This bitfield defines the instruction size.

- **00**: 8-bit instruction
- **01**: 16-bit instruction
- **10**: 24-bit instruction
- **11**: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate

This bit sets the DTR mode for the instruction phase.

- **0**: DTR mode disabled for the instruction phase
- **1**: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode

This bitfield defines the instruction phase mode of operation.

- **000**: No instruction
- **001**: Instruction on a single line
- **010**: Instruction on two lines
- **011**: Instruction on four lines
- **100**: Instruction on eight lines
- Others: Reserved

### 23.7.20 OCTOSPI wrap timing configuration register (OCTOSPI_WPTCR)

Address offset: 0x0148

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bit 31 Reserved, must be kept at reset value.
Bit 30  **SSHIFT**: Sample shift
By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The firmware must assure that SSHIFT=0 when the data phase is configured in DTR mode (when DDTR = 1).

Bit 29  Reserved, must be kept at reset value.

Bit 28  **DHQC**: Delay hold quarter cycle
Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.
0: No quarter cycle delay
1: 1/4 cycle delay inserted

Bits 27:5  Reserved, must be kept at reset value.

Bits 4:0  **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

### 23.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR)

Address offset: 0x0150
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

**Bits 31:0**  
**ALTERNATE[31:0]: Alternate bytes**  
Optional data to be sent to the external SPI device right after the address

---

**Bit 29**  
**DQSE** (DQS enable)  
This bit enables the data strobe management.  
0: DQS disabled  
1: DQS enabled

**Bit 28**  
Reserved, must be kept at reset value.

**Bit 27**  
**DDTR** (data double transfer rate)  
This bit sets the DTR mode for the data phase.  
0: DTR mode disabled for the data phase  
1: DTR mode enabled for the data phase

**Bits 26:24**  
**DMODE[2:0]: Data mode**  
This bitfield defines the data phase mode of operation.  
000: No data  
001: Data on a single line  
010: Data on two lines  
011: Data on four lines  
100: Data on eight lines  
Others: Reserved

**Bits 23:22**  
Reserved, must be kept at reset value.

**Bits 21:20**  
**ABSIZE[1:0]: Alternate-byte size**  
This bitfield defines the alternate-byte size.  
00: 8-bit alternate bytes  
01: 16-bit alternate bytes  
10: 24-bit alternate bytes  
11: 32-bit alternate bytes

---

**Bits 31:30**  
Reserved, must be kept at reset value.

---

**Bit 29**  
**DQSE**: DQS enable  
This bit enables the data strobe management.  
0: DQS disabled  
1: DQS enabled

**Bit 28**  
Reserved, must be kept at reset value.

**Bit 27**  
**DDTR**: data double transfer rate  
This bit sets the DTR mode for the data phase.  
0: DTR mode disabled for the data phase  
1: DTR mode enabled for the data phase

**Bits 26:24**  
**DMODE[2:0]: Data mode**  
This bitfield defines the data phase mode of operation.  
000: No data  
001: Data on a single line  
010: Data on two lines  
011: Data on four lines  
100: Data on eight lines  
Others: Reserved

**Bits 23:22**  
Reserved, must be kept at reset value.

**Bits 21:20**  
**ABSIZE[1:0]: Alternate-byte size**  
This bitfield defines the alternate-byte size.  
00: 8-bit alternate bytes  
01: 16-bit alternate bytes  
10: 24-bit alternate bytes  
11: 32-bit alternate bytes
Bit 19 **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate-bytes phase.
0: DTR mode disabled for alternate-bytes phase
1: DTR mode enabled for alternate-bytes phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for instruction phase
1: DTR mode enabled for instruction phase
23.7.24 OCTOSPI write timing configuration register (OCTOSPI_WTCR)

Address offset: 0x0188
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:0 INSTRUCTION[31:0]: Instruction
Instruction to be sent to the external SPI device
23.7.26 OCTOSPI write alternate bytes register (OCTOSPI_WABR)

Address offset: 0x01A0
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

```
+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+
```

Bits 31:0 ALTERNATE[31:0]: Alternate bytes
Optional data to be sent to the external SPI device right after the address

23.7.27 OCTOSPI HyperBus latency configuration register (OCTOSPI_HLCR)

Address offset: 0x0200
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

```
+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+
| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+
| 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |
+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+----+
```

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 TRWR[7:0]: Read-write minimum recovery time
Device read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles

Bits 15:8 TACC[7:0]: Access time
Device access time according to the memory latency, expressed in number of communication clock cycles

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 WZL: Write zero latency
This bit enables zero latency on write operations.
0: Latency on write accesses
1: No latency on write accesses
**Bit 0 LM: Latency mode**
This bit selects the latency mode.
0: Variable initial latency
1: Fixed latency

Refer to Section 2.3 for the register boundary addresses.
24 Secure digital input/output MultiMediaCard interface (SDMMC)

24.1 SDMMC main features

The SD/SDIO, embedded MultiMediaCard (eMMC) host interface (SDMMC) provides an interface between the AHB bus and SD memory cards, SDIO cards and eMMC devices.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website at www.jedec.org, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website at www.sdcard.org.

The SDMMC features include the following:

- Compliance with *Embedded MultiMediaCard System Specification Version 5.1*. Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit. (HS200 SDMMC_CK speed limited to maximum allowed I/O speed) (HS400 is not supported).

- Full compatibility with previous versions of MultiMediaCards (backward compatibility).

- Full compliance with *SD memory card specifications version 6.0*. (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).

- Full compliance with *SDIO card specification version 4.0*. Card support for two different databus modes: 1-bit (default) and 4-bit. (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).

- Data transfer up to 208 Mbyte/s for the 8-bit mode. (depending maximum allowed I/O speed).

- Data and command output enable signals to control external bidirectional drivers.

- IDMA linked list support

The MultiMediaCard/SD bus connects cards to the host.

The current version of the SDMMC supports only one SD/SDIO/eMMC card at any one time and a stack of eMMC.

24.2 SDMMC implementation

<table>
<thead>

</tr>
</tbody>
</table>

1. X = supported.
24.3 SDMMC bus topology

Communication over the bus is based on command/response and data transfers.

The basic transaction on the SD/SDIO/eMMC bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

Data transfers are done in the following ways:
- Block mode: data block(s) with block size $2^N$ bytes with $N$ in the range 0-14.
- SDIO multibyte mode: single data block with block size range 1-512 bytes
- eMMC Stream mode: continuous data stream

Data transfers to/from eMMC cards are done in data blocks or streams.

Figure 152. SDMMC “no response” and “no data” operations

Figure 153. SDMMC (multiple) block read operation

Note: The Stop Transmission command is not required at the end of an eMMC multiple block read with predefined block count.
Figure 154. SDMMC (multiple) block write operation

Note: The Stop Transmission command is not required at the end of an eMMC multiple block write with predefined block count.

Note: The SDMMC does not send any data as long as the Busy signal is asserted (SDMMC_D0 pulled low).

Figure 155. SDMMC (sequential) stream read operation

Stream data transfer operates only in a 1-bit wide bit bus configuration on SDMMC_D0 in single data rate modes (DS, HS, and SDR).
# SDMMC operation modes

## Table 211. SDMMC operation modes SD and SDIO

<table>
<thead>
<tr>
<th>SDIO Bus Speed modes (1)(2)</th>
<th>Max Bus Speed (3) [Mbyte/s]</th>
<th>Max Clock frequency (4) [MHz]</th>
<th>Signal Voltage [V]</th>
</tr>
</thead>

<td>200</td>
<td>1.8/1.2V</td>
</tr>
</tbody>
</table>

1. SDR single data rate signaling.
2. DDR double data rate signaling. (data is sampled on both SDMMC_CK clock edges).
3. eMMC bus speed with 8bit bus width.
4. Maximum frequency depending on maximum allowed I/O speed.
5. Supported signal voltage level depends on I/O port characteristics, refer to device datasheet.

HS200 mode requires variable delay support using sampling point tuning.
24.5 SDMMC functional description

The SDMMC consists of four parts:

- The AHB slave interface accesses the SDMMC adapter registers, and generates interrupt signals and IDMA control signals.
- The SDMMC adapter block provides all functions specific to the eMMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The internal DMA (IDMA) block with its AHB master interface.
- A delay block (DLYB) taking care of the receive data sample clock alignment. The delay block is NOT part of the SDMMC. A delay block is mandatory when supporting SDR104 or HS200.

24.5.1 SDMMC block diagram

Figure 157 shows the SDMMC block diagram.

![SDMMC block diagram](image)

24.5.2 SDMMC pins and internal signals

Table 213 lists the SDMMC internal input/output signals, Table 214 the SDMMC pins (alternate functions).

</tbody>
</table>
24.5.3 General description

The SDMMC lines have different operating modes:

- By default, SDMMC_D0 line is used for data transfer. After initialization, the host can change the data bus width.
- For an eMMC, 1-bit (SDMMC_D0), 4-bit (SDMMC_D[3:0]) or 8-bit (SDMMC_D[7:0]) data bus widths can be used.
- For an SD or an SDIO card, 1-bit (SDMMC_D0) or 4-bit (SDMMC_D[3:0]) can be used. All data lines operate in push-pull mode.

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the data lines is indicated with I/O direction signals. The SDMMC_D0DIR signal indicates the I/O direction for the SDMMC_D0 data line, the SDMMC_D123DIR for the SDMMC_D[3:1] data lines.

SDMMC_CMD only operates in push-pull mode:

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the SDMMC_CMD line is indicated with the I/O direction signal SDMMC_CDIR.
SDMMC\_CK clock to the card originates from `sdmmc\_ker\_ck`:
- When the `sdmmc\_ker\_ck` clock has 50 % duty cycle, it can be used even in bypass mode (CLKDIV = 0).
- When the `sdmmc\_ker\_ck` duty cycle is not 50 %, the CLKDIV must be used to divide it by 2 or more (CLKDIV > 0).
- The phase relation between the SDMMC\_CMD / SDMMC\_D[7:0] outputs and the SDMMC\_CK can be selected through the NEGEDGE bit. The phase relation depends on the CLKDIV, NEGEDGE, and DDR settings. See Figure 158.

**Figure 158. SDMMC Command and data phase relation**

</tbody>
</table>

By default, the `sdmmc\_io\_in\_ck` feedback clock input is selected for sampling incoming data in the SDMMC receive path. It is derived from the SDMMC\_CK pin.

For tuning the phase of the sampling clock to accommodate the receive data timing, the DLYB delay block available on the device can be connected between `sdmmc\_io\_in\_ck` signal (DLYB input dlyb\_in\_ck) and `sdmmc\_fb\_ck` clock input of SDMMC (DLYB output dlyb\_out\_ck). Selecting the `sdmmc\_fb\_ck` clock input in the receive path then enables using the phase-tuned sampling clock for the incoming data. This is required for SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.
When using an external driver (a voltage switch transceiver), the SDMMC_CKIN feedback clock input can be selected to sample the receive data.

For an SD/SDIO/eMMC card, the clock frequency can vary between 0 and 208 MHz (limited by maximum I/O speed).

Depending on the selected bus mode (SDR or DDR), one bit or two bits are transferred on SDMMC_D[7:0] lines with each clock cycle. The SDMMC_CMD line transfers only one bit per clock cycle.

24.5.4 SDMMC adapter

The SDMMC adapter (see Figure 157: SDMMC block diagram) is a multimedia/secure digital memory card bus master that provides an interface to a MultiMediaCard stack or to a secure digital memory card. It consists of the following subunits:

- Control unit
- Data transmit path
- Command path
- Data receive path
- Response path
- Receive data path clock multiplexer
- Delay block (DLYB), external to the SDMMC
- Adapter register block
- Data FIFO
- Internal DMA (IDMA)

Note: The adapter registers and FIFO use the AHB clock domain (sdmmc_hclk). The control unit, command path and data transmit path use the SDMMC adapter clock domain (sdmmc_ker_ck). The response path and data receive path use the SDMMC adapter feedback clock domain from the sdmmc_io_in_ck, or SDMMC_CKIN, or from the sdmmc_fb_ck generated by DLYB.

The DLYB delay block on the device can be used in conjunction with the SDMMC adapter, to tune the phase of the sampling clock for incoming data in SDMMC receive mode. It is required for the SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

Adapter register block

The adapter register block contains all system control registers, the SDMMC command and response registers and the data FIFO.

This block also generates the signals from the corresponding bit location in the SDMMC Clear register that clear the static flags in the SDMMC adapter.

Control unit

The control unit illustrated in Figure 159, contains the power management functions, the SDMMC_CK clock management with divider, and the I/O direction management.
The power management subunit disables the card bus output signals during the power-off and power-up phases.

There are three power phases:
- power-off
- power-up
- power-on

The clock management subunit uses the sdmmc_ker_ck to generate the SDMMC_CK and provides the division control. It also takes care of stopping the SDMMC_CK for i.e. flow control.

The clock outputs are inactive:
- after reset
- during the power-off or power-up phases
- if the power saving mode (register bit PWRSAV) is enabled and the card bus is in the Idle state for eight clock periods. The clock is stopped eight cycles after both the command/response CPSM and data path DPSM subunits have enter the Idle phase. The clock is restarted when the command/response CPSM or data path DPSM is activated (enabled).

The I/O management subunit takes care of the SDMMC_Dn and SDMMC_CMD I/O direction signals, which controls the external voltage transceiver.

**Command/response path**

The command/response path subunit transfers commands and responses on the SDMMC_CMD line. The command path is clocked on the SDMMC_CK and sends commands to the card. The response path is clocked on the sdmmc_rx_ck and receives responses from the card.
Command/response path state machine (CPSM)

- When the command register is written to and the enable bit is set, command transfer starts. When the command has been sent the CRC is appended and the command path state machine (CPSM) sets the status flags and:
  - if a response is not required enters the Idle state.
  - If a response is required, it waits for the response.

- When the response is received,
  - for a response with CRC, the received CRC code and the internally generated code are compared, and the appropriate status flag is set according the result.
  - for a response without CRC, no CRC is checked, and the appropriate status flag is not set.

When ever the CPSM is active, i.e. not in the Idle state, the CPSMACT bit is set.
• **Idle**: The command path is inactive. When the command control register is written and the enable bit (CPSMEN) is set, the CPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit) and moves
  – to the Send state when WAITPEND = 0 and BOOTEN = 0.
  – to the Pending state when WAITPEND = 1.
  – to the Boot state when BOOTEN = 1.

• **Send**: The command is sent and the CRC is appended.
  – When CMDTRANS bit is set or when BOOTEN bit is set and BOOTMODE is alternative boot, and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM at the end of the command.
  – When the CMDTRANS bit is set and the CMD_SUSPEND bit is 0 the interrupt period is terminated at the end of the command.
  – When CMDSTOP bit is set the CPSM Abort signal is issued to the DPSM at the end of the command.
  – If no response is expected (WAITRESP = 00) the CPSM moves to the Idle state and the CMDSENT flag is set. When BOOTMODE = 1 and BOOTEN = 0 the CMDSENT flag is delayed 56 cycles after the command end bit, otherwise the
CMDSENT flag is generated immediately after the command end bit. The RESPCMDR and RESPxR registers are not modified.
- If a command response is expected (WAITRESP = not 00) the CPSM moves to the Wait state and start the response timeout.

- **Wait:** The command path waits for a response.
  - When WAITINT bit is 0 the command timer starts running and the CPSM waits for a start bit.
    a) If a start bit is detected before the timeout the CPSM moves to the Receive state.
    b) If the timeout is reached before the CPSM detect a response start bit, the timeout flag (CTIMEOUT) is set and the CPSM moves to the Idle state.
    The RESPCMDR and RESPxR registers are not modified.
  - When WAITINT bit is 1, the timer is disabled and the CPSM waits for an interrupt request (response start bit) from one of the cards.
    a) When a start bit is detected the CPSM moves to the Receive state.
    b) When writing WAITINT to 0 (interrupt mode abort), the host sends a response by its self and on detecting the start bit the CPSM move to the Receive state.

- **Receive:** The command response is received. Depending the response mode bits WAITRESP in the command control register, the response can be either short or long, with CRC or without CRC. The received CRC code when present is verified against the internally generated CRC code.
  - When the CMDGSUSPEND bit is set and the SDIO Response bit BS = 0 (response bit [39]), the interrupt period is started after the response.
    When the CMDGSUSPEND bit is cleared, or the CMDGSUSPEND bit is 1 and the SDIO Response bit BS = 1 (response bit [39]), there is no interrupt period started.
  - When the CMDTRANS bit is set and the CMDGSUSPEND bit is set and the SDIO Response bit DF= 1 (response bit [32]) the interrupt period is terminated after the response.
  - When the CRC status passes or no CRC is present the CMDREND flag is set, the CPSM moves to the Idle state.
    The RESPCMDR and RESPxR registers are updated with received response.
    - When BOOTMODE = 1 and BOOTEN = 0 the CMDREND flag is delayed 56 cycles after the response end bit, otherwise the CMDREND flag is generated immediately after the response end bit.
    - When CMDTRANS bit is set and the DTDIR = transmit, the CPSM DataEnable signal is issued to the DPSM at the end of the command response.
  - When the CRC status fails the CCRCFAIL flag is set and the CPSM moves to the Idle state.
    The RESPCMDR and RESPxR registers are updated with received response.

- **Pending:** According the pending WAITPEND bit in the command register, the CPSM enters the pending state.
  - When DATALENGTH <= 5 bytes the CPSM moves to the Sent state and generates the DataEnable signal to start the data transfer aligned with the CMD12 Stop Transmission command.
  - When DATALENGTH > 5 bytes, the CPSM DataEnable signal is issued to the DPSM to start the data transfer. The CPSM waits for a send CMD signal from the
DPSM before moving to the Send state. This enables i.e. the CMD12 Stop Transmission command to be sent aligned with the data.

– When writing WAITPEND to 0, the CPSM moves to the Send state.

• **Boot:** If the BOOTEN bit is set in the command register, the CPSM enters the Boot state, and when:
  – BOOTMODE = 0 the SDMMC_CMD line is driven low and when CMDTRANS bit is set and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM. This enables normal boot operation. This state is left at the end of the boot procedure by clearing the register bit BOOTEN, which cause the SDMMC_CMD line to be driven high and the CPSM Abort signal is issued to the DPSM, before moving to the Idle state. The CMDSENT flag is generated 56 cycles after SDMMC_CMD line is high.
  – BOOTMODE = 1, move to the Send state. This enables sending of the CMD0 (boot). Clearing BOOTEN has no effect.

**Note:** The CPSM remains in the Idle state for at least eight SDMMC_CK periods to meet the NCC and NRC timing constraints. NCC is the minimum delay between two host commands, and NRC is the minimum delay between the host command and the card response.

**Note:** The response timeout has a fixed value of 64 SDMMC_CK clock periods.

A command is a token that starts an operation. Commands are sent from the host to either a single card (addressed command) or all connected cards (broadcast command are available for e•MMC V3.31 or previous). Commands are transferred serially on the SDMMC_CMD line. All commands have a fixed length of 48 bits. The general format for a command token for SD-Memory cards, SDIO cards, and e•MMC cards is shown in Table 216.

The command token data is taken from 2 registers, one containing a 32-bits argument and the other containing the 6-bits command index (six bits sent to a card).

### Table 216. Command token format

<table>

</tbody>
</table>

Next to the command data there are command type (WAITRESP) bits controlling the command path state machine (CPSM). These bits also determine whether the command requires a response, and whether the response is short (48 bit) or long (136 bits) long, and if a CRC is present or not.

A response is a token that is sent from an addressed card or synchronously from all connected cards to the host as an answer to a previous received command. All responses are sent via the command line SDMMC_CMD. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type. Response tokens R1, R2, R3, R4, R5, and R6 have various
coding schemes, depending on their content. The general formats for the response tokens for SD-Memory cards, SDIO cards, and eMMC cards are shown in Table 217, Table 218 and Table 219.

A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value denoted by x in the tables below indicates a variable entry. Most responses, except some, are protected by a CRC. Every command code word is terminated by the end bit (always 1).

The response token data is stored in 5 registers, four containing the 32-bits card status, OCR register, argument or 127-bits CID or CSD register including internal CRC, and one register containing the 6-bits command index.

</tbody>
</table>

The command/response path operates in a half-duplex mode, so that either commands can be sent or responses can be received. If the CPSM is not in the Send state, the
SDMMC_CMD output is in the Hi-Z state. Data sent on SDMMC_CMD are synchronous with the SDMMC_CK according the NEGEDGE register bit see Figure 158.

The command and short response with CRC, the CRC generator calculates the CRC checksum for all 40 bits before the CRC code. This includes the start bit, transmission bit, command index, and command argument (or card status).

For the long response the CRC checksum is calculated only over the 120 bits of R2 CID or CSD. Note that the start bit, transmission bit and the six reserved bits are not used in the CRC calculation.

The CRC checksum is a 7-bit value:
\[
\text{CRC}[6:0] = \text{remainder } \left(\frac{(M(x) \cdot x^7)}{G(x)}\right)
\]
\[
G(x) = x^7 + x^3 + 1
\]
\[
M(x) = (\text{first bit}) \cdot x^n + (\text{second bit}) \cdot x^{n-1} + \ldots + (\text{last bit before CRC}) \cdot x^0
\]
Where \( n = 39 \) or 119.

The CPSM can send a number of specific commands to handle various operating modes when CPSMEN is set, see Table 220.

Table 220. Specific Commands overview

</tr>
</tbody>
</table>

\(^1\) When CMDTRANS is set, also a stop_transmission command must be send to move the DPSM to Idle.

