.</p> <p>It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the USART_CR1 register, in order to respect the TE=0 minimum period.</p>
Bit 20	Reserved, must be kept at reset value.
Bit 19	<p>RWU: Receiver wakeup from Mute mode.</p> <p>This bit indicates if the USART is in mute mode. It is cleared/set by hardware when a wakeup/mute sequence is recognized. The mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.</p> <p>When wakeup on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.</p> <p>0: Receiver in active mode 1: Receiver in mute mode</p> <p>Note: If the USART does not support the wakeup from stop feature, this bit is reserved and forced by hardware to '0'.</p>
Bit 18	<p>SBKF: Send break flag.</p> <p>This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.</p> <p>0: No break character is transmitted 1: Break character is transmitted</p>
Bit 17	<p>CMF: Character match flag.</p> <p>This bit is set by hardware, when the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register.</p> <p>An interrupt is generated if CMIE=1 in the USART_CR1 register.</p> <p>0: No character match detected 1: Character match detected</p>
Bit 16	<p>BUSY: Busy flag.</p> <p>This bit is set and reset by hardware. It is active when a communication is on-going on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).</p> <p>0: USART is idle (no reception) 1: Reception on-going</p>
Bit 15	<p>ABRF: Auto baud rate flag.</p> <p>This bit is set by hardware when the automatic baud rate has been set (RXNE is also set, generating an interrupt if RXNEIE=1) or when the auto baud rate operation was completed without success (ABRE=1) (ABRE, RXNE and FE are also set in this case).</p> <p>It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART_RQR register.</p> <p>Note: If the USART does not support the auto baud rate feature, this bit is reserved and forced by hardware to '0'.</p>
Bit 14	<p>ABRE: Auto baud rate error.</p> <p>This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed).</p> <p>It is cleared by software, by writing 1 to the ABRRQ bit in the USART_CR3 register.</p> <p>Note: If the USART does not support the auto baud rate feature, this bit is reserved and forced by hardware to '0'.</p>
Bit 13	<p>UDR: SPI slave underrun error flag.</p> <p>In slave transmission mode, this flag is set when the first clock for data transmission appears while the software has not yet loaded any value into USARTx_DR.</p> <p>0: No underrun error 1: underrun error</p>

	<p>Note: If the USART does not support the SPI slave mode, this bit is reserved and forced by hardware to '0'.</p>
Bit 12	<p>EOBF: End of block flag.</p> <p>This bit is set by hardware when a complete block has been received (for example T=1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.</p> <p>An interrupt is generated if the EOBFIE=1 in the USART_CR2 register.</p> <p>It is cleared by software, writing 1 to the EOBCF in the USART_ICR register.</p> <p>0: End of block not reached 1: End of block (number of characters) reached</p> <p>Note: If Smartcard mode is not supported, this bit is reserved and forced by hardware to '0'.</p> <p>Please refer to Section 20.4 USART implementation.</p>
Bit 11	<p>RTOF: Receiver timeout.</p> <p>This bit is set by hardware when the timeout value programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.</p> <p>An interrupt is generated if RTOIE=1 in the USART_CR2 register.</p> <p>In Smartcard mode, the timeout corresponds to the CWT or BWT timings.</p> <p>0: Timeout value not reached 1: Timeout value reached without any data reception</p> <p>Note: If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), the RTOF flag is set.</p> <p>The counter counts even if RE=0 but RTOF is set only when RE=1. If the timeout has already elapsed when RE is set, then RTOF is set.</p> <p>If the USART does not support the receiver timeout feature, this bit is reserved and forced by hardware to '0'.</p>
Bit 10	<p>CTS: CTS flag.</p> <p>This bit is set/reset by hardware. It is an inverted copy of the status of the nCTS input pin.</p> <p>0: nCTS line set 1: nCTS line reset</p> <p>Note: If the hardware flow control feature is not supported, this bit is reserved and forced by hardware to '0'.</p>
Bit 9	<p>CTSIF: CTS interrupt flag.</p> <p>This bit is set by hardware when the nCTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.</p> <p>An interrupt is generated if CTSIE=1 in the USART_CR3 register.</p> <p>0: No change occurred on the nCTS status line 1: A change occurred on the nCTS status line</p> <p>Note: If the hardware flow control feature is not supported, this bit is reserved and forced by hardware to '0'.</p>
Bit 8	<p>LBDF: LIN break detection flag.</p> <p>This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDICF in the USART_ICR.</p> <p>An interrupt is generated if LBDIE=1 in the USART_CR2 register.</p> <p>0: LIN Break not detected 1: LIN break detected</p> <p>Note: If the USART does not support LIN mode, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>
Bit 7	<p>TXE/TXFNF: Transmit data register empty/TXFIFO not full.</p> <p>When FIFO mode is disabled, TXE is set by hardware when the content of the USARTx_TDR register has been transferred into the shift register. It is cleared by a write to the USARTx_TDR register. The TXE flag can also be set by writing 1 to the TXFRQ in the USART_RQR register, in order to discard the data (only in Smartcard T=0 mode, in case of transmission failure).</p>

	<p>When FIFO mode is enabled, TXFNF is set by hardware when TXFIFO is not full, and so data can be written in the USART_TDR. Every write in the USART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data cannot be written into the USART_TDR.</p> <p>Note: The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF should be checked prior to writing in TXFIFO. (TXFNF and TXFE are set at the same time).</p> <p>An interrupt is generated if the TXEIE/TXFNFIE bit = 1 in the USART_CR1 register.</p> <p>0: Data register is full/transmit FIFO is full</p> <p>1: Data register/transmit FIFO is not full</p> <p>Note: This bit is used during single buffer transmission.</p>
Bit 6	<p>TC: Transmission complete</p> <p>This bit indicates when the last data written in the USART_TDR has been transmitted out of the shift register.</p> <p>It is set by hardware if the transmission of a frame containing data is complete and if TXE/TXFE is set. An interrupt is generated if TCIE=1 in the USART_CR1 register. It is cleared by software, writing 1 to the TCCF in the USART_ICR register or by a write to the USART_TDR register.</p> <p>An interrupt is generated if TCIE=1 in the USART_CR1 register.</p> <p>0: Transmission is not complete</p> <p>1: Transmission is complete</p> <p>Note: If TE bit is reset and no transmission is on-going, the TC bit is set immediately.</p>
Bit 5	<p>RXNE/RXFNE: Read data register not empty/RXFIFO not empty.</p> <p>RXNE bit is set by hardware when the content of the USARTx_RDR shift register has been transferred to the USARTx_RDR register. It is cleared by a read to the USARTx_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USARTx_RQR register. RXFNE bit is set by hardware when the RXFIFO is not empty, and so data can be read from the USART_RDR register. Every read of the USART_RDR frees a location in the RXFIFO. It is cleared when the RXFIFO is empty.</p> <p>The RXNE/RXFNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register.</p> <p>An interrupt is generated if RXNEIE/RXFNEIE=1 in the USART_CR1 register.</p> <p>0: Data is not received</p> <p>1: Received data is ready to be read</p>
Bit 4	<p>IDLE: Idle line detected.</p> <p>This bit is set by hardware when an idle line is detected. An interrupt is generated if IDLEIE=1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART_ICR register.</p> <p>0: No idle line is detected</p> <p>1: Idle line is detected</p> <p>Note: The IDLE bit is not set again until the RXNE bit has been set (i.e. a new idle line occurs).</p> <p>If mute mode is enabled (MME=1), IDLE is set if the USART is not mute (RWU=0), whatever the mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.</p>
Bit 3	<p>ORE: Overrun error.</p> <p>This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the USARTx_RDR register while RXNE=1 (RXFF=1 in case FIFO mode is enabled). It is cleared by a software, writing 1 to the ORECF, in the USARTx_ICR register.</p> <p>An interrupt is generated if RXNEIE/ RXFNEIE=1 or EIE=1 in the USARTx_CR1 register.</p> <p>0: No overrun error</p> <p>1: Overrun error is detected</p> <p>Note: When this bit is set, the USART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi-buffer communication if the EIE bit is set.</p> <p>This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the USART_CR3 register.</p>
Bit 2	<p>NF: START bit noise detection flag.</p> <p>This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NFCF bit in the USART_ICR register.</p> <p>0: No noise is detected</p>

	<p>1: Noise is detected</p> <p>Note: This bit does not generate an interrupt as it appears at the same time as the RXNE/RXFNE bit which itself generates an interrupt. An interrupt is generated when the NF flag is set during multi-buffer communication if the EIE bit is set.</p> <p>Note: When the line is noise-free, the NF flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (refer to Section 20.5.6 Tolerance of the USART receiver to clock deviation).</p> <p>Note: In FIFO mode, this error is associated with the character in the USARTx_RDR.</p>
Bit 1	<p>FE: Framing error.</p> <p>This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART_ICR register. In Smartcard mode, in transmission, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).</p> <p>An interrupt is generated if EIE=1 in the USART_CR1 register.</p> <p>0: No framing error is detected</p> <p>1: Framing error or break character is detected</p> <p>Note: In FIFO mode, this error is associated with the character in the USARTx_RDR.</p>
Bit 0	<p>PE: Parity error.</p> <p>This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the USART_ICR register.</p> <p>An interrupt is generated if PEIE=1 in the USART_CR1 register.</p> <p>0: No parity error</p> <p>1: Parity error</p>

Note: In FIFO mode, this error is associated with the character in the USARTx_RDR.

20.7.9 Interrupt flag clear register (USART_ICR)

Address offset: 0x20

Reset value: 0x0000

Bits 31:20	Reserved, must be kept at reset value.
Bit 19:18	Reserved, must be kept at reset value.
Bit 17	<p>CMCF: Character match clear flag.</p> <p>Writing 1 to this bit clears the CMF flag in the USART_ISR register.</p>
Bit 16:14	Reserved, must be kept at reset value.
Bit 13	<p>UDRCF: SPI slave underrun clear flag.</p> <p>Writing 1 to this bit clears the UDRF flag in the USART_ISR register.</p> <p>Note: If the USART does not support SPI slave mode, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation.</p>
Bit 12	<p>EOBCF: End of block clear flag.</p> <p>Writing 1 to this bit clears the EOBF flag in the USART_ISR register.</p>

	Note: If the USART does not support Smartcard mode, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation .
Bit 11	RTOCF : Receiver timeout clear flag. Writing 1 to this bit clears the RTOF flag in the USART_ISR register. Note: If the USART does not support the receiver timeout feature, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation .
Bit 10	Reserved, must be kept at reset value.
Bit 9	CTSCF : CTS clear flag. Writing 1 to this bit clears the CTSIF flag in the USART_ISR register. Note: If the hardware flow control feature is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation .
Bit 8	LBDCF : LIN break detection clear flag. Writing 1 to this bit clears the LBDF flag in the USART_ISR register. Note: If LIN mode is not supported, this bit is reserved and forced by hardware to '0'. Please refer to Section 20.4 USART implementation .
Bit 7	TCBGTCF : Transmission complete before Guard Time clear flag writing 1 to this bit clears the TCBGT flag in the USART_ISR register.
Bit 6	TCCF : Transmission complete clear flag writing 1 to this bit clears the TC flag in the USART_ISR register.
Bit 5	TXFECF : TXFIFO empty clear flag. Writing 1 to this bit clears the TXFE flag in the USART_ISR register.
Bit 4	IDLECF : Idle line detected clear flag. Writing 1 to this bit clears the IDLE flag in the USART_ISR register.
Bit 3	ORECF : Overrun error clear flag. Writing 1 to this bit clears the ORE flag in the USART_ISR register.
Bit 2	NECF : Noise detected clear flag. Writing 1 to this bit clears the NF flag in the USART_ISR register.
Bit 1	FE CF : Framing error clear flag. Writing 1 to this bit clears the FE flag in the USART_ISR register.
Bit 0	PECF : Parity error clear flag. Writing 1 to this bit clears the PE flag in the USART_ISR register.

20.7.10 Receive data register (USART_RDR)

Address offset: 0x24

Reset value: undefined

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	RDR[8:0]								
							r	r	r	r	r	r	r	r	r

Bits 31:9	Reserved, must be kept at reset value.
Bits 8:0	RDR[8:0] : Receive data value. Contains the received data character. The RDR register provides the parallel interface between the input shift register and the

	internal bus (see Figure 113. USART block diagram). When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.
--	---

20.7.11 Transmit data register (USART_TDR)

Address offset: 0x28

Reset value: undefined

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	TDR[8:0]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:9	Reserved, must be kept at reset value.
Bits 8:0	TDR[8:0]: Transmit data value. Contains the data character to be transmitted. The USARTx_TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 113. USART block diagram). When transmitting with the parity enabled (PCE bit set to 1 in the USART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity. Note: This register must be written only when TXE/TXFNF=1.

20.7.12 Prescaler register (USARTx_PRESC)

This register can only be written when the USART is disabled (UE=0).

Address offset: 0x2C

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRESCALER[3:0]			
												rw	rw	rw	rw

Bits 31:4	Reserved, must be kept at reset value.
Bits 3:0	PRESCALER[3:0]: Clock prescaler. The USART input clock can be divided by a prescaler: 0000: Input clock not divided 0001: Input clock divided by 2 0010: Input clock divided by 4

0011: Input clock divided by 6
0100: Input clock divided by 8
0101: Input clock divided by 10
0110: Input clock divided by 12
0111: Input clock divided by 16
1000: Input clock divided by 32
1001: Input clock divided by 64
1010: Input clock divided by 128
1011: Input clock divided by 256
Remaining combinations: Reserved.
Note: When PRESCALER is programmed with a value different to the allowed ones, programmed prescaler value is «1011», i.e. input clock divided by 256.

20.8 USART register map

Table 72. USART register map

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

21 Universal Asynchronous Receiver Transmitter (LPUART)

21.1 LPUART introduction

The universal asynchronous receiver transmitter (LPUART) is a UART which allows bidirectional UART communications.

Note: In the BlueNRG-LP, the LPUART kernel clock is a fixed 16 MHz clock.
The LPUART includes all necessary hardware support to make asynchronous serial communications possible with minimum power consumption.
It supports half-duplex single-wire communications and modem operations (CTS/RTS). It also supports multiprocessor communications. DMA (direct memory access) can be used for data transmission/reception.

21.2 LPUART main features

- Full-duplex asynchronous communications
- NRZ standard format (mark/space)
- Programmable baud rate
- Two internal FIFOs for transmit and receive data
- Each FIFO can be enabled/disabled by software and comes with status flags for FIFO states
- Dual clock domain with a dedicated kernel clock allowing baud rate programming independent from the PCLK reprogramming
- Programmable data word length (7 or 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Single-wire half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
- Transfer detection flags:
 - Receive buffer full
 - Transmit buffer empty
 - Busy and end of transmission flags
- Parity control:
 - Transmits parity bit
 - Checks parity of received data byte
- Four error detection flags:
 - Overrun error
 - Noise detection
 - Frame error
 - Parity error
- Interrupt sources with flags
- Multiprocessor communications
- The LPUART enters mute mode if the address does not match
- Wakeup from mute mode (by idle line detection or address mark detection).

21.3 LPUART functional description

Any LPUART bidirectional communication requires a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):

- **RX**: Receive Data Input. This is the serial data input
- **TX**: Transmit Data Output

When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In single-wire mode, this I/O is used to transmit and receive the data.

Through these pins, serial data are transmitted and received in normal LPUART mode as frames comprising:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (7 or 8 or 9 bits) least significant bit first
- 1, 2 Stop bits indicating that the frame is complete
- The LPUART interface uses a baud rate generator
- A status register (LPUART_ISR)
- Receive and transmit data registers (LPUART_RDR, LPUART_TDR)
- A baud rate register (LPUART_BRR).

Refer to [Section 21.5 LPUART registers](#) for the definitions of each bit. The following pins are required in RS232 hardware flow control mode:

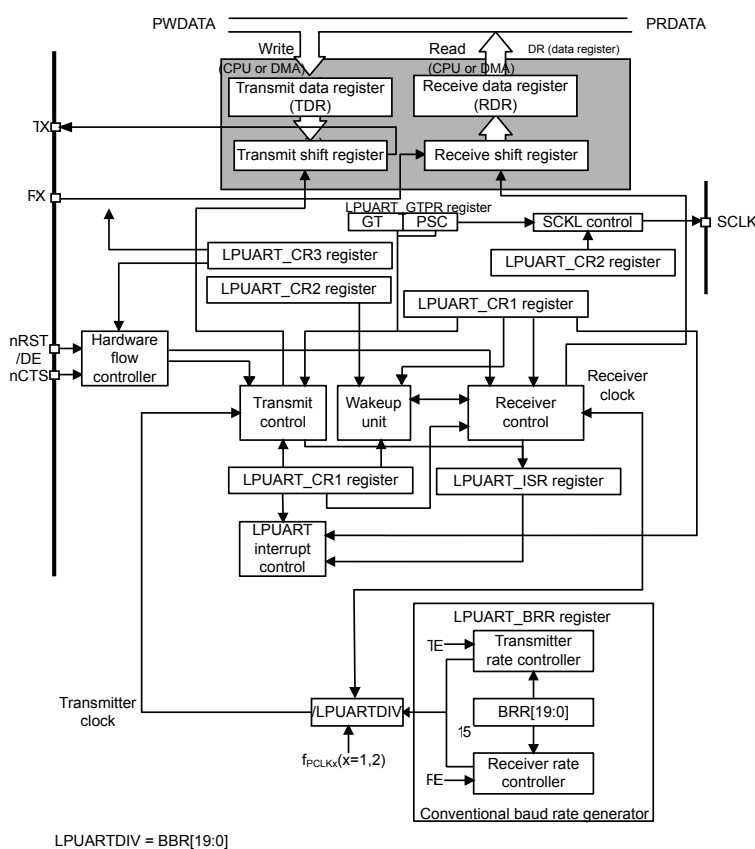

- **nCTS**: Clear To Send blocks the data transmission at the end of the current transfer when high
- **nRTS**: Request to send indicates that the LPUART is ready to receive data (when low).

The following pin is required in RS485 hardware control mode:

- **DE**: Driver enable activates the transmission mode of the external transceiver.

Note: **DE** and **nRTS** share the same pin.

Figure 138. LPUART Block diagram

21.3.1 LPUART character description

Word length may be selected as being either 7 or 8 or 9 bits by programming the M bits (M0: bit 12 and M1: bit 28) in the LPUART_CR1 register (see [Figure 114. Word length programming](#)).

- 7-bit character length: $M[1:0] = 10$
- 8-bit character length: $M[1:0] = 00$
- 9-bit character length: $M[1:0] = 01$

In default configuration, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

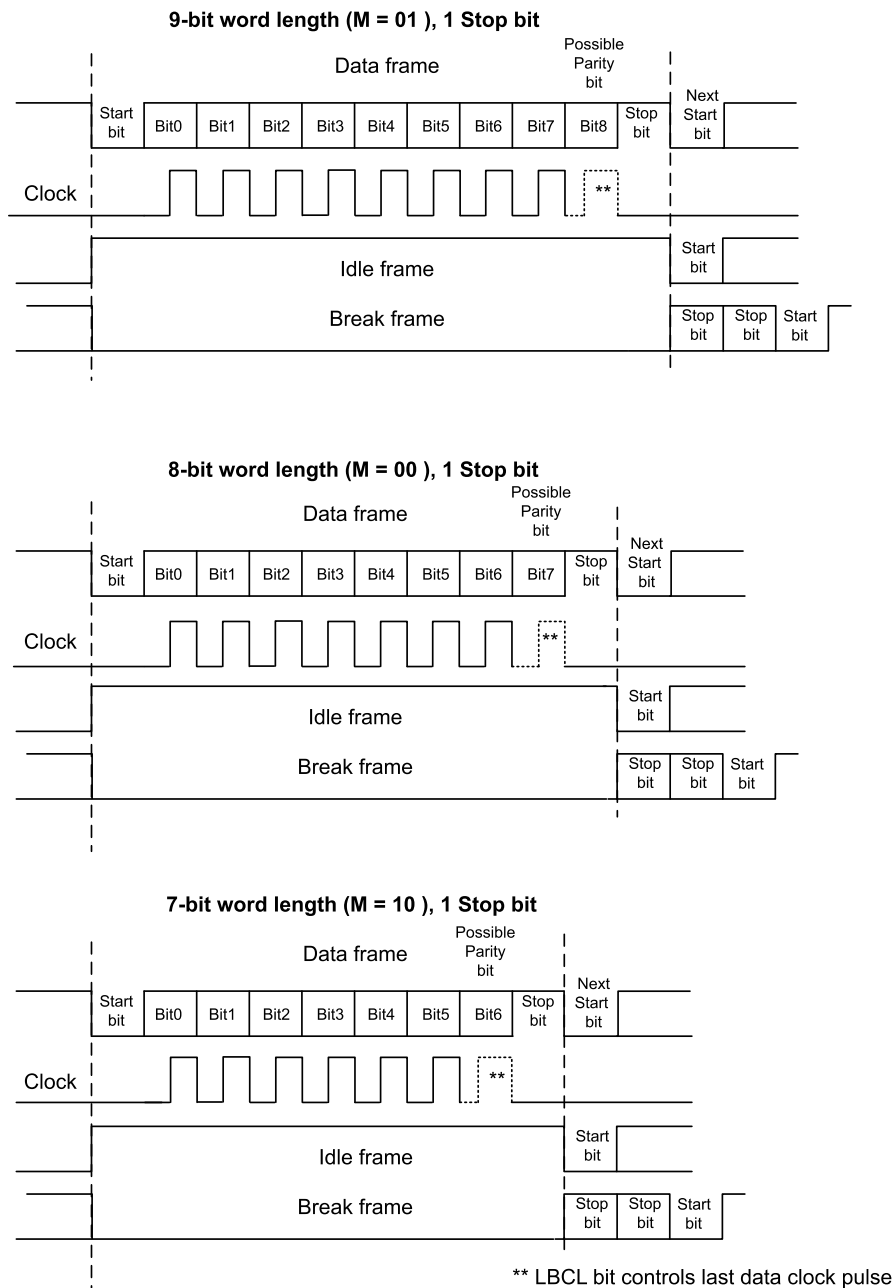

An Idle character is interpreted as an entire frame of “1”s. (The number of “1”s includes the number of stop bits).

A break character is interpreted on receiving "0"s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator, the clock for each is generated when the enable bit is set respectively for the transmitter and receiver.

The details of each block is given below.

Figure 139. LPUART word length programming

21.3.2 FIFOs and thresholds

The LPUART can operate in FIFO mode, with the FIFO buffers having a depth of 8 bytes. The LPUART comes with a transmit FIFO (TXFIFO) and a receive FIFO (RXFIFO). The FIFO mode is enabled by setting the bit 29 FIFOEN in USARTx_CR1 register.

Being 9 bits the maximum data word length, the TXFIFO is 9-bits wide. However the RXFIFO is by default 12-bits wide. This is due to the fact that the receiver does not only put the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

Note: *The received data is stored in the RXFIFO with its flags. But If you read RDR, you read just the data. The status flags are available in the LPUART_ISR register.*

It is possible to define the TXFIFO and RXFIFO levels at which the Tx and RX interrupt are triggered. These thresholds are programmed through bit fields RXFTCFG and TXFTCFG in LPUART_CR3 control register.

In this case:

- The receive interrupt is generated when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields.
- The transmit interrupt is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bits fields.

RXFIFO threshold

The RXFIFO threshold is configured using the RXFTCFG bits fields in the LPUART_CR3 register.

When the number of received data is equal to the programmed RXFTCFG, the flag RXFT in the LPUART_ISR register is set.

Having RXFT flag set means that there are RXFTCFG data received: 1 data in LPUART_RDR and (RXFTCFG - 1) data in the RXFIFO. So, when the RXFTCFG is programmed to «101», the RXFT flag is set when 8 data are received: 7 data in the RXFIFO and 1 data in the LPUARTx_RDR. Consequently, the 9th received data does not set the overrun flag.

21.3.3

Transmitter

The transmitter can send data words of either 7 or 8 or 9 bits depending on the M bit status. The transmit enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin.

Character transmission

During an LPUART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the LPUART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see [Figure 106. Transfer sequence flowchart for SMBus slave transmitter N bytes + PEC](#)).

When FIFO mode is enabled, data written to the LPUART_TDR register is queued in the TXFIFO.

Every character is preceded by a start bit which is a logic level low for one bit period. The character is terminated by a configurable number of stop bits.

The following stop bits are supported by LPUART: 1 and 2 stop bits.

Note: The TE bit must be set before writing the data to be transmitted to the LPUART_TDR.

Note: The TE bit should not be reset during transmission of data. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters get frozen. The current data being transmitted is lost. An idle frame is sent after the TE bit is enabled.

Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in control register 2, bits 13,12.

- **1 stop bit:** This is the default value of the number of stop bits.
- **2 Stop bits:** This is supported by normal LPUART, single-wire and modem modes. An idle frame transmission includes the stop bits.