### Data path

The data path subunit transfers data on the SDMMC_D[7:0] lines to and from cards. The data transmit path is clocked on the SDMMC_CK and sends data to the card. The data receive path is clocked on the sdmmc_rx_ck and receives data from the card. Figure 162 shows the data path block diagram.
The card data bus width can be programmed in the clock control register bits WIDBUS. The supported data bus width modes are:

- If the wide bus mode is not enabled, only one bit is transferred over SDMMC_D0.
- If the 4-bit wide bus mode is enabled, data is transferred at four bits over SDMMC_D[3:0].
- If the 8-bit wide bus mode is enabled, data is transferred at eight bits over SDMMC_D[7:0].

Next to the data bus width the data sampling mode can be programmed in the clock control register bit DDR. The supported data sampling modes are:

- Single data rate signaling (SDR), data is clocked on the rising edge of the clock.
- Double data rate signaling (DDR), data is clocked on the both edges of the clock. DDR mode is only supported in wide bus mode (4-bit wide and 8-bit wide).

Note: The data sampling mode only applies to the SDMMC_D[7:0] lines. (not applicable to the SDMMC_CMD line.)
In DDR mode, data is sampled on both edges of the SDMMC_CK according to the following rules, see also Figure 163 and Figure 164:

- On the rising edge of the clock odd bytes are sampled.
- On the falling edge of the clock even bytes are sampled.
- Data payload size is always a multiple of 2 Bytes.
- Two CRC16 are computed per data line
  - Odd bits CRC16 clocked on the falling edge of the clock.
  - Even bits CRC16 clocked on the rising edge of the clock.
- Start, end bits and idle conditions are full cycle.
- CRC status / boot acknowledgment and busy signaling are full cycle and are only sampled on the rising edge of the clock.

In DDR mode the SDMMC_CK clock division must be >= 2.

**Figure 164. DDR mode CRC status / boot acknowledgment clocking**

- Send: the DPSM moves to the Wait_S state. If there is data in the transmit FIFO, the DPSM moves to the Send state, and the data path subunit starts sending data to a card.
- Receive: the DPSM moves to the Wait_R state and waits for a start bit. When it receives a start bit, the DPSM moves to the Receive state, and the data path subunit starts receiving data from a card.
For boot operation with acknowledgment the DPSM moves to the Wait_Ack state and waits for the boot acknowledgment before moving to the Wait_R state.

The DPSM operates at SDMMC_CK. The DPSM has the following states, as shown in Figure 165. When ever the DPSM is active, i.e. not in the Idle state, the DPSMACT bit is set.

**Figure 165. Data path state machine (DPSM)**

- **Idle** state: the data path is inactive, and the SDMMC_D[7:0] outputs are according the PWRCTRL setting. The DPSM is activated either by sending a command with CMDTRANS bit set or by setting the DTEN bit, or by detecting Busy on SDMMC_D0 (that is, after a command with R1b response).

  When not busy, the DPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit), loads the data counter with a new (DATALENGTH) value and:
  - When the data direction bit (DTDIR) indicates send, moves to the Wait_S.
  - When the data direction bit (DTDIR) indicates receive, moves to the Wait_R when BOOTACKEN register bit is clear.
    - Wait_B when BOOTACKEN register bit is set and start the acknowledgment timeout.

  When busy the DPSM keeps the SDMMC_CK clock active and move to the Busy state.
Note: **DTEN must not be used to start data transfer with SD, SDIO and eMMC cards.**

- **Wait_Ack** state: the data path waits for the boot acknowledgment token.
  - The DPSM moves to the Wait_R state if it receives an error free acknowledgment before a timeout.
  - When a pattern different from the acknowledgment is received an acknowledgment status error is generated, and the ack fail status flag (ACKFAIL) is set. The DPSM stays in Wait_Ack.
  - If it reaches a timeout (ACKTIME) before it detects a start bit, it sets the timeout status flag (ACKTIMEOUT). The DPSM stays in Wait_Ack.
  - When the CPSM Abort signal is set it moves to the Idle state and sets the DABORT flag.

- **Wait_R** state: the data path, if the data counter is not zero and data is not hold, waits for a start bit on SDMMC_D[n:0]. If the data counter is zero or data is hold, wait for the FIFO to be empty.
  - In block mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DBLOCKSIZE.
  - In SDIO multibyte mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DATALENGTH.
  - In stream mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data counter with DATALENGTH.
  - if the data counter (DATACOUNT) equals zero (end of data) the DPSM moves to the Idle state when the receive FIFO is empty and the DATAEND flag is set.
  - If it reaches a timeout (DATATIME) before it detects a start bit, it sets the timeout status flag (DTIMEOUT) and the DPSM stays in the Wait_R state.
  - If the CPSM Abort signal is set:
    - If DATACOUNT > 0, the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST, and sets the DABORT flag.
    - If DATACOUNT is zero normal operation is continued, there is no DABORT flag since the transfer has completed normally.
  - if the DTHOLD bit is set:
    - When DATACOUNT > 0, the DPSM moves to the Idle state when the receive FIFO is empty and when IDMAEN = 0 reset with FIFORST, and issues the DHOLD flag. When holding the timeout is disabled. When an CPSM Abort signal is received during holding, the transfer is aborted.
- When DATACOUNT = 0, the transfer is completed normally and there is no DHOLD flag.
  - When DPSM has been started with DTEN, after an error (DTIMEOUT) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.

- **R_W** state: the data path Read Wait the bus.
  - The DPSM moves to the Wait_R state when the Read Wait stop bit (RWSTOP) is set, and start the receive timeout.
  - If the CPSM Abort signal is set, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then moves to the Idle state and sets the DABORT flag.

- **Receive** state: the data path receives serial data from a card. Pack the data in bytes and written it to the data FIFO. Depending on the transfer mode selected in the data control register (DTMODE), the data transfer mode can be either block or stream:
  - In block mode, when the data block size (DBLOCKSIZE) number of data bytes are received, the DPSM waits until it receives the CRC code.
  - In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are received, the DPSM waits until it receives the CRC code.

  a) If the received CRC code matches the internally generated CRC code, the DPSM moves to the
    - R_W state when RWSTART = 1 and DATACOUNT > zero, the DBCKEND flag is set.
    - Wait_R state otherwise.

  b) If the received CRC code fails the internally generated CRC code any further data reception is prevented.
    - When not all data has been received (DATACOUNT > 0), the CRC fail status flag (DCRCFAIL) is set and the DPSM stays in the Receive state.
    - When all data has been received (DATACOUNT = 0), wait for the FIFO to be empty after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.

  - In stream mode, the DPSM receives data while the data counter DATACOUNT > 0. When the counter is zero, the remaining data in the shift register is written to the data FIFO, and the DPSM moves to the Wait_R state.

  - When a FIFO overrun error occurs, the DPSM sets the FIFO overrun error flag (RXOVERR) and any further data reception is prevented. The DPSM stays in the Receive state.

  - When an CPSM Abort signal is received:
    - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted. The remaining data in the shift register is written to the data FIFO, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and the DABORT flag is set.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT=0, the transfer is completed normally. The DPSM stays in the Receive state no DABORT flag is generated.

  - When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or RXOVERR) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.
- **Wait_S** state: the data path waits for data to be available from the FIFO.
  - If the data counter DATACOUNT > 0, waits until the data FIFO empty flag (TXFIFOE) is de-asserted and DTHOLD is not set, and moves to the Send state.
  - If the data counter (DATACOUNT) = 0 the DPSM moves to the Idle state.
    - When DTHOLD is disabled, the DATAEND flag is set.
    - When DTHOLD is enabled, the DHOLD flag is set.
  - When DTHOLD is set and the DATACOUNT > 0
    - When IDMA is enabled, the DBCKEND flag is set and subsequently the FIFO is flushed, furthermore the DPSM moves to the Idle state and the DHOLD flag is set.
    - When IDMA is disabled the DBCKEND flag is set. Wait for the FIFO to be reset by software with FIFORST, then DPSM moves to the Idle state and issues the DHOLD flag.
  - When DTHOLD is set and DATACOUNT = 0 the transfer is completed normally.
  - When receiving the CPSM Abort signal
    - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and sets the DABORT flag.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT=0, normal operation is continued, there is no DABORT flag since the transfer has completed normally.

  *Note: The DPSM remains in the Wait_S state for at least two clock periods to meet the N_WR timing requirements, where N_WR is the number of clock cycles between the reception of the card response and the start of the data transfer from the host.*

- **Send** state: the DPSM starts sending data to a card. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block, SDIO multibyte or stream:
  - In block mode, when the data block size (DBLOCKSIZE) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In stream mode, the DPSM sends data to a card while the data counter DATACOUNT > 0. When the data counter reaches zero moves to the Busy state and start the transmit timeout.
  Before sending the last stream Byte according to DATACOUNT, the DPSM issues a trigger on the send CMD signal. This signal is used by the CPSM to sent any pending command. (i.e. CMD12 Stop Transmission command)
  - If a FIFO underrun error occurs, the DPSM sets the FIFO underrun error flag (TXUNDERR). The DPSM stays in the Send state.
  - When receiving the CPSM Abort signal
    - If the CPSM Abort signal is received before the 2 last bits of the transfer with DATACOUNT=0, the transfer is aborted. The DPSM sends a last data bit followed by an end bit. The FIFO is disabled/flushed, and the DPSM moves to the Busy state to wait for not busy before setting the DABORT flag.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer
with DATACOUNT=0, the transfer is completed normally, there is no DABORT flag.

- **Busy** state: the DPSM waits for the CRC status token when expected, and wait for a not busy signal:
  - If a CRC status token is expected and indicate "non-erroneous transmission" or when there is no CRC expected:
    - it moves to the Wait_S state when SDMMC_D0 is not low (the card is not busy).
    - When the card is busy SDMMC_D0 is low it remains in the Busy state.
  - If a CRC status token is expected and indicates "erroneous transmission".
    - When not all data has been send (DATACOUNT > 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set. The FIFO is disabled/flushed and the DPSM stays in the Busy state.
    - When all data has been send (DATACOUNT = 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.
  - If a CRC status (Ncrc) timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.
  - If a busy timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.
  - When receiving the CPSM Abort signal in the Busy state:
    - If the CPSM Abort signal is received before the 2 last bits of the CRC response with DATACOUNT > 0, the data transfer is aborted. The DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
    - If the CPSM Abort signal is received during or after the 2 last bits of the CRC response when DATACOUNT = 0 or when no CRC is expected and DATACOUNT = 0 and there has been no DTIMEOUT error, the DPSM stays in the Busy state no DABORT flag is generated, since the transfer may completed normally.
    - If the CPSM Abort signal is received when a DTIMEOUT error has occurred the DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
  - When entering the Busy state due to an abort in the Send state, the DPSM waits for not busy before moving to the Idle state and the DABORT flag is set.
  - When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or DTIMEOUT) the DPSM moves to the Idle state when the FIFO is reset.
  - When the DPSM has been started due to Busy on SDMMC_D0, waits for not busy after which the Busy end status flag (BUSYD0END) is set and the DPSM moves to the Idle state.
The data timer (DATATIME) is enabled when the DPSM is in the Wait_R or Busy state 2 cycles after the data block end bit, or data read command end bit, or R1b response, and generates the data timeout error (DTIMEOUT):

- When transmitting data, the timeout occurs
  - when a CRC status is expected and no start bit is received withing 8 SDMMC_CK cycles, the DTIMEOUT flag is set.
  - when the Busy state takes longer than the programmed timeout period., the DTIMEOUT flag is set.

- When receiving data, the timeout occurs
  - when there is still data to be received DATACOUNT > 0 and no start bit is received before the programmed timeout period, the DTIMEOUT flag is set.

- After a R1b response, the timeout occurs
  - when the Busy state takes longer than the programmed timeout period., the DTIMEOUT flag is set.

When DATATIME = 0,

- In receive the start bit must be present 2 cycles after the data block end bit or data read command end bit.
- In transmit busy is timed out 2 cycles after the CRC token end bit or stream data end bit.
- After a R1b response busy is timed out 2 cycles after the response end bit.

Data can be transferred from the card to the host (transmit, send) or vice versa (receive). Data are transferred via the SDMMC_Dn data lines, they are stored in a FIFO.

### Table 223. Data token format

<table>
<thead>
<tr>

**Data FIFO**

The data FIFO (first-in-first-out) subunit contains the transmit and receive data buffer. A single FIFO is used for either transmit or receive as selected by the DTDIR bit. The FIFO contain a 32-bit wide, 16-word deep data buffer and control logic. Because the data FIFO operates in the AHB clock domain (sdmmc_hclk), all signals from the subunits in the SDMMC clock domain (SDMMC_CK/sdmmc_rx_ck) are resynchronized.
The FIFO can be in one of the following states:

- The transmit FIFO refers to the transmit logic and data buffer when sending data out to the card. (DTDIR = 0)
- The receive FIFO refers to the receive logic and data buffer when receiving data in from the card. (DTDIR = 1)

The end of a correctly completed SDMMC data transfer from the FIFO is indicated by the DATAEND flags driven by the data path subunit. Any incorrect (aborted) SDMMC data transfer from the FIFO is indicated by one of the error flags (DCRCFAIL, DTIMEOUT, DABORT) driven by the data path subunit, or one of the FIFO error flags (TXUNDERR, RXOVERR) driven by the FIFO control.

The data FIFO can be accessed in the following ways, see Table 226.

### Table 226. Data FIFO access

<table>
<thead>
<tr>
<th>Data FIFO access</th>
<th>IDMAEN</th>
</tr>
</thead>
<tbody>
<tr>
<td>From firmware via AHB slave interface</td>
<td>0</td>
</tr>
<tr>
<td>From IDMA via AHB master interface</td>
<td>1</td>
</tr>
</tbody>
</table>

Transmit FIFO:

Data can be written to the transmit FIFO when the DPSM has been activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface. The transmit FIFO is accessible via sequential addresses. The transmit FIFO contains a data output register that holds the data word pointed to by the read pointer. When the data path subunit has loaded its shift register, it increments the read pointer and drives new data out.

The transmit FIFO is handled in the following way:

1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   - For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in transmit mode (DTDIR = 0).
   - Configures the FIFO in transmit mode.
3. Enable the data transfer
   - either by sending a command from the CPSM with the CMDTRANS bit set
   - or by setting DTEN bit
4. When (DPSMACT = 1) write data to the FIFO.
   - The DPSM stays in the Wait_S state until FIFO is full (TXFIFOF = 1), or the number indicated by DATALENGTH.
- The SDMMC keeps sending data as long as FIFO is not empty, hardware flow control during data transfer is used to prevent FIFO underrun.

5. Write data to the FIFO.
   - When the FIFO is handled by software, wait until the FIFO is half empty (TXFIFOHE flag), write data to the FIFO until FIFO is full (TXFIFOF = 1), or last data has been written.
   - When the FIFO is handled by the IDMA, the IDMA transfers the FIFO data.

6. When last data has been written wait for end of data (DATAEND flag)
   - SDMMC has completely sent all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer error or transfer hold when IDMAEN = 0, firmware must stop writing to the FIFO and flush and reset the FIFO with the FIFORST register bit.

The transmit FIFO status flags are listed in Table 227.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TXFIFOF</td>
<td>Set to high when all transmit FIFO words contain valid data.</td>
</tr>
<tr>
<td>TXFIFOE</td>
<td>Set to high when the transmit FIFO does not contain valid data.</td>
</tr>
<tr>
<td>TXFIFOHE</td>
<td>Set to high when half or more transmit FIFO words are empty.</td>
</tr>
<tr>
<td>TXUNDERR</td>
<td>Set to high when an underrun error occurs. This flag is cleared by writing to the SDMMC Clear register.</td>
</tr>
</tbody>
</table>

Receive FIFO:

Data can be read from the receive FIFO when the DPSM is activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface. When the data path subunit receives a word of data, it drives the data on the write databus. The write pointer is incremented after the write operation completes. On the read side, the contents of the FIFO word pointed to by the current value of the read pointer is driven onto the read databus. The receive FIFO is accessible via sequential addresses.

The receive FIFO is handled in the following way:
1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   – For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in receive mode (DTDIR = 1).
   – Configures the FIFO in receive mode.
3. Enable the DPSM transfer
   – either by sending a command from the CPSM with the CMDTRANS bit set
   – or by setting DTEN bit.
4. When (DPSMACT = 1) the FIFO is ready to receive data.
   – The DPSM writes the received data to the FIFO.
   - The SDMMC keeps receiving data as long as FIFO is not full, hardware flow control during the data transfer is used to prevent FIFO overrun.
5. Read data from the FIFO.
   – When the FIFO is handled by software, wait until the FIFO is half full (RXFIFOHF flag), read data from the FIFO until FIFO is empty (RXFIFOE = 1).
   - When last data has been received, read data from the FIFO until FIFO is empty (DATAEND = 1).
   – When the FIFO is handled by the IDMA, the IDMA transfers the FIFO data.
6. SDMMC has completely received all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer hold when IDMAEN = 0, the firmware must read the remaining data until the FIFO is empty and reset the FIFO with the FIFORST register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

In case of a data transfer error when IDMAEN = 0, the firmware must stop reading the FIFO and flush and reset the FIFO with the FIFORST register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

The receive FIFO status flags are listed in Table 228.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RXFIFOF</td>
<td>Set to high when all receive FIFO words contain valid data</td>
</tr>
<tr>
<td>RXFIFOE</td>
<td>Set to high when the receive FIFO does not contain valid data.</td>
</tr>
<tr>
<td>RXFIFOHF</td>
<td>Set to high when half or more receive FIFO words contain valid data.</td>
</tr>
<tr>
<td>RXOVERR</td>
<td>Set to high when an overrun error occurs. This flag is cleared by writing to the SDMMC Clear register.</td>
</tr>
</tbody>
</table>

**CLKMUX unit**

The CLKMUX selects the source for clock sdmmc_rx_ck to be used with the received data and command response. The receive data clock source can be selected by the clock control register bit SELCLKRX, between:

- sdmmc_io_in_ck bus master main feedback clock.
- SDMMC_CKIN external bus feedback clock.
- sdmmc_fb_ck bus tuned feedback clock.

The sdmmc_io_in_ck is selected when there is no external driver, with DS and HS.
The SDMMC_CKIN is selected when there is an external driver with SDR12, SDR25, SDR50 and DDR50.

The sdmmc_fb_ck clock input must be selected when the DLYB block on the device is used with SDR104, HS200 and optionally with SDR50 and DDR50 modes.

The sdmmc_rx_ck source must be changed when the CPSM and DPSM are in the Idle state.

### 24.5.5 SDMMC AHB slave interface

The AHB slave interface generates the interrupt requests, and accesses the SDMMC adapter registers and the data FIFO. It consists of a data path, register decoder, and interrupt logic.

#### SDMMC FIFO

The FIFO access is restricted to word access only:

- In transmit FIFO mode
  - Data are written to the FIFO in words (32-bits) until all data according to \( \text{DATALENGTH} \) has been transferred. When the \( \text{DATALENGTH} \) is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are written with a word transfer.

- In receive FIFO mode
  - Data are read from the FIFO in words (32-bits) until all data according to \( \text{DATALENGTH} \) has been transferred. When the \( \text{DATALENGTH} \) is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are read with a word transfer padded with 0 value bytes.

When accessing the FIFO with half word or byte accesses an AHB bus fault is generated.

#### SDMMC interrupts

The interrupt logic generates an interrupt request signal that is asserted when at least one of the unmasked status flags is active. A mask register is provided to allow selection of the conditions that generate an interrupt. A status flag generates the interrupt request if a corresponding mask flag is set. Some status flags require an implicit clear in the clear register.

### 24.5.6 SDMMC AHB master interface

The AHB master interface is used to transfer the data between a memory and the FIFO using the SDMMC IDMA.
SDMMC IDMA

Direct memory access (DMA) is used to provide high-speed transfer between the SDMMC FIFO and the memory. The AHB master optimizes the bandwidth of the system bus. The SDMMC internal DMA (IDMA) provides one channel to be used either for transmit or receive.

The IDMA is enabled by the IDMAEN bit and supports burst transfers of 8 beats.

- **In transmit burst transfer mode:**
  - Data are fetched in burst from memory whenever the FIFO is empty for the number of burst transfers, until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of the burst size the remaining, smaller then burst size data is transferred using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are fetched with a word transfer.

- **In receive burst transfer mode:**
  - Data are stored in burst into memory whenever the FIFO contains the number of burst transfers, until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of the burst transfer the remaining, smaller then burst size data, is transferred using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are stored with halfword and or byte transfers.

In addition the IDMA provides the following channel configurations selected by bit IDMABMODE:

- single buffered channel
- linked list channel

**Single buffered channel**

In single buffer configuration the data at the memory side is accessed in a linear matter starting from the base address IDMABASE. When the IDMA has finished transferring all data the and the DPSM has completed the transfer the DATAEND flag is set.

**Linked list channel**

In linked list configuration, IDMAMODE = 1, the data at the memory side is subsequently accessed from linked buffers, located at base address IDMABASE. The size of the memory buffers is defined by IDMABSIZE. The buffer size must be an integer multiple of the burst size. The bit ULA is used to indicate if a new linked list buffer configuration has to be loaded from the linked list table. A new linked list configuration is loaded when the ULA bit for the current linked list item is set.

The first linked list item configuration is programmed by firmware directly in the SDMMC registers.

When the IDMA has finished transferring all the data of one linked list buffer, according IDMABSIZE, and when the linked list item ULA bit is set, the IDMA loads the new linked list item from the linked list table, and continues transferring data from the next linked list buffer. When the IDMA has finished transferring all data, according IDMABSIZE and ULA, and the DPSM has completed the transfer, according DATALENGHT, the DATAEND flag is set.
In the following cases, the linked list provides more buffer space than the data to transfer which means the current linked list buffer data has not completely be transfered:

- the ULA bit is set, and all SDMMC data according DATALENGTH has been transfered (DATAEND flag)
- a transfer error (DCRCFAIL when DATACOUNT > 0, RXOVERR, TXUNDERR) occurs
- a transfer is hold (DTHOLD)

In all above cases, the IDMA linked list is stopped and the FIFO is flushed/reset. Before starting or restarting a new SDMMC transfer, the software must initialize a new linked list with correct IDMABASE and IDMABSIZE.

When a IDMA transfer error occurs (see Section : IDMA transfer error management) or when the linked list does not provide sufficient buffer space:

- the linked list ends with ULA = 0 and all last linked list buffer data has been transfered, and not all SDMMC data according DATALENGTH has been transfered. The SDMMC transfer is stopped and an IDMA transfer error is generated (see Section : IDMA transfer error management).

For a given linked list item, the base address is given by the linked list base IDMABA register value plus the linked list offset IDMALA register value.

The content of each linked list item can be specified by the ULS bit, which makes possible to optionally load the IDMABSIZ, resulting in a 3-word linked list structure. When the IDMABSIZ is not to be loaded (i.e. fixed size buffers) a compacted reduced 2-word linked list structure can be used containing only the IDMABASER and the IDMALAR values.

For a given linked list item, the base address is given by the linked list base IDMABA register value plus the linked list offset IDMALA register value.

The content of each linked list item can be specified by the ULS bit, which makes possible to optionally load the IDMABSIZ, resulting in a 3-word linked list structure. When the IDMABSIZ is not to be loaded (i.e. fixed size buffers) a compacted reduced 2-word linked list structure can be used containing only the IDMABASER and the IDMALAR values.

**Figure 167. Linked list structures**

There is no restriction on mixing both linked list item structures in a single list, this enables the IDMABSIZ to be updated only when needed.

Whenever a linked list buffer has been transfered and the current buffer ULA = 1, an end-of-linked-list-buffer-transfer-complete interrupt (IDMABTC) may be generated (if interrupt is enabled).
Linked list acknowledgment

In the case where software dynamically updates the linked list, during the SDMMC transfer, the availability of a new linked list buffer can be acknowledged by the acknowledge buffer ready (ABR) bit.

When ABR acknowledges that the new linked list buffer is ready, the IDMA continues transferring data from the new linked list buffer.

When ABR indicates that the new linked list buffer is not ready, an IDMA transfer error is generated (see Section : IDMA transfer error management). Depending when the IDMA transfer error occurs, it normally causes the generation of an TXUNDERR or RXOVERR error. When a linked list buffer is not acknowledged in time the SDMMC transfer is stopped.

The ABR information is “don’t care” when starting the linked list from software programmed register information. The first linked list buffer must be ready to be used before starting the SDMMC transfer.

IDMA transfer error management

An IDMA transfer error can occur:

- When reading or writing a reserved address space (for data or linked list information).
- When there is no more linked list buffer space to store received SDMMC data.
- When all linked list buffer data has been transferred and still more SDMMC data needs to be sent.
- When the availability of a linked list buffer is not acknowledged.

On a IDMA transfer error subsequent IDMA transfers are disabled and an IDMATE flag is set and hardware flow control is disabled. Depending when the IDMA transfer error occurs, it normally causes the generation of a TXUNDERR or RXOVERR error.

The behavior of the IDMATE flag depend on when the IDMA transfer error occurs during the SDMMC transfer:

- An IDMA transfer error is detected before any SDMMC transfer error (TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT):
  - The IDMATE flag is set at the same time as the SDMMC transfer error flag.
  - The TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT interrupt is generated.
- An IDMA transfer error is detected during a STOP_TRANSNMISSION command:
  - The IDMATE flag is set at the same time as the DABORT flag.
  - The DABORT interrupt is generated.
- An IDMA transfer error is detected at the end of the SDMMC transfer (DHOLD, or DATAEND):
  - The IDMATE flag is set at the end of the SDMMC transfer.
  - A SDMMC transfer end interrupt is generated and a DHOLD or DATAEND flag is set.

The IDMATE is generated on an other SDMMC transfer interrupt (TXUNDERR, RXOVERR, DCRCFAIL, DTIMEOUT, DABORT, DHOLD, or DATAEND).
### 24.5.7 AHB and SDMMC_CK clock relation

The AHB must at least have 3x more bandwidth than the SDMMC bus bandwidth i.e. for SDR50 4-bit mode (50 Mbyte/s) the minimum sdmmc_hclk frequency is 37.5 MHz (150 Mbyte/s).

### 24.6 Card functional description

#### 24.6.1 SD I/O mode

The following features are SDMMC specific operations:
- SDIO interrupts
- SDIO suspend/resume operation (write and read suspend)
- SDIO Read Wait operation by stopping the clock
- SDIO Read Wait operation by SDMMC_D2 signaling

<table>

**SD I/O interrupts**

To allow the SD I/O card to interrupt the host, an interrupt function is available on pin 8 (shared with SDMMC_D1 in 4-bit mode) on the SD interface. The use of the interrupt is optional for each card or function within a card. The SD I/O interrupt is level-sensitive, which means that the interrupt line must be held active (low) until it is either recognized and acted upon by the host or deasserted due to the end of the interrupt period. After the host has serviced the interrupt, the interrupt status bit is cleared via an I/O write to the appropriate bit in the SD I/O card internal registers. The interrupt output of all SD I/O cards is active low and the application must provide external pull-up resistors on all data lines (SDMMC_D[3:0]).

In SD 1-bit mode pin 8 is dedicated to the interrupt function (IRQ), and there are no timing constraints on interrupts.

In SD 4-bit mode the host samples the level of pin 8 (SDMMC_D1/IRQ) into the interrupt detector only during the interrupt period. At all other times, the host interrupt ignores this value. The interrupt period begins when interrupts are enabled at the card and SDIOEN bit is set see register settings in Table 230.

In 4-bit mode the card can generate a synchronous or asynchronous interrupt as indicated by the card CCCR register SAI and EAI bits.

- Synchronous interrupt, require the SDMMC_CK to be active.
- Asynchronous interrupt, can be generated when the SDMMC_CK is stopped, 4 cycles after the start of the card interrupt period following the last data block.

The timing of the interrupt period is depended on the bus speed mode:
In DS, HS, SDR12, and SDR25 mode, selected by register bit BUSSPEED, the interrupt period is synchronous to the SD clock.

- The interrupt period ends at the next clock from the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set.
- The interrupt period resumes 2 SDMMC_CK after the completion of the data block.
- At the data block gap the interrupt period is limited to 2 SDMMC_CK cycles.

*Note:* DTEN must not be used to start data transfer with SD and eMMC cards.

**Figure 169. Synchronous interrupt period data read**

**Figure 170. Synchronous interrupt period data write**
In SDR50, SDR104, and DDR50, selected by register bit BUSSPEED, due to propagation delay from the card to host, the interrupt period is asynchronous.

- The card interrupt period ends after 0 to 2 SDMMC_CK cycles after the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set. At the host the interrupt period ends after the end bit of a command that transfers data block(s). A card interrupt issued in the 1 to 2 cycles after the command end bit are not detected by the host during this interrupt period.
- The card interrupt period resumes 2 to 4 SDMMC_CK after the completion of the last data block. The host resumes the interrupt period always 2 cycles after the last data block.
- There is NO interrupt period at the data block gap.

**Note:** *DTEN must not be used to start data transfer with SD and eMMC cards.*

**Figure 171. Asynchronous interrupt period data read**
When transferring Open-ended multiple block data and using DTMODE “block data transfer ending with STOP_TRANSMISSION command”, the SDMMC masks the interrupt period after the last data block until the end of the CMD12 STOP_TRANSMISSION command.

The interrupt period is applicable for both memory and I/O operations.

In 4-bit mode interrupts can be differentiated from other signaling according Table 231.

**SD I/O suspend and resume**

This function is NOT supported in SDIO version 4.00 or later.

Within a multifunction SD I/O or a card with both I/O and memory functions, there are multiple devices (I/O and memory) that share access to the eMMC/SD bus. To share access to the host among multiple devices, SD I/O and combo cards optionally implement the concept of suspend/resume. When a card supports suspend/resume, the host can temporarily halt (suspend) a data transfer operation to one function or memory to free the bus for a higher-priority transfer to a different function or memory. After this higher-priority transfer is complete, the original transfer is restarted (resume) where it left off.

To perform the suspend/resume operation on the bus, the host performs the following steps:
1. Determines the function currently using the SDMMC_D[3:0] line(s)
2. Requests the lower-priority or slower transaction to suspend
3. Waits for the transaction suspension to complete
4. Begins the higher-priority transaction
5. Waits for the completion of the higher priority transaction
6. Restores the suspended transaction

The card receiving a suspend command responds with its current bus status. Only when the bus has been suspended by the card the bus status indicates suspension completed.

There are different suspend cases conditions:
- Suspend request accepted prior to the start of data transfer.
- Suspend request not accepted, (due to data being transfered at the same time), the host keeps checking the request until it is accepted. (data transfer has suspended)
- Suspend request during write busy.
- Suspend request with write multiple.
- Suspend request during Read Wait.

For the host to know if the bus has been released it must check the status of the suspend request, suspension completed.

When the bus status of the suspend request response indicates suspension completed, the card has released the bus. At this time the state of the suspended operation must be saved where after an other operation can start.

The suspend command must be sent with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

The hardware does not save the number of remaining data to be transfered when resuming the suspended operation. It is up to firmware to determine the data that has been transferred and resume with the correct remaining number of data bytes.

While receiving data from the card, the SDMMC can suspend the read operation after the read data block end (DPSM in Wait_R). After receiving the suspend acknowledgment response from the card the following steps must be taken by firmware:

1. The normal receive process must be stopped by setting DTHOLD bit.
   a) The remaining number of data bytes in the FIFO must be read until the receive FIFO is empty (RXFIFOE flag is set), and when IDMAEN = 0 the FIFO must be reset with FIFORST.
2. The confirmation that all data has been read from the FIFO, and that the suspend is completed is indicated by the DHOLD flag.
   a) The remaining number of data bytes (multiple of data blocks) still to be read when resuming the operation must be determined from the remaining number of bytes indicated by the DATACOUNT.

Note: When a DTIMEOUT flag occurs during the suspend procedure, this must be ignored.

To resume receiving data from the card, the following steps must be taken by firmware:
1. The remaining number of data bytes (multiple of data blocks) must be programmed in \textit{DATALENGTH}.
2. The DPSM must be configured to receive data in the DTDIR bit.
3. The resume command must be sent from the CPSM, with the CMDTRANS bit set and the CMDSUSPEND bit set, which ends the interrupt period when data transfer is resumed (response bit DF = 1) and enabled the DPSM, after which the card resumes sending data.

While sending data to the card, the SDMMC can suspend the write operation after the write data block CRC status end (DPSM in Busy). Before sending the suspend command to the card the following steps must be taken by firmware:
1. Enable DHOLD flag (and DBCKEND flag when IDMAEN = 0)
2. The DPSM must be prevented from start sending a new data block by setting DTHOLD.
3. When IDMAEN = 0: When receiving the DBCKEND flag the data transfer is stopped. Firmware can stop filling the FIFO, after which the FIFO must be reset with FIFORST. Any bytes still in the FIFO need to be rewritten when resuming the operation.
4. When receiving the DHOLD flag the data transfer is stopped. The remaining number of data bytes still to be written when resuming must be determined from the remaining number of bytes indicated by the DATACOUNT.
5. To suspend the card the suspend command must be sent by the CPSM with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

To resume sending data to the card, the following steps must be taken by firmware:
1. The remaining number of data bytes must be programmed in \textit{DATALENGTH}.
2. The DPSM must be configured for transmission with DTDIR set and enabled by having the CPSM send the resume command with the CMDTRANS bit set and the CMDSUSPEND bit set. This ends the interrupt period and start the data transfer. The DPSM either goes to the Wait\_S state when SDMMC\_D0 does not signal busy, or goes to the Busy state when busy is signaled.
3. When IDMAEN = 1: The IDMA needs to be reprogrammed for the remaining bytes to be transfered.
4. When IDMAEN = 0: Firmware must start filling the FIFO with the remaining data.

\textbf{SD I/O Read Wait}

There are 2 methods to pause the data transfer during the Block gap:
1. Stopping the SDMMC\_CK.
2. Using Read Wait signaling on SDMMC\_D2.

The SDMMC can perform a Read Wait with register settings according \textit{Table 230}.

Depending the SDMMC operation mode (DS, HS, SDR12, SDR25) or (SDR50, SDR104, DDR) each method has a different characteristic.

The timing for pause read operation by stopping the SDMMC\_CK for DS, HS, SDR12, and SDR25, the SDMMC\_CK may be stopped 2 SDMMC\_CK cycles after the end bit. When ready the host resumes by restarting clock, see \textit{Figure 173}.  

\textit{Table 230}
The timing for pause read operation by stopping the SDMMC_CK for SDR50, SDR104, and DDR50, the SDMMC_CK may be stopped minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, after the end bit. When ready the host resumes by restarting clock, see Figure 174. (In DDR50 mode the SDMMC_CK must only be stopped after the falling edge, when the clock line is low.)

In Read Wait SDMMC_CK clock stopping, when RWSTART is set, the DSPM stops the clock after the end bit of the current received data block CRC. The clock start again after writing 1 to the RWSTOP bit, where after the DPSM waits for a start bit from the card.

As SDMMC_CK is stopped, no command can be issued to the card. During a Read Wait interval, the SDMMC can still detect SDIO interrupts on SDMMC_D1.

The optional Read Wait signaling on SDMMC_D2 (RW) operation is defined only for the SD 1-bit and 4-bit modes. The Read Wait operation enables the host to signal a card that is reading multiple registers (IO_RW_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the host to send commands to any function within the SD I/O device. To determine when a card supports the Read Wait protocol, the host must test capability bits in the internal card registers.

The timing for Read Wait with a SDMMC_CK less then 50MHz (DS, HS, SDR12, SDR25) is based on the interrupt period generated by the card on SDMMC_D1. The host by asserting SDMMC_D2 low during the interrupt period requests the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z, see Figure 175.
For SDR50, SDR104 with a SDMMC_CK more than 50MHz, and DDR50, the card treats the Read Wait request on SDMMC_D2 as an asynchronous event. The host by asserting SDMMC_D2 low after minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, request the card to enter Read Wait. To exit Read Wait the host must raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z. The host must raise SDMMC_D2 on the SDMMC_CK clock (see Figure 176).

In Read Wait SDMMC_D2 signaling, when RWSTART is set, the DPSM drives SDMMC_D2 after the end bit of the current received data block CRC. The Read Wait signaling on SDMMC_D2 is removed when writing 1 to the RWSTOP bit. The DPSM remains in R_W state for two more SDMMC_CK clock cycles to drive SDMMC_D2 to 1 for one clock cycle (in accordance with SDIO specification), where after the DPSM waits for a start bit from the card.

During the Read Wait signaling on SDMMC_D2 commands can be issued to the card. During the Read Wait interval, the SDMMC can detect SDIO interrupts on SDMMC_D1.

### 24.6.2 CMD12 send timing

CMD12 is used to stop/abort the data transfer, the card data transmission is terminated two clock cycles after the end bit of the Stop Transmission command.
Table 232. CMD12 use cases

<table>
<thead>
<tr>
<th>Data operation</th>
<th>Stop Transmission command CMD12</th>

</tr>
<tr>
<td>SDMMC block read with predefined block count</td>
<td></td>
<td>The Stop Transmission command is not required at the end of this type of multiple block read. (sending the Stop Transmission command after the card has transmitted the last block is regarded as an illegal command.) Transaction can be aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.</td>
</tr>
</tbody>
</table>

All data write and read commands can be aborted any time by a Stop Transmission command CMD12. The following data abort procedure applies during an ongoing data transfer:
1. Load CMD12 Stop Transmission command in registers and set the CMDSTOP bit.
   a) This causes the CPSM Abort signal to be generated when the command is sent to
      the DPSM.
2. Configure the CPSM to send a command immediately (clear WAITPEND bit).
   a) The card, when sending data, stops data transfer 2 cycles after the Stop
      Transmission command end bit.
      The card when no data is being sent, does not start sending any new data.
   b) The host, when sending data, sends one last data bit followed by an end bit after
      the Stop Transmission command end bit.
      The host when not sending data, does not start sending any new data.
3. When IDMAEN = 0, the FIFO need to be reset with FIFORST.
   a) When writing data to the card. On the CMDREND flag, firmware must stop writing
      data to the FIFO. Subsequently the FIFO must be reset with FIFORST, this flushes
      the FIFO.
   b) When reading data from the card. On the CMDREND flag, firmware must read the
      remaining data from the FIFO. Subsequently the FIFO must be reset with
      FIFORST.
4. When IDMAEN = 1, hardware takes care of the FIFO.
   a) When writing data to the card. On the CPSM Abort signal, hardware stops the
      IDMA and subsequently the FIFO is flushed.
   b) When reading data from the card. On the CPSM Abort signal, hardware instructs
      the IDMA to transfer the remaining data from the FIFO to RAM.
5. When the FIFO is empty/reset the DABORT flag is generated.

Stream operation and CMD12
To stop the stream transfer after the last byte to be transferred, the CMD12 end bit timing
must be sent aligned with the data stream end of last byte. The following write stream data
procedure applies:
1. Initialize the stream data in the DPSM, DTMODE = MCC stream data transfer.
2. Send the WRITE_DATA_STREAM command from the CPSM with CMDTRANS = 1.
3. Preload CMD12 in command registers, with the CMDSTOP bit set.
4. Configure the CPSM to send a command only after a wait pending (WAITPEND = 1)
   end of last data (according DATALENGTH).
5. Enabling the CPSM to send the STOP_TRANSMISSION command, the stream data
   end bit and command end bit are aligned.
   a) When DATALENGTH > 5 bytes, Command CMD12 is waited in the CPSM to be
      aligned with the data transfer end bit.
   b) When DATALENGTH < 5 bytes, Command CMD12 is started before and the
      DPSM remains in the Wait_S state to align the data transfer end with the CMD12
      end bit.
6. The write stream data can be aborted any time by clearing the WAITPEND bit. This
   causes the Preloaded CMD12 to be sent immediately and stop the write data stream.
To stop the read stream transfer after the last byte, the CMD12 end bit timing must occur after the last data stream byte. The following read stream data procedure applies:

1. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   a) The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.

2. Send CMD12 by the CPSM.
   a) CMD12 stops the card sending data.

*Note:* The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

**Block operation and CMD12**

To stop block transfer at the end of the data, the CMD12 end bit must be sent after the last block end bit.

When writing data to the card the CMD12 end bit must be sent after the write data block CRC token end bit. This requires the CMD12 sending to be tied to the data block transmission timing. To stop an Open-ended Multiple block write, the following procedure applies:

1. Before starting the data transfer, set DTMODE to "block data transfer ending with STOP_TRANSMISSION command".

2. Wait for all data to be sent by the DPSM and the CRC token to be received, (DATAEND flag).
   a) The DPSM does not send more data than indicated by DATALENGTH.

3. Send CMD12 by the CPSM.
   a) CMD12 sets the card to Idle mode.

When reading data from the card the CMD12 end bit must be sent earliest at the same time as the card read data block last data bit. This requires the CMD12 sending to be tied to the data block reception timing. The following stop Open-ended Multiple block read data block procedure applies:
1. Before starting the data transfer, set DTMODE to “block data transfer ending with
   STOP_TRANSMISSION command”.
2. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   a) The DPSM does not receive more data than indicated by DATALENGTH, even if
      the card is sending more data.
3. Send CMD12 with CMDSTOP bit set by the CPSM.
   a) CMD12 stops the Card sending more data and set the card to Idle mode. Any
      ongoing block transfer is aborted by the Card.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even
when the card continues sending data.

24.6.3 Sleep (CMD5)

The eMMC card may be switched between a Sleep state and a Standby state by CMD5. In
the Sleep state the power consumption of the card is minimized and the Vcc power supply
may be switched off.

The CMD5 (SLEEP) is used to initiate the state transition from Standby state to Sleep state.
The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Sleep
state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:
1. Enable interrupt on BUSYD0END.
2. Send CMD5 (SLEEP).
3. On BUSYD0END interrupt, card is in Sleep state
4. Vcc power supply can be switched off

The CMD5 (AWAKE) is used to initiate the state transition from Sleep state to Standby state.
The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The
Standby state is reached when the card stops pulling down the SDMMC_DO line.

To set the card into Sleep state the following procedure applies:
1. Switch on Vcc power supply and wait unit minimum operating level is reached.
2. Enable interrupt on BUSYD0END.
3. Send CMD5 (AWAKE).
4. On BUSYD0END interrupt card is in Standby state.

The Vcc power supply can be switched off only after the Sleep state has been reached. The
Vcc supply must be reinstalled before CMD5 (AWAKE) is sent.
24.6.4 Interrupt mode (Wait-IRQ)

The host and card enter and exit interrupt mode (Wait-IRQ) simultaneously. In interrupt mode there is no data transfer. The only message allowed is an interrupt service request response from the card or the host. For the interrupt mode to work correctly the SDMMC_CK frequency must be set in accordance with the achievable SDMMC_CMD data rate in Open Drain mode, which depend on the capacitive load and pull-up resistor. The CLKDIV must be set >1, and the SETCLKRX must select either the sdmmc_io_in_ck or SDMMC_CLKin source.

The host must ensure that the card is in Standby state before issuing the CMD40 (GO_IRQ_STATE). While waiting for an interrupt response the SDMMC_CK clock signal must be kept active.

A card in interrupt mode (IRQ state):
- is waiting for an internal card interrupt event. Once the event occurs, the card starts to send the interrupt service request response. The response is sent in open-drain mode.
- while waiting for the internal card interrupt event, the card also monitors the SDMMC_CMD line for a start bit. Upon detection of a start bit the card aborts the interrupt mode and switch to Standby state.

The host in interrupt mode (CPSM Wait state waiting for interrupt):
- is waiting for a card interrupt service request response (start bit).
- while waiting for a card interrupt service request response the host may abort the interrupt mode (by clearing the WAITINT register bit), which causes the host to send an interrupt service request response R5 with RCA = 0x0000 in open-drain mode.