A break transmission is 10 low bits (when M[1:0] = 00) or 11 low bits (when M[1:0] = 01) or 9 low bits (when M[1:0] = 10) followed by 2 stop bits. It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

Figure 140. Configurable stop bits

Character transmission procedure

1. Program the M bits in LPUART_CR1 to define the word length.
2. Select the desired baud rate using the LPUART_BRR register.
3. Program the number of stop bits in LPUART_CR2.
4. Enable the LPUART by writing the UE bit in LPUART_CR1 register to 1.
5. Select DMA enable (DMAT) in LPUART_CR3 if Multi buffer Communication is to take place. Configure the DMA register as explained in [Section 21.3.6 Multiprocessor communication](#).
6. Set the TE bit in LPUART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the LPUART_TDR register. Repeat this for each data to be transmitted in case of single buffer.
 - When FIFO mode is disabled, writing a data in the LPUART_TDR clears the TXE flag.
 - When FIFO mode is enabled, writing a data in the LPUART_TDR adds one data to the TXFIFO and write operations in the LPUART_TDR are made when TXFNF flag is set. This flag remains set until the TXFIFO is full.
8. After writing the last data into the LPUART_TDR register, wait until TC=1. This indicates that the transmission of the last frame is complete. This is required for instance when the LPUART is disabled or enters the Halt mode to avoid corrupting the last transmission.
 - When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
 - When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.

Single byte communication

- When FIFO mode is disabled:

Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware and it indicates:

- The data has been moved from the LPUART_TDR register to the shift register and the data transmission has started.
- The LPUART_TDR register is empty.
- The next data can be written in the LPUART_TDR register without overwriting the previous data.

This flag generates an interrupt if the TXEIE bit is set.

When a transmission is taking place, a write instruction to the LPUART_TDR register stores the data in the TDR register and which is copied in the shift register at the end of the current transmission.

When no transmission is taking place, a write instruction to the LPUART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

- When FIFO mode is enabled, the TXFNF (TXFIFO Not Full) flag is set by hardware and it indicates:
 - The TXFIFO is not full.
 - The LPUART_TDR register is empty.
 - The next data can be written in the LPUART_TDR register without overwriting the previous data. When a transmission is taking place, a write operation to the LPUART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO into the shift register at the end of the current transmission.

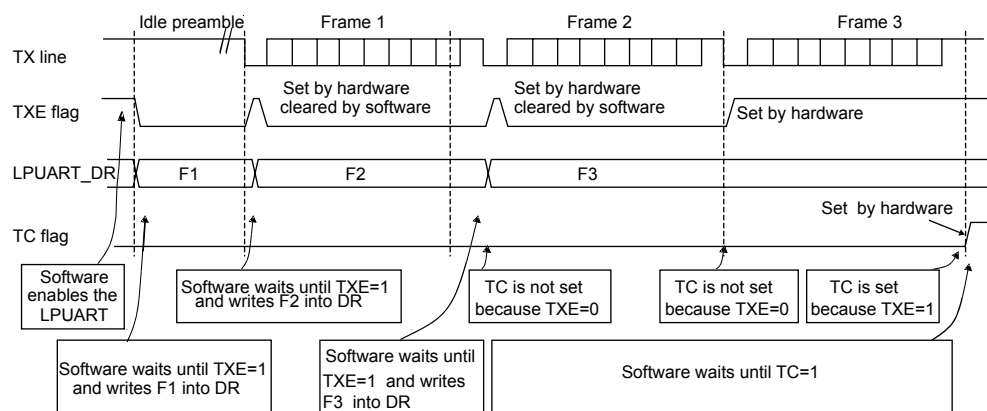

When the TXFIFO is not full, the TXFNF flag stays at 1 even after a write in LPUART_TDR. It is cleared when the TXFIFO is full. This flag generates an interrupt if TXFNEIE bit is set.

Alternatively, interrupts can be generated and data can be written into TXFIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed threshold.

If a frame is transmitted (after the stop bit) and the TXE flag (TXFE is case of FIFO mode) is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the LPUART_CR1 register.

After writing the last data in the LPUART_TDR register, it is mandatory to wait for TC=1 before disabling the LPUART or causing the microcontroller to enter the low-power mode (See Figure 141. TC/TXE behavior when transmitting).

Figure 141. TC/TXE behavior when transmitting

Note: When FIFO management is enabled, the TXFNF flag is used for data transmission.

Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bits (see Figure 109. Bus transfer diagrams for SMBus slave receiver (SBC=1)).

If a '1' is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The LPUART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

Idle characters

Setting the TE bit drives the LPUART to send an idle frame before the first data frame.

21.3.4 Receiver

The LPUART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the LPUART_CR1 register.

Start bit detection

In LPUART, for START bit detection, a falling edge should be detected first on the Rx line, then a sample is taken in the middle of the start bit to confirm that it is still '0'. If the start sample is at '1', then the noise error flag (NF) is set, then the START bit is discarded and the receiver waits for a new START bit. Otherwise, the receiver continues to sample all incoming bits normally.

Character reception

During an LPUART reception, data shifts in least significant bit first (default configuration) through the RX pin. In this mode, the LPUART_RDR register consists of a buffer (RDR) between the internal bus and the received shift register.

Character reception procedure

1. Program the M bits in LPUART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register LPUART_BRR.
3. Program the number of stop bits in LPUART_CR2.
4. Enable the LPUART by writing the UE bit in LPUART_CR1 register to 1.
5. Select DMA enable (DMAR) in LPUART_CR3 if multi-buffer communication is to take place. Configure the DMA register as explained in [Section 21.3.6 Multiprocessor communication](#).
6. Set the RE bit LPUART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received:

- When FIFO mode is disabled, the RXNE bit is set. It indicates that the content of the shiftregister is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set indicating that the RXFIFO is not empty. A read of LPUART_RDR gets the oldest entry in the RXFIFO. When a data is received, it is stored in the RXFIFO, with error bits associated with that data.
- An interrupt is generated if the RXNEIE (RXFNEIE in case of FIFO mode) bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.
- In multi buffer communication:
 - When FIFO mode is disabled, the RXNE flag is set after every byte received and is cleared by the DMA read of the Receive Data Register.
 - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. DMA request is triggered by RXFIFO if not empty i.e. there is a data in the RXFIFO to be read.
- In single buffer mode:
 - When FIFO mode is disabled, clearing the RXNE bit is performed by a software read to the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.
 - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every read of LPUART_RDR register, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by writing 1 to the RXFRQ bit in the LPUART_RQR register. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set. Alternatively, interrupts can be generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

Break character

When a break character is received, the LPUART handles it as a framing error.

Idle character

When an idle frame is detected, there is the same procedure as for a received data character plus an interrupt if the IDLEIE bit is set.

Overrun error

- FIFO mode disabled

An overrun error occurs when a character is received when RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte received. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:

- The ORE bit is set.
- The RDR content is not lost. The previous data is available when a read to LPUART_RDR is performed.
- The shift register is overwritten. After that point, any data received during overrun is lost.

- An interrupt is generated if either the RXNEIE bit is set or EIE bit is set.
- FIFO mode enabled.

An overrun error occurs when the shift register is ready to be transferred when the receive FIFO is full. Data cannot be transferred from the shift register to the LPUART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty. An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:

- The ORE bit is set.
- The first entry in the RXFIFO is not lost. It is available when a read to LPUART_RDR is performed.
- The shift register is overwritten. After that point, any data received during overrun is lost.
- An interrupt is generated if either the RXFNEIE bit is set or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the ICR register.

Note: The ORE bit, when set, indicates that at least 1 data has been lost.

Note: When the FIFO mode is disabled, there are two possibilities.

- if $RXNE=1$, then the last valid data is stored in the receive register RDR and can be read
- if $RXNE=0$, then it means that the last valid data has already been read and thus there is nothing to be read in the RDR. This can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.

Selecting the clock source

The clock source frequency is f_{CK} (16 MHz).

The f_{CK} can be divided by a programmable factor in the LPUARTx_PRESC register.

Figure 142. lpuart_ker_ck clock divider block diagram

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver samples each incoming baud as close as possible to the middle of the baud-period. Only a single sample is taken of each of the incoming bauds.

Note: There is no noise detection for data.

Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:

- The FE bit is set by hardware
- The invalid data is transferred from the Shift register to the LPUART_RDR register
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multi-buffer communication an interrupt is issued if the EIE bit is set in the LPUART_CR3 register.

The FE bit is reset by writing 1 to the FECF in the LPUART_ICR register.

Configurable stop bits during reception

The number of stop bits to be received can be configured through the LPUART_CR2 register control bits: it can be either 1 or 2 in normal mode.

- **1 stop bit:** Sampling for 1 stop Bit is done on the 8th, 9th and 10th samples.

- **2 stop bits:** Sampling for the 2 stop bits is done in the middle of the second stop bit. The RXNE and FE flags are set just after this sample, i.e. during the second stop bit. The first stop bit is not checked for framing error.

21.3.5 Baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the same value as programmed in the LPUART_BRR register.

$$Tx/Rx_{baud} = \frac{256 \times f_{CKPRES}}{LPUARTDIV} \quad (7)$$

LPUARTDIV is coded on the LPUART_BRR register.

Note: *The baud counters are updated to the new value in the baud registers after a write operation to LPUART_BRR. Hence the baud rate register value should not be changed during communication. It is forbidden to write values less than 0x300 in the LPUART_BRR register. f_{CK} must be in the range (3 x baud rate) to (4096 x baud rate).*

21.3.6 Multiprocessor communication

It is possible to perform multiprocessor communication with the LPUART (with several LPUARTs connected in a network). For instance one of the LPUARTs can be the master, its TX output connected to the RX inputs of the other LPUARTs. The others are slaves, their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient should actively receive the full message contents, thus reducing redundant LPUART service overhead for all non addressed receivers.

The non addressed devices may be placed in mute mode by means of the muting function. In order to use the mute mode feature, the MME bit must be set in the LPUART_CR1 register.

Note: *When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two UCLK cycles) otherwise mute mode might remain active.*

In mute mode:

- None of the reception status bits can be set
- All the receive interrupts are inhibited
- The RWU bit in LPUART_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the LPUART_RQR register, under certain conditions.

The LPUART can enter or exit from mute mode using one of two methods, depending on the WAKE bit in the LPUART_CR1 register:

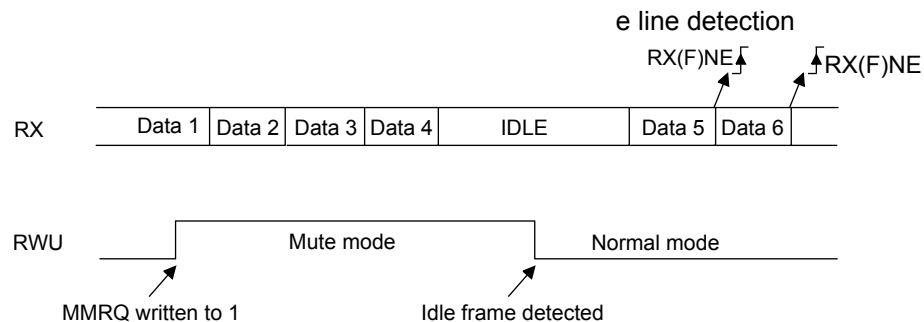

- Idle line detection if the WAKE bit is reset
- Address mark detection if the WAKE bit is set

Idle line detection (WAKE=0)

The LPUART enters mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

It wakes up when an Idle frame is detected. Then the RWU bit is cleared by hardware but the IDLE bit is not set in the LPUART_ISR register. An example of mute mode behavior using Idle line detection is given in [Figure 121. Mute mode using Idle line detection.](#)

Figure 143. Mute mode using idle line detection

Note: If the MMRQ is set while the IDLE character has already elapsed, mute mode is not entered (RWU is not set). If the LPUART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

4-bit/7-bit address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a '1', otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4- bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the LPUART_CR2 register.

Note: In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The LPUART enters mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the LPUART enters mute mode.

The LPUART also enters mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

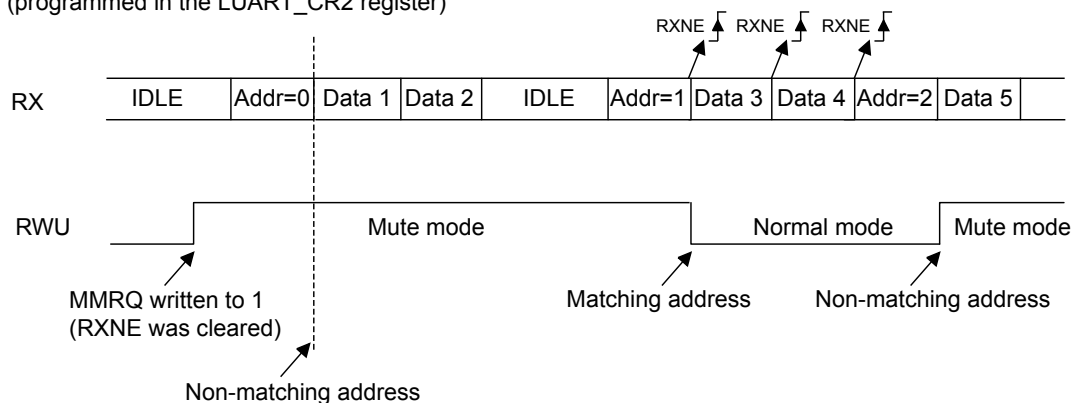

The LPUART exits from mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: When FIFO management is enabled, when MMRQ bit is set while the receiver is sampling the last bit of a data; this data may be received before effectively entering in mute mode.

An example of mute mode behavior using address mark detection is given in [Figure 122. Mute mode using address mark detection](#).

Figure 144. Mute mode using address mark detection

In this example, the current address of the receiver is 1 (programmed in the LUART_CR2 register)

21.3.7 Parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the LPUART_CR1 register. Depending on the frame length defined by the M bits, the possible LPUART frame formats are as listed in [Table 73. Frame formats](#).

Table 73. Frame formats

M bits	PCE bit	LPUART frame ⁽¹⁾
00	0	SB 8-bit data STB
00	1	SB 7-bit data PB STB
01	0	SB 9-bit data STB
01	1	SB 8-bit data PB STB
10	0	SB 7-bit data STB
10	1	SB 6-bit data PB STB

1. *Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register the PB is always taking the MSB position (8th or 7th, depending on the M bit value).*

Even parity

The parity bit is calculated to obtain an even number of “1”s inside the frame which is made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit is 0 if even parity is selected (PS bit in LPUART_CR1 = 0).

Odd parity

The parity bit is calculated to obtain an odd number of “1”s inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit is 1 if odd parity is selected (PS bit in LPUART_CR1 = 1).

Parity checking in reception

If the parity check fails, the PE flag is set in the LPUART_ISR register and an interrupt is generated if PEIE is set in the LPUART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the LPUART_ICR register.

Parity generation in transmission

If the PCE bit is set in LPUART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1”s if even parity is selected (PS=0) or an odd number of “1”s if odd parity is selected (PS=1)).

21.3.8 Single-wire half-duplex communication

Single-wire half-duplex mode is selected by setting the HDSEL bit in the LPUART_CR3 register.

The LPUART can be configured to follow a single-wire half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and full-duplex communication is made with a control bit HDSEL in LPUART_CR3.

As soon as HDSEL is written to 1:

- The TX and RX lines are internally connected
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal LPUART mode. Any conflicts on the line must be managed by software (by the use of a centralized arbiter, for instance). In particular, the transmission is never blocked by hardware and continues as soon as data is written in the data register while the TE bit is set.

Note: As the TX line and the RX lines are connected together, all the transmitted data are stored in the RX FIFO as the data received from an external device. The software has to take care to discard its “own” information after a transmit phase. In half-duplex mode, it is always wise to read back the transmitted data to check if they are correct as there is no hardware protection against possible collision between nodes. If the software does not want to have the RX FIFO storing the transmitted value then it has to disable the receiver part while transmitting (by clearing the RE bit in USART_CR1 register).

Note: In LPUART, in the case of 1-STOP bit configuration, the RXNE flag is set in the middle of the STOP bit.

21.3.9 Continuous communication using DMA

The LPUART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

Note: Please, refer to [Section 20.4 USART implementation](#) to determine if the DMA mode is supported. If DMA is not supported, use the LPUSRT to perform continuous communication. When FIFO is disabled, you can clear the TXE/ RXNE flags in the LPUART_ISR register.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the LPUART_CR3 register. Data is loaded from an SRAM area configured using the DMA peripheral to the LPUART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for LPUART transmission, use the following procedure (x denotes the channel number):

1. Write the LPUART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the LPUART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register.
5. Configure DMA interrupt generation after half/full transfer as required by the application.
6. Clear the TC flag in the LPUART_ISR register by setting the TCCF bit in the LPUART_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the LPUART communication is complete. This is required to avoid corrupting the last transmission before disabling the LPUART or entering stop mode. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

Figure 145. Transmission using DMA

Note: When FIFO management is enabled, the DMA request is triggered by transmit FIFO not full (i.e. TXFNF = 1).

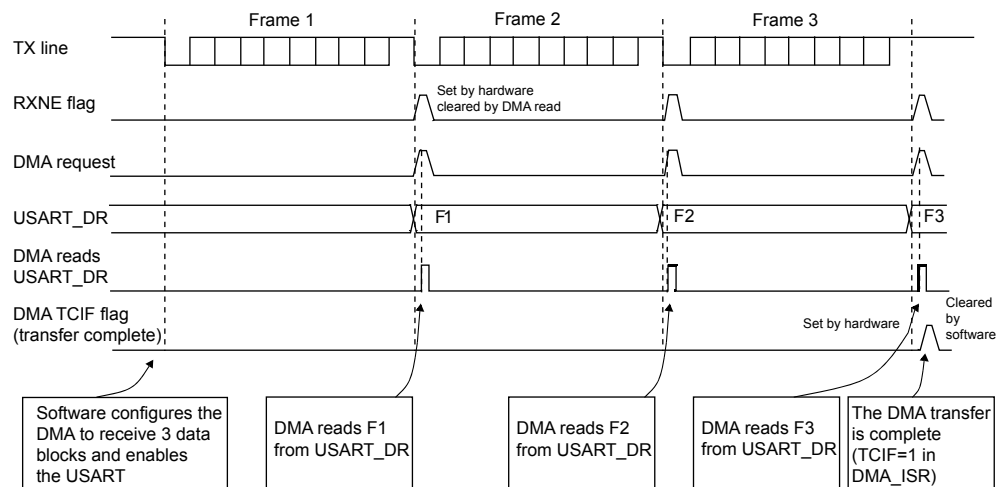

Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in LPUART_CR3 register. Data is loaded from the LPUART_RDR register to an SRAM area configured using the DMA peripheral whenever a data byte is received. To map a DMA channel for LPUART reception, use the following procedure:

1. Write the LPUART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from LPUART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

Figure 146. Reception using DMA

Note: When FIFO management is enabled, the DMA request is triggered by receive FIFO not empty (i.e. $RXFNE = 1$).

Error flagging and interrupt generation in multibuffer communication

In multibuffer communication if any error occurs during the transaction the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single-byte reception, there is a separate error flag interrupt enable bit (EIE bit in the LPUART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

21.3.10 RS232 Hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the nCTS input and the nRTS output.

Figure 135. Hardware flow control between 2 USARTs shows how to connect 2 devices in this mode:

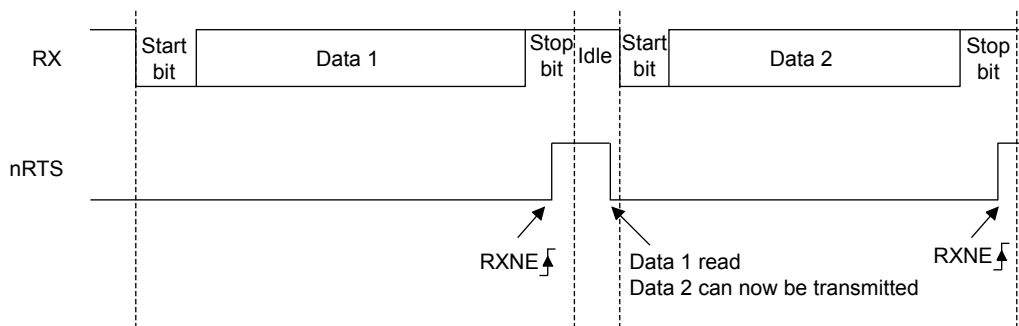

Figure 147. Hardware flow control between 2 LPUARTs

RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the LPUART_CR3 register).

RS232 RTS flow control

If the RTS flow control is enabled (RTSE=1), then nRTS is asserted (tied low) as long as the LPUART receiver is ready to receive a new data. When the receive register is full, nRTS is deasserted, indicating that the transmission is expected to stop at the end of the current frame. Figure 136. RS232 RTS flow control shows an example of communication with RTS flow control enabled.

Figure 148. RS232 RTS flow control

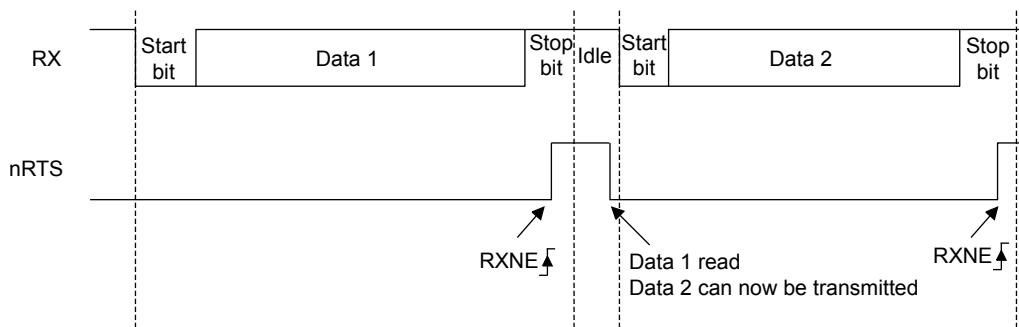

Note: When FIFO mode is enabled, nRTS is deasserted only when RXFIFO is full.

RS232 CTS flow control

If the CTS flow control is enabled (CTSE=1), then the transmitter checks the nCTS input before transmitting the next frame. If nCTS is asserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE=0), otherwise the transmission does not occur. When nCTS is de-asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE=1, the CTSIF status bit is automatically set by hardware as soon as then CTS input toggles. It indicates when the receiver becomes ready or not ready for communication.

An interrupt is generated if the CTSIE bit in the LPUART_CR3 register is set. shows an example of communication with CTS flow control enabled.

Figure 149. RS232 RTS flow control

Note: For a correct behavior, nCTS must be asserted at least 3 LPUART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

RS485 driver enable

The driver enable feature is enabled by setting bit DEM in the LPUART_CR3 control register. This allows the user to activate the external transceiver control through the DE (DriverEnable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the START bit. It is programmed using the DEAT [4:0] bit fields in the LPUART_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bit fields in the LPUART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the LPUART_CR3 control register.

In LPUART, the DEAT and DEDT are expressed in LPUART clock source (f_{CK}) cycles:

- The driver enable assertion time=
 - $(1 + (\text{DEAT} \times P)) \times f_{\text{CK}}$, if $P \neq 0$
 - $(1 + \text{DEAT}) \times f_{\text{CK}}$, if $P = 0$
 - The driver enable de-assertion time=
 - $(1 + (\text{DEDT} \times P)) \times f_{\text{CK}}$, if $P \neq 0$
 - $(1 + \text{DEDT}) \times f_{\text{CK}}$, if $P = 0$
- with $P = \text{BRR}[20:11]$

21.4 LPUART interrupts

Table 74. LPUART interrupt requests

Interrupt event	Event flag	Enable control bit
Transmit data register empty	TXE	TXEIE
Transmit FIFO not full	TXFNF	TXFNFIE
Transmit FIFO empty	TXFE	TXFEIE
CTS interrupt	CTSIF	CTSIE
Transmission complete	TC	TCIE
Receive data register not empty (data ready to be read)	RXNE	RXNEIE
Receive FIFO not empty	RXFNE	RXFNEIE
Receive FIFO full	RXFF	RXFFIE
Overrun error detected	ORE	RXNEIE/RXF-NEIE
Idle line detected	IDLE	IDLEIE
Parity error	PE	PEIE
Noise Flag, Overrun error and Framing Error in multi-buffer communication	NF or ORE or FE	EIE
Character match	CMF	CMIE

These events generate an interrupt if the corresponding enable control bit is set.

21.5 LPUART registers

Refer to [Section 1.3 Acronyms](#) for a list of abbreviations used in register descriptions.