When sending the interrupt service request response, the sender bit-wise monitors the SDMMC_CMD bit stream. The sender whose interrupt service request response bit does not correspond to the bit on the SDMMC_CMD line stops sending. In the case of multiple senders only one successfully sends its full interrupt service request response. If the host sends simultaneously, it loses sending after the transmission bit.

To handle the interrupt mode, the following procedure applies:

![CMD5 Sleep Awake procedure](image)
1. Set the SDMMC_CK frequency in accordance with the achievable SDMMC_CMD data rate in Open-drain mode, CLKDIV must be set >1, and SETCLKRX must select the sdmmc_io_in_ck.

2. Load CMD40 (GO_IRQ_STATE) in the command registers.

3. Enable wait for interrupt by setting WAITINT register bit.

4. Configure the CPSM to send a command immediately.
   a) This causes the CMD40 to be sent and the CPSM to be halted in the Wait state, waiting for an interrupt service request response.

5. To exit the wait for interrupt state (CPSM Wait state):
   a) Upon the detection of an interrupt service request response start bit the CPSM moves to the Receive state where the response is received. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.
   b) To abort the interrupt mode the host clears the WAITINT register bit, which causes the host to send an interrupt service request response by itself. This moves the CPSM to the Receive state. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.

*Note:* On a simultaneous send interrupt service request response start bit collision the host loses the bus access after the transmission bit.

### 24.6.5 Boot operation

In boot operation mode the host can read boot data from the card by either one of the 2 boot operation functions:

1. Normal boot. (keeping CMD line low)
2. Alternative boot (sending CMD0 with argument 0xFFFFFFFFA)

The boot data can be read according to the following configuration options, depending on card register settings:

- The partition from which boot data is read (EXT_CSD Byte[179])
- The boot data size (EXT_CSD Byte[226])
- The bus configuration during boot (EXT_CSD Byte[177])
- Receiving boot acknowledgment from the card. (EXT_CSD Byte[179])

If boot acknowledgment is enabled the card send pattern 010 on SDMMC_D0 within 50ms after boot mode has been requested by either CMD line going low or after CMD0 with argument 0xFFFFFFFFA. A boot acknowledgment timeout (ACKTIMEOUT) and acknowledgment status (ACKFAIL) is provided.

**Normal boot operation**

If the SDMMC_CMD line is held low for at least 74 clock cycles after card power-up or reset, before the first command is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD line goes low, the card starts to send the first boot code data on the SDMMC_Dn line(s). The host must keep the SDMMC_CMD line low until after all boot data has been read. The host can terminate boot mode by pulling the SDMMC_CMD line high.
To perform the normal boot procedure the following steps are needed:

1. Reset the card.
2. If a boot acknowledgment is requested, enable the BOOTACKEN and set the ACKTIME and ACKFAIL and ACKTIMEOUT interrupt.
3. Enable data reception by setting the DPSM in receive mode (DTDIR) and the number of data bytes to be received in DATALENGTH.
4. Enable the DTIMEOUT, DATAEND, and CMDSENT interrupts for end of boot command confirmation.
5. Select the normal boot operation mode in BOOTMODE, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN. This causes:
   - the SDMMC_CMD to be driven low. (BOOTMODE = normal boot).
   - the ACK timeout to start.
   - DPSM to be enabled.
6. The incorrect reception of the boot acknowledgment can be detected with ACKFAIL flag or ACKTIMEOUT flag when enabled.
   - when an incorrect boot acknowledgment is received, the ACKFAIL flag occurs.
   - when the boot acknowledgment is not received in time, the ACKTIMEOUT flag occurs.
7. When all boot data has been received, the DATAEND flag occurs.
   - when data CRC fails, the DCRCFAIL flag is also generated.
   - when the data timeout occurs, the DTIMEOUT flag is also generated.
8. When the last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   - SDMMC has completely received all data and the DPSM is disabled.
9. The boot procedure is terminated by firmware clearing BOOTEN, which causes the SDMMC_CMD line to go high. The CMDSENT flag is generated 56 cycles later to indicate that a new command can be sent.
   a) If the boot procedure is aborted by firmware before all data has been received, the CPSM Abort signal stops data reception and disables the DPSM which triggers an DABORT flag when enabled.
10. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command.
Alternative boot operation

After card power-up or reset, if the host send CMD0 with the argument 0xFFFFFFFFFA after 74 clock cycles before CMD0 is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD0 with argument 0xFFFFFFFFFA has been sent, the card starts to send the first boot code data on the SDMMC_Dn line(s). The master terminates boot operation by sending CMD0 (Reset).

**Figure 180. Alternative boot mode operation**

To perform the alternative boot procedure the following steps needed:

1. Move the SDMMC to power-off state, and reset the card
2. Move the SDMMC to power-on state. This guarantees the 74 SCDMMC_CK cycles to be clocked before any command.
3. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKTIMEOUT flag.
4. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data to be received in DATALENGTH. Enable the DTIMEOUT and DATAEND flags.
5. Select the alternative boot operation mode in BOOTMODE, load the CMD0 with the 0xFFFFFFFFFA argument in the command registers. Enable CMDSENT flag for end of
boot command confirmation, and enable boot in BOOTEN. The boot procedure is 
started by enabling the CPSM with CPSMEN. This causes:
   – the loaded command and argument to be sent out. (BOOTMODE = alternative 
   boot).
   – the ACK timeout to start.
   – DPSM to be enabled.
6. When the command has been sent the CMDSENT flag is generated, at which time the 
BOOTEN bit must be cleared.
7. the reception of the boot acknowledgment can be detected with ACKFAIL flag when 
enabled.
   – when the boot acknowledgment is not received in time the ACKTIMEOUT flag 
occurs.
8. when all boot data has been received the DATAEND flag occurs.
   – when data CRC fails the DCRCFAIL flag is also generated.
   – when the data timeout occurs the DTIMEOUT flag is also generated.
9. When last data has been received, read data from the FIFO until FIFO is empty after 
which end of data DATAEND flag is generated.
   – SDMMC has completely received all data and the DPSM is disabled.
10. The BOOTEN bit must be cleared, before terminating the boot procedure by sending 
CMD0 (Reset) with BOOTMODE = alternative boot. This causes the CMDSENT flag to 
occur 56 cycles after the Command.
   – if the boot procedure is aborted by firmware before all data has been received the 
   CPSM Abort signal stops the data transfer and disable the DPSM which triggers 
an DABORT flag when enabled.
11. The CMDSENT flag signals the end of the boot procedure and the card is ready to 
receive a new command. When the RESET command has been sent successfully, the 
BOOTMODE control bit has to be cleared to terminate the boot operation.

24.6.6 Response R1b handling

When sending commands which have a R1b response the busy signaling is reflected in the 
BUSYD0 register bit and the release of busy with the BUSYD0END flag. The SDMMC_D0 
line is sampled at the end of the R1b response and signaled in the BUSYD0 register bit. The 
BUSYD0 register bit is reset to not busy when the SDMMC_D0 line release busy, at the 
same time the BUSYD0END flag is generated.
The expected maximum busy time must be set in the DATATIME register before sending the command. When enabled, the DTIMEOUT flag is set when after the R1b response busy stays active longer then the programmed time.

To detect the SDMMC_D0 busy signaling when sending a Command with R1b response the following procedure applies:

- Enable CMDREND flag
- Send Command through CPSM.
- On the CMDREND flag check the BUSYD0 register bit.
  - If BUSYD0 signals not busy, signal busy release to the Firmware
  - If BUSYD0 signals busy, wait for BUSYD0END flag
- On BUSYD0END flag signal busy released to the firmware.
- On DTIMEOUT flag busy is active longer then programmed time.

### 24.6.7 Reset and card cycle power

**Reset**

Following reset the SDMMC is in the reset state. In this state the SDMMC is disabled and no command nor data can be transfered. The SDMMC_D[7:0], and SDMMC_CMD are in HiZ and the SDMMC_CK is driven low.

Before moving to the power-on state the SDMMC must be configured.

In the power-on state the SDMMC_CK clock is running. First 74 SDMMC_CK cycles are clocked after which the SDMMC is enabled and command and data can be transfered.

The SDMMC states are controlled by Firmware with the PWRCTRL register bits according to Figure 182.

**Card cycle power**

To perform a card cycle power the following procedure applies:
1. Reset the SDMMC with the RCC.SDMMCxRST register bit. This resets the SDMMC to the reset state and the CPSM and DPSM to the Idle state.

2. Disable the Vcc power to the card.

3. Set the SDMMC in power-cycle state. This makes that the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low, to prevent the card from being supplied through the signal lines.

4. After minimum 1 ms enable the Vcc power to the card.

5. After the power ramp period set the SDMMC to the power-off state for minimum 1 ms. The SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are set to drive “1”.

6. After the 1 ms delay set the SDMMC to power-on state in which the SDMMC_CK clock is enabled.

7. After 74 SDMMC_CK cycles the first command can be sent to the card.

Figure 183. Card cycle power / power up diagram

24.7 Hardware flow control

The hardware flow control during data transfer functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.

The behavior is to stop SDMMC_CK during data transfer and freeze the SDMMC state machines. The data transfer is stalled when the FIFO is unable to transmit or receive data. The data transfer remains stalled until the transmit FIFO is half full or all data according DATALENIGHT has been stored, or until the receive FIFO is half empty. Only state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be filled or emptied even if flow control is activated.

On an IDMA linked list transfer error, the hardware flow control is disabled. As a consequence, depending on when the IDMA linked list transfer error occurs, an underrun or overrun error may also occur (see Section : IDMA transfer error management).
To enable hardware flow control during data transfer, the HWFC_EN register bit must be set to 1. After reset hardware flow control is disabled.

Hardware flow control must only be used when the SDMMC_Dn data is cycle-aligned with the SDMMC_CK. Whenever the sdmmc_fb_ck from the DLYB delay block is used, i.e. in the case of SDR104 mode with a t\text{OP} and Dt\text{OP} delay > 1 cycle, hardware flow control can not be used.

### 24.8 Ultra-high-speed phase I (UHS-I) voltage switch

UHS-I mode (SDR12, SDR25, SDR50, SDR104, and DDR50) requires the support for 1.8V signaling. After power up the card starts in 3.3V mode. CMD11 invokes the voltage switch sequence to the 1.8V mode. When the voltage sequence is completed successfully the card enters UHS-I mode with default SDR12 and card input and output timings are changed.

**Figure 184. CMD11 signal voltage switch sequence**

To perform the signal voltage switch sequence the following steps are needed:

1. Before starting the Voltage Switch procedure, the SDMMC_CK frequency must be set in the range 100 kHz - 400 kHz.
2. The host starts the Voltage Switch procedure by setting the VSWITCHEN bit before sending the CMD11.
3. The card returns an R1 response.
   - if the response CRC is pass, the Voltage Switch procedure continues the host does no longer drive the CMD and SDMMC_D[3:0] signals until completion of the voltage switch sequence. Some cycles after the response the SDMMC_CK is stopped and the CKSTOP flag is set.
   - if the response CRC is fail (CCRCFAIL flag) or no response is received before the timeout (CTIMEOUT flag), the Voltage Switch procedure is stopped.
4. The card drives CMD and SDMMC_D[3:0] to low at the next clock after the R1 response.
5. The host, after having received the R1 response, may monitor the SDMMC_D0 line using the BUSYD0 register bit. The SDMMC_D0 line is sampled two SDMMC_CK clock cycles after the Response. The Firmware may read the BUSYD0 register bit following the CKSTOP flag.
   - When the BUSYD0 is detected low the host firmware switches the Voltage regulator to 1.8V, after which it instructs the SDMMC to start the timing critical
section of the Voltage Switch sequence by setting register bit VSWITCH. The hardware continues to stop the SDMMC_CK by holding it low for at least 5 ms.

– When the BUSYD0 is detected high the host aborts the Voltage Switch sequence and cycle power the card.

6. The card after detecting SDMMC_CK low begins switching signaling voltage to 1.8 V.

7. The host SDMMC hardware after at least 5 ms restarts the SDMMC_CK.

8. The card within 1 ms from detecting SDMMC_CK transition drives CMD and DAT[3:0] high for at least 1 SDMMC_CK cycle and then stop driving CMD and DAT[3:0].

9. The host SDMMC hardware, 1 ms after the SDMMC_CK has been restarted, the SDMMC_D0 is sampled into BUSYD0 and the VSWEND flag is set.

10. The host, on the VSWEND flag, checks SDMMC_D0 line using the BUSYD0 register bit, to confirm completion of voltage switch sequence:

– When BUSYD0 is detected high, Voltage Switch has been completed successfully.
– When BUSYD0 is detected low, Voltage Switch has failed, the host cycles the card power.

The minimum 5 ms time to stop the SDMMC_CK is derived from the internal un-gated SDMMC_CK clock, which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The >5 ms time is counted by $2^{12}$ cycles (10.24 ms @ 400 kHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time for the SDMMC_CK clock to be stopped is longer.

The maximum 1 ms time for the card to drive the SDMMC_Dn and SDMMC_CMD lines high is derived from the internal ungated SDMMC_CK which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The SDMMC checks the lines after >1 ms time which is counted by $2^5$ cycles (1.28 ms @ 25 MHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time to check the lines is longer.

The signal voltage level is supported through an external voltage translation transceiver like STMicroelectronics ST6G3244ME.
To interface with an external driver (a voltage switch transceiver), next to the standard signals the SDMMC uses the following signals:

**SDMMC_CKIN** feedback input clock

**SDMMC_CDIR** I/O direction control for the CMD signal.

**SDMMC_D0DIR** I/O direction control for the SDMMC_D0 signal.

**SDMMC_D123DIR** I/O direction control for the SDMMC_D1, SDMMC_D2 and SDMMC_D3 signals.

The voltage transceiver signals **EN** and **SEL** are to be handled through general-purpose I/O.

The polarity of the SDMMC_CDIR, SDMMC_D0DIR and SDMMC_D123DIR signals can be selected through SDMMC_POWER.DIRPOL control bit.

24.10 SDMMC registers

The device communicates to the system via 32-bit control registers accessible via AHB slave interface.

The peripheral registers have to be accessed by words (32-bit). Byte (8-bit) and halfword (16-bit) accesses trigger an AHB bus error.

24.10.1 SDMMC power control register (SDMMC_POWER)

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 DIRPOL: Data and command direction signals polarity selection
This bit can only be written when the SDMMC is in the power-off state (PWRCTRL = 00).
0: Voltage transceiver IOs driven as output when direction signal is low.
1: Voltage transceiver IOs driven as output when direction signal is high.

Bit 3 VSWITCHEN: Voltage switch procedure enable
This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
This bit is used to stop the SDMMC_CK after the voltage switch command response:
0: SDMMC_CK clock kept unchanged after successfully received command response.
1: SDMMC_CK clock stopped after successfully received command response.

Bit 2 VSWITCH: Voltage switch sequence start
This bit is used to start the timing critical section of the voltage switch sequence:
0: Voltage switch sequence not started and not active.
1: Voltage switch sequence started or active.

Bits 1:0 PWRCTRL[1:0]: SDMMC state control bits
These bits can only be written when the SDMMC is not in the power-on state (PWRCTRL ≠ 11).
These bits are used to define the functional state of the SDMMC signals:
00: After reset, Reset: the SDMMC is disabled and the clock to the Card is stopped, SDMMC_D[7:0], and SDMMC_CMD are HiZ and SDMMC_CK is driven low.
When written 00, power-off: the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven high.
01: Reserved. (When written 01, PWRCTRL value does not change)
10: Power-cycle, the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low.
11: Power-on: the card is clocked, The first 74 SDMMC_CK cycles the SDMMC is still disabled. After the 74 cycles the SDMMC is enabled and the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are controlled according the SDMMC operation.
Any further write is ignored, PWRCTRL value keeps 11.
24.10.2 SDMMC clock control register (SDMMC_CLKCR)

Address offset: 0x004
Reset value: 0x0000 0000

The SDMMC_CLKCR register controls the SDMMC_CK output clock, the sdmmc_rx_ck receive clock, and the bus width.

| Bits 31:22 | Reserved, must be kept at reset value. |
| Bits 21:20 | **SELCLKRX[1:0]**: Receive clock selection |
| These bits can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0) |
| 00: sdmmc_io_in_ck selected as receive clock |
| 01: SDMMC_CKIN feedback clock selected as receive clock |
| 10: sdmmc_fb_ck tuned feedback clock selected as receive clock. |
| 11: Reserved (select sdmmc_io_in_ck) |

| Bit 19 | **BUSSPEED**: Bus speed for selection of SDMMC operating modes |
| This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0) |
| 0: DS, HS, SDR12, SDR25, Legacy compatible, High speed SDR, High speed DDR bus speed mode selected |
| 1: SDR50, DDR50, SDR104, HS200 bus speed mode selected. |

| Bit 18 | **DDR**: Data rate signaling selection |
| This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0) |
| DDR rate must only be selected with 4-bit or 8-bit wide bus mode. (WIDBUS > 00). DDR = 1 has no effect when WIDBUS = 00 (1-bit wide bus). |
| If DDR rate must only be selected with clock division >1. (CLKDIV > 0) |
| 0: SDR Single data rate signaling |
| 1: DDR double data rate signaling |

| Bit 17 | **HWFC_EN**: Hardware flow control enable |
| This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0) |
| 0: Hardware flow control is disabled |
| 1: Hardware flow control is enabled |
| When Hardware flow control is enabled, the meaning of the TXFIFOE and RXFIFOF flags change, see SDMMC status register definition in Section 24.10.11. |
Bit 16 **NEGEDGE**: SDMMC\_CK dephasing selection bit for data and command
This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).
When clock division = 1 (CLKDIV = 0), this bit has no effect. Data and Command change on SDMMC\_CK falling edge.
0: When clock division >1 (CLKDIV > 0) and DDR = 0:
– Command and data changed on the sdmcc\_ker\_ck falling edge succeeding the rising edge of SDMMC\_CK.
– SDMMC\_CK edge occurs on sdmcc\_ker\_ck rising edge.
When clock division >1 (CLKDIV > 0) and DDR = 1:
– Command changed on the sdmcc\_ker\_ck falling edge succeeding the rising edge of SDMMC\_CK.
– Data changed on the sdmcc\_ker\_ck falling edge succeeding a SDMMC\_CK edge.
– SDMMC\_CK edge occurs on sdmcc\_ker\_ck rising edge.
1: When clock division >1 (CLKDIV > 0) and DDR = 0:
– Command and data changed on the same sdmcc\_ker\_ck rising edge generating the SDMMC\_CK falling edge.
When clock division >1 (CLKDIV > 0) and DDR = 1:
– Command changed on the same sdmcc\_ker\_ck rising edge generating the SDMMC\_CK falling edge.
– Data changed on the SDMMC\_CK falling edge succeeding a SDMMC\_CK edge.
– SDMMC\_CK edge occurs on sdmcc\_ker\_ck rising edge.

Bits 15:14 **WIDBUS[1:0]**: Wide bus mode enable bit
This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).
00: Default 1-bit wide bus mode: SDMMC\_D0 used (Does not support DDR)
01: 4-bit wide bus mode: SDMMC\_D[3:0] used
10: 8-bit wide bus mode: SDMMC\_D[7:0] used

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PWRSAV**: Power saving configuration bit
This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).
For power saving, the SDMMC\_CK clock output can be disabled when the bus is idle by setting PWRSAV:
0: SDMMC\_CK clock is always enabled
1: SDMMC\_CK is only enabled when the bus is active

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **CLKDIV[9:0]**: Clock divide factor
This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).
This field defines the divide factor between the input clock (sdmmc\_ker\_ck) and the output clock (SDMMC\_CK):
SDMMC\_CK frequency = sdmmc\_ker\_ck / [2 * CLKDIV].
0x000: SDMMC\_CK frequency = sdmmc\_ker\_ck / 1 (Does not support DDR)
0x001: SDMMC\_CK frequency = sdmmc\_ker\_ck / 2
0x002: SDMMC\_CK frequency = sdmmc\_ker\_ck / 4
0x0XX: etc..
0x080: SDMMC\_CK frequency = sdmmc\_ker\_ck / 256
0xXXX: etc..
0x3FF: SDMMC\_CK frequency = sdmmc\_ker\_ck / 2046
Note: 1 While the SD/SDIO card or e-MMC is in identification mode, the SDMMC_CK frequency must be less than 400 kHz.

2 The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.

3 At least seven sdmmc_hclk clock periods are needed between two write accesses to this register. SDMMC_CK can also be stopped during the Read Wait interval for SD I/O cards: in this case the SDMMC_CLKCR register does not control SDMMC_CK.

### 24.10.3 SDMMC argument register (SDMMC_ARGR)

Address offset: 0x008

Reset value: 0x0000 0000

The SDMMC_ARGR register contains a 32-bit command argument, which is sent to a card as part of a command message.

Bits 31:0 CMDARG[31:0]: Command argument

These bits can only be written by firmware when CPSM is disabled (CPSMEN = 0). Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.

### 24.10.4 SDMMC command register (SDMMC_CMDR)

Address offset: 0x00C

Reset value: 0x0000 0000

The SDMMC_CMDR register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>
Bits 31:17  Reserved, must be kept at reset value.

Bit 16 **CMDSUSPEND**: The CPSM treats the command as a Suspend or Resume command and signals interrupt period start/end
   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   CMDSUSPEND = 1 and CMDTRANS = 0 Suspend command, start interrupt period when response bit BS=0.
   CMDSUSPEND = 1 and CMDTRANS = 1 Resume command with data, end interrupt period when response bit DF=1.

Bit 15 **BOOTEN**: Enable boot mode procedure
   0: Boot mode procedure disabled
   1: Boot mode procedure enabled

Bit 14 **BOOTMODE**: Select the boot mode procedure to be used
   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0)
   0: Normal boot mode procedure selected
   1: Alternative boot mode procedure selected.

Bit 13 **DTHOLD**: Hold new data block transmission and reception in the DPSM
   If this bit is set, the DPSM does not move from the Wait_S state to the Send state or from the Wait_R state to the Receive state.

Bit 12 **CPSMEN**: Command path state machine (CPSM) enable bit
   This bit is written 1 by firmware, and cleared by hardware when the CPSM enters the Idle state.
   If this bit is set, the CPSM is enabled.
   When DTEN = 1, no command is transferred nor boot procedure is started. CPSMEN is cleared to 0.
   During Read Wait with SDMMC_CK stopped no command is sent and CPSMEN is kept 0.

Bit 11 **WAITPEND**: CPSM waits for end of data transfer (CmdPend internal signal) from DPSM
   This bit when set, the CPSM waits for the end of data transfer trigger before it starts sending a command.
   WAITPEND is only taken into account when DTMODE = eMMC stream data transfer,
   WIDBUS = 1-bit wide bus mode, DPSMACT = 1 and DTDIR = from host to card.

Bit 10 **WAITINT**: CPSM waits for interrupt request
   If this bit is set, the CPSM disables command timeout and waits for an card interrupt request (Response).
   If this bit is cleared in the CPSM Wait state, it causes the abort of the interrupt mode.

Bits 9:8 **WAITRESP[1:0]**: Wait for response bits
   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.
   00: No response, expect CMDSENT flag
   01: Short response, expect CMDREND or CCRCFAIL flag
   10: Short response, expect CMDREND flag (No CRC)
   11: Long response, expect CMDREND or CCRCFAIL flag
Bit 7 **CMDSTOP**: The CPSM treats the command as a Stop Transmission command and signals abort to the DPSM.

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues the abort signal to the DPSM when the command is sent.

Bit 6 **CMDTRANS**: The CPSM treats the command as a data transfer command, stops the interrupt period, and signals DataEnable to the DPSM.

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues an end of interrupt period and issues DataEnable signal to the DPSM when the command is sent.

Bits 5:0 **CMDINDEX[5:0]**: Command index

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

The command index is sent to the card as part of a command message.

---

**Note:**

1. At least seven sdmmc_hclk clock periods are needed between two write accesses to this register.

2. MultiMediaCard can send two kinds of response: short responses, 48 bits, or long responses, 136 bits. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software distinguishes the type of response according to the send command.

---

**24.10.5 SDMMC command response register (SDMMC_RESPCMDR)**

Address offset: 0x010

Reset value: 0x0000 0000

The SDMMC_RESPCMDR register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

Bits 31:6 **Reserved**, must be kept at reset value.

Bits 5:0 **RESPCMD[5:0]**: Response command index

Read-only bit field. Contains the command index of the last command response received.
24.10.6 SDMMC response x register (SDMMC_RESPxR)

Address offset: 0x010 + 0x004 * x, (x = 1 to 4)

Reset value: 0x0000 0000

The SDMMC_RESP1/2/3/4R registers contain the status of a card, which is part of the received response.

<table>
<thead>
<tr>
<th>CARDSTATUS[31:16]</th>

</table>

<table>
<thead>
<tr>
<th>CARDSTATUS[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>r r r r r r r r r r r r r r</td>
</tr>
</tbody>
</table>

Bits 31:0 CARDSTATUS[31:0]: Card status according to the table below.

See Table 234.

The card status size is 32 or 128 bits, depending on the response type.

Table 234. Response type and SDMMC_RESPxR registers

<table>
<thead>
<tr>
<th>Register</th>
<th>Short response</th>
<th>Long response</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>SDMMC_RESP4R</td>
<td>all 0</td>
<td>Card status[31:0][2]</td>
</tr>
</tbody>
</table>

1. The most significant bit of the card status is received first.

2. The SDMMC_RESP4R register LSB is always 0.

24.10.7 SDMMC data timer register (SDMMC_DTIMER)

Address offset: 0x024

Reset value: 0x0000 0000

The SDMMC_DTIMER register contains the data timeout period, in card bus clock periods.

A counter loads the value from the SDMMC_DTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

<table>

</tbody>
</table>
Bits 31:0  DATATIME[31:0]: Data and R1b busy timeout period
   This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and
   DPSMACT = 0).
   Data and R1b busy timeout period expressed in card bus clock periods.

Note:  A data transfer must be written to the data timer register and the data length register before
being written to the data control register.

24.10.8  SDMMC data length register (SDMMC_DLENR)

Address offset: 0x028

Reset value: 0x0000 0000

The SDMMC_DLENR register contains the number of data bytes to be transferred. The
value is loaded into the data counter when data transfer starts.

</tr>
</tbody>
</table>

Bits 31:25  Reserved, must be kept at reset value.

Bits 24:0  DATALENGTH[24:0]: Data length value
   This register can only be written by firmware when DPSM is inactive (DPSMACT = 0).
   Number of data bytes to be transferred.
   When DDR = 1 DATALENGTH is truncated to a multiple of 2. (The last odd byte is not
   transferred)
   When DATALENGTH = 0 no data are transferred, when requested by a CPSMEN and
   CMDTRANS = 1 also no command is transfered. DTEN and CPSMEN are cleared to 0.

Note:  For a block data transfer, the value in the data length register must be a multiple of the block
size (see SDMMC_DCTRL). A data transfer must be written to the data timer register and
the data length register before being written to the data control register.

For an SDMMC multibyte transfer the value in the data length register must be between 1
and 512.
24.10.9  SDMMC data control register (SDMMC_DCTRL)

Address offset: 0x02C
Reset value: 0x0000 0000

The SDMMC_DCTRL register control the data path state machine (DPSM).

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

<td>RWMOD: Read Wait mode</td>
</tr>
<tr>
<td>9</td>
<td>RWSTOP: Read Wait stop</td>
</tr>
<tr>
<td>8</td>
<td>RWSTART: Read Wait start</td>
</tr>
</tbody>
</table>

Bits 31:14  Reserved, must be kept at reset value.

Bit 13  **FIFORST**: FIFO reset, flushes any remaining data
- This bit can only be written by firmware when IDMAEN= 0 and DPSM is active (DPSMACT = 1). This bit only takes effect when a transfer error or transfer hold occurs.
- 0: FIFO not affected.
- 1: Flush any remaining data and reset the FIFO pointers. This bit is automatically cleared to 0 by hardware when DPSM gets inactive (DPSMACT = 0).

Bit 12  **BOOTACKEN**: Enable the reception of the boot acknowledgment
- This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
- 0: Boot acknowledgment disabled, not expected to be received
- 1: Boot acknowledgment enabled, expected to be received

Bit 11  **SDIOEN**: SD I/O interrupt enable functions
- This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
- If this bit is set, the DPSM enables the SD I/O card specific interrupt operation.

Bit 10  **RWMOD**: Read Wait mode
- This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
- 0: Read Wait control using SDMMC_D2
- 1: Read Wait control stopping SDMMC_CK

Bit 9  **RWSTOP**: Read Wait stop
- This bit is written by firmware and auto cleared by hardware when the DPSM moves from the R_W state to the Wait_R or Idle state.
- 0: No Read Wait stop.
- 1: Enable for Read Wait stop when DPSM is in the R_W state.

Bit 8  **RWSTART**: Read Wait start
- If this bit is set, Read Wait operation starts.
Bits 7:4  **DBLOCKSIZE[3:0]:** Data block size

This bit can only be written by firmware when DPSM is inactive (DPSM_ACT = 0).
Define the data block length when the block data transfer mode is selected:

- 0000: Block length = $2^0 = 1$ byte
- 0001: Block length = $2^1 = 2$ bytes
- 0010: Block length = $2^2 = 4$ bytes
- 0011: Block length = $2^3 = 8$ bytes
- 0100: Block length = $2^4 = 16$ bytes
- 0101: Block length = $2^5 = 32$ bytes
- 0110: Block length = $2^6 = 64$ bytes
- 0111: Block length = $2^7 = 128$ bytes
- 1000: Block length = $2^8 = 256$ bytes
- 1001: Block length = $2^9 = 512$ bytes
- 1010: Block length = $2^{10} = 1024$ bytes
- 1011: Block length = $2^{11} = 2048$ bytes
- 1100: Block length = $2^{12} = 4096$ bytes
- 1101: Block length = $2^{13} = 8192$ bytes
- 1110: Block length = $2^{14} = 16384$ bytes
- 1111: Reserved

When DATALENGTH is not a multiple of DBLOCKSIZE, the transferred data is truncated at a multiple of DBLOCKSIZE. (None of the remaining data are transferred.)

When DDR = 1, DBLOCKSIZE = 0000 must not be used. (No data are transferred)

Bits 3:2  **DTMODE[1:0]:** Data transfer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSM_ACT = 0).

- 00: Block data transfer ending on block count.
- 01: SDIO multibyte data transfer.
- 10: e-MMC Stream data transfer. (WIDBUS must select 1-bit wide bus mode)
- 11: Block data transfer ending with STOP_TRANSMISSION command (not to be used with DTEN initiated data transfers).

Bit 1  **DTDIR:** Data transfer direction selection

This bit can only be written by firmware when DPSM is inactive (DPSM_ACT = 0).

- 0: From host to card.
- 1: From card to host.

Bit 0  **DTEN:** Data transfer enable bit

This bit can only be written by firmware when DPSM is inactive (DPSM_ACT = 0). This bit is cleared by Hardware when data transfer completes.

This bit must only be used to transfer data when no associated data transfer command is used, i.e. must not be used with SD or e-MMC cards.

- 0: Do not start data transfer without CPSM data transfer command.
- 1: Start data transfer without CPSM data transfer command.

### 24.10.10 SDMMC data counter register (SDMMC_DCNTR)

Address offset: 0x030

Reset value: 0x0000 0000

The SDMMC_DCNTR register loads the value from the data length register (see SDMMC_DLENR) when the DPSM moves from the Idle state to the Wait_R or Wait_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then
moves to the Idle state and when there has been no error, and no transmit data transfer hold, the data status end flag (DATAEND) is set.

</tbody>
</table>

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATACOUNT[24:0]**: Data count value
When read, the number of remaining data bytes to be transferred is returned. Write has no effect.

**Note:** This register must be read only after the data transfer is complete, or hold. When reading after an error event the read data count value may be different from the real number of data bytes transferred.

### 24.10.11 SDMMC status register (SDMMC_STAR)

Address offset: 0x034
Reset value: 0x0000 0000

The SDMMC_STAR register is a read-only register. It contains two types of flag:
- Static flags (bits [28, 21, 11:0]): these bits remain asserted until they are cleared by writing to the SDMMC interrupt Clear register (see SDMMC_ICR)
- Dynamic flags (bits [20:12]): these bits change state depending on the state of the underlying logic (for example, FIFO full and empty flags are asserted and deasserted as data while written to the FIFO)

</table>

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTC**: IDMA buffer transfer complete
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 27 **IDMATE**: IDMA transfer error
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 26 **CKSTOP**: SDMMC_CK stopped in Voltage switch procedure
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
Bit 25 **VSWEND**: Voltage switch critical timing section completion  
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 24 **ACKTIMEOUT**: Boot acknowledgment timeout  
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 23 **ACKFAIL**: Boot acknowledgment received (boot acknowledgment check fail)  
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 22 **SDIOIT**: SDIO interrupt received  
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 21 **BUSYD0END**: end of SDMMC_D0 Busy following a CMD response detected  
This indicates only end of busy following a CMD response. This bit does not signal busy due to data transfer. Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.  
0: card SDMMC_D0 signal does NOT signal change from busy to not busy.  
1: card SDMMC_D0 signal changed from busy to NOT busy.

Bit 20 **BUSYD0**: Inverted value of SDMMC_D0 line (Busy), sampled at the end of a CMD response and a second time 2 SDMMC_CK cycles after the CMD response  
This bit is reset to not busy when the SDMMC_D0 line changes from busy to not busy. This bit does not signal busy due to data transfer. This is a hardware status flag only, it does not generate an interrupt.  
0: card signals not busy on SDMMC_D0.  
1: card signals busy on SDMMC_D0.

Bit 19 **RXFIFOE**: Receive FIFO empty  
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes full.

Bit 18 **TXFIFOE**: Transmit FIFO empty  
This bit is cleared when one FIFO location becomes full.

Bit 17 **RXFIFOF**: Receive FIFO full  
This bit is cleared when one FIFO location becomes empty.

Bit 16 **TXFIFOF**: Transmit FIFO full  
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes empty.

Bit 15 **RXFIFOHF**: Receive FIFO half full  
There are at least half the number of words in the FIFO. This bit is cleared when the FIFO becomes half+1 empty.

Bit 14 **TXFIFOHE**: Transmit FIFO half empty  
At least half the number of words can be written into the FIFO. This bit is cleared when the FIFO becomes half+1 full.

Bit 13 **CPSMACT**: Command path state machine active, i.e. not in Idle state  
This is a hardware status flag only, does not generate an interrupt.

Bit 12 **DPSMACT**: Data path state machine active, i.e. not in Idle state  
This is a hardware status flag only, does not generate an interrupt.

Bit 11 **DABORT**: Data transfer aborted by CMD12  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
Bit 10 **DBCKEND**: Data block sent/received
DBCKEND is set when:
- CRC check passed and DPSM moves to the R_W state
- IDMAEN = 0 and transmit data transfer hold and DATACOUNT >0 and DPSM moves to Wait_S.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 9 **DHO</br>LD**: Data transfer Hold
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 8 **DATAEND**: Data transfer ended correctly
DATAEND is set if data counter DATACOUNT is zero and no errors occur, and no transmit data transfer hold.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 7 **CMDSENT**: Command sent (no response required)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 6 **CMDREND**: Command response received (CRC check passed, or no CRC)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 5 **RXOVERR**: Received FIFO overrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 4 **TXUNDERR**: Transmit FIFO underrun error (masked by hardware when IDMA is enabled)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 3 **DTIMEOUT**: Data timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 2 **CTIMEOUT**: Command response timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
The Command Timeout period has a fixed value of 64 SDMMC_CK clock periods.

Bit 1 **DCRCFAIL**: Data block sent/received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 0 **CCRCFAIL**: Command response received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

*Note:* FIFO interrupt flags must be masked in SDMMC_MASKR when using IDMA mode.
24.10.12 SDMMC interrupt clear register (SDMMC_ICR)

Address offset: 0x038

Reset value: 0x0000 0000

The SDMMC_ICR register is a write-only register. Writing a bit with 1 clears the corresponding bit in the SDMMC_STAR status register.

| Bit 31:29 Reserved, must be kept at reset value. |
| Bit 28 IDMABTCC: IDMA buffer transfer complete clear bit |
| Set by software to clear the IDMABTC flag. |
| 0: IDMABTC not cleared |
| 1: IDMABTC cleared |

| Bit 27 IDMATEC: IDMA transfer error clear bit |
| Set by software to clear the IDMATE flag. |
| 0: IDMATE not cleared |
| 1: IDMATE cleared |

| Bit 26 CKSTOPOC: CKSTOP flag clear bit |
| Set by software to clear the CKSTOP flag. |
| 0: CKSTOP not cleared |
| 1: CKSTOP cleared |

| Bit 25 VSWEndC: VSWEND flag clear bit |
| Set by software to clear the VSWEND flag. |
| 0: VSWEND not cleared |
| 1: VSWEND cleared |

| Bit 24 ACKTIMEOUTC: ACKTIMEOUT flag clear bit |
| Set by software to clear the ACKTIMEOUT flag. |
| 0: ACKTIMEOUT not cleared |
| 1: ACKTIMEOUT cleared |

| Bit 23 ACKFAILC: ACKFAIL flag clear bit |
| Set by software to clear the ACKFAIL flag. |
| 0: ACKFAIL not cleared |
| 1: ACKFAIL cleared |

| Set by software to clear the SDIOIT flag. |
| 0: SDIOIT not cleared |
| 1: SDIOIT cleared |
Bit 21 **BUSYD0ENDC**: BUSYD0END flag clear bit
   Set by software to clear the BUSYD0END flag.
   0: BUSYD0END not cleared
   1: BUSYD0END cleared

Bits 20:12 Reserved, must be kept at reset value.

Bit 11 **DABORTC**: DABORT flag clear bit
   Set by software to clear the DABORT flag.
   0: DABORT not cleared
   1: DABORT cleared

Bit 10 **DBCKENDC**: DBCKEND flag clear bit
   Set by software to clear the DBCKEND flag.
   0: DBCKEND not cleared
   1: DBCKEND cleared

Bit 9 **DHOLDC**: DHOLD flag clear bit
   Set by software to clear the DHOLD flag.
   0: DHOLD not cleared
   1: DHOLD cleared

Bit 8 **DATAENDC**: DATAEND flag clear bit
   Set by software to clear the DATAEND flag.
   0: DATAEND not cleared
   1: DATAEND cleared

Bit 7 **CMDSENTC**: CMDSENT flag clear bit
   Set by software to clear the CMDSENT flag.
   0: CMDSENT not cleared
   1: CMDSENT cleared

Bit 6 **CMDRENDC**: CMDREND flag clear bit
   Set by software to clear the CMDREND flag.
   0: CMDREND not cleared
   1: CMDREND cleared

Bit 5 **RXOVERRC**: RXOVERR flag clear bit
   Set by software to clear the RXOVERR flag.
   0: RXOVERR not cleared
   1: RXOVERR cleared

Bit 4 **TXUNDERRC**: TXUNDErr flag clear bit
   Set by software to clear TXUNDErr flag.
   0: TXUNDErr not cleared
   1: TXUNDErr cleared

Bit 3 **DTIMEOUTC**: DTIMEOUT flag clear bit
   Set by software to clear the DTIMEOUT flag.
   0: DTIMEOUT not cleared
   1: DTIMEOUT cleared
24.10.13 SDMMC mask register (SDMMC_MASKR)

Address offset: 0x03C
Reset value: 0x0000 0000

The interrupt mask register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 IDMA_TBCTIE: IDMA buffer transfer complete interrupt enable
Set and cleared by software to enable/disable the interrupt generated when the IDMA has transferred all data belonging to a memory buffer.
0: IDMA buffer transfer complete interrupt disabled
1: IDMA buffer transfer complete interrupt enabled

Bit 27 Reserved, must be kept at reset value.

Bit 26 CKSTOPIE: Voltage Switch clock stopped interrupt enable
Set and cleared by software to enable/disable interrupt caused by Voltage Switch clock stopped.
0: Voltage Switch clock stopped interrupt disabled
1: Voltage Switch clock stopped interrupt enabled

Bit 25 VSWENDIE: Voltage switch critical timing section completion interrupt enable
Set and cleared by software to enable/disable the interrupt generated when voltage switch critical timing section completion.
0: Voltage switch critical timing section completion interrupt disabled
1: Voltage switch critical timing section completion interrupt enabled
Bit 24 **ACKTIMEOUTIE**: Acknowledgment timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment timeout.
0: Acknowledgment timeout interrupt disabled
1: Acknowledgment timeout interrupt enabled

Bit 23 **ACKFAILIE**: Acknowledgment Fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment Fail.
0: Acknowledgment Fail interrupt disabled
1: Acknowledgment Fail interrupt enabled

Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable
Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.
0: SDIO Mode interrupt received interrupt disabled
1: SDIO Mode interrupt received interrupt enabled

Bit 21 **BUSYD0ENDIE**: BUSYD0END interrupt enable
Set and cleared by software to enable/disable the interrupt generated when SDMMC_D0 signal changes from busy to NOT busy following a CMD response.
0: BUSYD0END interrupt disabled
1: BUSYD0END interrupt enabled

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.
0: Tx FIFO empty interrupt disabled
1: Tx FIFO empty interrupt enabled

Bit 17 **RXFIFOFIE**: Rx FIFO full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.
0: Rx FIFO full interrupt disabled
1: Rx FIFO full interrupt enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **RXFIFOHFIIE**: Rx FIFO half full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.
0: Rx FIFO half full interrupt disabled
1: Rx FIFO half full interrupt enabled

Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.
0: Tx FIFO half empty interrupt disabled
1: Tx FIFO half empty interrupt enabled

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **DABORTIE**: Data transfer aborted interrupt enable
Set and cleared by software to enable/disable interrupt caused by a data transfer being aborted.
0: Data transfer abort interrupt disabled
1: Data transfer abort interrupt enabled

Bit 10 **DBCKENDIE**: Data block end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data block end.
0: Data block end interrupt disabled
1: Data block end interrupt enabled
Bit 9 **D HOLDIE**: Data hold interrupt enable
Set and cleared by software to enable/disable the interrupt generated when sending new
data is hold in the DPSM Wait_S state.
0: Data hold interrupt disabled
1: Data hold interrupt enabled

Bit 8 **DATAENDIE**: Data end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data end.
0: Data end interrupt disabled
1: Data end interrupt enabled

Bit 7 **CMDSENTIE**: Command sent interrupt enable
Set and cleared by software to enable/disable interrupt caused by sending command.
0: Command sent interrupt disabled
1: Command sent interrupt enabled

Bit 6 **CMDRENDIE**: Command response received interrupt enable
Set and cleared by software to enable/disable interrupt caused by receiving command
response.
0: Command response received interrupt disabled
1: Command Response received interrupt enabled

Bit 5 **RXOVERRIE**: Rx FIFO overrun error interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO overrun error.
0: Rx FIFO overrun error interrupt disabled
1: Rx FIFO overrun error interrupt enabled

Bit 4 **TXUNDERRIE**: Tx FIFO underrun error interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO underrun error.
0: Tx FIFO underrun error interrupt disabled
1: Tx FIFO underrun error interrupt enabled

Bit 3 **DTIMEOUTIE**: Data timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by data timeout.
0: Data timeout interrupt disabled
1: Data timeout interrupt enabled

Bit 2 **CTIMEOUTIE**: Command timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by command timeout.
0: Command timeout interrupt disabled
1: Command timeout interrupt enabled

Bit 1 **DCRCFAILIE**: Data CRC fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by data CRC failure.
0: Data CRC fail interrupt disabled
1: Data CRC fail interrupt enabled

Bit 0 **CCRCFAILIE**: Command CRC fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by command CRC failure.
0: Command CRC fail interrupt disabled
1: Command CRC fail interrupt enabled
24.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER)

Address offset: 0x040  
Reset value: 0x0000 0000  
The SDMMC_ACKTIMER register contains the acknowledgment timeout period, in SDMMC_CK bus clock periods.