21.5.1 Control register 1 (LPUART_CR1)

Address offset: 0x00

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RXFFIE	TXFEIE	FIFOEN	M1	Res.	Res.	DEAT[4:0]				DEDT[4:0]					
rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	CMIE	MME	M0	WAKE	PCE	PS	PEIE	TXEIE TXFNFIE	TCIE	RXNEIE RXFNEIE	IDLEIE	TE	RE	Res.	UE
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw

Bit 31	RXFFIE : RXFIFO full interrupt enable. This bit is set and cleared by software. 0: Interrupt is inhibited 1: An LPUART interrupt is generated when RXFF=1 in the LPUART_ISR register Note: When FIFO mode is disabled, this bit is reserved and must be kept at reset value.
Bit 30	TXFEIE : TXFIFO empty interrupt enable. This bit is set and cleared by software. 0: Interrupt is inhibited 1: An LPUART interrupt is generated when TXFE=1 in the LPUART_ISR register. Note: When FIFO mode is disabled, this bit is reserved and must be kept at reset value.
Bit 29	FIFOEN : FIFO mode enable. This bit is set and cleared by software. 0: FIFO mode is disabled 1: FIFO mode is enabled
Bit 28	M1 : Word length. This bit, with bit 12 (M0) determines the word length. It is set or cleared by software. M[1:0] = 00: 1 start bit, 8 data bits, n stop bit M[1:0] = 01: 1 start bit, 9 data bits, n stop bit M[1:0] = 10: 1 start bit, 7 data bits, n Stop bit This bit can only be written when the LPUART is disabled (UE=0). Note: in 7-bits data length mode, the Smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.
Bit 27	Reserved, must be kept at reset value.
Bit 26	Reserved, must be kept at reset value.
Bits 25:21	DEAT[4:0] : Driver enable assertion time. This 5-bit value defines the time between the activation of the DE (driver enable) signal and the beginning of the start bit. It is expressed in UCLK (LPUART clock) clock cycles. For more details, refer to RS485 driver enable section. This bit field can only be written when the LPUART is disabled (UE=0).
Bits 20:16	DEDT[4:0] : Driver enable de-assertion time. This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in UCLK (LPUART clock) clock cycles. For more details, refer to RS485 driver enable section. If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed. This bit field can only be written when the LPUART is disabled (UE=0).
Bit 15	Reserved, must be kept at reset value.
Bit 14	CMIE : Character match interrupt enable. This bit is set and cleared by software. 0: Interrupt is inhibited 1: An LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register
Bit 13	MME : Mute mode enable. This bit activates the mute mode function of the LPUART. When set, the LPUART can switch between the active and mute modes, as defined by the WAKE bit. It is set and cleared by software. 0: Receiver in active mode permanently 1: Receiver can switch between mute mode and active mode
Bit 12	M0 : Word length. This bit, with bit 28 (M1) determines the word length. It is set or cleared by software. See Bit 28 (M1) description. This bit can only be written when the LPUART is disabled (UE=0).
Bit 11	WAKE : Receiver wake-up method. This bit determines the LPUART wake-up method from mute mode. It is set or cleared by software.

	<p>0: Idle line</p> <p>1: Address mark</p> <p>This bit field can only be written when the LPUART is disabled (UE=0).</p>
Bit 10	<p>PCE: Parity control enable.</p> <p>This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).</p> <p>0: Parity control disabled</p> <p>1: Parity control enabled</p> <p>This bit field can only be written when the LPUART is disabled (UE=0).</p>
Bit 9	<p>PS: Parity selection.</p> <p>This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.</p> <p>0: Even parity</p> <p>1: Odd parity</p> <p>This bit field can only be written when the LPUART is disabled (UE=0).</p>
Bit 8	<p>PEIE: PE interrupt enable.</p> <p>This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited</p> <p>1: An LPUART interrupt is generated whenever PE=1 in the LPUART_ISR register</p>
Bit 7	<p>TXEIE/TXFNFIE: Transmit data register empty/TXFIFO not full interrupt enable. This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited</p> <p>1: An LPUART interrupt is generated whenever TXE/TXFNF=1 in the LPUART_ISR register</p>
Bit 6	<p>TCIE: Transmission complete interrupt enable. This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited</p> <p>1: An LPUART interrupt is generated whenever TC=1 in the LPUART_ISR register</p>
Bit 5	<p>RXNEIE/RXFNEIE: Receive data register not empty/RXFIFO not empty interrupt enable. This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited</p> <p>1: An LPUART interrupt is generated whenever ORE=1 or RXNE/RXFNE=1 in the LPUART_ISR register</p>
Bit 4	<p>IDLEIE: IDLE interrupt enable.</p> <p>This bit is set and cleared by software.</p> <p>0: Interrupt is inhibited</p> <p>1: An LPUART interrupt is generated whenever IDLE=1 in the LPUART_ISR register</p>
Bit 3	<p>TE: Transmitter enable.</p> <p>This bit enables the transmitter. It is set and cleared by software.</p> <p>0: Transmitter is disabled</p> <p>1: Transmitter is enabled</p> <p>Note: During transmission, a “0” pulse on the TE bit (“0” followed by “1”) sends a preamble (idle line) after the current word. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the LPUART_ISR register.</p> <p>When TE is set there is a 1 bit-time delay before the transmission starts.</p>
Bit 2	<p>RE: Receiver enable.</p> <p>This bit enables the receiver. It is set and cleared by software.</p> <p>0: Receiver is disabled</p>

	1: Receiver is enabled and begins searching for a start bit
Bit 1	Reserved, must be kept at reset value.
Bit 0	<p>UE: LPUART enable.</p> <p>When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART_ISR are reset. This bit is set and cleared by software.</p> <p>0: LPUART prescaler and outputs disabled, low-power mode</p> <p>1: LPUART enabled</p> <p>Note: In order to go into low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART_ISR to be set before resetting the UE bit.</p> <p>The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.</p>

21.5.2 Control register 2 (LPUART_CR2)

Address offset: 0x04

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADD[7:4]				ADD[3:0]				Res.	Res.	Res.	Res.	MSBFI RST	DATAINV	TXINV	RXINV
rw	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWAP	Res.	STOP[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	ADDM7	Res.	Res.	Res.	Res.
rw		rw	rw								rw				

Bits 31:28	<p>ADD[7:4]: Address of the LPUART node.</p> <p>This bit-field gives the address of the LPUART node or a character code to be recognized.</p> <p>This is used in multiprocessor communication during mute mode or stop mode, for wakeup with 7- bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. It may also be used for character detection during normal reception, mute mode inactive (for example, end of block detection in ModBus protocol). In this case, the whole received character (8-bit) is compared to the ADD[7:0] value and CMF flag is set on match.</p> <p>This bit field can only be written when reception is disabled (RE=0) or the LPUART is disabled (UE=0).</p>
Bits 27:24	<p>ADD[3:0]: Address of the LPUART node.</p> <p>This bit-field gives the address of the LPUART node or a character code to be recognized.</p> <p>This is used in multiprocessor communication during Mute mode or Stop mode, for wakeup with address mark detection.</p> <p>This bit field can only be written when reception is disabled (RE=0) or the LPUART is disabled (UE=0)</p>
Bit 23:20	Reserved, must be kept at reset value.
Bit 19	<p>MSBFIRST: Most significant bit first.</p> <p>This bit is set and cleared by software.</p> <p>0: Data is transmitted/received with data bit 0 first, following the start bit</p> <p>1: Data is transmitted/received with the MSB (bit 7/8) first, following the start bit. This bit field can only be written when the LPUART is disabled (UE=0).</p>
Bit 18	<p>DATAINV: Binary data inversion.</p> <p>This bit is set and cleared by software.</p> <p>0: Logical data from the data register are sent/received in positive/direct logic. (1=H, 0=L)</p>

	<p>1: Logical data from the data register are sent/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.</p> <p>This bit field can only be written when the LPUART is disabled (UE=0).</p>
Bit 17	<p>TXINV: TX pin active level inversion. This bit is set and cleared by software.</p> <p>0: TX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)</p> <p>1: TX pin signal values are inverted. (VDD=0/mark, Gnd=1/idle). This allows the use of an external inverter on the TX line.</p> <p>This bit field can only be written when the LPUART is disabled (UE=0).</p>
Bit 16	<p>RXINV: RX pin active level inversion. This bit is set and cleared by software.</p> <p>0: RX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)</p> <p>1: RX pin signal values are inverted. (VDD =0/mark, Gnd=1/idle). This allows the use of an external inverter on the RX line.</p> <p>This bit field can only be written when the LPUART is disabled (UE=0).</p>
Bit 15	<p>SWAP: Swap TX/RX pins.</p> <p>This bit is set and cleared by software.</p> <p>0: TX/RX pins are used as defined in standard pinout</p> <p>1: The TX and RX pins functions are swapped. This allows to work in the case of a cross-wired connection to another UART.</p> <p>This bit field can only be written when the LPUART is disabled (UE=0).</p>
Bit 14	Reserved, must be kept at reset value.
Bits 13:12	<p>STOP[1:0]: STOP bits.</p> <p>These bits are used for programming the stop bits.</p> <p>00: 1 stop bit</p> <p>01: Reserved</p> <p>10: 2 stop bits</p> <p>11: Reserved</p> <p>This bit field can only be written when the LPUART is disabled (UE=0).</p>
Bit 11:5	Reserved, must be kept at reset value.
Bit 4	<p>ADDM7: 7-bit Address Detection/4-bit Address Detection.</p> <p>This bit is for selection between 4-bit address detection or 7-bit address detection.</p> <p>0: 4-bit address detection</p> <p>1: 7-bit address detection (in 8-bit data mode)</p> <p>This bit can only be written when the LPUART is disabled (UE=0).</p> <p>Note: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.</p>
Bits 3:0	Reserved, must be kept at reset value.

21.5.3 Control register 3 (LPUART_CR3)

Address offset: 0x08

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TXFTCFG			RXFTI E.	RXFTCFG			Res.	TXFTIE	Res.	Res.		Res.	Res.	Res.	Res.

rw	rw	rw	rw		rw	rw	rw	rw	rw			rw			rw

Bits 31:29	TXFTCFG : TXFIFO threshold configuration. 000: TXFIFO reaches 1/8 of its depth 001: TXFIFO reaches 1/4 of its depth 110: TXFIFO reaches 1/2 of its depth 011: TXFIFO reaches 3/4 of its depth 100: TXFIFO reaches 7/8 of its depth 101: TXFIFO becomes empty Remaining combinations: Reserved.
Bit 28	RXFTIE : RXFIFO threshold interrupt enable. This bit is set and cleared by software. 0: Interrupt is inhibited 1: An LPUART interrupt is generated when Receive FIFO reaches the threshold programmed in RXFTCFG
Bits 27:25	RXFTCFG : Receive FIFO threshold configuration. 000: Receive FIFO reaches 1/8 of its depth 001: Receive FIFO reaches 1/4 of its depth 110: Receive FIFO reaches 1/2 of its depth 011: Receive FIFO reaches 3/4 of its depth 100: Receive FIFO reaches 7/8 of its depth 101: Receive FIFO becomes full Remaining combinations: Reserved.
Bit 24	Reserved, must be kept at reset value.
Bit 23	TXFTIE : TXFIFO threshold interrupt enable. This bit is set and cleared by software. 0: Interrupt is inhibited 1: An LPUART interrupt is generated when TXFIFO reaches the threshold programmed in TXFTCFG
Bits 22:16	Reserved, must be kept at reset value.
Bit 15	DEP : Driver enable polarity selection. 0: DE signal is active high 1: DE signal is active low This bit can only be written when the LPUART is disabled (UE=0).
Bit 14	DEM : Driver enable mode. This bit allows the user to activate the external transceiver control through the DE signal. 0: DE function is disabled 1: DE function is enabled. The DE signal is output on the RTS pin. This bit can only be written when the LPUART is disabled (UE=0).
Bit 13	DDRE : DMA disable on reception error. 0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data is transferred. 1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE before clearing the error flag. This bit can only be written when the LPUART is disabled (UE=0). Note: The reception errors are: parity error, framing error or noise error.

Bit 12	<p>OVRDIS: Overrun disable.</p> <p>This bit is used to disable the receive overrun detection.</p> <p>0: Overrun Error Flag, ORE, is set when received data is not read before receiving new data</p> <p>1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the LPUART_RDR register.</p> <p>This bit can only be written when the LPUART is disabled (UE=0).</p> <p>Note: This control bit allows checking the communication flow w/o reading the data.</p>
Bit 11	Reserved, must be kept at reset value.
Bit 10	<p>CTSIE: CTS interrupt enable.</p> <p>0: Interrupt is inhibited</p> <p>1: An interrupt is generated whenever CTSIF=1 in the LPUART_ISR register</p>
Bit 9	<p>CTSE: CTS enable.</p> <p>0: CTS hardware flow control disabled</p> <p>1: CTS mode enabled, data is only transmitted when the nCTS input is asserted (tied to 0). If the nCTS input is de-asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while nCTS is asserted, the transmission is postponed until nCTS is asserted.</p> <p>This bit can only be written when the LPUART is disabled (UE=0).</p>
Bit 8	<p>RTSE: RTS enable.</p> <p>0: RTS hardware flow control disabled</p> <p>1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The nRTS output is asserted (pulled to 0) when data can be received.</p> <p>This bit can only be written when the LPUART is disabled (UE=0).</p>
Bit 7	<p>DMAT: DMA enable transmitter. This bit is set/reset by software.</p> <p>1: DMA mode is enabled for transmission</p> <p>0: DMA mode is disabled for transmission</p>
Bit 6	<p>DMAR: DMA enable receiver. This bit is set/reset by software.</p> <p>1: DMA mode is enabled for reception</p> <p>0: DMA mode is disabled for reception</p>
Bit 5:4	Reserved, must be kept at reset value.
Bit 3	<p>HDSEL: Half-duplex selection.</p> <p>Selection of single-wire half-duplex mode.</p> <p>0: Half-duplex mode is not selected</p> <p>1: Half-duplex mode is selected</p> <p>This bit can only be written when the LPUART is disabled (UE=0).</p>
Bit 2:1	Reserved, must be kept at reset value.
Bit 0	<p>EIE: Error interrupt enable.</p> <p>Error interrupt enable bit is required to enable interrupt generation in case of a framing error, overrun error or noise flag (FE=1 or ORE=1 or NF=1 in the LPUART_ISR register).</p> <p>0: Interrupt is inhibited</p> <p>1: An interrupt is generated when FE=1 or ORE=1 or NF=1 in the LPUART_ISR register</p>

21.5.4 Baud rate register (LPUART_BRR)

This register can only be written when the LPUART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BRR[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BRR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20	Reserved, must be kept at reset value.
Bits 19:0	BRR[19:0]

Note: *It is forbidden to write values less than 0x300 in the LPUART_BRR register. Provided that LPUART_BRR must be $\geq 0x300$ and LPUART_BRR is 20 bits, care should be taken when generating high baud rates using high fck values. f_{ck} must be in the range $[3 \times \text{baud rate} .. 4096 \times \text{baud rate}]$.*

21.5.5 Request register (LPUART_RQR)

Address offset: 0x18

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TXFRQ	RXFRQ	MMRQ	SBKRQ	Res.
											w	w	w	w	

Bits 31:5	Reserved, must be kept at reset value.
Bit 4	TXFRQ: Transmit data flush request. This bit is used when FIFO mode is enabled. TXFRQ bit is set to flush the whole FIFO. This sets the flag TXFE (TXFIFO empty, bit 23 in the LPUART_ISR register). Note: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data is written in the data register.
Bit 3	RXFRQ: Receive data flush request. Writing 1 to this bit clears the RXNE flag. This allows the received data to be discarded without reading it, and avoid an overrun condition.
Bit 2	MMRQ: Mute mode request. Writing 1 to this bit puts the LPUART in mute mode and resets the RWU flag.
Bit 1	SBKRQ: Send break request. Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available. Note: In the case the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.
Bit 0	Reserved, must be kept at reset value.

21.5.6 Interrupt and status register (LPUART_ISR)

Address offset: 0x1C

Reset value: 0x00C0 (in case FIFO disabled)

Reset value: 0x0800C0 (in case FIFO enabled)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TXFT	RXFT	Res.	RXFF	TXFE	RE ACK	TE ACK	Res.	RWU	SBKF	CMF	BUSY
				r	r		r	r	r	r		r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CTS	CTSIF	Res.	TXE	TC	RXNE	IDLE	ORE	NF	FE	PE
					r	r		r	r	r	r	r	r	r	r

Bits 31:28	Reserved, must be kept at reset value.
Bit 27	TXFT : TXFIFO threshold flag. This bit is set by hardware when the TXFIFO reaches the programmed threshold in TXFTCFG in LPUARTx_CR3 register, i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit = 1 (bit 31) in the LPUART_CR3 register. 0: TXFIFO does not reach the programmed threshold 1: TXFIFO reached the programmed threshold
Bit 26	RXFT : RXFIFO threshold flag. This bit is set by hardware when the RXFIFO reaches the programmed threshold in RXFTCFG in LPUARTx_CR3 register, i.e. the Receive FIFO contains RXFTCFG data. An interrupt is generated if the RXFTIE bit = 1 (bit 27) in the LPUART_CR3 register. 0: Receive FIFO does not reach the programmed threshold 1: Receive FIFO reached the programmed threshold
Bit 25	Reserved, must be kept at reset value.
Bit 24	RXFF : RXFIFO Full. This bit is set by hardware when RXFIFO is Full. An interrupt is generated if the RXFFIE bit = 1 in the LPUART_CR1 register. 0: RXFIFO is not full 1: RXFIFO is full
Bit 23	TXFE : TXFIFO empty. This bit is set by hardware when TXFIFO is empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the LPUART_RQR register. An interrupt is generated if the TXFEIE bit = 1 (bit 30) in the LPUART_CR1 register. 0: TXFIFO is not empty 1: TXFIFO is empty
Bit 22	REACK : Receive enable acknowledge flag. This bit is set/reset by hardware when the Receive Enable value is taken into account by the LPUART. It can be used to verify that the LPUART is ready for reception before entering Stop mode. Note: If the LPUART does not support the wakeup from Stop feature, this bit is reserved and forced by hardware to '0'.
Bit 21	TEACK : Transmit enable acknowledge flag. This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART.

	It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the LPUART_CR1 register, in order to respect the TE=0 minimum period.
Bit 20	Reserved, must be kept at reset value.
Bit 19	<p>RWU: Receiver wakeup from mute mode.</p> <p>This bit indicates if the LPUART is in mute mode. It is cleared/set by hardware when a wakeup/mute sequence is recognized. The mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART_CR1 register.</p> <p>When wakeup on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART_RQR register.</p> <p>0: Receiver in active mode 1: Receiver in mute mode</p> <p>Note: If the LPUART does not support the wakeup from stop feature, this bit is reserved and forced by hardware to '0'.</p>
Bit 18	<p>SBKF: Send break flag.</p> <p>This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the LPUART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.</p> <p>0: No break character is transmitted 1: Break character is transmitted</p>
Bit 17	<p>CMF: Character match flag.</p> <p>This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART_ICR register.</p> <p>An interrupt is generated if CMIE=1 in the LPUART_CR1 register.</p> <p>0: No character match detected 1: Character match detected</p>
Bit 16	<p>BUSY: Busy flag.</p> <p>This bit is set and reset by hardware. It is active when a communication is on-going on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).</p> <p>0: LPUART is idle (no reception) 1: Reception on-going</p>
Bit 15:11	Reserved, must be kept at reset value.
Bit 10	<p>CTS: CTS flag.</p> <p>This bit is set/reset by hardware. It is an inverted copy of the status of the nCTS input pin.</p> <p>0: nCTS line set 1: nCTS line reset</p> <p>Note: If the hardware flow control feature is not supported, this bit is reserved and forced by hardware to '0'.</p>
Bit 9	<p>CTSIF: CTS interrupt flag.</p> <p>This bit is set by hardware when the nCTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART_ICR register.</p> <p>An interrupt is generated if CTSIE=1 in the LPUART_CR3 register.</p> <p>0: No change occurred on the nCTS status line 1: A change occurred on the nCTS status line</p> <p>Note: If the hardware flow control feature is not supported, this bit is reserved and forced by hardware to '0'.</p>
Bit 8	Reserved, must be kept at reset value.
Bit 7	<p>TXE/TXFNF: Transmit data register empty/TXFIFO not full.</p> <p>When FIFO mode is disabled, TXE is set by hardware when the content of the LPUARTx_TDR register has been transferred into the shift register. It is cleared by a write to the LPUARTx_TDR register.</p>

	<p>When FIFO mode is enabled, TXFNF is set by hardware when TXFIFO is not full, and so data can be written in the LPUART_TDR. Every write in the LPUART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data can not be written into the LPUART_TDR.</p> <p>Note: The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF should be checked prior to writing in TXFIFO. (TXFNF and TXFE is set at the same time).</p> <p>An interrupt is generated if the TXEIE/TXFNFIE bit = 1 in the LPUART_CR1 register.</p> <p>0: Data register is full/Transmit FIFO is full</p> <p>1: Data register/Transmit FIFO is not full</p> <p>Note: This bit is used during single buffer transmission.</p>
Bit 6	<p>TC: Transmission complete.</p> <p>This bit is set by hardware if the transmission of a frame containing data is complete and if TXE/TXFF is set. An interrupt is generated if TCIE=1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the TCCF in the LPUART_ICR register or by a write to the LPUART_TDR register.</p> <p>An interrupt is generated if TCIE=1 in the LPUART_CR1 register.</p> <p>0: Transmission is not complete</p> <p>1: Transmission is complete</p> <p>Note: If TE bit is reset and no transmission is on-going, the TC bit is set immediately.</p>
Bit 5	<p>RXNE/RXFNE: Read data register not empty/RXFIFO not empty.</p> <p>RXNE bit is set by hardware when the content of the LPUARTx_RDR shift register has been transferred to the LPUARTx_RDR register. It is cleared by a read to the LPUARTx_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUARTx_RQR register. RXFNE bit is set by hardware when the RXFIFO is not empty, and so data can be read from the LPUART_RDR register. Every read of the LPUART_RDR frees a location in the RXFIFO. It is cleared when the RXFIFO is empty.</p> <p>The RXNE/RXFNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.</p> <p>An interrupt is generated if RXNEIE/RXFNEIE=1 in the LPUART_CR1 register.</p> <p>0: Data is not received</p> <p>1: Received data is ready to be read</p>
Bit 4	<p>IDLE: Idle line detected.</p> <p>This bit is set by hardware when an idle line is detected. An interrupt is generated if IDLEIE=1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.</p> <p>0: No Idle line is detected</p> <p>1: Idle line is detected</p> <p>Note: The IDLE bit is not set again until the RXNE bit has been set (i.e. a new idle line occurs).</p> <p>If mute mode is enabled (MME=1), IDLE is set if the LPUART is not mute (RWU=0), whatever the mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.</p>
Bit 3	<p>ORE: Overrun error.</p> <p>This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the LPUARTx_RDR register while RXNE=1 (RXFF=1 in case FIFO mode is enabled). It is cleared by a software, writing 1 to the ORECF, in the LPUARTx_ICR register.</p> <p>An interrupt is generated if RXNEIE/ RXFNEIE=1 or EIE=1 in the LPUARTx_CR1 register.</p> <p>0: No overrun error</p> <p>1: Overrun error is detected</p> <p>Note: When this bit is set, the LPUART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi-buffer communication if the EIE bit is set.</p> <p>This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the LPUART_CR3 register.</p>
Bit 2	<p>NF: START bit noise detection flag.</p> <p>This bit is set by hardware when noise is detected on the START bit of a received frame. It is cleared by software, writing 1 to the NFCF bit in the LPUART_ICR register.</p> <p>0: No noise is detected</p>

	<p>1: Noise is detected</p> <p>Note: This bit does not generate an interrupt as it appears at the same time as the RXNE/RXFNE bit which itself generates an interrupt. An interrupt is generated when the NF flag is set during multi buffer communication if the EIE bit is set.</p> <p>Note: In FIFO mode, this error is associated with the character in the LPUART_RDR.</p>
Bit 1	<p>FE: Framing error.</p> <p>This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the LPUART_ICR register. In Smartcard mode, in transmission, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).</p> <p>An interrupt is generated if EIE=1 in the LPUART_CR1 register.</p> <p>0: No framing error is detected</p> <p>1: Framing error or break character is detected</p> <p>Note: In FIFO mode, this error is associated with the character in the LPUART_RDR.</p>
Bit 0	<p>PE: Parity error.</p> <p>This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the LPUART_ICR register.</p> <p>An interrupt is generated if PEIE=1 in the LPUART_CR1 register.</p> <p>0: No parity error</p> <p>1: Parity error</p> <p>Note: In FIFO mode, this error is associated with the character in the LPUART_RDR.</p>

21.5.7 Interrupt flag clear register (LPUART_ICR)

Address offset: 0x20

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:21	Reserved, must be kept at reset value.
Bit 20	<p>WUCF: Wakeup from Stop mode clear flag. Writing 1 to this bit clears the WUF flag in the LPUART_ISR register.</p> <p>Note: If the LPUART does not support the wakeup from stop feature, this bit is reserved and forced by hardware to '0'.</p>
Bit 19:18	Reserved, must be kept at reset value.
Bit 17	<p>CMCF: Character match clear flag.</p> <p>Writing 1 to this bit clears the CMF flag in the LPUART_ISR register.</p>
Bit 16:10	Reserved, must be kept at reset value.
Bit 9	<p>CTSCF: CTS clear flag.</p> <p>Writing 1 to this bit clears the CTSIF flag in the LPUART_ISR register.</p>
Bit 8:7	Reserved, must be kept at reset value.
Bit 7	Reserved, must be kept at reset value.