A counter loads the value from the SDMMC_ACKTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait_Ack state. If the timer reaches 0 while the DPSM is in this state, the acknowledgment timeout status flag is set.

<table>

</tr>
</tbody>
</table>

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **ACKTIME[24:0]**: Boot acknowledgment timeout period  
This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).  
Boot acknowledgment timeout period expressed in card bus clock periods.

*Note:* The data transfer must be written to the acknowledgment timer register before being written to the data control register.

24.10.15 SDMMC data FIFO registers x (SDMMC_FIFORx)

Address offset: 0x080 + 0x004 * x, (x =0 to 15)  
Reset value: 0x0000 0000  
The receive and transmit FIFOs can be only read or written as word (32-bit) wide registers. The FIFOs contain 16 entries on sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO. The FIFO register interface takes care of correct data alignment inside the FIFO, the FIFO register address used by the CPU does matter.

When accessing SDMMC_FIFOR with half word or byte access an AHB bus fault is generated.

<table>

</tr>
</tbody>
</table>

When accessing SDMMC_FIFOR with half word or byte access an AHB bus fault is generated.
Bits 31:0 **FIFODATA[31:0]**: Receive and transmit FIFO data
This register can only be read or written by firmware when the DPSM is active (DPSMACT = 1).
The FIFO data occupies 16 entries of 32-bit words.

### 24.10.16 SDMMC DMA control register (SDMMC_IDMACTRLR)

Address offset: 0x050
Reset value: 0x0000 0000

The receive and transmit FIFOs can be read or written as 32-bit wide registers. The FIFOs contain 32 entries on 32 sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO.

</tbody>
</table>

RM0481  Secure digital input/output MultiMediaCard interface (SDMMC)
Bit 31 **ULA**: Update SDMMC_IDMALAR from linked list when in linked list mode
(SDMMC_IDMACTRLR.IDMABMODE select linked list mode)

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: SDMMC_IDMALAR is not to be updated, last linked list item.
1: SDMMC_IDMALAR is to be updated from linked list table.

Bit 30 **ULS**: Update SDMMC_IDMABSIZE from the next linked list when in linked list mode
(SDMMC_IDMACTRLR.IDMABMODE select linked list mode and ULA = 1)

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
0: SDMMC_IDMABSIZE is not to be updated from next linked list table.
1: SDMMC_IDMABSIZE is to be updated from next linked list table.

Bit 29 **ABR**: Acknowledge linked list buffer ready

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).
This bit is not taken into account when starting the first linked list buffer from the software
programmed register information. ABR is only taken into account on subsequent loaded
linked list items.
0: Loaded linked list buffer is not ready (this causes a linked list IDMA transfer error to be
     generated).
1: Loaded linked list buffer ready acknowledge. Linked list buffer data are transfered by
    IDMA.

Bits 28:16 Reserved, must be kept at reset value.

Bits 15:2 **IDMALA[13:0]**: Word aligned linked list item address offset

Linked list item offset pointer to the base of the next linked list item structure.
Linked list item base address is IDMABA + IDMALA.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0 Reserved, must be kept at reset value.

### 24.10.20 SDMMC IDMA linked list memory base register

Bits 31:2 **IDMABA[29:0]**: Word aligned Linked list memory base address

Linked list memory base pointer.
These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).

Bits 1:0 Reserved, must be kept at reset value.
## 24.10.21 SDMMC register map

25 Delay block (DLYB)

25.1 Introduction

The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or Octo-SPI interface.

The delay is voltage- and temperature-dependent, that may require the application to reconfigure and recenter the output clock phase with the receive data.

25.2 DLYB main features

The delay block has the following features:

- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

25.3 DLYB functional description

25.3.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

![Figure 186. DLYB block diagram]
25.3.2 DLYB pins and internal signals

Table 236 lists the DLYB internal signals.

</tr>
</tbody>
</table>

25.3.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFGR).

**Note:** UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFGR register.

**Note:** SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFGREG.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

<table>
<thead>
<tr>
<th>DEN</th>
<th>SEN</th>
<th>UNIT</th>
<th>SEL</th>
<th>LNG</th>
<th>LNGF</th>
<th>Output clock</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Enabled (≠ Input clock)</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
<td>Unit delay</td>
<td>Output clock phase</td>
<td>Length</td>
<td>Length flag</td>
<td>Disabled</td>

<tr>
<td>1</td>
<td>0</td>
<td>Unit delay(1)</td>
<td>Output clock phase(2)</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Enabled (≠ selected phase)</td>
</tr>
</tbody>
</table>

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.
25.3.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].
      If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

25.3.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

Octo-SPI use case:

The delay block is used in conjunction with Octo-SPI interface to allow shifting the input data sampling signal. This sampling signal can be the feedback clock or the data strobe (DQS) signal, which is delivered by certain type of devices. Note that in case DQS is used, the calibration procedure must be performed beforehand with a free running clock, as DQS is a discontinuous signal.

In case of SDR (single data rate) mode the user must typically shift the sampling signal by half period, so that the sampling edges are positioned in the middle of the valid data phase.
In case of DDR (dual data rate) mode, for which data are transitioning at start and middle of period, typical value must be close to N/4, once the calibration is completed.

In case of high frequencies and tight timing constraints, the delay setting granularity (10) might be too coarse. Since in most cases it is not necessary to have a possible delay value covering the whole sampling clock period, the "Unit" value can be overridden by application in order to improve the accuracy of the sampling edge position (example: providing a twice as small "Unit" gives twice better timing accuracy. The counterpart being that the maximum possible delay is divided by 2).

SDMMC use case:

The delay block is used in conjunction with SDMMC interface variable delay. For correct sampling point tuning the delay value must cover a whole SDMMC_CK clock period. After having tuned the delay line length the individual delays are used in the sampling point tuning to find the optimal sampling point.

25.4 DLYB registers

All registers can be accessed in word, half-word and byte access.

Refer to Section 2.3 on page 111 for the register boundary addresses.
26  Analog-to-digital converters (ADC1/2)

26.1  Introduction

This section describes the implementation of up to 2 ADCs:
- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).

Each ADC consists of a 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

26.2  ADC main features

- High-performance features
  - Up to 2 ADCs which can operate in dual mode:
    - ADC1 is connected to 18 external channels and to 2 internal channels
    - ADC2 is connected to 18 external channels and to 2 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Manage single-ended or differential inputs
  - AHB slave bus interface to allow fast data handling
  - Self-calibration
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Up to 4 injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Four dedicated data registers for the injected channels

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
Analog-to-digital converters (ADC1/2)

- Allows slow bus frequency application while keeping optimum ADC performance
- Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)

- Oversampler
  - 16-bit data register
  - Oversampling ratio adjustable from 2 to 256x
  - Programmable data shift up to 8 bits

- Data preconditioning
  - Offset compensation

- Analog input channels
  - External analog inputs (per ADC):
    - Up to 6 fast channels from GPIO pads
    - Up to 12 slow channels from GPIO pads
  - 1 channel for the internal temperature sensor ($V_{SENSE}$)
  - 1 channel for the internal reference voltage ($V_{REFINT}$)
  - 1 channel for monitoring the external VBAT power supply pin
  - 1 channel for monitoring the internal $V_{DDCORE}$ supply

- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions

- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode

- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events

- 3 analog watchdogs per ADC
  - Watchdog can perform filtering to ignore out-of-range data

- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

*Figure 187* shows the block diagram of one ADC.

</table>
26.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The ADC input clock can be selected between two different clock sources (see Figure 188: ADC clock scheme):

1. The ADC clock can be a specific clock source (adc_ker_ck_input), independent and asynchronous with the AHB clock.
   Refer to section Reset and clock control (RCC) for more information on how to generate the ADC dedicated clock. To select this scheme, CKMODE[1:0] bits of ADC_CCR register must be set to 00.
2. The ADC clock can be derived from the AHB clock interface divided by a programmable factor of 1, 2 or 4. To select this scheme, CKMODE[1:0] bits of ADC_CCR must be different from 00. The programmable divider factor can be configured through to CKMODE[1:0] bits of ADC_CCR.
   The prescaling factor of 1 (CKMODE[1:0] = 01) can be used only if the AHB prescaler is set to 1 (HPRE[3:0] = 0xx in the RCC_CFG register).

Option 1 has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 12, 16, 32, 64, 128, 256, using the prescaler configured with bits PRESC[3:0] in the ADC_CCR register.

Option 2 has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock is configured through CKMODE[1:0] bits must be compliant with the operating frequency specified in the datasheet.
Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- \( F_{adc_hclk} \geq F_{ADC} / 4 \) if the resolution of all channels are 12-bit or 10-bit
- \( F_{adc_hclk} \geq F_{ADC} / 3 \) if there are some channels with resolutions equal to 8-bit (and none with lower resolutions)
- \( F_{adc_hclk} \geq F_{ADC} / 2 \) if there are some channels with resolutions equal to 6-bit

Constraints between ADC clocks

When several ADC interfaces are used simultaneously, it is mandatory to use the same clock source from the RCC block without prescaler ratio for all ADC interfaces.
26.4.4 ADC connectivity

ADC inputs are connected to the external channels as well as internal sources as described below.

26.4.5 **Slave AHB interface**

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:
- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

26.4.6 **ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)**

By default, the ADC is in Deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit Deep-power-down mode by setting bit DEEPPWD = 0.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the bit ADVREGEN = 1 into ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{\text{ADCVREG_STUP}}$) before launching a calibration or enabling the ADC. This delay must be implemented by software.

For the startup time of the ADC voltage regulator, refer to device datasheet for $T_{\text{ADCVREG_STUP}}$ parameter.

When ADC operations are complete, the ADC can be disabled (ADEN = 0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN = 0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC Deep-power-down mode by setting bit DEEPPWD = 1 into ADC_CR register. This is particularly interesting before entering Stop mode.

*Note:* *Writing DEEPPWD = 1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.*

*When the internal voltage regulator is disabled (ADVREGEN = 0), the internal analog calibration is kept.*

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or re-apply the calibration factor which was previously saved (refer to *Section 26.4.8: Calibration (ADCAL, ADCALDIFF, ADC_CALFACT)*).
26.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN = 0). Note that the DIFSEL[i] bits corresponding to single-ended channels are always programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage V_{INP[i]} (positive input) and V_{REF-} (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage V_{INP[i]} (positive input) and V_{INN[i]} (negative input).

The output data for the differential mode is an unsigned data. When V_{INP[i]} equals V_{REF-}, V_{INN[i]} equals V_{REF+} and the output data is 0x000 (12-bit resolution mode). When V_{INP[i]} equals V_{REF+}, V_{INN[i]} equals V_{REF-} and the output data is 0xFFF.

$$\text{Converted value} = \frac{\text{ADC Full \ Scale}}{2} \times \left[ 1 + \frac{V_{\text{INP}} - V_{\text{INN}}}{V_{\text{REF+}}} \right]$$

When ADC is configured as differential mode, both inputs should be biased at (V_{REF+})/2 voltage.

The input signals are supposed to be differential (common mode voltage should be fixed).

Internal channels (such as V_{REFINT} and V_{SENSE}) are used in single-ended mode only.

For a complete description of how the input channels are connected for each ADC, refer to Section 26.4.4: ADC connectivity.

Caution: When configuring the channel “i” in differential input mode, its negative input voltage V_{INN[i]} is connected to another channel. As a consequence, this channel is no longer usable in single-ended mode or in differential mode and must never be configured to be converted. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable. Only exception is interleaved mode for ADC master and the slave.

26.4.8 Calibration (ADCAL, ADCALDIF, ADC_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 7-bit wide and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the offset error which may vary from chip to chip due to process or bandgap variation.

The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF = 0 before launching a calibration which will be applied for single-ended input conversions.
- Write ADCALDIF = 1 before launching a calibration which will be applied for differential input conversions.

The calibration is then initiated by software by setting bit ADCAL = 1. Calibration can only be initiated when the ADC is disabled (when ADEN = 0). ADCAL bit stays at 1 during all the
calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[6:0] or CALFACT_D[6:0] of ADC_CALFACT register (depending on single-ended or differential input calibration)

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before re-enabling the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in Standby or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when $V_{REF+}$ voltage changed more than 10%.

**Software procedure to calibrate the ADC**

1. Ensure DEEPPWD = 0, ADVREGEN = 1 and that ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN = 0.
3. Select the input mode for this calibration by setting ADCALDIF = 0 (single-ended input) or ADCALDIF = 1 (differential input).
4. Set ADCAL = 1.
5. Wait until ADCAL = 0.
6. The calibration factor can be read from ADC_CALFACT register.

![Figure 191. ADC calibration](image-url)
Software procedure to reinject a calibration factor into the ADC

1. Ensure ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new calibration factors.
3. When a conversion is launched, the calibration factor is injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.

Figure 192. Updating the ADC calibration factor

Converting single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF = 0 and one with ADCALDIF = 1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF = 0). This updates the register CALFACT_S[6:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF = 1). This updates the register CALFACT_D[6:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration is automatically injected into the analog ADC.
26.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in Section 26.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)).

Once DEEPPWD = 0 and ADVREGEN = 1, the ADC can be enabled and the ADC needs a stabilization time of \( t_{\text{STAB}} \) before it starts converting accurately, as shown in Figure 194. Two control bits enable or disable the ADC:

- \( \text{ADEN} = 1 \) enables the ADC. The flag ADRDY is set once the ADC is ready for operation.
- \( \text{ADDIS} = 1 \) disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting \( \text{ADSTART} = 1 \) (refer to Section 26.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting \( \text{JADSTART} = 1 \) or when an external injected trigger event occurs, if injected triggers are enabled.

### Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set \( \text{ADEN} = 1 \).
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE = 1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

**Caution:** ADEN bit cannot be set when ADCAL is set and during four ADC clock cycles after the ADCAL bit is cleared by hardware (end of the calibration).
Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP = 1 and JADSTP = 1 and then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS = 1.
3. If required by the application, wait until ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 194. Enabling / disabling the ADC

26.4.10 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the DIFSEL[i] control bits in the ADC_DIFSEL register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFGR, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).
- ADC_TRy registers can be modified when an analog-to-digital conversion is ongoing (refer to Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD1HTx, AWD2LTx, AWDx) for details).

The software is allowed to write the ADSTP or JADSTP control bits of the ADC_CR register only if the ADC is enabled, possibly converting, and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).
The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN = 1). Refer to Section 26.6.16: ADC injected sequence register (ADC_JSQR) for additional details.

Note: There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN = 0 as well as all the bits of ADC_CR register).

26.4.11 Channel selection (SQRx, JSQRx)

The ADC features up to 20 multiplexed channels per ADC, out of which:

- Up to 18 analog inputs coming from GPIO pads (ADC_INP/INN[i]) depending on the products, not all of them are available on GPIO pads.
- ADC is connected to 4 internal analog inputs:
  - the internal temperature sensor (VSENSE)
  - the internal reference voltage (VREFINT)
  - the VBAT monitoring channel (VBAT/4)
  - the internal digital core voltage (VDDCORE)

To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming bits VREFEN, VBATEN or TSEN in the ADC_CCR registers.

Refer to Table ADC interconnection in Section 26.4.2: ADC pins and internal signals for the connection of the above internal analog inputs to external ADC pins or internal signals.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC1/2_INP/INN3, ADC1/2_INP/INN8, ADC1/2_INP/INN2, ADC1/2_INN/INP2, ADC1/2_INP/INN0, ADC1/2_INP/INN2, ADC1/2_INP/INN2, ADC1/2_INP/INN15.

- A regular group is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.

- An injected group is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP = 1 (refer to Section 26.4.17: Stopping an ongoing conversion (ADSTP, JADSTP)).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 (injected conversions ongoing) only when the context queue is enabled (JQDIS = 0 in ADC_CFRG register). Refer to Section 26.4.21: Queue of context for injected conversions...
26.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 2.5 ADC clock cycles
- SMP = 001: 6.5 ADC clock cycles
- SMP = 010: 12.5 ADC clock cycles
- SMP = 011: 24.5 ADC clock cycles
- SMP = 100: 47.5 ADC clock cycles
- SMP = 101: 92.5 ADC clock cycles
- SMP = 110: 247.5 ADC clock cycles
- SMP = 111: 640.5 ADC clock cycles

The total conversion time is calculated as follows:

\[ T_{\text{CONV}} = \text{Sampling time} + 12.5 \text{ ADC clock cycles} \]

Example:

With \( F_{\text{adc, ref, ck}} = 30 \text{ MHz} \) and a sampling time of 2.5 ADC clock cycles:

\[ T_{\text{CONV}} = (2.5 + 12.5) \text{ ADC clock cycles} = 15 \text{ ADC clock cycles} = 500 \text{ ns} \]

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

Note: Depending on the ADC conversion mode, the real sampling time can vary compared to the SMP value programmed above, while the equivalent total conversion time \( T_{\text{CONV}} \) does not change:

- For the first conversion in scan or continuous mode and all the conversions in discontinuous mode, the real sampling time is 0.5 clock cycle less compared to the value configured above.
- For the second and subsequent conversions in scan or continuous mode, 0.5 cycle is added to the configured sampling time. This additional 0.5 clock cycle overlaps with the previous conversion cycle.

Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.
Bulb sampling mode

When the BULB bit is set in ADC register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion, after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The bulb mode is effective starting from the second conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The bulb mode is neither compatible with the continuous conversion mode nor with the injected channel conversion.

When the BULB bit is set, it is not allowed to set SMPTRIG bit in ADC_CFGR2.

Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed though SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected, each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

When a software trigger is selected, the software trigger is not the ADSTART bit in ADC_CR but the SWTRIG bit. SWTRIG bit has to be set to start the sampling period, and the SWTRIG bit has to be cleared to end the sampling period and start the conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is neither compatible with the continuous conversion mode, nor with the injected channel conversion.

When SMPTRIG bit is set, it is not allowed to set BULB bit.

I/O analog switch voltage booster

The resistance of the I/O analog switches increases when the $V_{DDA}$ voltage is too low. The sampling time must consequently be adapted accordingly (refer to the device datasheet for the corresponding electrical characteristics). This resistance can be minimized at low $V_{DDA}$.
by enabling an internal voltage booster through BOOSTE bit or by selecting a $V_{DD}$ booster voltage (if $V_{DD} > 2.7$ V) through the ADVREADY bit of the PWR_PMCR register.

**SMPPLUS control bit**

The SMPPLUS bit can be used to change the sampling time from 2.5 ADC clock cycles to 3.5 ADC clock cycles.

### 26.4.13 Single conversion mode (CONT = 0)

In single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel)
- External hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 16-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

*Note: To convert a single channel, program a sequence with a length of 1.*

### 26.4.14 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set
After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

**Note:**

*To convert a single channel, program a sequence with a length of 1.*

*It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.*

*Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to **Auto-injection mode** section.*

### 26.4.15 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART = 1.

When ADSTART is set, the conversion starts:

- Immediately: if EXTEN = 0x0 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN is not equal to 0x0

Software starts ADC injected conversions by setting JADSTART = 1.

When JADSTART is set, the conversion starts:

- Immediately, if JEXTEN = 0x0 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN is not equal to 0x0

**Note:**

*In auto-injection mode (JAUTO = 1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).*

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART = 0 and JADSTART = 0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:

- In single mode with software regular trigger (CONT = 0, EXTSEL = 0x0)
  - At any end of regular conversion sequence (EOS assertion) or at any end of subgroup processing if DISCEN = 1
- In all cases (CONT = x, EXTSEL = x)
  - After execution of the ADSTP procedure asserted by the software.

**Note:**

*In continuous mode (CONT = 1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.*

When a hardware trigger is selected in single mode (CONT = 0 and EXTSEL ≠ 0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.
JADSTART is cleared by hardware:

- In single mode with software injected trigger (JEXTSEL = 0x0)
  - At any end of injected conversion sequence (JEOS assertion) or at any end of subgroup processing if JDISCEN = 1
- In all cases (JEXTSEL = x)
  - After execution of the JADSTP procedure asserted by the software.

**Note:** When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.

### 26.4.16 ADC timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = \left[ 2.5 \text{ min} + 12.5 \text{ 12bit} \right] \times T_{\text{ADC_CLK}}
\]

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = 83.33 \text{ ns}_{\text{min}} + 416.67 \text{ ns}_{\text{12bit}} = 500.0 \text{ ns (for } F_{\text{ADC_CLK}} = 30 \text{ MHz)}
\]

**Figure 196. Analog to digital conversion time**

1. \( T_{\text{SMPL}} \) depends on SMP[2:0].
2. \( T_{\text{SAR}} \) depends on RES[2:0].
26.4.17 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP = 1 and injected conversions ongoing by setting JADSTP = 1.

Stopping conversions resets the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion).

The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

![Figure 197. Stopping ongoing regular conversions](MSv30533V2)
26.4.18 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (such as timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS = 0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART = 1 and the injected trigger selection is effective once software has set bit JADSTART = 1.

Any hardware triggers which occur while a conversion is ongoing are ignored.

- If bit ADSTART = 0, any regular hardware triggers which occur are ignored.
- If bit JADSTART = 0, any injected hardware triggers which occur are ignored.