Bit 6	TCCF : Transmission complete clear flag. Writing 1 to this bit clears the TC flag in the LPUART_ISR register.
Bit 5	Reserved, must be kept at reset value.
Bit 4	IDLECF : Idle line detected clear flag. Writing 1 to this bit clears the IDLE flag in the LPUART_ISR register.
Bit 3	ORECF : Overrun error clear flag. Writing 1 to this bit clears the ORE flag in the LPUART_ISR register.
Bit 2	NECF : Noise detected clear flag. Writing 1 to this bit clears the NF flag in the LPUART_ISR register.
Bit 1	FECF : Framing error clear flag. Writing 1 to this bit clears the FE flag in the LPUART_ISR register.
Bit 0	PECF : Parity error clear flag. Writing 1 to this bit clears the PE flag in the LPUART_ISR register.

21.5.8 Receive data register (LPUART_RDR)

Address offset: 0x24

Reset value: undefined

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	RDR[8:0]								
							r	r	r	r	r	r	r	r	r

Bits 31:9	Reserved, must be kept at reset value.
Bits 8:0	RDR[8:0] : Receive data value Contains the received data character. The RDR register provides the parallel interface between the input shift register and the internal bus (see Figure 113. USART block diagram). When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

21.5.9 Transmit data register (LPUART_TDR)

Address offset: 0x28

Reset value: undefined

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	TDR[8:0]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:9	Reserved, must be kept at reset value.
Bits 8:0	TDR[8:0] : Transmit data value contains the data character to be transmitted. The TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 113. USART block diagram). When transmitting with the parity enabled (PCE bit set to 1 in the LPUART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

Note: This register must be written only when TXE/TXFNF=1.

21.5.10 Prescaler register (LPUART_PRESC)

This register can only be written when the USART is disabled (UE=0).

Address offset: 0x2C

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

22 Serial peripheral interface / inter-IC sound (SPI/I2S)

In the BlueNRG-LP device, only SPI2 and SPI3 supports I²S protocol in addition to SPI features. SPI1 does not support I²S.

22.1 Introduction

The SPI/I²S interface can be used to communicate with external devices using the SPI protocol or the I²S audio protocol. SPI or I²S mode is selectable by software. SPI Motorola mode is selected by default after a device reset. The serial peripheral interface (SPI) protocol supports half-duplex, full-duplex and simplex synchronous, serial communication with external devices. The interface can be configured as master and in this case it provides the communication clock (SCK) to the external slave device. The interface is also capable of operating in multimaster configuration.

The inter-IC sound (I²S) protocol is also a synchronous serial communication interface. It can operate in slave or master mode with half-duplex communication. It can address four different audio standards including the Philips I²S standard, the MSB- and LSB-justified standards and the PCM standard.

22.2 SPI main features

- Master or slave operation
- Full-duplex synchronous transfers on three lines
- Half-duplex synchronous transfer on two lines (with bidirectional dataline)
- Simplex synchronous transfers on two lines (with unidirectional dataline)
- 4-bit to 16-bit data size selection
- Multimaster mode capability
- 8 master mode baud rate prescalers up to $f_{PCLK}/2$
- Slave mode frequency up to $f_{PCLK}/2$
- NSS management by hardware or software for both master and slave: dynamic change of master/slave operations
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Dedicated transmission and reception flags with interrupt capability
- SPI bus busy status flag
- SPI Motorola support
- Hardware CRC feature for reliable communication:
 - CRC value can be transmitted as last byte in Tx mode
 - Automatic CRC error checking for last received byte
- Master mode fault, overrun flags with interrupt capability
- CRC error flag
- Two 32-bit embedded Rx and Tx FIFOs with DMA capability
- SPI TI mode support.

22.3 I2S main features

- Half-duplex communication (only transmitter or receiver)
- Master or slave operations
- 8-bit programmable linear prescaler to reach accurate audio sample frequencies (from 8 kHz to 96 kHz)
- Data format may be 16-bit, 24-bit or 32-bit
- Packet frame is fixed to 16-bit (16-bit data frame) or 32-bit (16-bit, 24-bit, 32-bit data frame) by audio channel

- Programmable clock polarity (steady-state)
- Underrun flag in slave transmission mode, overrun flag in reception mode (master and slave) and frame error flag in reception and transmitter mode (slave only)
- 16-bit register for transmission and reception with one data register for both channel sides
- Supported I²S protocols:
 - I²S Philips standard
 - MSB-Justified standard (Left-Justified)
 - LSB-Justified standard (Right-Justified)
 - PCM standard (with short and long frame synchronization on 16-bit channel frame or 16-bit data frame extended to 32-bit channel frame)
- Data direction is always MSB first
- DMA capability for transmission and reception (16-bit wide)
- Master clock can be output to drive an external audio component. Ratio is fixed at $256 \times F_S$ (where F_S is the audio sampling frequency).

22.4 SPI/I2S implementation

This manual describes the full set of features implemented in SPI1, SPI2 and SPI3.

Table 76. BlueNRG-LP SPI implementation describes the SPI/I²S implementation in the BlueNRG-LP device.

Table 76. BlueNRG-LP SPI implementation

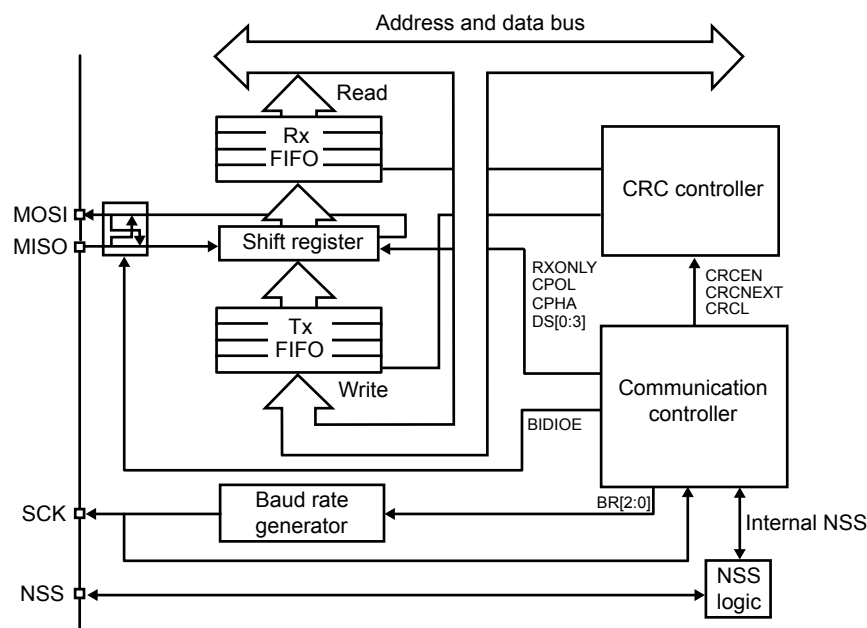

SPI features	SPI1	SPI2	SPI3
Hardware CRC calculation	X	X	X
Rx/Tx FIFO	X	X	X
NSS pulse mode	X	X	X
I ² S mode	-	X	X
TI mode	X	X	X

Note: X = supported.

22.5 SPI functional description

22.5.1 General description

The SPI allows synchronous, serial communication between the MCU and external devices. The application software can manage the communication by polling the status flag or using dedicated SPI interrupt. The main elements of SPI and their interactions are shown in the following block diagram.

Figure 150. SPI block diagram

Four I/O pins are dedicated to SPI communication with external devices.

- **MISO:** Master In / Slave Out data. In the general case, this pin is used to transmit data in slave mode and receive data in master mode.
- **MOSI:** Master Out / Slave In data. In the general case, this pin is used to transmit data in master mode and receive data in slave mode.
- **SCK:** Serial Clock output pin for SPI masters and input pin for SPI slaves.

Note: If the SPI is in master mode and the internal pull-up/-down of the pad is used, the software must take care to activate the pull polarity (up or down) of the I/O to be coherent with the CPOL programming (pull-down if CPOL=0 and pull-up if CPOL=1).

- **NSS:** Slave select pin. Depending on the SPI and NSS settings, this pin can be used to either:
 - select an individual slave device for communication
 - synchronize the data frame or
 - detect a conflict between multiple masters

See [Section 22.5.4 Slave select \(NSS\) pin management](#) for details.

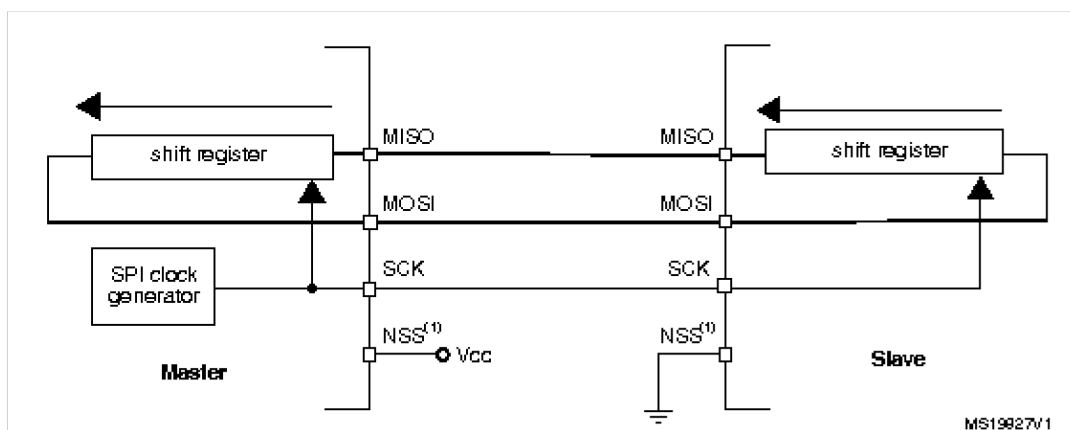

The SPI bus allows the communication between one master device and one or more slave devices. The bus consists of at least two wires - one for the clock signal and the other for synchronous data transfer. Other signals can be added depending on the data exchange between SPI nodes and their slave select signal management.

22.5.2 Communications between one master and one slave

The SPI allows the MCU to communicate using different configurations, depending on the device targeted and the application requirements. These configurations use 2 or 3 wires (with software NSS management) or 3 or 4 wires (with hardware NSS management). Communication is always initiated by the master.

Full-duplex communication

By default, the SPI is configured for full-duplex communication. In this configuration, the shift registers of the master and slave are linked using two unidirectional lines between the MOSI and the MISO pins. During SPI communication, data is shifted synchronously on the SCK clock edges provided by the master. The master transmits the data to be sent to the slave via the MOSI line and receives data from the slave via the MISO line. When the data frame transfer is complete (all the bits are shifted) the information between the master and slave is exchanged.

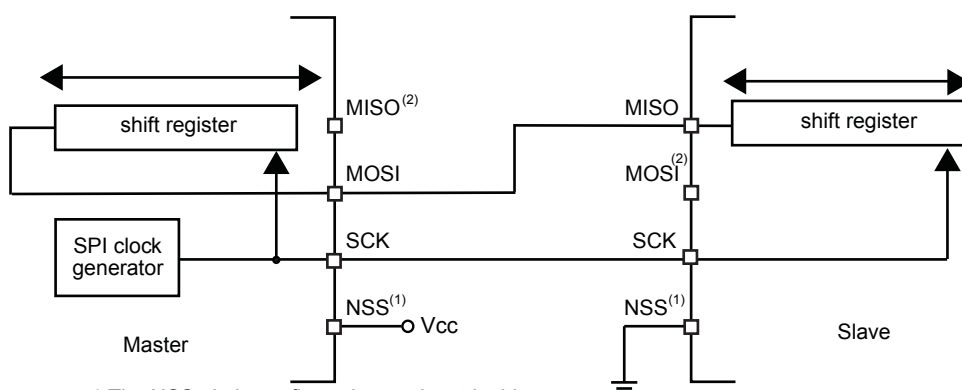

Figure 151. Full-duplex single master/single slave application

1. The NSS pin is configured as an input in this case.

1) The NSS pin is configured as an input in this case.

Half-duplex communication

The SPI can communicate in half-duplex mode by setting the BIDIMODE bit in the SPIx_CR1 register. In this configuration, one single cross connection line is used to link the shift registers of the master and slave together. During this communication, the data is synchronously shifted between the shift registers on the SCK clock edge in the transfer direction selected reciprocally by both master and slave with the BDIOE bit in their SPIx_CR1 registers. In this configuration, the master's MISO pin and the slave's MOSI pin are free for other application uses and act as GPIOs.

Figure 152. Half-duplex single master/single slave application

1. The NSS pin is configured as an input in this case.
2. In this configuration, the master's MISO pin and the slave's MOSI pin can be used as GPIOs.

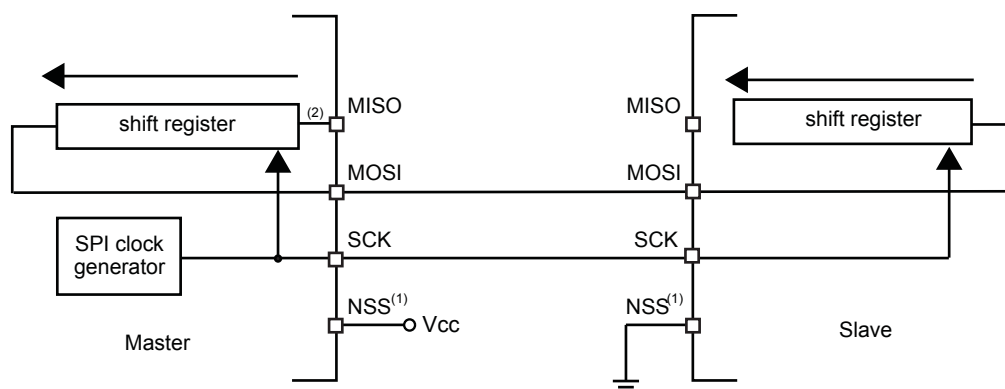

Simplex communications

The SPI can communicate in simplex mode by setting the SPI in transmit-only or in receive-only using the RXONLY bit in the SPIx_CR2 register. In this configuration, only one line is used for the transfer between the shift registers of the master and slave. The remaining MISO and MOSI pins pair is not used for communication and can be used as standard GPIOs.

- **Transmit-only mode (RXONLY=0):** The configuration settings are the same as for full-duplex. The application has to ignore the information captured on the unused input pin. This pin can be used as a standard GPIO.

- Receive-only mode (RXONLY=1):** The application can disable the SPI output function by setting the RXONLY bit. In slave configuration, the MISO output is disabled and the pin can be used as a GPIO. The slave continues to receive data from the MOSI pin while its slave select signal is active (see [Section 22.5.4 Slave select \(NSS\) pin management](#)). Received data events appear depending on the data buffer configuration. In the master configuration, the MOSI output is disabled and the pin can be used as a GPIO. The clock signal is generated continuously as long as the SPI is enabled. The only way to stop the clock is to clear the RXONLY bit or the SPE bit and wait until the incoming pattern from the MISO pin is finished and fills the data buffer structure, depending on its configuration.

Figure 153. Simplex single master/single slave application (master in transmit-only/slave in receive-only mode)

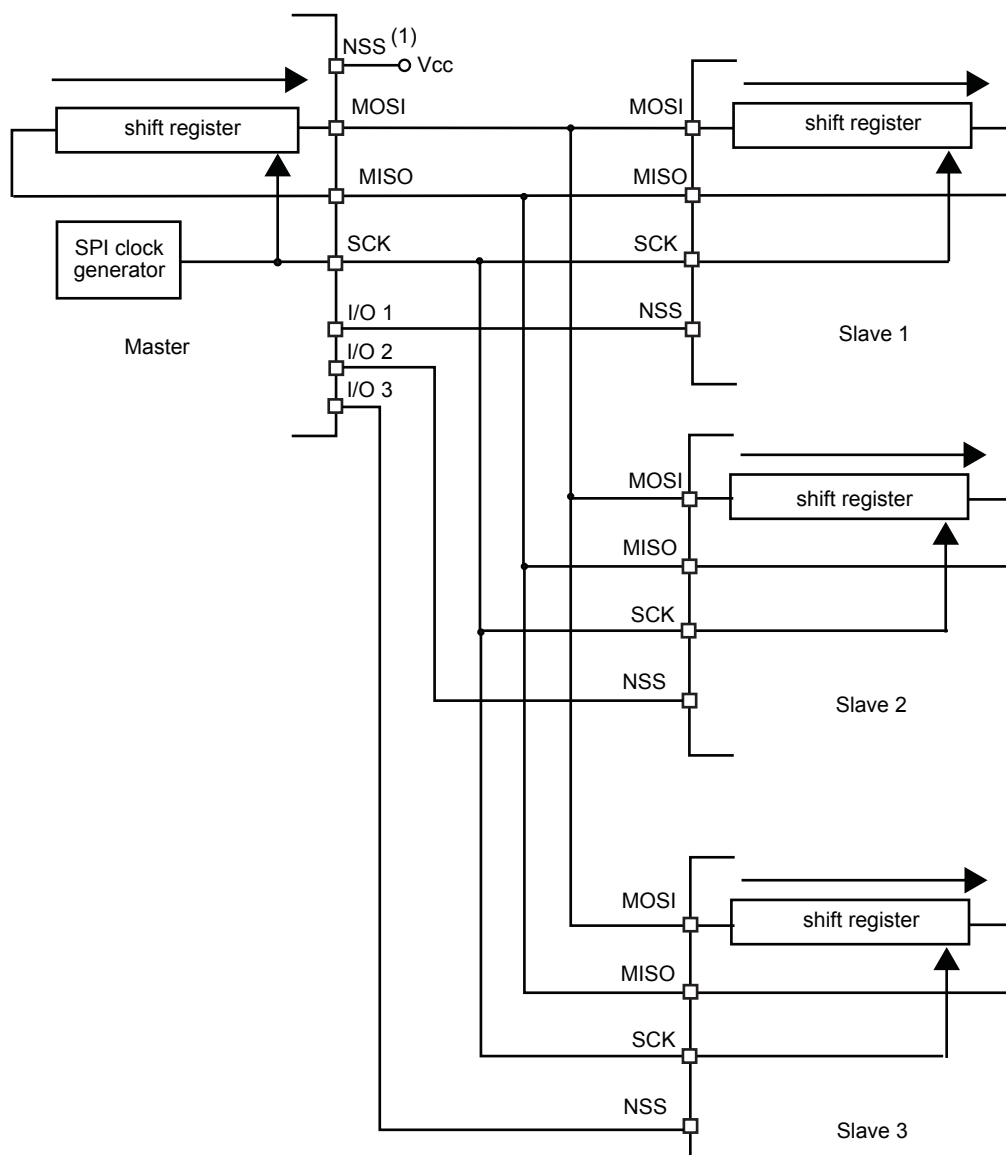

1. The NSS pin is configured as an input in this case.
2. The input information is captured in the shift register and must be ignored in standard transmit only mode (for example, OVF flag)
3. In this configuration, both the MISO pins can be used as GPIOs.

Note: Any simplex communication can be alternatively replaced by a variant of the half-duplex communication with a constant setting of the transaction direction (bidirectional mode is enabled while BDIO bit is not changed).

22.5.3 Standard multi-slave communication

In a configuration with two or more independent slaves, the master uses GPIO pins to manage the chip select lines for each slave (see [Figure 154. Master and three independent slaves](#)). The master must select one of the slaves individually by pulling low the GPIO connected to the slave NSS input. When this is done, a standard master and dedicated slave communication is established.

Figure 154. Master and three independent slaves

1. As MISO pins of the slaves are connected together, all slaves must have the GPIO configuration of their MISO pin set as alternate function open-drain (see [Table 7. GPIO alternate options AF3 - AF4](#)).

22.5.4 Slave select (NSS) pin management

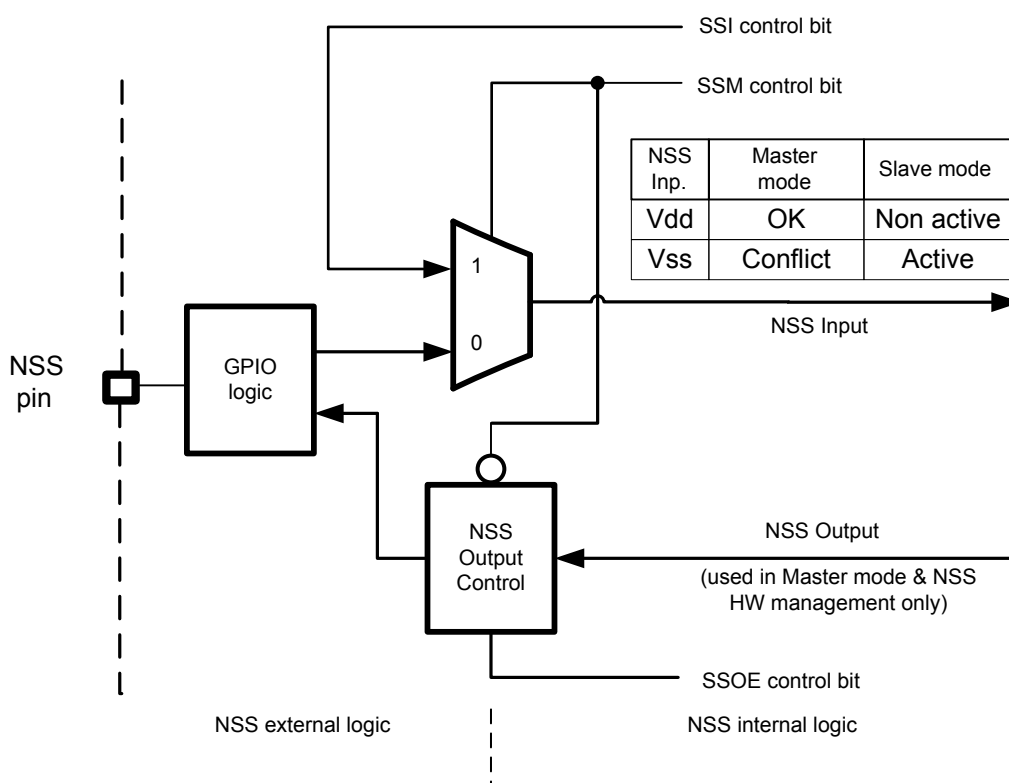

In slave mode, the NSS works as a standard “chip select” input and lets the slave communicate with the master. In master mode, NSS can be used either as output or input. As an input it can prevent multimaster bus collision, and as an output it can drive a slave select signal of a single slave.

Hardware or software slave select management can be set using the SSM bit in the SPIx_CR1 register:

- **SoftwareNSS management (SSM = 1):** in this configuration, slave select information is driven internally by the SSI bit value in register SPIx_CR1. The external NSS pin is free for other application uses.

- **Hardware NSS management (SSM = 0):** in this case, there are two possible configurations. The configuration used depends on the NSS output configuration (SSOE bit in register SPIx_CR1).
 - **NSS output enable (SSM=0,SSOE = 1):** this configuration is only used when the MCU is set as master. The NSS pin is managed by the hardware. The NSS signal is driven low as soon as the SPI is enabled in master mode (SPE=1), and is kept low until the SPI is disabled (SPE =0). A pulse can be generated between continuous communications if NSS pulse mode is activated (NSSP=1). The SPI cannot work in multimaster configuration with this NSS setting.
 - **NSS output disable (SSM=0, SSOE = 0):** if the microcontroller is acting as the master on the bus, this configuration allows multimaster capability. If the NSS pin is pulled low in this mode, the SPI enters master mode fault state and the device is automatically reconfigured in slave mode. In slave mode, the NSS pin works as a standard “chip select” input and the slave is selected while NSS line is at low level.

Figure 155. Hardware/software slave select management

22.5.5 Communication formats

During SPI communication, receive and transmit operations are performed simultaneously. The serial clock (SCK) synchronizes the shifting and sampling of the information on the data lines. The communication format depends on the clock phase, the clock polarity and the data frame format. To be able to communicate together, the master and slaves devices must follow the same communication format.

Clock phase and polarity controls

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPIx_CR1 register. The CPOL (clock polarity) bit controls the idle state value of the clock when no data is being transferred. This bit affects both master and slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.