Table 243 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

Table 243. Configuring the trigger polarity for regular external triggers

<table>

</tr>
</tbody>
</table>

Note: The polarity of the regular trigger cannot be changed on-the-fly.
Table 244. Configuring the trigger polarity for injected external triggers

<table>
<thead>
<tr>
<th>JEXTEN[1:0]</th>
<th>Source</th>
</tr>
</thead>
</table>
| 00          | - If JQDIS = 1 (Queue disabled): Hardware trigger detection disabled, software trigger detection enabled  
             | - If JQDIS = 0 (Queue enabled), Hardware and software trigger detection disabled                  |
| 01          | Hardware Trigger with detection on the rising edge                   |
| 10          | Hardware Trigger with detection on the falling edge                  |
| 11          | Hardware Trigger with detection on both the rising and falling edges |

Note: The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS = 0). Refer to Section 26.4.21: Queue of context for injected conversions.

The EXTSEL and JEXTSEL control bits select which out of 32 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

Note: The regular trigger selection cannot be changed on-the-fly. The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 26.4.21: Queue of context for injected conversions on page 1041.

Figure 199. Triggers shared between ADC master and slave
Refer to Table ADC interconnection in Section 26.4.2: ADC pins and internal signals for the list of all the external triggers that can be used for regular conversion.

26.4.19 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.

2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once).

3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. Figure 200 shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 2.5 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

Auto-injection mode

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence is stopped upon DMA Transfer Complete event.
26.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (subgroup) of n conversions \((n \leq 8)\) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of \(n\) is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next \(n\) conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:

- **DISCEN = 1, \(n = 3\)**, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ... 
- **DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11**
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

---

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.
**Note:** The channel numbers referred to in the above example might not be available on all microcontrollers.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

**Injected group mode**

This mode is enabled by setting the JDISCEN bit in the ADC_CFRGR register. It converts the sequence selected in the ADC_JSQ register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where 'n' is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQ registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQ register.

Example:

- JDISCEN = 1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

**Note:** The channel numbers referred to in the above example might not be available on all microcontrollers.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

**26.4.21 Queue of context for injected conversions**

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFRGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:

- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL bits in ADC_JSQ register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQ register)
All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:

- The JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFGR:
  - If JQM = 0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence is served according to the last active context.
  - If JQM = 1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.
- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP = 1 or when disabling the ADC by setting ADDIS = 1:
  - If JQM = 0, the Queue is maintained with the last active context.
  - If JQM = 1, the Queue becomes empty and triggers are ignored.

Note: When configured in discontinuous mode (bit JDISCEN = 1), only the last trigger of the injected sequence changes the context and consumes the Queue. The 1st trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):

- 1st trigger, discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out
- 2nd trigger, disc. Sequence 1: 2nd conversion.
- 3rd trigger, discontinuous. Sequence 1: 3rd conversion.
- 4th trigger, discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.
- 5th trigger, discontinuous. Sequence 2: 2nd conversion.
- 6th trigger, discontinuous. Sequence 2: 3rd conversion.
Behavior when changing the trigger or sequence context

*Figure 201* and *Figure 202* show the behavior of the context Queue when changing the sequence or the triggers.

**Figure 201. Example of JSQR queue of context (sequence change)**

<table>
<thead>
<tr>

<tr>
<td>Trigger 1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Trigger 2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ADC J context (returned by reading JSQR)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ADC state</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 4 conversions, hardware trigger 1
Queue of context: Behavior when a queue overflow occurs

The Figure 203 and Figure 204 show the behavior of the context Queue if an overflow occurs before or during a conversion.

Figure 203. Example of JSQR queue of context with overflow before conversion

Figure 204. Example of JSQR queue of context with overflow during conversion

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 3 conversions, hardware trigger 1
P4: sequence of 4 conversions, hardware trigger 1
It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

Queue of context: Behavior when the queue becomes empty

*Figure 205* and *Figure 206* show the behavior of the context Queue when the Queue becomes empty in both cases JQM = 0 or 1.

**Figure 205. Example of JSQR queue of context with empty queue (case JQM = 0)**

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

   **Note:** When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.
Flushing the queue of context

The figures below show the behavior of the context Queue in various situations when the queue is flushed.

Figure 206. Example of JSQR queue of context with empty queue (JQM = 1)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 207. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion.

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 208. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion and a new trigger occurs

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 209. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs outside an ongoing conversion

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 210. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 1)

Queue is flushed and becomes empty (P2 is lost)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 211. Flushing JSQR queue of context by setting ADDIS = 1 (JQM = 0)

Queue is flushed and maintains the last active context (P2 which was not consumed is lost)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS = 1 into the ADC_CFGR register.

26.4.22 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the control bits RES[1:0]. Figure 217, Figure 218, Figure 219 and Figure 220 show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 245.
26.4.23 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

26.4.24 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

26.4.26 Data management

Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 16 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 16 bits wide.

The ALIGN bit in the ADC_CFGR register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in Figure 217, Figure 218, Figure 219 and Figure 220.

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in Figure 219 and Figure 220.

Note: Left-alignment is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the ALIGN bit value is ignored and the ADC only provides right-aligned data.

Offset

An offset y (y = 1,2,3,4) can be applied to a channel by setting the bit OFFSET_EN = 1 into ADC_OFRy register. The channel to which the offset will be applied is programmed into the bits OFFSET_CH[4:0] of ADC_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSET[11:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

Note: Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSET_EN bit in ADC_OFRy register is ignored (considered as reset).

Table 248 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

Offset compensation

When SATEN bit is set in ADC_OFRy register during offset operation, data are unsigned. All the offset data saturate at 0x000 (in 12-bit mode). When OFFSETPOS bit is set, the offset direction is positive and the data saturate at 0xFFF (in 12-bit mode). In 8-bit mode, data saturate at 0x00 and 0xFF, respectively.

The analog watchdog comparison is performed before the offset compensation.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) notifies when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (three stages) is overflowed.

The OVR flag is set when a new conversion completes while ADC_CR register FIFO was full. An interrupt is generated if OVRIE bit is set to 1.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP to 1. Since ADC_DR FIFO features three stages, up to three data are stored in the FIFO.

OVR flag is cleared by software by writing 1 to it.

It is possible to configure if data is preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- **OVRMOD = 0**: The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (three stages) and the new conversion is discarded and lost. In this mode, ADC_DR FIFO is disabled. If the FIFO is full, any further conversion is performed but the resulting data is also discarded. EOC
is cleared by reading ADC_DR register. However, the FIFO can still contain previously converted data.

- OVRMOD = 1: The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversions is performed normally and the ADC_DR register always contains the latest converted data.

**Figure 221. Example of overrun (OVRMOD = 0)**
Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events or FIFO overflow as an error.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMAEN bit set to 1 in the ADC_CFGR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.
Despite this, if an overrun occurs (OVR = 1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section: ADC overrun (OVR, OVRMOD)).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG of the ADC_CFGR register in single ADC mode, or with bit DMACFG of the ADC_CCR register in dual ADC mode:

- DMA one shot mode (DMACFG = 0)
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMACFG = 1)
  This mode is suitable when programming the DMA in circular mode.

DMA one shot mode (DMACFG = 0)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

DMA circular mode (DMACFG = 1)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

26.4.27 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.
When AUTDLY = 1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see Figure 223).
- For an injected conversion: when the JEOS bit has been cleared (see Figure 224).

This is a way to automatically adapt the speed of the ADC to the speed of the system which reads the data.

The delay is inserted after each regular conversion (whatever DISCEN = 0 or 1) and after each sequence of injected conversions (whatever JDISCEN = 0 or 1).

**Note:** There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

**Note:** This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to restart a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 224).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 226).

The behavior is slightly different in auto-injected mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 227).

To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO = 1, CONT = 1 and AUTDLY = 1), follow the following procedure:

1. Wait until JEOS = 1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP = 1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can restart if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

26.4.28 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

**Figure 228. Analog watchdog guarded area**

AWDx flag and interrupt

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDxIE in the ADC_IER register (x = 1,2,3).

AWDx (x = 1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

**Description of analog watchdog 1**

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels\(^{(1)}\) remain within a configured voltage range (window).

*Table 247* shows how the ADC_CFGR registers should be configured to enable the analog watchdog on one or more channels.

**Table 247. Analog watchdog channel selection**

1. Selected by the AWD1[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.
These thresholds are programmed in bits HT1[11:0] and LT1[11:0] of the ADC_TR1 register for the analog watchdog 1. When converting data with a resolution of less than 12 bits (according to bits RES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned) before the offset compensation stage.

*Table 248* describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

### Analog watchdog filter for watchdog 1

When an ADC is configured with only one input channel (selecting several channels in scan mode not allowed), a valid ADC conversion data interval can be configured through the ADC_TR1 register:

- When converted data belong to the interval defined in ADC_TR1, a DMA request is generated.
- Otherwise, no DMA request is issued. RDATA register is updated at each conversion. If data are out-of-range a number of times higher than the value specified in AWDFILT bit of ADC_TR1, the AWDx flag is set an the corresponding interrupt is issued.

### Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDxCH[19:0] (x = 2,3). The corresponding watchdog is enabled when any bit of AWDxCH[19:0] (x = 2,3) is set.

They are limited to a resolution of 8 bits and only the 8 MSBs of the thresholds can be programmed into HTx[7:0] and LTx[7:0]. *Table 249* describes how the comparison is performed for all the possible resolutions.
ADCy_AWDx_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADCy_AWDx_OUT (y = ADC number, x = watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCy_AWDx_OUT signal as ETR.

ADCy_AWDx_OUT is activated when the associated analog watchdog is enabled:

- ADCy_AWDx_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCy_AWDx_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCy_AWDx_OUT is also reset when disabling the ADC (when setting ADDIS = 1).

Note: AWDx flag is set by hardware and reset by software: AWDx flag has no influence on the generation of ADCy_AWDx_OUT (ex: ADCy_AWDx_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

- All injected channels 1, 2, 3, 4 are guarded
Analog watchdog threshold control

LTx[11:0] and HTx[11:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTx[11:0] and HTx[11:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new interval, no interrupt and AWDx_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion which started after the threshold update. If AWD_xOUT is already asserted, programming the new thresholds does not deassert the AWDx_OUT signal.

Analog watchdog with offset compensation

When the offset compensation is enabled, the analog watchdog compares the threshold before the data compensation.

26.4.29 Oversampler

The oversampling unit performs data pre-processing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)
\]

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVFS[2:0] bits in the ADC_CFGR2 register, and can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256x 12-bit results), which is first shifted right. It is then truncated to the 16 least significant bits, rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

Note: If the intermediary result after the shifting exceeds 16-bit, the result is truncated as is, without saturation.
Figure 233. 20-bit to 16-bit result truncation

Figure 234 gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

Figure 234. Numerical example with 5-bit shift and rounding

Table 250 gives the data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.

Table 250. Maximum output results versus N and M (gray cells indicate truncation)

</tbody>
</table>

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N
conversions, with an equivalent delay equal to $N \times T_{\text{CONV}} = N \times (t_{\text{SMPL}} + t_{\text{SAR}})$. The flags are set as follow:

- The end of the sampling phase (EOSMP) is set after each sampling phase
- The end of conversion (EOC) occurs once every $N$ conversions, when the oversampled result is available
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (that is after $N \times$ sequence length conversions total)

**ADC operating modes supported when oversampling (single ADC mode)**

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous conversion modes
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits in ADC_CFGR register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

**Note:** The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR is ignored and the data are always provided right-aligned.

Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSET_EN bit in ADC_OFRy register is ignored (considered as reset).

**Analog watchdog**

The analog watchdog functionality is maintained, with the following difference:

- The RES[1:0] bits are ignored, the comparison is always done by using the full 12-bit values HT1[11:0] and LT1[11:0] for AWD1, and the 8-MSB value of HT2/HT3[7:0] and LT2/LT3[7:0] for AWD2 and AWD3.
- The comparison is done on the most significant 12-bit of the 16-bit oversampled results ADC_DR[15:4] for AWD1, and ADC_DR[15:8] for AWD2 and ADW3.

**Note:** Care must be taken when using high shifting values, this reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HTx[7:0] / LTx[7:0] (AWD1/2/3), with HT1[11:8] and LT1[11:8] kept reset (AWD1 only).

**Triggered mode**

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The Figure 235 below shows how conversions are started in response to triggers during discontinuous mode.
If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

**Injected and regular sequencer management when oversampling**

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

**Oversampling regular channels only**

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
- In resumed mode, the accumulation restarts from 0 (previous conversions results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer is blocked.

The **Figure 236** gives examples for a 4x oversampling ratio.
**Figure 236. Regular oversampling modes (4x ratio)**

Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.
Oversampling regular and injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on Figure 237 below.

Figure 237. Regular and injected oversampling modes used simultaneously

Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on Figure 238 below.
Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The Figure 239 below shows how the conversions are sequenced.

![Figure 239. Oversampling in auto-injected mode](image)

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO = 1, DISCEN = 0, JDISCEN = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Dual ADC modes supported when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

Combined modes summary

The Table 251 below summarizes all combinations, including modes not supported.

26.4.30 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see Figure 240).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADC_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + regular simultaneous mode
- Regular simultaneous mode + alternate trigger mode
- Injected simultaneous mode + interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADC_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCE, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

To start a conversion in dual mode, the user must program the bits EXTEN, EXTSEL, JEXTEN, JEXTSEL of the master ADC only, to configure a software or hardware trigger, and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADC_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADC_CSR).
1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.

2. The ADC common data register (ADC_CDR) contains both the master and slave ADC regular converted data.
Injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in Figure 241), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

Figure 241. Injected simultaneous mode on 4 channels: dual ADC mode

If JDISCEN = 1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the
Analog-to-digital converters (ADC1/2) RM0481

ongoing regular sequence and the associated delay phases are ignored. There is the same behavior for regular sequences occurring on the slave ADC.

**Regular simultaneous mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) aborts the current simultaneous conversions, which are restarted once the injected conversion is completed.

*Note:* *Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).*

In regular simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Software is notified by interrupts when it can read the data:

- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in Figure 242), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADC_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits MDMA[1:0] must be kept cleared.
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Using MDMA mode, which leaves one DMA channel free for other uses:
  - Configure MDMA[1:0] = 0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADC_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADC_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADC_CDR register.
  - Both EOC flags are cleared when the DMA reads the ADC_CDR register.

*Note:* *In MDMA mode (MDMA[1:0] = 0b10 or 0b11), the user must program the same number of conversions in the master’s sequence as in the slave’s sequence. Otherwise, the remaining conversions does not generate a DMA request.*
If DISCEN = 1 then each "n" simultaneous conversions of the regular sequence require a regular trigger event to occur ("n" is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADC_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADC_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multiple-DMA mode is used: bits MDMA must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master’s sequence is equal to the number of conversions in the slave’s.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

**Note:** This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

**Interleaved mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates two conversions in interleaved mode is configured in the DELAY bits in the ADC_CCR register. This delay starts counting one half cycle after the end of the sampling phase of the master conversion. This way, an ADC cannot start a
conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

**Note:** It is possible to enable only the EOC interrupt of the slave and read the common data register (ADC_CDR). But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as following:

- Configure MDMA[1:0] = 0b10 or 0b11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADC_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADC_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADC_CCR register.
- Both EOC flags are cleared when the DMA reads the ADC_CCR register.

**Figure 243. Interleaved mode on one channel in continuous conversion mode: dual ADC mode**

![Diagram](https://example.com/diagram.png)
If DISCEN = 1, each “n” simultaneous conversions (“n” is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is restarted from the master (see Figure 245 below).

**Alternate trigger mode**

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN must not be 0x0.
Injected discontinuous mode disabled (JDISCEN = 0 for both ADC)

1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

**Figure 246. Alternate trigger: injected group of each ADC**

**Note:** Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.
Injected discontinuous mode enabled (JDISCEN = 1 for both ADC)

If the injected discontinuous mode is enabled for both master and slave ADCs:

- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

**Figure 247. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode**

Combined regular/injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

*Note:* In combined regular/injected simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Combined regular simultaneous + alternate trigger mode

This mode is selected by programming bits DUAL[4:0] = 00010.

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. **Figure 248** shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.
Note: In combined regular simultaneous + alternate trigger mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

**Figure 248. Alternate + regular simultaneous**

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. **Figure 249** shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

**Figure 249. Case of trigger occurring during injected conversion**

**Combined injected simultaneous plus interleaved**

This mode is selected by programming bits DUAL[4:0] = 00011

It is possible to interrupt an interleaved conversion with a simultaneous injected event.

In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master’s one. **Figure 250, Figure 251** and **Figure 252** show the behavior using an example.

**Caution:** In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.

DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to Figure 253: DMA Requests in regular simultaneous mode when MDMA = 0b00).

Figure 253. DMA Requests in regular simultaneous mode when MDMA = 0b00

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this MDMA bits must be configured in the ADC_CCR register:

- **MDMA = 0b10**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADC_CDR contains the two half-words representing two ADC-converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.
  
  This mode is used in interleaved mode and in regular simultaneous mode when resolution is 10-bit or 12-bit.

**Example:**

Interleaved dual mode: a DMA request is generated each time 2 data items are available:

1st DMA request: \( \text{ADC}_\text{CDR}[31:0] = \text{SLV}_\text{ADC}_\text{DR}[15:0] | \text{MST}_\text{ADC}_\text{DR}[15:0] \)

2nd DMA request: \( \text{ADC}_\text{CDR}[31:0] = \text{SLV}_\text{ADC}_\text{DR}[15:0] | \text{MST}_\text{ADC}_\text{DR}[15:0] \)
Figure 254. DMA requests in regular simultaneous mode when MDMA = 0b10

Figure 255. DMA requests in interleaved mode when MDMA = 0b10
Note: When using MDMA mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- MDMA = 0b11: This mode is similar to the MDMA = 0b10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.
  This mode is used in interleaved and regular simultaneous mode when resolution is 6-bit or when resolution is 8-bit and data is not signed (offsets must be disabled for all the involved channels).

  **Example:**

  Interleaved dual mode: a DMA request is generated each time 2 data items are available:

  1st DMA request: ADC_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]
  2nd DMA request: ADC_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]

**Overrun detection**

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the MDMA configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

**DMA one shot mode/ DMA circular mode when MDMA mode is selected**

When MDMA mode is selected (0b10 or 0b11), bit DMACFG of the ADC_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section **Section : Managing conversions using the DMA** (bits DMACFG of master and slave ADC_CFGR are not relevant).

**Stopping the conversions in dual ADC modes**

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.

**26.4.31 Temperature sensor**

The temperature sensor can be used to measure the junction temperature (Tj) of the device.

The temperature sensor is internally connected to the ADC input channels which are used to convert the sensor output voltage to a digital value (see **Table: ADC interconnection** in **Section 26.4.2: ADC pins and internal signals** for more details). When not in use, the sensor can be put in power down mode. It support the temperature range –40 to 125 °C.

**Figure 256** shows the block diagram of connections between the temperature sensor and the ADC.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).
The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by ST during production.

During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference (refer to the datasheet for additional information).

The temperature sensor is internally connected to the ADC input channel which is used to convert the sensor’s output voltage to a digital value. Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal temperature sensor.

When not in use, the sensor can be put in power-down mode. 

*Figure 256* shows the block diagram of the temperature sensor.

---

**Figure 256. Temperature sensor channel block diagram**

---

**Reading the temperature**

To use the sensor:

1. Select the ADC input channels that is connected to $V_{SENSE}$.
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the bit in the ADC_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting $V_{SENSE}$ data in the ADC data register.
6. Calculate the actual temperature using the following formula:
where:
- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.
- TS_DATA is the actual temperature sensor output value converted by ADC.

Refer to the device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.

**Note:** The sensor has a startup time after waking from power-down mode before it can output VSENSE at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and bits should be set at the same time.

### 26.4.32 V\textsubscript{BAT} supply monitoring

The VBATEN bit in the ADC_CCR register is used to switch to the battery voltage. As the V\textsubscript{BAT} voltage could be higher than V\textsubscript{DDA}, to ensure the correct operation of the ADC, the V\textsubscript{BAT} pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect V\textsubscript{BAT}/4 to the ADC input channels (see Table: ADC interconnection in Section 26.4.2: ADC pins and internal signals for more details). As a consequence, the converted digital value is one third of the V\textsubscript{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the V\textsubscript{BAT}/4 voltage.

*Figure 257* shows the block diagram of the V\textsubscript{BAT} sensing feature.

\[
\text{Temperature (in °C)} = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + \text{TS\_CAL1\_TEMP}
\]
1. The VBATEN bit must be set to enable the conversion of internal channel for VBAT/4.

### 26.4.33 Monitoring the internal voltage reference

It is possible to monitor the internal voltage reference (VREFINT) to have a reference point for evaluating the ADC VREF+ voltage level.

Refer to Table: ADC interconnection in Section 26.4.2: ADC pins and internal signals for details on the ADC input channels to which the internal voltage reference is internally connected.

Refer to the electrical characteristics section of the product datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

*Figure 258* shows the block diagram of the VREFINT sensing feature.

1. The VREFEN bit into ADC_CCR register must be set to enable the conversion of internal channels (VREFINT).
Calculating the actual VREF+ voltage using the internal reference voltage

VREF+ voltage may be subject to variations or not precisely known. The embedded internal reference voltage VREFINT and its calibration data acquired by the ADC during the manufacturing process at VREF+_charac can be used to evaluate the actual VREF+ voltage level.

The following formula gives the actual VREF+ voltage supplying the device:

\[ V_{\text{REF+}} = V_{\text{REF+_Charac}} \times \frac{\text{VREFINT}_\text{CAL}}{\text{VREFINT}_\text{DATA}} \]

Where:

- \( V_{\text{REF+_Charac}} \) is the value of VREF+ voltage characterized at VREFINT during the manufacturing process. It is specified in the device datasheet.
- \( \text{VREFINT}_\text{CAL} \) is the VREFINT calibration value
- \( \text{VREFINT}_\text{DATA} \) is the actual VREFINT output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between VREF+ and the voltage applied on the converted channel.