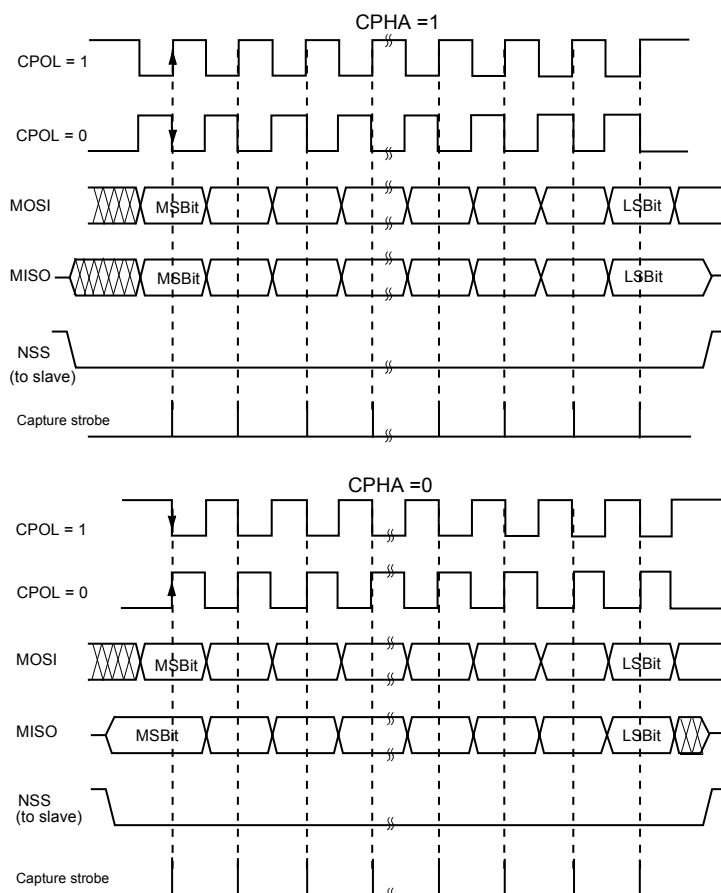

If the CPHA bit is set, the second edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set). Data are latched on each occurrence of this clock transition type. If the CPHA bit is reset, the first edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is set, rising edge if the CPOL bit is reset). Data are latched on each occurrence of this clock transition type.

The combination of CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edge.

Figure 156. Data clock timing diagram shows an SPI full-duplex transfer with the four combinations of the CPHA and CPOL bits.

Note: Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit. The idle state of SCK must correspond to the polarity selected in the SPIx_CR1 register (by pulling up SCK if CPOL=1 or pulling down SCK if CPOL=0).

Figure 156. Data clock timing diagram

1. The order of data bits depends on LSBFIRST bit setting.

Data frame format

The SPI shift register can be set up to shift out MSB-first or LSB-first, depending on the value of the LSBFIRST bit. The data frame size is chosen by using the DS bits. It can be set from 4-bit up to 16-bit length and the setting applies for both transmission and reception.

Whatever the selected data frame size, read access to the FIFO must be aligned with the FRXTH level. When the SPIx_DR register is accessed, data frames are always right-aligned into either a byte (if the data fits into a byte) or a half-word (see Figure 157. Data alignment when data length is not equal to 8-bit or 16-bit). During communication, only bits within the data frame are clocked and transferred.

Figure 157. Data alignment when data length is not equal to 8-bit or 16-bit

Note: The minimum data length is 4 bits. If a data length of less than 4 bits is selected, it is forced to an 8-bit data frame size.

22.5.6 Configuration of SPI

The configuration procedure is almost the same for master and slave. For specific mode setups, follow the dedicated sections. When a standard communication is to be initialized, perform these steps:

1. Write proper GPIO registers: configure GPIO for MOSI, MISO and SCK pins.
2. Write to the SPI_CR1 register:
 - a. Configure the serial clock baud rate using the BR[2:0] bits ⁽¹⁾.
 - b. Configure the CPOL and CPHA bits combination to define one of the four relationships between the data transfer and the serial clock (CPHA must be cleared in NSSP mode) ⁽²⁾.
 - c. Select simplex or half-duplex mode by configuring RXONLY or BIDIMODE and BIDIOE (RXONLY and BIDIMODE cannot be set at the same time).
 - d. Configure the LSBFIRST bit to define the frame format ⁽²⁾.
 - e. Configure the CRCL and CRCEN bits if CRC is needed (while SCK clock signal is at idle state).
 - f. Configure SSM and SSI ⁽²⁾ ⁽³⁾.
 - g. Configure the MSTR bit (in multimaster NSS configuration, avoid conflict state on NSS if master is configured to prevent MODF error).
3. Write to SPI_CR2 register:
 - a. Configure the DS[3:0] bits to select the data length for the transfer.
 - b. Configure SSOE ⁽⁴⁾ ⁽²⁾ ⁽³⁾.
 - c. Set the FRF bit if the TI protocol is required (keep NSSP bit cleared in TImode).
 - d. Set the NSSP bit if the NSS pulse mode between two data units is required (keep CHPA and TI bits cleared in NSSP mode).
 - e. Configure the FRXTH bit. The RXFIFO threshold must be aligned to the read access size for the SPIx_DR register.
 - f. Initialize LDMA_TX and LDMA_RX bits if DMA is used in packed mode.
4. Write to SPI_CRCPR register: Configure the CRC polynomial if needed.
5. Write proper DMA registers: Configure DMA streams dedicated for SPI Tx and Rx in DMA registers if the DMA streams are used.

Note:

1. The step is not required in slave mode except slave working at TI mode.
2. Step is not required in TI mode.
3. Step is not required in NSSP mode.
4. Step is not required in slave mode.

22.5.7 Procedure to enable SPI

It is recommended to enable the SPI slave before the master sends the clock. If not, undesired data transmission might occur. The data register of the slave must already contain data to be sent before starting communication with the master (either on the first edge of the communication clock, or before the end of the on-going communication if the clock signal is continuous). The SCK signal must be settled at an idle state level corresponding to the selected polarity before the SPI slave is enabled.

The master at full-duplex (or in any transmit-only mode) starts to communicate when the SPI is enabled and TXFIFO is not empty, or with the next write to TXFIFO.

In any master receive-only mode (RXONLY=1 or BIDIMODE=1 & BIDIOE=0), the master starts to communicate and the clock starts running immediately after SPI is enabled.

To deal with DMA, follow the dedicated section.

22.5.8 Data transmission and reception procedures

RXFIFO and TXFIFO

All SPI data transactions pass through the 32-bit embedded FIFOs. This enables the SPI to work in a continuous flow, and prevents overruns when the data frame size is short. Each direction has its own FIFO called TXFIFO and RXFIFO. These FIFOs are used in all SPI modes except for receiver-only mode (slave or master) with CRC calculation enabled (see [Section 22.5.13 CRC calculation](#)).

The handling of FIFOs depends on the data exchange mode (duplex, simplex), data frame format (number of bits in the frame), access size performed on the FIFO data registers (8-bit or 16-bit), and whether or not data packing is used when accessing the FIFOs (see [Section 22.5.12 TI mode](#)).

A read access to the SPIx_DR register returns the oldest value stored in RXFIFO that has not been read yet. A write access to the SPIx_DR stores the written data in the TXFIFO at the end of a send queue. The read access must be always aligned with the RXFIFO threshold configured by the FRXTH bit in SPIx_CR2 register. FTLVL[1:0] and FRLVL[1:0] bits indicate the current occupancy level of both FIFOs.

A read access to the SPIx_DR register must be managed by the RXNE event. This event is triggered when data is stored in RXFIFO and the threshold (defined by FRXTH bit) is reached. When RXNE is cleared, RXFIFO is considered to be empty. In a similar way, write access of a data frame to be transmitted is managed by the TXE event. This event is triggered when the TXFIFO level is less than or equal to half of its capacity. Otherwise TXE is cleared and the TXFIFO is considered as full. In this way, RXFIFO can store up to four data frames, whereas TXFIFO can only store up to three when the data frame format is not greater than 8 bits. This difference prevents possible corruption of 3x 8-bit data frames already stored in the TXFIFO when software tries to write more data in 16-bit mode into TXFIFO. Both TXE and RXNE events can be polled or handled by interrupts. See

[Figure 159. Master full-duplex communication through Figure 162. Master full-duplex communication in packed mode.](#)

Another way to manage the data exchange is to use DMA (see [Section 10 DMA controller \(DMA\)](#)).

If the next data is received when the RXFIFO is full, an overrun event occurs (see description of OVR flag in [Section 22.5.9 SPI status flags](#)). An overrun event can be polled or handled by an interrupt.

The BSY bit being set indicates on-going transaction of a current data frame. When the clock signal runs continuously, the BSY flag stays set between data frames at master but becomes low for a minimum duration of one SPI clock at slave between each data frame transfer.

Sequence handling

A few data frames can be passed at single sequence to complete a message. When transmission is enabled, a sequence begins and continues while any data is present in the TXFIFO of the master. The clock signal is provided continuously by the master until TXFIFO becomes empty, then it stops waiting for additional data.

In receive-only modes, half-duplex (BIDIMODE=1, BIDIOE=0) or simplex (BIDIMODE=0, RXONLY=1) the master starts the sequence immediately when both SPI is enabled and receive-only mode is activated. The clock signal is provided by the master and it does not stop until either SPI or receive-only mode is disabled by the master. The master receives data frames continuously up to this moment.

While the master can provide all the transactions in continuous mode (SCK signal is continuous) it has to respect slave capability to handle data flow and its content at anytime. When necessary, the master must slow down the communication and provide either a slower clock or separate frames or data sessions with sufficient delays. Be aware there is no underflow error signal for master or slave in SPI mode, and data from the slave is always transacted and processed by the master even if the slave could not prepare it correctly in time. It is preferable for the slave to use DMA, especially when data frames are shorter and bus rate is high.

Each sequence must be encased by the NSS pulse in parallel with the multi-slave system to select just one of the slaves for communication. In a single slave system it is not necessary to control the slave with NSS, but it is often better to provide the pulse here too, to synchronize the slave with the beginning of each data sequence. NSS can be managed by both software and hardware (see [Section 22.5.4 Slave select \(NSS\) pin management](#)).

When the BSY bit is set it signifies an on-going data frame transaction. When the dedicated frame transaction is finished, the RXNE flag is raised. The last bit is just sampled and the complete data frame is stored in the RXFIFO.

Procedure to disable the SPI

When SPI is disabled, it is mandatory to follow the disable procedures described in this paragraph. It is important to do this before the system enters a low-power mode when the peripheral clock is stopped. On-going transactions can be corrupted in this case. In some modes the disable procedure is the only way to stop continuous communication running.

Master in full-duplex or transmit only mode can finish any transaction when it stops providing data for transmission. In this case, the clock stops after the last data transaction. Special care must be taken in packing mode when an odd number of data frames are transacted to prevent some dummy byte exchange (refer to Data packing section). Before the SPI is disabled in these modes, the user must follow the standard disable procedure. When the SPI is disabled at the master transmitter while a frame transaction is on-going or next data frame is stored in TXFIFO, the SPI behavior is not guaranteed.

When the master is in any receive-only mode, the only way to stop the continuous clock is to disable the peripheral by SPE=0. This must occur in specific time window within last data frame transaction just between the sampling time of its first bit and before its last bit transfer starts (in order to receive a complete number of expected data frames and to prevent any additional "dummy" data reading after the last valid data frame). A specific procedure must be followed when disabling SPI in this mode.

Data received but not read remains stored in RXFIFO when the SPI is disabled, and must be processed the next time the SPI is enabled, before starting a new sequence. To prevent having unread data, ensure that RXFIFO is empty when disabling the SPI, by using the correct disabling procedure, or by initializing all the SPI registers with a software reset via the control of a specific register dedicated to peripheral reset (see the SPIIRST bits in the RCC_APB1RSTR registers).

Standard disable procedure is based on pulling BSY status together with FTLVL[1:0] to check if a transmission session is fully completed. This check can be done in specific cases, too, when it is necessary to identify the end of on-going transactions, for example:

- When NSS signal is managed by software and master has to provide proper end of NSS pulse for slave, or
- When transactions' streams from DMA or FIFO are completed while the last data frame or CRC frame transaction is still on-going in the peripheral bus.

The correct disable procedure is (except when receive-only mode is used):

1. Wait until FTLVL[1:0] = 00 (no more data to transmit).
2. Wait until BSY=0 (the last data frame is processed).
3. Disable the SPI(SPE=0).
4. Read data until FRLVL[1:0] = 00 (read all the received data).

The correct disable procedure for certain receive-only modes is:

1. Interrupt the receive flow by disabling SPI (SPE=0) in the specific time window while the last data frame is on-going.
2. Wait until BSY=0 (the last data frame is processed).
3. Read data until FRLVL[1:0] = 00 (read all the received data).

Note:

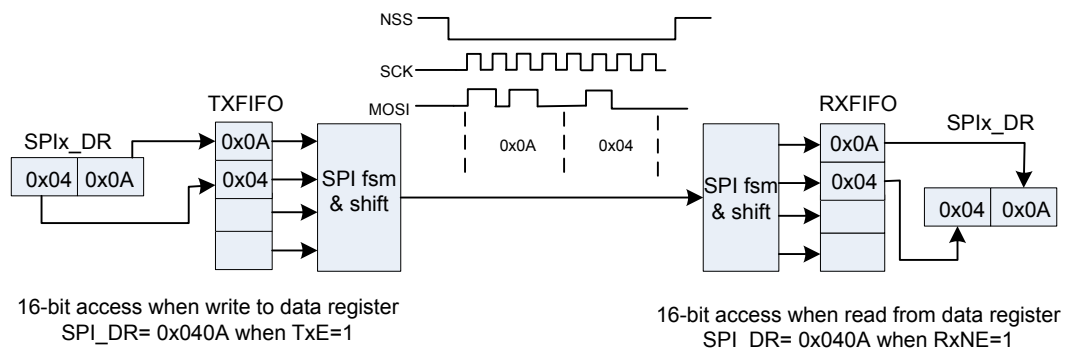

If packing mode is used and an odd number of data frames with a format less than or equal to 8 bits (fitting into one byte) has to be received, FRXTH must be set when FRLVL[1:0] = 01, in order to generate the RXNE event to read the last odd data frame and to keep good FIFO pointer alignment.

Data packing

When the data frame size fits into one byte (less than or equal to 8 bits), data packing is used automatically when any read or write 16-bit access is performed on the SPIx_DR register. The double data frame pattern is handled in parallel in this case. At first, the SPI operates using the pattern stored in the LSB of the accessed word, then with the other half stored in the MSB. [Figure 158. Packing data in FIFO for transmission and reception](#) provides an example of data packing mode sequence handling. Two data frames are sent after the single 16-bit access the SPIx_DR register of the transmitter. This sequence can generate just one RXNE event in the receiver if the RXFIFO threshold is set to 16 bits (FRXTH=0). The receiver then has to access both data frames by a single 16-bit read of SPIx_DR as a response to this single RXNE event. The Rx FIFO threshold setting and the following read access must be always kept aligned at the receiver side, as data can be lost if it is not in line.

A specific problem appears if an odd number of such “fit into one byte” data frames must be handled. On the transmitter side, writing the last data frame of any odd sequence with an 8-bit access to SPIx_DR is enough. The receiver has to change the Rx_FIFO threshold level for the last data frame received in the odd sequence of frames in order to generate the RXNE event.

Figure 158. Packing data in FIFO for transmission and reception

Communication using DMA (direct memory addressing)

To operate at its maximum speed and to facilitate the data register read/write process required to avoid overrun, the SPI features a DMA capability, which implements a simple request/acknowledge protocol.

A DMA access is requested when the TXE or RXNE enable bit in the SPIx_CR2 register is set. Separate requests must be issued to the Tx and Rx buffers.

- In transmission, a DMA request is issued each time TXE is set to 1. The DMA then writes to the SPIx_DR register.
- In reception, a DMA request is issued each time RXNE is set to 1. The DMA then reads the SPIx_DR register.

See [Figure 159. Master full-duplex communication](#) through [Figure 162. Master full-duplex communication in packed mode](#).

When the SPI is used only to transmit data, it is possible to enable only the SPI Tx DMA channel. In this case, the OVR flag is set because the data received is not read. When the SPI is used only to receive data, it is possible to enable only the SPI Rx DMA channel.

In transmission mode, when the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the BSY flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or entering the Stop mode. The software must first wait until FTLVL[1:0]=00 and then until BSY=0.

When starting communication using DMA, to prevent DMA channel management raising error events, these steps must be followed in order:

1. Enable DMA Rx buffer in the RXDMAEN bit in the SPI_CR2 register, if DMA Rx is used.
2. Enable DMA streams for Tx and Rx in DMA registers, if the streams are used.
3. Enable DMA Tx buffer in the TXDMAEN bit in the SPI_CR2 register, if DMA Tx is used.
4. Enable the SPI by setting the SPE bit.

To close communication it is mandatory to follow these steps in order:

1. Disable DMA streams for Tx and Rx in the DMA registers, if the streams are used.

2. Disable the SPI by following the SPI disable procedure.
3. Disable DMA Tx and Rx buffers by clearing the TXDMAEN and RXDMAEN bits in the SPI_CR2 register, if DMA Tx and/or DMA Rx are used.

Packing with DMA

If the transfers are managed by DMA (TXDMAEN and RXDMAEN set in the SPIx_CR2 register) packing mode is enabled/disabled automatically depending on the PSIZE value configured for SPI TX and the SPI RX DMA channel. If the DMA channel PSIZE value is equal to 16-bit and SPI data size is less than or equal to 8-bit, then packing mode is enabled. The DMA then automatically manages the write operations to the SPIx_DR register.

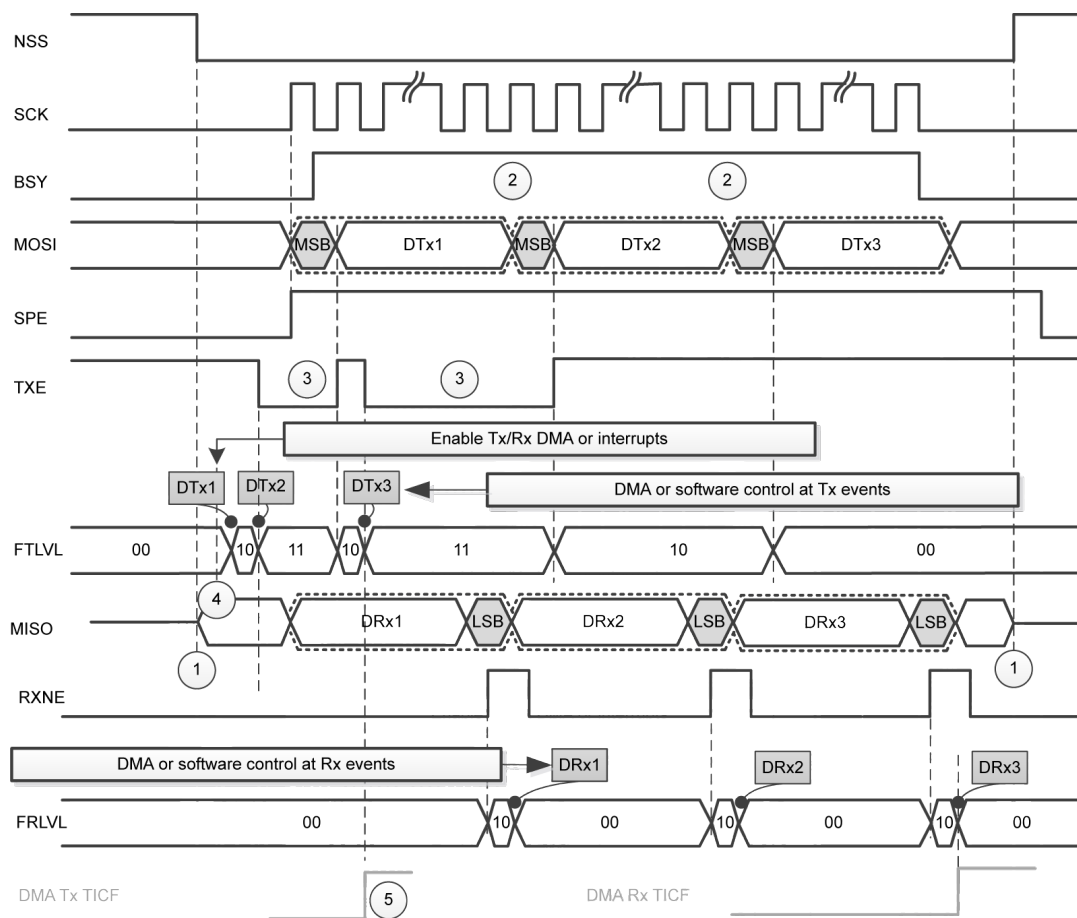

If data packing mode is used and the number of data to transfer is not a multiple of two, the LDMA_TX/LDMA_RX bits must be set. The SPI then considers only one data for the transmission or reception to serve the last DMA transfer (for more details refer to Data packing).

Communication diagrams

Some typical timing schemes are explained in this section. These schemes are valid no matter if the SPI events are handled by pulling, interrupts or DMA. For simplicity, the LSBFIRST=0, CPOL=0 and CPHA=1 setting is used as a common assumption here. No complete configuration of DMA streams is provided.

The following numbered notes are common for [Figure 159. Master full-duplex communication](#) through [Figure 162. Master full-duplex communication in packed mode](#).

1. The slave starts to control MISO line as NSS is active and SPI is enabled, and is disconnected from the line when one of them is released. Sufficient time must be provided for the slave to prepare data dedicated to the master in advance before its transaction starts. At the master, the SPI peripheral takes control at MOSI and SCK signals (occasionally at NSS signal as well) only if SPI is enabled. If SPI is disabled the SPI peripheral is disconnected from GPIO logic, so the levels at these lines depends on GPIO setting exclusively.
2. At the master, BSY stays active between frames if the communication (clock signal) is continuous. At the slave, BSY signal always goes down for at least one clock cycle between data frames.
3. The TXE signal is cleared only if TXFIFO is full.
4. The DMA arbitration process starts just after the TXDMAEN bit is set. The TXE interrupt is generated just after the TXEIE is set. As the TXE signal is at an active level, data transfers to TxFIFO start, until TxFIFO becomes full or the DMA transfer completes.
5. If all the data to be sent can fit into TxFIFO, the DMA TxTCIF flag can be raised even before communication on the SPI bus starts. This flag always rises before the SPI transaction is completed.
6. The CRC value for a package is calculated continuously frame by frame in the SPIx_TxCRCR and SPIx_RxCRCR registers. The CRC information is processed after the entire data package has completed, either automatically by DMA (Tx channel must be set to the number of data frames to be processed) or by SW (the user must handle CRCNEXT bit during the last data frame processing). While the CRC value calculated in SPIx_TxCRCR is simply sent out by transmitter, received CRC information is loaded into RxFIFO and then compared with the SPIx_RxCRCR register content (CRC error flag can be raised here if any difference). This is why the user must take care to flush this information from the FIFO, either by software reading out all the stored content of RxFIFO, or by DMA when the proper number of data frames is preset for Rx channel (number of data frames + number of CRC frames) (see the settings at the example assumption).
7. In data packed mode, TxE and RxNE events are paired and each read/write access to the FIFO is 16 bits wide until the number of data frames are even. If the TxFIFO is $\frac{3}{4}$ full, FTLVL status stays at FIFO full level. That is why the last odd data frame cannot be stored before the TxFIFO becomes $\frac{1}{2}$ full. This frame is stored into TxFIFO with an 8-bit access either by software or automatically by DMA when LDMA_TX control is set.
8. To receive the last odd data frame in packed mode, the Rx threshold must be changed to 8-bit when the last data frame is processed, either by software setting FRXTH=1 or automatically by a DMA internal signal when LDMA_RX is set.

Figure 159. Master full-duplex communication

Assumptions for master full-duplex communication example:

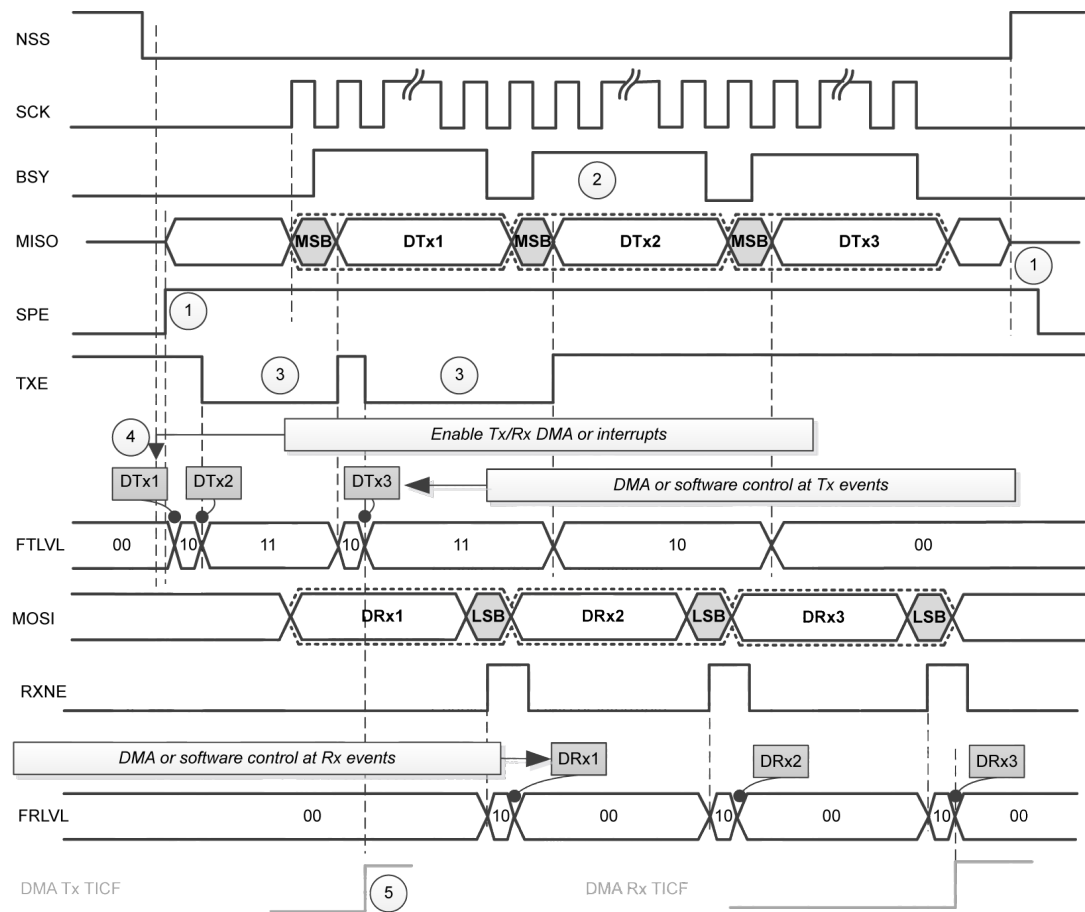

- Data size > 8 bit

If DMA is used:

- Number of Tx frames transacted by DMA is set to 3
- Number of Rx frames transacted by DMA is set to 3

See also: Communication diagrams section for details about common assumptions and notes.

Figure 160. Slave full-duplex communication

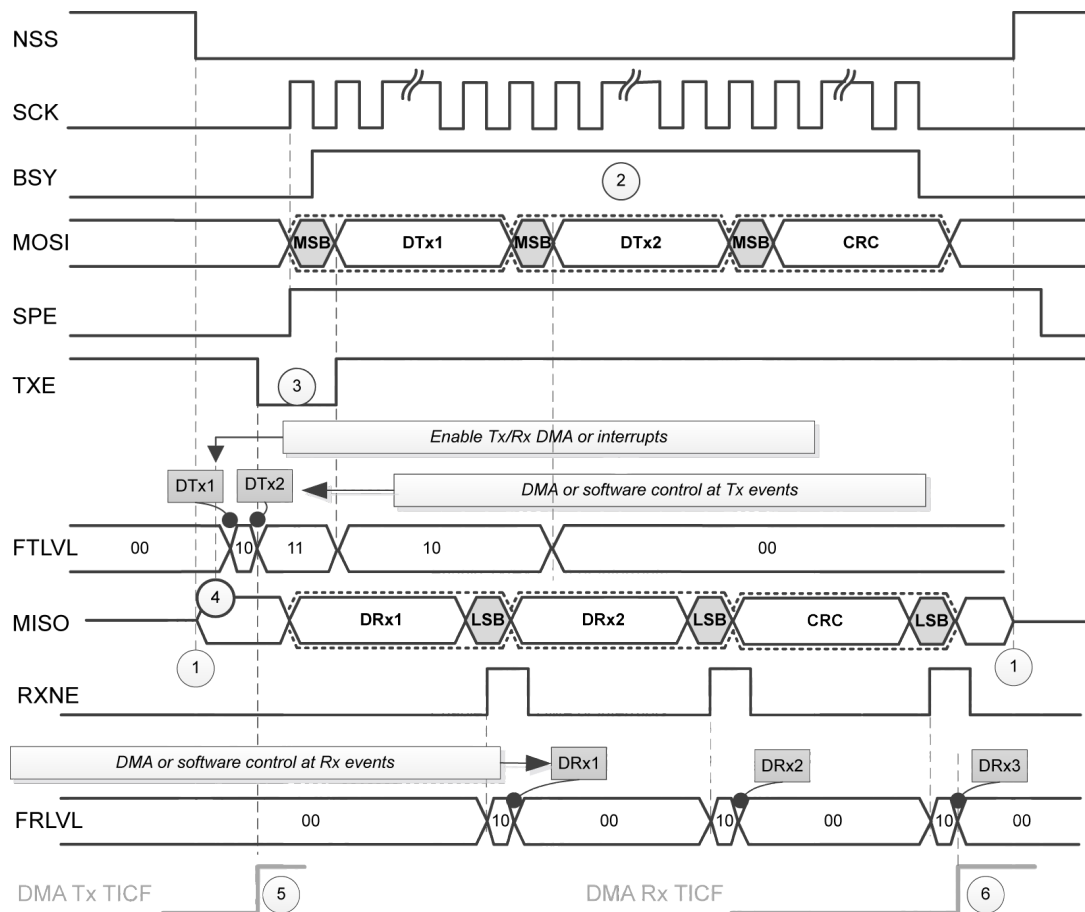

Assumptions for slave full-duplex communication example:

- Data size > 8bit

If DMA is used:

- Number of Tx frames transacted by DMA is set to 3
- Number of Rx frames transacted by DMA is set to 3

See also: Communication diagrams section for details about common assumptions and notes.

Figure 161. Master full-duplex communication with CRC

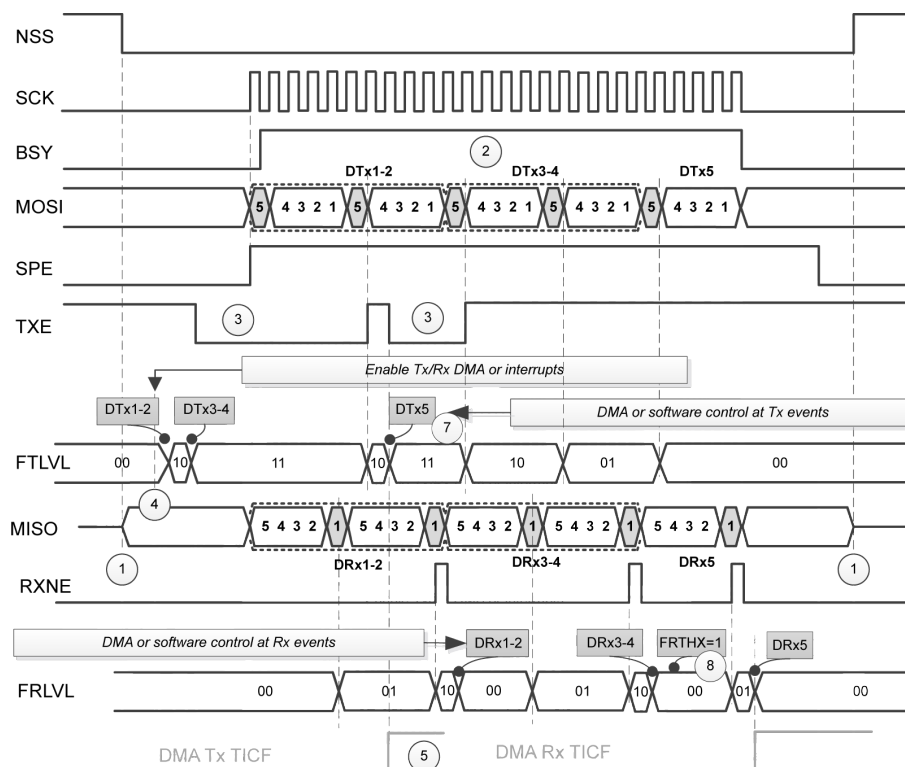

Assumptions for master full-duplex communication with CRC example:

- Data size = 16 bit
- CRC enabled

If DMA is used:

- Number of Tx frames transacted by DMA is set to 2
- Number of Rx frames transacted by DMA is set to 3

See also: Communication diagram section for details about common assumptions and notes.

Figure 162. Master full-duplex communication in packed mode

Assumptions for master full-duplex communication in packed mode example:

- Data size = 5 bit
- Read/write FIFO is performed mostly by 16-bit access
- FRXTH=0.

If DMA is used:

- Number of Tx frames to be transacted by DMA is set to 3
- Number of Rx frames to be transacted by DMA is set to 3
- PSIZE for both Tx and Rx DMA channel is set to 16-bit
- LDMA_TX=1 and LDMA_RX=1

See also: Communication diagrams section for details about common assumptions and notes.

22.5.9

SPI status flags

Three status flags are provided for the application to completely monitor the state of the SPI bus.

Tx buffer empty flag (TXE)

The TXE flag is set when transmission TXFIFO has enough space to store data to send. TXE flag is linked to the TXFIFO level. The flag goes high and stays high until the TXFIFO level is lower or equal to 1/2 of the FIFO depth. An interrupt can be generated if the TXEIE bit in the SPIx_CR2 register is set. The bit is cleared automatically when the TXFIFO level becomes greater than 1/2.

Rx buffer not empty (RXNE)

The RXNE flag is set depending on the FRXTH bit value in the SPIx_CR2 register:

- If FRXTH is set, RXNE goes high and stays high until the RXFIFO level is greater or equal to 1/4 (8-bit).
- If FRXTH is cleared, RXNE goes high and stays high until the RXFIFO level is greater than or equal to 1/2 (16-bit).

An interrupt can be generated if the RXNEIE bit in the SPIx_CR2 register is set.

The RXNE is cleared by hardware automatically when the above conditions are no longer true.

Busy flag (BSY)

The BSY flag is set and cleared by hardware (writing to this flag has no effect).

When BSY is set, it indicates that a data transfer is in progress on the SPI (the SPI bus is busy).

The BSY flag can be used in certain modes to detect the end of a transfer so that the software can disable the SPI or its peripheral clock before entering a low-power mode which does not provide a clock for the peripheral. This avoids corrupting the last transfer.

The BSY flag is also useful for preventing write collisions in a multimaster system. The BSY flag is cleared under any one of the following conditions:

- When the SPI is correctly disabled
- When a fault is detected in master mode (MODF bit set to 1)
- In master mode, when it finishes a data transmission and no new data is ready to be sent
- In slave mode, when the BSY flag is set to '0' for at least one SPI clock cycle between each data transfer.

Note: When the next transmission can be handled immediately by the master (e.g. if the master is in receive-only mode or its Transmit FIFO is not empty), communication is continuous and the BSY flag remains set to '1' between transfers on the master side. Although this is not the case with a slave, it is recommended to use always the TXE and RXNE flags (instead of the BSY flags) to handle data transmission or reception operations.

22.5.10 SPI error flags

An SPI interrupt is generated if one of the following error flags is set and interrupt is enabled by setting the ERRIE bit.

Overrun flag (OVR)

An overrun condition occurs when data is received by a master or slave and the RXFIFO has not enough space to store this received data. This can happen if the software or the DMA did not have enough time to read the previously received data (stored in the RXFIFO) or when space for data storage is limited e.g. the RXFIFO is not available when CRC is enabled in receive-only mode so in this case the reception buffer is limited into a single data frame buffer (see [Section 22.5.13 CRC calculation](#)).

When an overrun condition occurs, the newly received value does not overwrite the previous one in the RXFIFO. The newly received value is discarded and all data transmitted subsequently is lost. Clearing the OVR bit is done by a read access to the SPI_DR register followed by a read access to the SPI_SR register.

Mode fault (MODF)

Mode fault occurs when the master device has its internal NSS signal (NSS pin in NSS hardware mode, or SSI bit in NSS software mode) pulled low. This automatically sets the MODF bit. Master mode fault affects the SPI interface in the following ways:

- The MODF bit is set and an SPI interrupt is generated if the ERRIE bit is set
- The SPE bit is cleared. This blocks all output from the device and disables the SPI interface.
- The MSTR bit is cleared, thus forcing the device into slave mode.

Use the following software sequence to clear the MODF bit:

1. Make a read or write access to the SPIx_SR register while the MODF bit is set.
2. Then write to the SPIx_CR1 register.

To avoid any multiple slave conflicts in a system comprising several MCUs, the NSS pin must be pulled high during the MODF bit clearing sequence. The SPE and MSTR bits can be restored to their original state after this clearing sequence. For security, hardware does not allow the SPE and MSTR bits to be set while the MODF bit is set. In a slave device the MODF bit cannot be set except as the result of a previous multimaster conflict.

CRC error (CRCERR)

This flag is used to verify the validity of the value received when the CRCEN bit in the SPIx_CR1 register is set. The CRCERR flag in the SPIx_SR register is set if the value received in the shift register does not match the receiver SPIx_RXCRCR value. The flag is cleared by the software.

TI mode frame format error (FRE)

A TI mode frame format error is detected when an NSS pulse occurs during an on-going communication when the SPI is operating in slave mode and configured to conform to the TI mode protocol. When this error occurs, the FRE flag is set in the SPIx_SR register. The SPI is not disabled when an error occurs, the NSS pulse is ignored, and the SPI waits for the next NSS pulse before starting a new transfer. The data may be corrupted since the error detection may result in the loss of two data bytes.

The FRE flag is cleared when SPIx_SR register is read. If the ERRIE bit is set, an interrupt is generated on the NSS error detection. In this case, the SPI should be disabled because data consistency is no longer guaranteed and communications should be reinitiated by the master when the slave SPI is enabled again.

22.5.11 NSS pulse mode

This mode is activated by the NSSP bit in the SPIx_CR2 register and it takes effect only if the SPI interface is configured as Motorola SPI master (FRF=0) with capture on the first edge (SPIx_CR1 CPHA=0, CPOL setting is ignored). When activated, an NSS pulse is generated between two consecutive data frame transfers when NSS stays at high level for the duration of one clock period at least. This mode allows the slave to latch data. NSSP pulse mode is designed for applications with a single master-slave pair.

Figure 163. NSSP pulse generation in Motorola SPI master mode illustrates NSS pin management when NSSP pulse mode is enabled.

Figure 163. NSSP pulse generation in Motorola SPI master mode

Note: Similar behavior is encountered when CPOL=0. In this case the sampling edge is the rising edge of SCK, and NSS assertion and de-assertion refer to this sampling edge.

22.5.12 TI mode

TI protocol in master mode

The SPI interface is compatible with the TI protocol. The FRF bit of the SPIx_CR2 register can be used to configure the SPI to be compliant with this protocol.

The clock polarity and phase are forced to conform to the TI protocol requirements whatever the values set in the SPIx_CR1 register. NSS management is also specific to the TI protocol which makes the configuration of NSS management through the SPIx_CR1 and SPIx_CR2 registers (SSM, SSI, SSOE) impossible in this case.

In slave mode, the SPI baud rate prescaler is used to control the moment when the MISO pinstate changes to HiZ when the current transaction finishes (see Figure 164. TI mode transfer). Any baud rate can be used, making it possible to determine this moment with optimal flexibility.

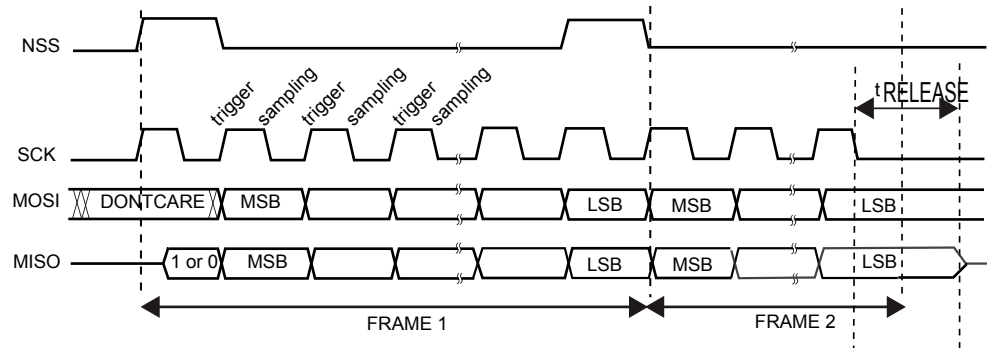

However, the baud rate is generally set to the external master clock baud rate. The delay for the MISO signal to become HiZ ($t_{release}$) depends on internal resynchronization and on the baud rate value set in through the BR[2:0] bits in the SPIx_CR1 register. It is given by the formula below:

$$\frac{t_{baud\ rate}}{2} + 4 \times t_{pclk} < t_{release} < \frac{t_{baud\ rate}}{2} + 6 \times t_{pclk} \quad (8)$$

If the slave detects a misplaced NSS pulse during a data frame transaction the TIFRE flag is set.

If the data size is equal to 4-bits or 5-bits, the master in full-duplex mode or transmit-only mode uses a protocol with one more dummy data bit added after LSB. TI NSS pulse is generated above this dummy bit clock cycle instead of the LSB in each period. This feature is not available for Motorola SPI communications (FRF bit set to 0).

Figure 164. TI mode transfer shows the SPI communication waveforms when TI mode is selected.

Figure 164. TI mode transfer

22.5.13 CRC calculation

Two separate CRC calculators are implemented in order to check the reliability of transmitted and received data. The SPI offers CRC8 or CRC16 calculation independently of the frame data length, which can be fixed to 8-bit or 16-bit. For all the other data frame lengths, no CRC is available.

CRC principle

CRC calculation is enabled by setting the CRCEN bit in the SPIx_CR1 register before the SPI is enabled (SPE = 1). The CRC value is calculated using an odd programmable polynomial on each bit. The calculation is processed on the sampling clock edge defined by the CPHA and CPOL bits in the SPIx_CR1 register. The calculated CRC value is checked automatically at the end of the data block as well as for transfer managed by CPU or by the DMA. When a mismatch is detected between the CRC calculated internally on the received data and the CRC sent by the transmitter, a CRCERR flag is set to indicate a data corruption error. The right procedure for handling the CRC calculation depends on the SPI configuration and the chosen transfer management.

Note: The polynomial value should only be odd. No even values are supported.

CRC transfer managed by CPU

Communication starts and continues normally until the last data frame has to be sent or received in the SPIx_DR register. Then, the CRCNEXT bit has to be set in the SPIx_CR1 register to indicate that the CRC frame transaction follows after the transaction of the currently processed data frame. The CRCNEXT bit must be set before the end of the last data frame transaction. CRC calculation is frozen during CRC transaction.

The received CRC is stored in the RXFIFO like a data byte or word. That is why in CRC mode only, the reception buffer has to be considered as a single 16-bit buffer used to receive-only one data frame at a time.

A CRC-format transaction usually takes one more data frame to communicate at the end of data sequence. However, when setting an 8-bit data frame checked by 16-bit CRC, two more frames are necessary to send the complete CRC.

When the last CRC data is received, an automatic check is performed comparing the received value and the value in the SPIx_RXCRC register. Software has to check the CRCERR flag in the SPIx_SR register to determine if the data transfers were corrupted or not. Software clears the CRCERR flag by writing '0' to it.

After the CRC reception, the CRC value is stored in the RXFIFO and must be read in the SPIx_DR register in order to clear the RXNE flag.

CRC transfer managed by DMA

When SPI communication is enabled with CRC communication and DMA mode, the transmission and reception of the CRC at the end of communication is automatic (with the exception of reading CRC data in receive-only mode). The CRCNEXT bit does not have to be handled by the software. The counter for the SPI transmission DMA channel has to be set to the number of data frames to transmit excluding the CRC frame. On the receiver side, the received CRC value is handled automatically by DMA at the end of the transaction but the user must take care to flush out received CRC information from RXFIFO as it is always loaded into it. In full-duplex mode, the counter of the reception DMA channel can be set to the number of data frames to receive including the CRC, which means, for example, in the specific case of an 8-bit data frame checked by 16-bit CRC:

$DMA_RX = Numb_of_data + 2$

In receive-only mode, the DMA reception channel counter should contain only the amount of data transferred, excluding the CRC calculation. Then, based on the complete transfer from DMA, all the CRC values must be read back by software from FIFO as it works as a single buffer in this mode.

At the end of the data and CRC transfers, the CRCERR flag in the SPIx_SR register is set if corruption occurred during the transfer.

If packing mode is used, the LDMA_RX bit needs managing if the number of data is odd.

Resetting the SPIx_TXCRC and SPIx_RXCRC values

The SPIx_TXCRC and SPIx_RXCRC values are cleared automatically when new data is sampled after a CRC phase. This allows the use of DMA circular mode (not available in receive-only mode) in order to transfer data without any interruption, (several data blocks covered by intermediate CRC checking phases).

If the SPI is disabled during a communication the following sequence must be followed:

1. Disable the SPI
2. Clear the CRCEN bit
3. Enable the CRCEN bit
4. Enable the SPI

Note: When the SPI is in slave mode, the CRC calculator is sensitive to the SCK slave input clock as soon as the CRCEN bit is set, and this is the case whatever the value of the SPE bit. In order to avoid any wrong CRC calculation, the software must enable CRC calculation only when the clock is stable (in steady-state). When the SPI interface is configured as a slave, the NSS internal signal needs to be kept low between the data phase and the CRC phase.

22.6 SPI interrupts

During SPI communication an interrupt can be generated by the following events:

- Transmit TXFIFO ready to be loaded
- Data received in Receive RXFIFO
- Master mode fault
- Overrun error
- TI frame format error

Interrupts can be enabled and disabled separately.

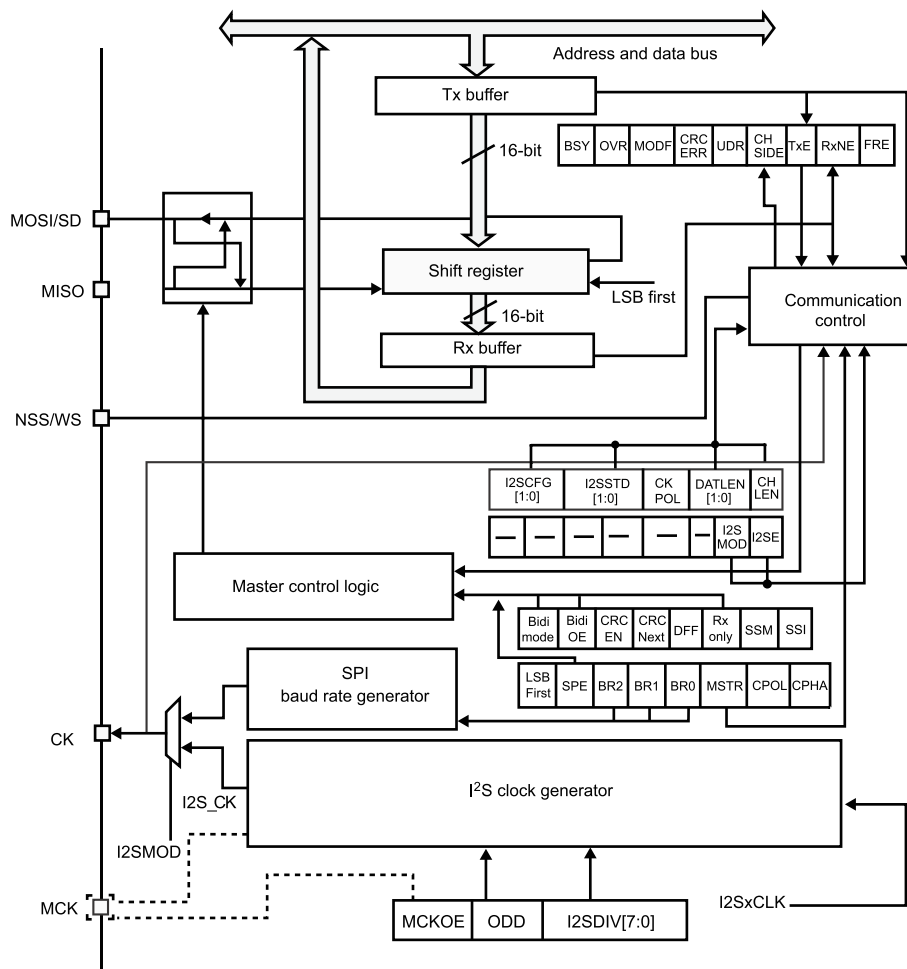

Table 77. SPI interrupts requests

Interrupt event	Event flag	Enable control bit
Transmit TXFIFO ready to be loaded	TXE	TXEIE
Data received in RXFIFO	RXNE	RXNEIE
Master mode fault event	MODF	ERRIE
Overrun error	OVR	
TI frame format error	FRE	

22.7 I2S functional description

22.7.1 I2S general description

The block diagram of the I²S is shown below.

Figure 165. I2S block diagram

The SPI can function as an audio I2S interface when the I2S capability is enabled (by setting the I2SMOD bit in the SPIx_I2SCFGR register). This interface mainly uses the same pins, flags and interrupts as the SPI.

The I2S shares three common pins with the SPI:

- SD: serial data (mapped on the MOSI pin) to transmit or receive the two time-multiplexed data channels (in half-duplex mode only).
- WS: word select (mapped on the NSS pin) is the data control signal output in master mode and input in slave mode.
- CK: serial clock (mapped on the SCK pin) is the serial clock output in master mode and serial clock input in slave mode.

An additional pin can be used when a master clock output is needed for some external audio devices:

- MCK: master clock (mapped separately) is used, when the I2S is configured in master mode (and when the MCKOE bit in the SPIx_I2SPR register is set), to output this additional clock generated at a preconfigured frequency rate equal to $256 \times f_s$, where f_s is the audio sampling frequency.

The I2S uses its own clock generator to produce the communication clock when it is set in master mode. This clock generator is also the source of the master clock output. Two additional registers are available in I2S mode. One is linked to the clock generator configuration SPIx_I2SPR and the other one is a generic I2S configuration register SPIx_I2SCFGR (audio standard, slave/master mode, data format, packet frame, clock polarity, etc.).

The SPIx_CR1 register and all CRC registers are not used in the I2S mode. Likewise, the SSOE bit in the SPIx_CR2 register and the MODF and CRCERR bits in the SPIx_SR are not used.

The I²S uses the same SPI register for data transfer (SPIx_DR) in 16-bit wide mode.

22.7.2 Supported audio protocols

The three-line bus has to handle only audio data generally time-multiplexed on two channels: the right channel and the left channel. However there is only one 16-bit register for transmission or reception. So, it is up to the software to write into the data register the appropriate value corresponding to each channel side, or to read the data from the data register and to identify the corresponding channel by checking the CHSIDE bit in the SPIx_SR register. Channel left is always sent first followed by the channel right (CHSIDE has no meaning for the PCM protocol).

Four data and packet frames are available. Data may be sent with a format of:

- 16-bit data packed in a 16-bit frame
- 16-bit data packed in a 32-bit frame
- 24-bit data packed in a 32-bit frame
- 32-bit data packed in a 32-bit frame

When using 16-bit data extended on a 32-bit packet, the first 16 bits (MSB) are the significant bits, the 16-bit LSB is forced to 0 without any need for software action or DMA request (only one read/write operation).

The 24-bit and 32-bit data frames need two CPU read or write operations to/from the SPIx_DR register or two DMA operations if the DMA is preferred for the application. For 24-bit data frame specifically, the 8 non significant bits are extended to 32 bits with 0-bits (by hardware).

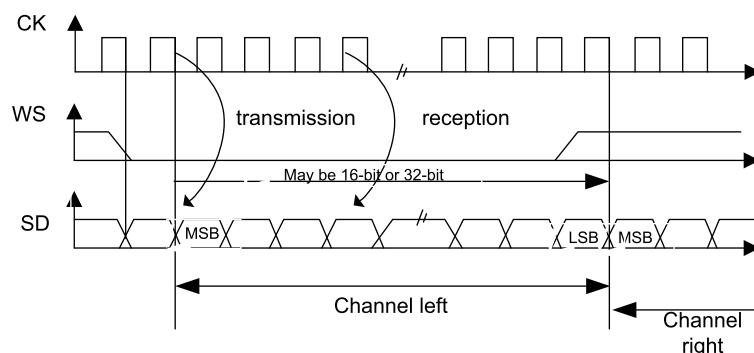

For all data formats and communication standards, the most significant bit is always sent first (MSB first).

The I²S interface supports four audio standards, configurable using the I2SSTD[1:0] and PCMSYNC bits in the SPIx_I2SCFGR register.

I²S Philips standard

For this standard, the WS signal is used to indicate which channel is being transmitted. It is activated one CK clock cycle before the first bit (MSB) is available.

Figure 166. I²S Philips protocol waveforms (16/32-bit full accuracy, CPOL = 0)

Data are latched on the falling edge of CK (for the transmitter) and are read on the rising edge (for the receiver). The WS signal is also latched on the falling edge of CK.

Figure 167. I²S Philips standard waveforms (24-bit frame with CPOL = 0)

This mode needs two write or read operations to/from the SPIx_DR register.

- In transmission mode:
If 0x8EAA33 has to be sent (24-bit):

Figure 168. Transmitting 0x8EAA33

- In reception mode:
If data 0x8EAA33 is received:

Figure 169. Receiving 0x8EAA33

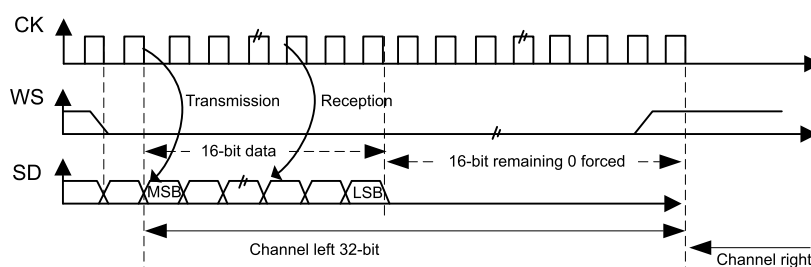

Figure 170. I²S Philips standard (16-bit extended to 32-bit packet frame with CPOL = 0)

When 16-bit data frame extended to 32-bit channel frame is selected during the I²S configuration phase, only one access to the SPIx_DR register is required. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format.

If the data to transmit or the received data are 0x76A3 (0x76A30000 extended to 32-bit), the operation shown in Figure 171. Example of 16-bit data frame extended to 32-bit channel frame is required.

Figure 171. Example of 16-bit data frame extended to 32-bit channel frame

Only one access to SPIx_DR

0x76A3

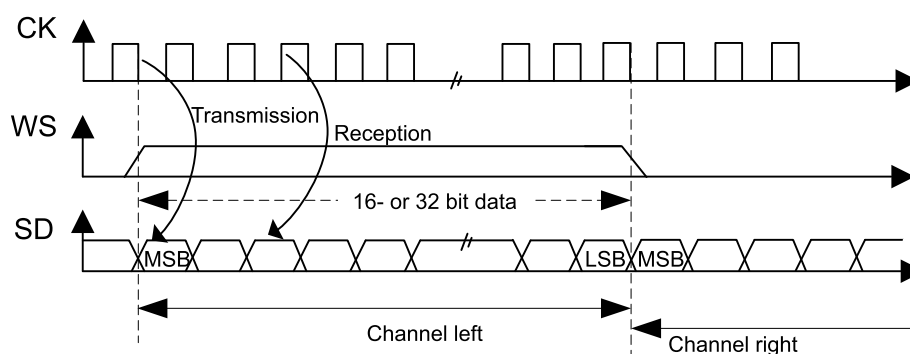

For transmission, each time an MSB is written to SPIx_DR, the TXE flag is set and its interrupt, if allowed, is generated to load the SPIx_DR register with the new value to send. This takes place even if 0x0000 have not yet been sent because it is done by hardware.

For reception, the RXNE flag is set and its interrupt, if allowed, is generated when the first 16 MSB half-word is received.

In this way, more time is provided between two write or read operations, which prevents underrun or overrun conditions (depending on the direction of the data transfer).

MSB justified standard

For this standard, the WS signal is generated at the same time as the first data bit, which is the MSB.

Figure 172. MSB justified 16-bit or 32-bit full-accuracy length with CPOL = 0

Data are latched on the falling edge of CK (for transmitter) and are read on the rising edge (for the receiver).

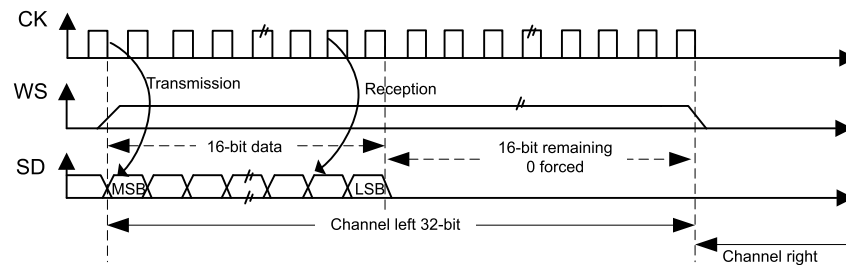

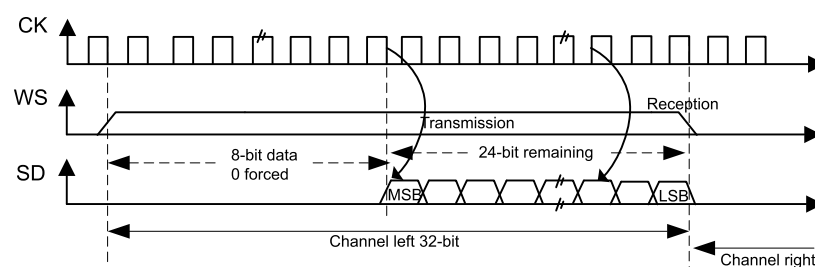

Figure 173. MSB justified 24-bit frame length with CPOL = 0

Figure 174. MSB justified 16-bit extended to 32-bit packet frame with CPOL = 0

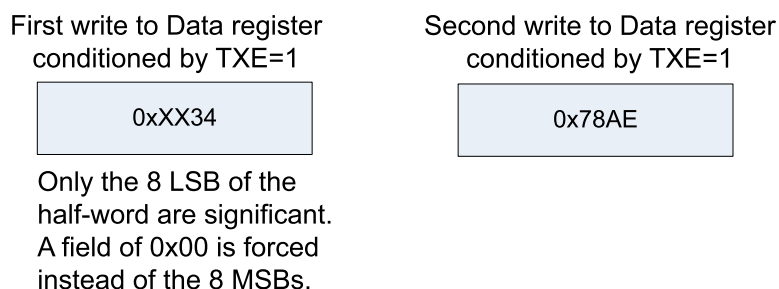

LSB justified standard

This standard is similar to the MSB justified standard (no difference for the 16-bit and 32-bit full-accuracy frame formats).

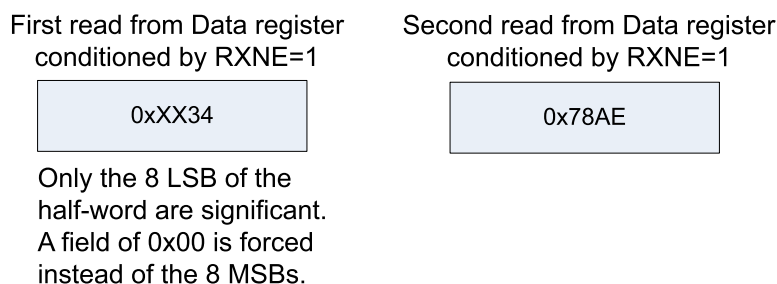

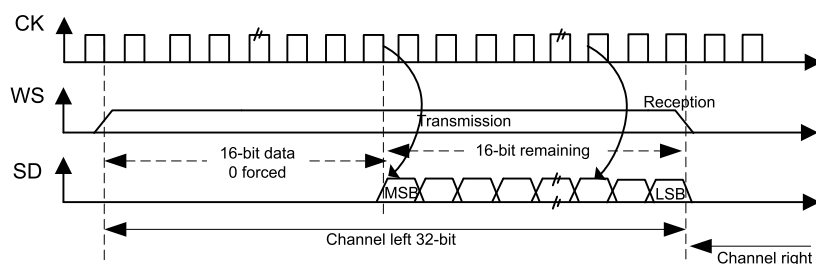

Figure 175. LSB justified 16-bit or 32-bit full-accuracy length with CPOL = 0

Figure 176. LSB justified 24-bit frame length with CPOL = 0

MS30104V1

- In transmission mode:
If data 0x3478AE has to be transmitted, two write operations to the SPIx_DR register are required by software or by DMA. The operations are shown below.

Figure 177. Operations required to transmit 0x3478AE

- In reception mode:
If data 0x3478AE are received, two successive read operations from the SPIx_DR register are required on each RXNE event.

Figure 178. Operations required to receive 0x3478AE

Figure 179. LSB justified 16-bit extended to 32-bit packet frame with CPOL = 0

When 16-bit data frame extended to 32-bit channel frame is selected during the I²S configuration phase. Only one access to the SPIx_DR register is required. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format. In this case it corresponds to the half-word MSB.

If the data to transmit or the received data are 0x76A3 (0x0000 76A3 extended to 32-bit), the operation shown in Figure 180. Example of 16-bit data frame extended to 32-bit channel frame (2) is required

Figure 180. Example of 16-bit data frame extended to 32-bit channel frame (2)

Only one access to the SPIx-DR register

0x76A3

In transmission mode, when a TXE event occurs, the application has to write the data to be transmitted (in this case 0x76A3). The 0x000 field is transmitted first (extension on 32-bit). The TXE flag is set again as soon as the effective data (0x76A3) is sent on SD.

In reception mode, RXNE is asserted as soon as the significant half-word is received (and not the 0x0000 field).

In this way, more time is provided between two write or read operations to prevent underrun or overrun conditions.

PCM standard

For the PCM standard, there is no need to use channel-side information. The two PCM modes (short and long frame) are available and configurable using the PCMSYNC bit in SPIx_I2SCFGR register.

Figure 181. PCM standard waveforms (16-bit)

For long frame synchronization, the WS signal assertion time is fixed to 13 bits in master mode. For short frame synchronization, the WS synchronization signal is only one cycle long.

Figure 182. PCM standard waveforms (16-bit extended to 32-bit packet frame)

Note: For both modes (master and slave) and for both synchronizations (short and long), the number of bits between two consecutive pieces of data (and so two synchronization signals) needs to be specified (DATLEN and CHLEN bits in the SPIx_I2SCFGR register) even in slave mode.

22.7.3 Clock generator

The I²S bitrate determines the dataflow on the I²S data line and the I²S clock signal frequency.

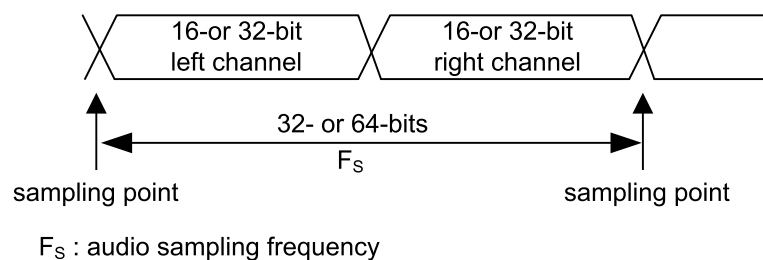

I²S bitrate = number of bits per channel × number of channels × sampling audio frequency.

The I²S bitrate, left and right channel, is calculated as follows:

I²S bitrate = $16 \times 2 \times f_s$ for a 16-bit audio

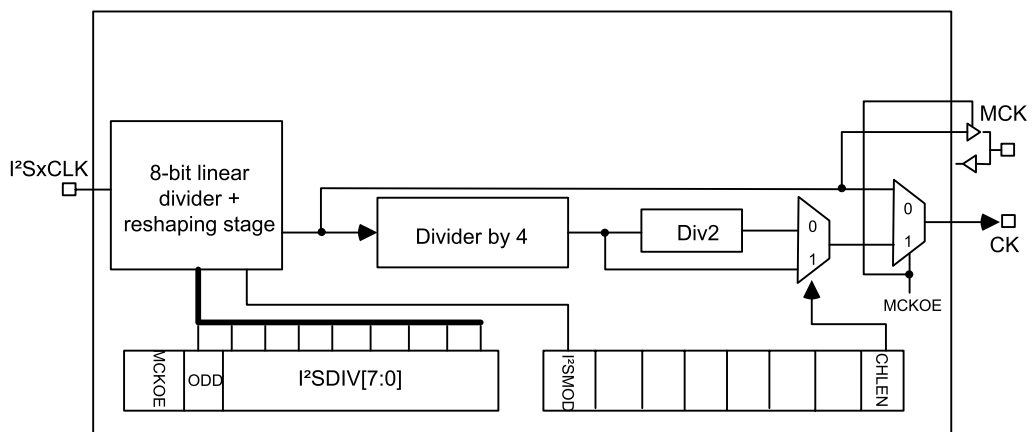

I²S bitrate = $32 \times 2 \times f_s$ for a 32-bit audio.

Figure 183. Audio sampling frequency definition

When the master mode is configured, a specific action needs to be taken to properly program the linear divider in order to communicate with the desired audio frequency.

Figure 184. I²S clock generator architecture

where x can be 2 or 3.

Figure 184. I²S clock generator architecture presents the communication clock architecture. The I²Sx clock is always a 32 MHz frequency clock.

Caution: In addition, it is mandatory to keep I2SxCLK frequency higher or equal to the APB clock used by the SPI/I2S block. If this condition is not respected, SPI/I2S does not work.

The audio sampling frequency may be 96 kHz, 48 kHz, 44.1 kHz, 32 kHz, 22.05 kHz, 16 kHz, 11.025 kHz or 8 kHz (or any other value within this range). In order to reach the desired frequency, the linear divider needs to be programmed according to the formulas below:

When the master clock is generated (MCKOE in the SPIx_I2SPR register is set):

$f_s = \text{I2SxCLK} / [256 * ((2 * \text{I2SDIV}) + \text{ODD})]$ whatever the channel frame width (16-bit wide or 32-bit wide).

When the master clock is disabled (MCKOE bit cleared):

$f_S = \text{I2SxCLK} / [(16 \times 2) \times ((2 \times \text{I2SDIV}) + \text{ODD})]$ when the channel frame is 16-bit wide.

$f_S = \text{I2SxCLK} / [(32 \times 2) \times ((2 \times \text{I2SDIV}) + \text{ODD})]$ when the channel frame is 32-bit wide.

Table 78. Audio frequency precision using I2SCLK = 32 MHz provides example precision values for different clock configurations.

Note: Other configurations are possible that allow optimum clock precision.

Table 78. Audio frequency precision using I2SCLK = 32 MHz

22.7.4

I2S master mode

The I²S can be configured in master mode. This means that the serial clock is generated on the CK pin as well as the word select signal WS. Master clock (MCK) may be output or not, controlled by the MCKOE bit in the SPIx_I2SPR register.

Procedure

1. Select the I2SDIV[7:0] bits in the SPIx_I2SPR register to define the serial clock baud rate to reach the proper audio sample frequency. The ODD bit in the SPIx_I2SPR register also has to be defined.
2. Select the CKPOL bit to define the steady level for the communication clock. Set the MCKOE bit in the SPIx_I2SPR register if the master clock MCK needs to be provided to the external DAC/ADC audio component (the I2SDIV and ODD values should be computed depending on the state of the MCK output, for more details refer to [Section 22.7.3 Clock generator](#)).

3. Set the I2SMOD bit in the SPIx_I2SCFGR register to activate the I²S functions and choose the I²S standard through the I2SSTD[1:0] and PCMSYNC bits, the data length through the DATLEN[1:0] bits and the number of bits per channel by configuring the CHLEN bit. Select also the I²S master mode and direction (transmitter or receiver) through the I2SCFG[1:0] bits in the SPIx_I2SCFGR register.
4. If needed, select all the potential interrupt sources and the DMA capabilities by writing the SPIx_CR2 register.
5. The I2SE bit in SPIx_I2SCFGR register must be set.

WS and CK are configured in output mode. MCK is also an output, if the MCKOE bit in SPIx_I2SPR is set.

Transmission sequence

The transmission sequence begins when a half-word is written into the Tx buffer.

Let us assume the first data written into the Tx buffer corresponds to the left channel data. When data are transferred from the Tx buffer to the shift register, TXE is set and data corresponding to the right channel have to be written into the Tx buffer. The CHSIDE flag indicates which channel is to be transmitted. It has a meaning when the TXE flag is set because the CHSIDE flag is updated when TXE goes high.

A full frame has to be considered as a left channel data transmission followed by a right channel data transmission. It is not possible to have a partial frame where only the left channel is sent.

The data half-word is parallel loaded into the 16-bit shift register during the first bit transmission, and then shifted out, serially, to the MOSI/SD pin, MSB first. The TXE flag is set after each transfer from the Tx buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPIx_CR2 register is set.

For more details about the write operations depending on the I²S standard mode selected, refer to [Section 22.7.2 Supported audio protocols](#).

To ensure a continuous audio data transmission, it is mandatory to write the SPIx_DR register with the next data to transmit before the end of the current transmission.

To switch off the I²S, by clearing I2SE, it is mandatory to wait for TXE = 1 and BSY = 0.

Reception sequence

The operating mode is the same as for transmission mode except for point 3, where the configuration should set the master reception mode through the I2SCFG[1:0] bits.

Whatever the data or channel length, the audio data are received by 16-bit packets. This means that each time the Rx buffer is full, the RXNE flag is set and an interrupt is generated if the RXNEIE bit is set in the SPIx_CR2 register. Depending on the data and channel length configuration, the audio value received for a right or left channel may result from one or two receptions into the Rx buffer.

Clearing the RXNE bit is performed by reading the SPIx_DR register.

CHSIDE is updated after each reception. It is sensitive to the WS signal generated by the I²S cell.

For more details about the read operations depending on the I²S standard mode selected, refer to [Section 22.7.2 Supported audio protocols](#).

If data is received while the previously received data have not been read yet, an overrun is generated and the OVR flag is set. If the ERRIE bit is set in the SPIx_CR2 register, an interrupt is generated to indicate the error.

To switch off the I²S, specific actions are required to ensure that the I²S completes the transfer cycle properly without initiating a new data transfer. The sequence depends on the configuration of the data and channel lengths, and on the audio protocol mode selected. In the case of:

- 16-bit data length extended on 32-bit channel length (DATLEN = 00 and CHLEN = 1) using the LSB justified mode (I2SSTD = 10)
 1. Wait for the second to last RXNE = 1 (n – 1)
 2. Then wait 17 I²S clock cycles (using a software loop)
 3. Disable the I²S (I2SE=0)
- 16-bit data length extended on 32-bit channel length (DATLEN = 00 and CHLEN = 1) in MSB justified, I²S or PCM modes (I2SSTD = 00, I2SSTD = 01 or I2SSTD = 11, respectively)
 1. Wait for the last RXNE
 2. Then wait 1 I²S clock cycle (using a software loop)
 3. Disable the I²S (I2SE=0)

- For all other combinations of DATLEN and CHLEN, whatever the audio mode selected through the I²S STD bits, carry out the following sequence to switch off the I²S:
 1. Wait for the second to last RXNE = 1 (n – 1)
 2. Then wait one I²S clock cycle (using a software loop)
 3. Disable the I²S (I2SE = 0)

Note: The BSY flag is kept low during transfers.

22.7.5 I2S slave mode

For the slave configuration, the I²S can be configured in transmission or reception mode. The operating mode is following mainly the same rules as described for the I²S master configuration. In slave mode, there is no clock to be generated by the I²S interface. The clock and WS signals are input from the external master connected to the I²S interface. There is then no need, for the user, to configure the clock.

The configuration steps to follow are listed below:

1. Set the I2SMOD bit in the SPIx_I2SCFGR register to select I²S mode and choose the I²S standard through the I2SSTD[1:0] bits, the data length through the DATLEN[1:0] bits and the number of bits per channel for the frame configuring the CHLEN bit. Select also the mode (transmission or reception) for the slave through the I2SCFG[1:0] bits in the SPIx_I2SCFGR register.
2. If needed, select all the potential interrupt sources and the DMA capabilities by writing the SPIx_CR2 register.
3. The I2SE bit in SPIx_I2SCFGR register must be set.

Transmission sequence

The transmission sequence begins when the external master device sends the clock and when the NSS_WS signal requests the transfer of data. The slave has to be enabled before the external master starts the communication. The I²S data register has to be loaded before the master initiates the communication.

For the I²S, MSB justified and LSB justified modes, the first data item to be written into the data register corresponds to the data for the left channel. When the communication starts, the data are transferred from the Tx buffer to the shift register. The TXE flag is then set in order to request the right channel data to be written into the I²S data register.

The CHSIDE flag indicates which channel is to be transmitted. Compared to the master transmission mode, in slave mode, CHSIDE is sensitive to the WS signal coming from the external master. This means that the slave needs to be ready to transmit the first data before the clock is generated by the master. WS assertion corresponds to left channel transmitted first.

Note: The I2SE has to be written at least two PCLK cycles before the first clock of the master comes on the CK line.

The data half-word is parallel-loaded into the 16-bit shift register (from the internal bus) during the first bit transmission, and then shifted out serially to the MOSI/SD pin MSB first. The TXE flag is set after each transfer from the Tx buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPIx_CR2 register is set.

Note that the TXE flag should be checked to be at 1 before attempting to write the Tx buffer.

For more details about the write operations depending on the I²S standard mode selected, refer to [Section 22.7.2 Supported audio protocols](#).

To secure a continuous audio data transmission, it is mandatory to write the SPIx_DR register with the next data to transmit before the end of the current transmission. An underrun flag is set and an interrupt may be generated if the data are not written into the SPIx_DR register before the first clock edge of the next data communication. This indicates to the software that the transferred data are wrong. If the ERRIE bit is set into the SPIx_CR2 register, an interrupt is generated when the UDR flag in the SPIx_SR register goes high. In this case, it is mandatory to switch off the I²S and to restart a data transfer starting from the left channel.

To switch off the I²S, by clearing the I2SE bit, it is mandatory to wait for TXE = 1 and BSY = 0.

Reception sequence

The operating mode is the same as for the transmission mode except for point 1, where the configuration should set the master reception mode using the I2SCFG[1:0] bits in the SPIx_I2SCFGR register.

Whatever the data length or the channel length, the audio data are received by 16-bit packets. This means that each time the RX buffer is full, the RXNE flag in the SPIx_SR register is set and an interrupt is generated if the RXNEIE bit is set in the SPIx_CR2 register. Depending on the data length and channel length configuration, the audio value received for a right or left channel may result from one or two receptions into the RX buffer.

The CHSIDE flag is updated each time data are received to be read from the SPIx_DR register. It is sensitive to the external WS line managed by the external master component.

Clearing the RXNE bit is performed by reading the SPIx_DR register.

For more details about the read operations depending on the I²S standard mode selected, refer to [Section 22.7.2 Supported audio protocols](#).

If data are received while the preceding received data have not yet been read, an overrun is generated and the OVR flag is set. If the bit ERRIE is set in the SPIx_CR2 register, an interrupt is generated to indicate the error.

To switch off the I²S in reception mode, I2SE has to be cleared immediately after receiving the last RXNE = 1.

Note: The external master components should have the capability of sending/receiving data in 16-bit or 32-bit packets via an audio channel.

22.7.6 I2S error flags

Underrun flag (UDR)

There are three error flags for the I²S cell.

In slave transmission mode this flag is set when the first clock for data transmission appears while the software has not yet loaded any value into SPIx_DR. It is available when the I2SMOD bit in the SPIx_I2SCFGR register is set. An interrupt may be generated if the ERRIE bit in the SPIx_CR2 register is set.

The UDR bit is cleared by a read operation on the SPIx_SR register.

Overrun flag (OVR)

This flag is set when data are received and the previous data have not yet been read from the SPIx_DR register. As a result, the incoming data are lost. An interrupt may be generated if the ERRIE bit is set in the SPIx_CR2 register.

In this case, the receive buffer contents are not updated with the newly received data from the transmitter device. A read operation to the SPIx_DR register returns the previous correctly received data. All other subsequently transmitted half-words are lost.

Clearing the OVR bit is done by a read operation on the SPIx_DR register followed by a read access to the SPIx_SR register.

Frame error flag (FRE)

This flag can be set by hardware only if the I²S is configured in slave mode. It is set if the external master is changing the WS line while the slave is not expecting this change. If the synchronization is lost, the following steps are required to recover from this state and resynchronize the external master device with the I²S slave device:

1. Disable the I²S.
2. Enable it again when the correct level is detected on the WS line (WS line is high in I²S mode or low for MSB- or LSB-justified or PCM modes).

Desynchronization between master and slave devices may be due to noisy environment on the SCK communication clock or on the WS frame synchronization line. An error interrupt can be generated if the ERRIE bit is set. The desynchronization flag (FRE) is cleared by software when the status register is read.

22.7.7 DMA features

In I²S mode, the DMA works in exactly the same way as it does in SPI mode. There is no difference except that the CRC feature is not available in I²S mode since there is no data transfer protection system.

22.8 I2S interrupts

Table 80. I²S interrupt request provides the list of I²S interrupts.

Table 80. I²S interrupt request

Interrupt event	Event flag	Enable control bit
Transmit buffer empty flag	TXE	TXEIE
Receive buffer not empty flag	RXNE	RXNEIE
Overrun error	OVR	ERRIE
Underrun error	UDR	
Frame error flag	FRE	

22.9 SPI and I²S registers

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit). SPI_DR, in addition, can be accessed by 8-bit access.

22.9.1 SPI control register 1 (SPIx_CR1)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	This bit is not used in I ² S mode.
Bit 1	CPOL: Clock polarity. 0: CK to 0 when idle 1: CK to 1 when idle Note: This bit should not be changed when communication is on-going. This bit is not used in I ² S mode and SPI TI mode.
Bit 0	CPHA: Clock phase. 0: The first clock transition is the first data capture edge 1: The second clock transition is the first data capture edge Note: This bit should not be changed when communication is on-going. This bit is not used in I ² S mode and SPI TI mode.

22.9.2 SPI control register 2 (SPIx_CR2)

Address offset: 0x04

Reset value: 0x0700

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	LDMA_TX	LDMA_RX	FRXTH	DS [3:0]				TXEIE	RXNEIE	ERRIE	FRF	NSSP	SSOE	TXDMAEN	RXDMAEN
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 15	Reserved, must be kept at reset value.
Bit 14	LDMA_TX: Last DMA transfer for transmission. This bit is used in data packing mode, to define if the total number of data to transmit by DMA is odd or even. It has significance only if the TXDMAEN bit in the SPIx_CR2 register is set and if packing mode is used (data length ≤ 8-bit and write access to SPIx_DR is 16-bit wide). It has to be written when the SPI is disabled (SPE = 0 in the SPIx_CR1 register). 0: Number of data to transfer is even 1: Number of data to transfer is odd Note: Refer to procedure for disabling the SPI if the CRCEN bit is set. This bit is not used in I ² S mode.
Bit 13	LDMA_RX: Last DMA transfer for reception. This bit is used in data packing mode, to define if the total number of data to receive by DMA is odd or even. It has significance only if the RXDMAEN bit in the SPIx_CR2 register is set and if packing mode is used (data length ≤ 8-bit and write access to SPIx_DR is 16-bit wide). It has to be written when the SPI is disabled (SPE = 0 in the SPIx_CR1 register). 0: Number of data to transfer is even 1: Number of data to transfer is odd Note: Refer to Procedure for disabling the SPI, if the CRCEN bit is set. This bit is not used in I ² S mode.
Bit 12	FRXTH: FIFO reception threshold. FRXTH is set according the read access (16-bit or 8-bit) to the FIFO. This bit is used to set the threshold of the RXFIFO that triggers an RXNE event. 0: RXNE event is generated if the FIFO level is greater than or equal to 1/2 (16-bit) 1: RXNE event is generated if the FIFO level is greater than or equal to 1/4 (8-bit)

Bit 12	Note: This bit is not used in I ² S mode.
Bit 11:8	<p>DS [3:0]: Data size.</p> <p>These bits configure the data length for SPI transfers:</p> <p>0000: Not used</p> <p>0001: Not used</p> <p>0010: Not used</p> <p>0011: 4-bit</p> <p>0100: 5-bit</p> <p>0101: 6-bit</p> <p>0110: 7-bit</p> <p>0111: 8-bit</p> <p>1000: 9-bit</p> <p>1001: 10-bit</p> <p>1010: 11-bit</p> <p>1011: 12-bit</p> <p>1100: 13-bit</p> <p>1101: 14-bit</p> <p>1110: 15-bit</p> <p>1111: 16-bit</p> <p>If software attempts to write one of the "Not used" values, they are forced to the value "0111"(8- bit).</p>
	Note: This bit is not used in I ² S mode.
Bit 7	<p>TXEIE: Tx buffer empty interrupt enable.</p> <p>0: TXE interrupt masked</p> <p>1: TXE interrupt not masked. Used to generate an interrupt request when the TXE flag is set.</p>
Bit 6	<p>RXNEIE: RX buffer not empty interrupt enable.</p> <p>0: RXNE interrupt masked</p> <p>1: RXNE interrupt not masked. Used to generate an interrupt request when the RXNE flag is set.</p>
Bit 5	<p>ERRIE: Error interrupt enable.</p> <p>This bit controls the generation of an interrupt when an error condition occurs (CRCERR, OVR, MODF in SPI mode, FRE at TI mode and UDR, OVR, and FRE in I²S mode).</p> <p>0: Error interrupt is masked</p> <p>1: Error interrupt is enabled</p>
Bit 4	<p>FRF: Frame format.</p> <p>0: SPI Motorola mode</p> <p>1: SPI TI mode</p> <p>Note: This bit must be written only when the SPI is disabled (SPE=0).</p> <p>This bit is not used in I²S mode.</p>
Bit 3	<p>NSSP: NSS pulse management.</p> <p>This bit is used in master mode only. It allows the SPI to generate an NSS pulse between two consecutive data when doing continuous transfers. In the case of a single data transfer, it forces the NSS pin high level after the transfer.</p> <p>It has no meaning if CPHA='1', or FRF='1'.</p> <p>0: No NSS pulse</p> <p>1: NSS pulse generated</p> <p>Note:</p> <p>1. This bit must be written only when the SPI is disabled (SPE=0).</p>

	2. This bit is not used in I ² S mode and SPI TI mode.
Bit 2	SSOE : SS output enable. 0: SS output is disabled in master mode and the SPI interface can work in multimaster configuration 1: SS output is enabled in master mode and when the SPI interface is enabled. The SPI interface cannot work in a multimaster environment. Note: This bit is not used in I ² S mode and SPI TI mode.
Bit 1	TXDMAEN : Tx buffer DMA enable. When this bit is set, a DMA request is generated whenever the TXE flag is set. 0: Tx buffer DMA disabled 1: Tx buffer DMA enabled
Bit 0	RXDMAEN : Rx buffer DMA enable. When this bit is set, a DMA request is generated whenever the RXNE flag is set. 0: Rx buffer DMA disabled 1: Rx buffer DMA enabled

22.9.3 SPI status register (SPIx_SR)

Address offset: 0x08

Reset value: 0x0002

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FTLVL[1:0]	FRLVL[2:0]	FRE	BSY	OVR	MODF	CRC ERR	UDR	CHSIDE	TXE	RXNE		
			r	r	r	r	r	r	r	rc_w0	r	r	r	r	r

Bits 15:13	Reserved, must be kept at reset value.
Bits 12:11	FTLVL[1:0] : FIFO transmission level. These bits are set and cleared by hardware. 00: FIFO empty 01: 1/4 FIFO 10: 1/2 FIFO 11: FIFO full (considered as FULL when the FIFO threshold is greater than 1/2) Note: These bits are not used in I ² S mode.
Bits 10:9	FRLVL[1:0] : FIFO reception level. These bits are set and cleared by hardware. 00: FIFO empty 01: 1/4 FIFO 10: 1/2 FIFO 11: FIFO full Note: These bits are not used in I ² S mode and in SPI receive-only mode while CRC calculation is enabled.
Bits 8	FRE : Frame format error. This flag is used for SPI in TI slave mode and I ² S slave mode. Refer to Section 22.5.10 SPI error flags and Section 22.7.6 I2S error flags . This flag is set by hardware and reset when SPIx_SR is read by software. 0: No frame format error

	1: A frame format error occurred
Bit 7	BSY: Busy flag. 0: SPI (or I ² S) not busy 1: SPI (or I ² S) is busy in communication or Tx buffer is not empty. This flag is set and cleared by hardware. Note: The BSY flag must be used with caution: refer to Section 22.5.9 SPI status flags .
Bit 6	OVR: Overrun flag. 0: No overrun occurred 1: Overrun occurred This flag is set by hardware and reset by a software sequence. Refer to Section 22.7.6 I2S error flags for the software sequence.
Bit 5	MODF: Mode fault. 0: No mode fault occurred 1: Mode fault occurred This flag is set by hardware and reset by a software sequence.
Bit 4	CRCERR: CRC error flag. 0: CRC value received matches the SPIx_RXCRCR value 1: CRC value received does not match the SPIx_RXCRCR value This flag is set by hardware and cleared by software writing 0.
Bit 3	UDR: Underrun flag. 0: No underrun occurred 1: Underrun occurred This flag is set by hardware and reset by a software sequence. Refer to Section 22.7.6 I2S error flags for the software sequence. Note: This bit is not used in SPI mode.
Bit 2	CHSIDE: Channel side. 0: Channel left has to be transmitted or has been received 1: Channel right has to be transmitted or has been received Note: This bit is not used in SPI mode. It has no significance in PCM mode.
Bit 1	TXE: Transmit buffer empty. 0: No more empty space in Tx buffer (software shall not write data to the Tx buffer). 1: At least one empty space in Tx buffer (software may write data to the Tx buffer).
Bit 0	RXNE: Receive buffer not empty. 0: Rx buffer empty 1: Rx buffer not empty

22.9.4

SPI data register (SPIx_DR)

Address offset: 0x0C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0	DR[15:0]: Data register.
	Data received or to be transmitted.
	The data register serves as an interface between the Rx and Tx FIFOs. When the data register is read, RxFIFO is accessed while the write to data register accesses TxFIFO (see Section 22.5.8 Data transmission and reception procedures).
	Note: Data is always right-aligned. Unused bits are ignored when writing to the register, and read as zero when the register is read. The Rx threshold setting must always correspond with the read access currently used.

22.9.5 SPI CRC polynomial register (SPIx_CRCPR)

Address offset: 0x10

Reset value: 0x0007

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRCPOLY[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0	CRCPOLY[15:0]: CRC polynomial register.
	This register contains the polynomial for the CRC calculation.
	The CRC polynomial (0007h) is the reset value of this register. Another polynomial can be configured as required.

Note: The polynomial value should be odd only. No even value is supported.

22.9.6 SPI Rx CRC register (SPIx_RXCRCR)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RxCRC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 15:0	RXCRC[15:0]: Rx CRC register.
	When CRC calculation is enabled, the RxCRC[15:0] bits contain the computed CRC value of the subsequently received bytes. This register is reset when the CRCEN bit in SPIx_CR1 register is written to 1. The CRC is calculated serially using the polynomial programmed in the SPIx_CRCPR register.
	Only the 8 LSB bits are considered when the data frame format is set to be 8-bit data (CRCL bit in the SPIx_CR1 is cleared). CRC calculation is done based on any CRC8 standard.
	The entire 16-bits of this register are considered when a 16-bit data frame format is selected (CRCL bit in the SPIx_CR1 register is set). CRC calculation is done based on any CRC16 standard.
	A read to this register when the BSY flag is set could return an incorrect value.

22.9.7 SPI Tx CRC register (SPIx_TXCRCR)

Address offset: 0x18

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TxCRC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 15:0	TxCRC[15:0]: Tx CRC register.
	When CRC calculation is enabled, the TxCRC[7:0] bits contain the computed CRC value of the subsequently transmitted bytes. This register is reset when the CRCEN bit of SPIx_CR1 is written to 1. The CRC is calculated serially using the polynomial programmed in the SPIx_CRCPR register.
	Only the 8 LSB bits are considered when the data frame format is set to be 8-bit data (CRCL bit in the SPIx_CR1 is cleared). CRC calculation is done based on any CRC8 standard.
	The entire 16-bits of this register are considered when a 16-bit data frame format is selected (CRCL bit in the SPIx_CR1 register is set). CRC calculation is done based on any CRC16 standard.
	Note: A read to this register when the BSY flag is set could return an incorrect value. These bits are not used in I ² S mode.

22.9.8 SPIx_I2S configuration register (SPIx_I2SCFGR)

Address offset: 0x1C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	ASTR TEN	I2SMOD	I2SE	I2SCFG	PCMSYNC	Res.	I2SSTD	CKPOL	DATLEN	CHLEN			
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 15:13	Reserved: Forced to 0 by hardware.
Bit 12	ASTRTEN: Asynchronous start enable. 0: The asynchronous start is disabled. When the I ² S is enabled in slave mode, the I ² S slave starts the transfer when the I ² S clock is received and an appropriate transition (depending on the protocol selected) is detected on the WS signal. 1: The asynchronous start is enabled. When the I ² S is enabled in slave mode, the I ² S slave immediately starts the transfer when the I ² S clock is received from the master without checking the expected transition of WS signal. Note: The appropriate transition is a falling edge on WS signal when I ² S Philips standard is used, or a rising edge for other standards.
Bit 11	I2SMOD: I ² S mode selection. 0: SPI mode is selected 1: I ² S mode is selected Note: This bit should be configured when the SPI is disabled.
Bit 10	I2SE: I ² S enable. 0: I ² S peripheral is disabled 1: I ² S peripheral is enabled Note: This bit is not used in SPI mode.
Bits 9:8	I2SCFG: I ² S configuration mode. 00: Slave - transmit 01: Slave - receive

	10: Master - transmit 11: Master - receive Note: These bits should be configured when the I ² S is disabled. They are not used in SPI mode.
Bit 7	PCMSYNC : PCM frame synchronization. 0: Short frame synchronization 1: Long frame synchronization Note: This bit has a meaning only if I2SSTD=11 (PCM standard is used). It is not used in SPI mode.
Bit 6	Reserved: forced to 0 by hardware.
Bits 5:4	I2SSTD : I ² S standard selection. 00: I ² S Philips standard. 01: MSB justified standard (left justified) 10: LSB justified standard (right justified) 11: PCM standard For more details on I ² S standards, refer to Section 22.7.2 Supported audio protocols . Note: For correct operation, these bits should be configured when the I ² S is disabled. They are not used in SPI mode.
Bit 3	CKPOL : Steady-state clock polarity. 0: I ² S clock steady-state is low level 1: I ² S clock steady-state is high level Note: For correct operation, this bit should be configured when the I ² S is disabled. It is not used in SPI mode.
Bits 2:1	DATLEN : Data length to be transferred. 00: 16-bit data length 01: 24-bit data length 10: 32-bit data length 11: Not allowed Note: For correct operation, these bits should be configured when the I ² S is disabled. They are not used in SPI mode.
Bit 0	CHLEN : Channel length (number of bits per audio channel). 0: 16-bit wide 1: 32-bit wide The bit write operation has a meaning only if DATLEN = 00 otherwise the channel length is fixed to 32-bit by hardware whatever the value filled in. Note: For the correct operation, this bit should be configured when the I ² S is disabled. It is not used in SPI mode.

22.9.9 SPIx_I2S prescaler register (SPIx_I2SPR)

Address offset: 0x20

Reset value: 0x0002

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	MCKOE	ODD	I2SDIV							

						rw	rw	rw
--	--	--	--	--	--	----	----	----

Bits 15:10	Reserved: forced to 0 by hardware.
Bit 9	MCKOE : Master clock output enable. 0: Master clock output is disabled 1: Master clock output is enabled Note: This bit should be configured when the I ² S is disabled. It is used only when the I ² S is in master mode. It is not used in SPI mode.
Bit 8	ODD : Odd factor for the prescaler. 0: Real divider value is = I2SDIV *2 1: Real divider value is = (I2SDIV * 2)+1. Refer to Section 22.7.3 Clock generator . Note: This bit should be configured when the I ² S is disabled. It is used only when the I ² S is in master mode. It is not used in SPI mode.
Bits 7:0	I2SDIV : I ² S linear prescaler. I2SDIV [7:0] = 0 or I2SDIV [7:0] = 1 are forbidden values. Refer to Section 22.7.3 Clock generator . Note: These bits should be configured when the I ² S is disabled. They are used only when the I ² S is in master mode. They are not used in SPI mode.

Refer to Table 3. BlueNRG-LP memory map and peripheral register boundary addresses.

23 Debug support (DBG)

23.1 SWD debug features

The BlueNRG-LP device JTAG ID[31:0] is the following:

- 0000 00100000000011110 00000100000 1
- (0x0201_E041)

The Cortex-M0+ subsystem of the BlueNRG-LP embeds 4 breakpoints and 2 watchpoints.

The BlueNRG-LP device embeds:

- the ARM serial wire debug port which enables serial wire debug (2-wire) to be connected to the CPU (default after power-on reset).

Note: When device enters in DEEPSTOP mode, the SWD debug port is not powered. As consequence, debug access is disabled and the chip cannot be accessed through SWD channel. One possible recovery option is to activate the internal embedded UART bootloader through the PA10 pin (just force PA10 high during hardware reset).

24 Radio sub-system (MR_BLE)

The radio sub-system (aka MR_BLE) inside the BlueNRG-LP is in charge of managing the Bluetooth feature. For information about the MR_BLE/Radio sub-system refer to "The BlueNRG-LP radio controller" Reference Manual (RM0480).

Table 81. MR_BLE/BlueNRG-LP dependencies provides information about dependencies linked to the IP integration inside the BlueNRG-LP device.

Table 81. MR_BLE/BlueNRG-LP dependencies

Parameter/feature	Implementation inside the BlueNRG-LP
Supported feature	
Bluetooth® standard 5.2 support	Yes
802.15.4 standard support	No
Base addresses	
GlobalStatMach RAM table base address	0x2000 00C0
RRM registers base address	0x6000 1400
Radio controller registers base address	0x6000 1000
BLE APB registers base address	0x6000 0000
WAKEUP registers base address	0x6000 1800
Interrupts mapping	
irq_BLE_int1	BLE_TXRX / line 18
irq_BLE_int2	BLE_AES / line 19
irq_BLE_int3	BLE_DBG / line 20
irq_mr_syst (aka irq_radio_control)	RADIO_CTRL / line 21
irq_rrm	MR_BLE / line 22
irq_radio_fsm	MR_BLE / line 22
irq_wakeup_cpu	CPU_WKUP / line 23
irq_wakeup_ble	BLE_WKUP / line 24
PWRC interfacing	
Sleep mode request	Only mode 0 supported
RCC interfacing	
Fast clock	Software enable / disable through RCC.APB2ENR register (MRBLEEN bit). Clock frequency managed through RCC.APB2ENR register (CLKBLEDIV bit field).
Slow clock	Software enable/disable through RCC.RCC_CR register. Clock source selection through RCC.RCC_CFGR register. Note: this clock source is common to all IPs using slow clock in the BlueNRG-LP device
MR_BLE reset	Software individual reset enable / disable through RCC.APB2RSTR register

Warning for interrupt clearance when system clock is faster than MR_BLE clock

The SW has to pay attention on the MR_BLE interrupt clearance management when the system clock frequency is faster than the MR_BLE clock.

Indeed, in this configuration, the AHB to APB transfers from the CPU to the MR_BLE flag register go through the APB down converter (in charge of guaranteeing a proper AHB protocol despite the frequency difference). This block adds some latency on the transfer and no HREADY (busy) information is raised on the AHB bus for a writing action.

For this reason, the instructions following a “clear flag write action” at SW level can still run while the interrupt is still active inside the MR_BLE (write not yet propagated internally).

The SW must take care that the effective clearance may happen up to 10 cycles after the write operation. This means the clear flag action must not be done at the very end of the interrupt handler.

This limitation concerns all the interrupt lines of the MR_BLE:

- radio controller interrupt (slow clock measurement) = line 21
- RRM and Radio FSM interrupts = line 22
- CPU wakeup interrupt = line 23
- BLE wakeup interrupt = line 24
- BLE transmission / reception interrupt = line 18
- BLE AES interrupt = line 19
- BLE debug interrupts = line 20

One option would be to clear the flags early in the interrupt handler to mask the system latency. The safest option is to read the flag register after write. This guarantees the write has been pushed inside the MR_BLE register.

Revision history

Table 82. Document revision history

Date	Version	Changes
06-Jul-2020	1	Initial release.
05-Jul-2021	2	<p>Updated Table 5. GPIO alternate options AF0 - AF2 and Table 6. GPIO alternate options AF3 - AF4.</p> <p>Updated Section 12 Analog digital converter (ADC) and all its subsequent sections.</p> <p>Added AF5, AF6, AF7 GPIO alternate options description.</p> <p>Removed reference to JTAG debug support.</p> <p>Added missing alternate functions for TX_SEQUENCE and RX_SEQUENCE and associated note.</p> <p>Updated LPMS/shutdown description.</p> <p>Added missing wakeup sources (PB0 to PB11).</p> <p>Updated Section 22 Serial peripheral interface / inter-IC sound (SPI/I2S) and all its subsequent sections.</p> <p>Updated type of USART_TX, USART_RX, LPUART_RX and LPUART_TX from I or O to I/O on AF tables.</p> <p>Updated Section 20.8 USART register map.</p> <p>Updated Section 9.4.6 SIZE register</p> <p>Added Section 9.5.7 Write page protection example and Section 24 Radio sub-system (MR_BLE).</p>
01-Apr-2022	3	<p>Updated Section 5.4.2 DEEPSTOP mode, Section 7.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A, B), Figure 82. Independent watchdog block diagram, Section 23.1 SWD debug features and minor text changes throughout the document.</p>