For applications where VREF+ value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from VREF+:

\[ V_{\text{CHANNEL}_x} = \frac{V_{\text{REF+}} \times \text{ADC}_\text{DATA}}{\text{FULL}_\text{SCALE}} \]

By replacing VREF+ by the formula provided above, the absolute voltage value is given by the following formula

\[ V_{\text{CHANNEL}_x} = \frac{V_{\text{REF+_Charac}} \times \text{VREFINT}_\text{CAL} \times \text{ADC}_\text{DATA}}{\text{VREFINT}_\text{DATA} \times \text{FULL}_\text{SCALE}} \]

Where:

- \( V_{\text{REF+_Charac}} \) is the value of VREF+ voltage characterized at VREFINT during the manufacturing process.
- \( \text{VREFINT}_\text{CAL} \) is the VREFINT calibration value
- \( \text{ADC}_\text{DATA} \) is the value measured by the ADC on channel x (right-aligned)
- \( \text{VREFINT}_\text{DATA} \) is the actual VREFINT output value converted by the ADC
- \( \text{FULL}_\text{SCALE} \) is the maximum digital value of the ADC output. For example with 12-bit resolution, it is \( 2^{12} - 1 = 4095 \) or with 8-bit resolution, \( 2^8 - 1 = 255 \).

Note: If ADC measurements are done using an output format other than 12-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

26.4.34 Monitoring the supply voltage

ADC2 is connected to the internal supply voltage. To use the ADC to measure this voltage, enable the connection through ADC option register.
26.5 ADC interrupts

For each ADC, an interrupt can be generated:
- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (flag OVR)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

Bits 31:11 Reserved, must be kept at reset value.

- **Bit 10 JQOVF: Injected context queue overflow**
  - This bit is set by hardware when an Overflow of the Injected Queue of Context occurs. It is cleared by software writing 1 to it. Refer to Section 26.4.21: Queue of context for injected conversions for more information.
  - 0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Injected context queue overflow has occurred

- **Bit 9 AWD3: Analog watchdog 3 flag**
  - This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_TR3 register. It is cleared by software writing 1 to it.
  - 0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Analog watchdog 3 event occurred

- **Bit 8 AWD2: Analog watchdog 2 flag**
  - This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_TR2 register. It is cleared by software writing 1 to it.
  - 0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Analog watchdog 2 event occurred

- **Bit 7 AWD1: Analog watchdog 1 flag**
  - This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_TR1 register. It is cleared by software, writing 1 to it.
  - 0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Analog watchdog 1 event occurred

- **Bit 6 JEOS: Injected channel end of sequence flag**
  - This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.
  - 0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
  - 1: Injected conversions complete
Bit 5  **JEOC**: Injected channel end of conversion flag
- This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register.
- 0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)
- 1: Injected channel conversion complete

Bit 4  **OVR**: ADC overrun
- This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.
- 0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
- 1: Overrun has occurred

Bit 3  **EOS**: End of regular sequence flag
- This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.
- 0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)
- 1: Regular Conversions sequence complete

Bit 2  **EOC**: End of conversion flag
- This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.
- 0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)
- 1: Regular channel conversion complete

Bit 1  **EOSMP**: End of sampling flag
- This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.
- 0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
- 1: End of sampling phase reached

Bit 0  **ADRDY**: ADC ready
- This bit is set by hardware after the ADC has been enabled (ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.
- It is cleared by software writing 1 to it.
- 0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
- 1: ADC is ready to start conversion
## 26.6.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x04  
Reset value: 0x0000 0000

</tbody>
</table>
Bit 5  **JEOCIE**: End of injected conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.
0: JEOC interrupt disabled.
1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.
*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

Bit 4  **OVRIE**: Overrun interrupt enable
This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.
0: Overrun interrupt disabled
1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.
*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 3  **EOSIE**: End of regular sequence of conversions interrupt enable
This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.
0: EOS interrupt disabled
1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.
*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 2  **EOCIE**: End of regular conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.
0: EOC interrupt disabled.
1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 1  **EOSMPIE**: End of sampling flag interrupt enable for regular conversions
This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.
0: EOSMP interrupt disabled.
1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 0  **ADRDYIE**: ADC ready interrupt enable
This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
0: ADRDY interrupt disabled
1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

#### Bit 31 ADCAL: ADC calibration

This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or Differential inputs mode.

- It is cleared by hardware after calibration is complete.
- 0: Calibration complete
- 1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.

**Note:** The software is allowed to launch a calibration by setting ADCAL only when ADEN = 0.

The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).

#### Bit 30 ADCALDIF: Differential mode for calibration

This bit is set and cleared by software to configure the single-ended or Differential inputs mode for the calibration.

- 0: Writing ADCAL launches a calibration in single-ended inputs mode.
- 1: Writing ADCAL launches a calibration in Differential inputs mode.

**Note:** The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

#### Bit 29 DEEPPWD: Deep-power-down enable

This bit is set and cleared by software to put the ADC in Deep-power-down mode.

- 0: ADC not in Deep-power down
- 1: ADC in Deep-power-down (default reset state)

**Note:** The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).
Bit 28 **ADVREGEN**: ADC voltage regulator enable

This bit is set by software to enable the ADC voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

0: ADC Voltage regulator disabled
1: ADC Voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to Section 26.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).

The software can program this bit field only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 27:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing
1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

**Note:** The software is allowed to set JADSTP only when JADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

**Note:** The software is allowed to set ADSTP only when ADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).
Bit 3  **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN, a conversion immediately starts (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (JEXTSEL = 0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
- in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

**Note:** The software is allowed to set JADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)
Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN, a conversion immediately starts (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (EXTSEL = 0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- in all cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

**Note:** The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

**Note:** The software is allowed to set ADDIS only when ADEN = 1 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

**Note:** The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)
26.6.4 ADC configuration register (ADC CfGR)

Bit 31 JQDIS: Injected queue disable
This bit is set and cleared by software to disable the injected queue mechanism:
0: Injected queue enabled
1: Injected queue disabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).
A set or reset of JQDIS bit causes the injected queue to be flushed and the JSQR register is cleared.

Bits 30:26 AWD1CH[4:0]: Analog watchdog 1 channel selection
These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.
00000: ADC analog input channel 0 monitored by AWD1 (available on ADC1 only)
00001: ADC analog input channel 1 monitored by AWD1
.....
10011: ADC analog input channel 19 monitored by AWD1
others: reserved, must not be used

Note: Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.
The channel selected by AWD1CH must be also selected into the SO[i] or JSQRi registers.
The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 JAUTO: Automatic injected group conversion
This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.
0: Automatic injected group conversion disabled
1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).
When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the bit JAUTO of the master ADC.
Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels
This bit is set and cleared by software
0: Analog watchdog 1 disabled on injected channels
1: Analog watchdog 1 enabled on injected channels
*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels
This bit is set and cleared by software
0: Analog watchdog 1 disabled on regular channels
1: Analog watchdog 1 enabled on regular channels
*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels
This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels
0: Analog watchdog 1 enabled on all channels
1: Analog watchdog 1 enabled on a single channel
*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 21 **JQM**: JSQR queue mode
This bit is set and cleared by software.
It defines how an empty Queue is managed.
0: JSQR mode 0: The Queue is never empty and maintains the last written configuration into JSQR.
1: JSQR mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.
Refer to Section 26.4.21: Queue of context for injected conversions for more information.
*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.

Bit 20 **JDISCEN**: Discontinuous mode on injected channels
This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.
0: Discontinuous mode on injected channels disabled
1: Discontinuous mode on injected channels enabled
*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.
When dual mode is enabled (bits DUAL of ADC_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.
Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel
001: 2 channels
...
111: 8 channels

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled
1: Discontinuous mode for regular channels enabled

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.

Bit 15 **ALIGN**: Data alignment

This bit is set and cleared by software to select right or left alignment. Refer to Section: Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN).

0: Right alignment
1: Left alignment

*Note:* The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.

0: Auto-delayed conversion mode off
1: Auto-delayed conversion mode on

*Note:* The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.
Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode
1: Continuous conversion mode

**Note:** *It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.*

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADC_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.

Bit 12 **OVRMOD**: Overrun mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.
1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

**Note:** The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

**Note:** The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: adc_ext_trg0
00001: adc_ext_trg1
00010: adc_ext_trg2
00011: adc_ext_trg3
00100: adc_ext_trg4
00101: adc_ext_trg5
00110: adc_ext_trg6
00111: adc_ext_trg7
...
11111: adc_ext_trg31

**Note:** The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 4:3 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit
01: 10-bit
10: 8-bit
11: 6-bit

**Note:** The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
### 26.6.5 ADC configuration register 2 (ADC_CFGR2)

#### Bit 2
Reserved, must be kept at reset value.

#### Bit 1 DMACFG: Direct memory access configuration
This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.
- 0: DMA One Shot mode selected
- 1: DMA Circular mode selected

For more details, refer to Section : Managing conversions using the DMA

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

In dual-ADC modes, this bit is not relevant and replaced by control bit DMACFG of the ADC_CCR register.

#### Bit 0 DMAEN: Direct memory access enable
This bit is set and cleared by software to enable the generation of DMA requests. This allows to use the DMA to manage automatically the converted data. For more details, refer to Section : Managing conversions using the DMA.
- 0: DMA disabled
- 1: DMA enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

In dual-ADC modes, this bit is not relevant and replaced by control bits MDMA[1:0] of the ADC_CCR register.
Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **SMPTRIG**: Sampling time control trigger mode

This bit is set and cleared by software to enable the sampling time control trigger mode.

- 0: Sampling time control trigger mode disabled
- 1: Sampling time control trigger mode enabled

The sampling time starts on the trigger rising edge, and the conversion on the trigger falling edge.

EXTEN bit should be set to 01. BULB bit must not be set when the SMPTRIG bit is set.

When EXTEN bit is set to 00, set SWTRIG to start the sampling and clear SWTRIG bit to start the conversion.

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 26 **BULB**: Bulb sampling mode

This bit is set and cleared by software to enable the bulb sampling mode.

- 0: Bulb sampling mode disabled
- 1: Bulb sampling mode enabled. The sampling period starts just after the previous end of conversion.

SAMPTRIG bit must not be set when the BULB bit is set.

The very first ADC conversion is performed with the sampling time specified in SMPx bits.

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 25 **SWTRIG**: Software trigger bit for sampling time control trigger mode

This bit is set and cleared by software to enable the bulb sampling mode.

- 0: Software trigger starts the conversion for sampling time control trigger mode
- 1: Software trigger starts the sampling for sampling time control trigger mode

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 24:17 Reserved, must be kept at reset value.

Bits 16:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

- 0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
- 1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 9 **TROVS**: Triggered Regular oversampling

This bit is set and cleared by software to enable triggered oversampling.

- 0: All oversampled conversions for a channel are done consecutively following a trigger
- 1: Each oversampled conversion for a channel needs a new trigger

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*
Bits 8:5 **OVSS[3:0]:** Oversampling shift  
This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.  
0000: No shift  
0001: Shift 1-bit  
0010: Shift 2-bits  
0011: Shift 3-bits  
0100: Shift 4-bits  
0101: Shift 5-bits  
0110: Shift 6-bits  
0111: Shift 7-bits  
1000: Shift 8-bits  
Other codes reserved  
*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 4:2 **OVS[2:0]:** Oversampling ratio  
This bitfield is set and cleared by software to define the oversampling ratio.  
000: 2x  
001: 4x  
010: 8x  
011: 16x  
100: 32x  
101: 64x  
110: 128x  
111: 256x  
*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 1 **JOVSE:** Injected oversampling Enable  
This bit is set and cleared by software to enable injected oversampling.  
0: Injected oversampling disabled  
1: Injected oversampling enabled  
*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)*

Bit 0 **ROVSE:** Regular oversampling Enable  
This bit is set and cleared by software to enable regular oversampling.  
0: Regular oversampling disabled  
1: Regular oversampling enabled  
*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)*
### 26.6.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x14

Reset value: 0x0000 0000

<table>

<td>29</td>
<td>28</td>
<td>27</td>
<td>26</td>
<td>25</td>
</tr>
</tbody>
</table>

Bit 31 **SMPPLUS**: Addition of one clock cycle to the sampling time.
- 1: 2.5 ADC clock cycle sampling time becomes 3.5 ADC clock cycles for the ADC_SMPR1 and ADC_SMPR2 registers.
- 0: The sampling time remains set to 2.5 ADC clock cycles remains

To make sure no conversion is ongoing, the software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0.

Bit 30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]**: Channel x sampling time selection (x = 9 to 0)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

- 000: 2.5 ADC clock cycles
- 001: 6.5 ADC clock cycles
- 010: 12.5 ADC clock cycles
- 011: 24.5 ADC clock cycles
- 100: 47.5 ADC clock cycles
- 101: 92.5 ADC clock cycles
- 110: 247.5 ADC clock cycles
- 111: 640.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

### 26.6.7 ADC sample time register 2 (ADC_SMPR2)

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]**: Channel x sampling time selection (x = 19 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

- 000: 2.5 ADC clock cycles
- 001: 6.5 ADC clock cycles
- 010: 12.5 ADC clock cycles
- 011: 24.5 ADC clock cycles
- 100: 47.5 ADC clock cycles
- 101: 92.5 ADC clock cycles
- 110: 247.5 ADC clock cycles
- 111: 640.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing). Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

Bits 27:16 **HT1[11:0]**: Analog watchdog 1 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 1. Refer to Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Bit 15  Reserved, must be kept at reset value.

Bits 14:12  **AWDFILT[2:0]**: Analog watchdog filtering parameter
   This bit is set and cleared by software.
   000: No filtering
   001: two consecutive detection generates an AWDx flag or an interrupt
   ...
   111: Eight consecutive detection generates an AWDx flag or an interrupt

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 11:0  **LT1[11:0]**: Analog watchdog 1 lower threshold
   These bits are written by software to define the lower threshold for the analog watchdog 1.
   Refer to Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **HT2[7:0]**: Analog watchdog 2 higher threshold
   These bits are written by software to define the higher threshold for the analog watchdog 2.
   Refer to Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **LT2[7:0]**: Analog watchdog 2 lower threshold
   These bits are written by software to define the lower threshold for the analog watchdog 2.
   Refer to Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **HT3[7:0]**: Analog watchdog 3 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 3. Refer to Section 26.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **LT3[7:0]**: Analog watchdog 3 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 3. This watchdog compares the 8-bit of LT3 with the 8 MSB of the converted data.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

</table>

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]**: 4th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 4th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.
Bits 22:18 **SQ3[4:0]**: 3rd conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 3rd in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]**: 2nd conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 2nd in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]**: 1st conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 1st in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]**: Regular channel sequence length
These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

- 0000: 1 conversion
- 0001: 2 conversions
- ...
- 1111: 16 conversions

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

*Note:* Some channels are not connected physically and must not be selected for conversion.

### 26.6.12 ADC regular sequence register 2 (ADC_SQR2)

Address offset: 0x34

Reset value: 0x0000 0000
Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]**: 9th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 9th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]**: 8th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 8th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]**: 7th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 7th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]**: 6th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 6th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]**: 5th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 5th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

*Note:* Some channels are not connected physically and must not be selected for conversion.

### 26.6.13 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x38

Reset value: 0x0000 0000
Bits 31:29  Reserved, must be kept at reset value.

Bits 28:24  **SQ14[4:0]**: 14th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 14th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23  Reserved, must be kept at reset value.

Bits 22:18  **SQ13[4:0]**: 13th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 13th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17  Reserved, must be kept at reset value.

Bits 16:12  **SQ12[4:0]**: 12th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 12th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11  Reserved, must be kept at reset value.

Bits 10:6  **SQ11[4:0]**: 11th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 11th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5  Reserved, must be kept at reset value.

Bits 4:0  **SQ10[4:0]**: 10th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 10th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

*Note:* Some channels are not connected physically and must not be selected for conversion.

### 26.6.14 ADC regular sequence register 4 (ADC_SQR4)

Address offset: 0x3C

Reset value: 0x0000 0000

Bits 31:11  Reserved, must be kept at reset value.

Bits 10:6  SQ16[4:0]: 16th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 16th in
the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures
that no regular conversion is ongoing).

Bit 5   Reserved, must be kept at reset value.

Bits 4:0  SQ15[4:0]: 15th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 15th in
the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures
that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

</tbody>
</table>
Bits 31:27 \textbf{JSQ4}[4:0]: 4th conversion in the injected sequence
These bits are written by software with the channel number (0 to 19) assigned as the 4th in
the injected conversion sequence.
\textit{Note:} The software is allowed to write these bits only when \textit{JADSTART} = 0 (which ensures
that no injected conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 \textbf{JSQ3}[4:0]: 3rd conversion in the injected sequence
These bits are written by software with the channel number (0 to 19) assigned as the 3rd in
the injected conversion sequence.
\textit{Note:} The software is allowed to write these bits only when \textit{JADSTART} = 0 (which ensures
that no injected conversion is ongoing).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 \textbf{JSQ2}[4:0]: 2nd conversion in the injected sequence
These bits are written by software with the channel number (0 to 19) assigned as the 2nd in
the injected conversion sequence.
\textit{Note:} The software is allowed to write these bits only when \textit{JADSTART} = 0 (which ensures
that no injected conversion is ongoing).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 \textbf{JSQ1}[4:0]: 1st conversion in the injected sequence
These bits are written by software with the channel number (0 to 19) assigned as the 1st in
the injected conversion sequence.
\textit{Note:} The software is allowed to write these bits only when \textit{JADSTART} = 0 (which ensures
that no injected conversion is ongoing).
Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: If JQDIS = 0 (queue enabled), hardware and software trigger detection disabled. Otherwise, the queue is disabled as well as hardware trigger detection (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

If JQM = 1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to Section 26.4.21: Queue of context for injected conversions)

Bits 6:2 **JEXTSEL[4:0]**: External Trigger Selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: adc_jext_trg0

00001: adc_jext_trg1

00010: adc_jext_trg2

00011: adc_jext_trg3

00100: adc_jext_trg4

00101: adc_jext_trg5

00110: adc_jext_trg6

00111: adc_jext_trg7

... 11111: adc_jext_trg31

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 1:0 **JL[1:0]**: Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

*Note:* Some channels are not connected physically and must not be selected for conversion.
26.6.17 ADC offset y register (ADC_OFRy)

Address offset: $0x60 + 0x04 \times (y - 1)$, ($y = 1$ to $4$)

Reset value: $0x0000 0000$

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31  | OFFSET_EN: Offset y enable   | This bit is written by software to enable or disable the offset programmed into bits OFFSET[11:0].
|     |                              | *Note:* The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
| 30-26 | OFFSET_CH[4:0]: Channel selection for the data offset y | These bits are written by software to define the channel to which the offset programmed into bits OFFSET[11:0] applies.
|     |                              | *Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
|     |                              | Some channels are not connected physically and must not be selected for the data offset y.
|     |                              | If OFFSET_EN is set, it is not allowed to select the same channel for different ADC_OFRy registers.
| 25  | SATEN: Saturation enable    | This bit is set and cleared by software to enable the saturation at 0x000 and 0xFFF for the offset function.
|     |                              | 0: No saturation control, offset result can be signed
|     |                              | 1: Saturation enabled, offset result unsigned and saturated at 0x000 and 0xFFF
|     |                              | *Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Bit 24 **OFFSETPOS**: Positive offset
This bit is set and cleared by software to enable the positive offset.
0: Negative offset
1: Positive offset

*Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:12 Reserved, must be kept at reset value.

Bits 11:0 **OFFSET[11:0]**: Data offset y for the channel programmed into bits OFFSET_CH[4:0]
These bits are written by software to define the offset to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset must be programmed in the bits OFFSET_CH[4:0]. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

*Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

If several offset (OFFSET) point to the same channel, only the offset with the lowest x value is considered for the subtraction.

*Ex:* if OFFSET1_CH[4:0] = 4 and OFFSET2_CH[4:0] = 4, this is OFFSET1[11:0] which is subtracted when converting channel 4.

### 26.6.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y - 1), (y = 1 to 4)

</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWD2CH[19:0]:** Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

- **AWD2CH[i] = 0:** ADC analog input channel i is not monitored by AWD2
- **AWD2CH[i] = 1:** ADC analog input channel i is monitored by AWD2

When **AWD2CH[19:0] = 000..0**, the analog Watchdog 2 is disabled

**Note:** The channels selected by **AWD2CH** must be also selected into the SQRi or JSQRi registers.

The software is allowed to write these bits only when **ADSTART = 0** and **JADSTART = 0** (which ensures that no conversion is ongoing).

Some channels are not connected physically and must not be selected for the analog watchdog.

### 26.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 DIFSEL[19:0]: Differential mode for channels 19 to 0.

These bits are set and cleared by software. They allow to select if a channel is configured as single-ended or Differential mode.

DIFSEL[i] = 0: ADC analog input channel is configured in single-ended mode
DIFSEL[i] = 1: ADC analog input channel i is configured in Differential mode

Note: The DIFSEL bits corresponding to channels that are either connected to a single-ended I/O port or to an internal channel must be kept their reset value (single-ended input mode).

The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).
### 26.6.22 ADC calibration factors (ADC_CALFACT)

</tbody>
</table>

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **CALFACT_D[6:0]**: Calibration Factors in differential mode
- These bits are written by hardware or by software.
- Once a differential inputs calibration is complete, they are updated by hardware with the calibration factors.
- Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new differential calibration is launched.
- **Note:** The software is allowed to write these bits only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **CALFACT_S[6:0]**: Calibration Factors in single-ended mode
- These bits are written by hardware or by software.
- Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.
- Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new single-ended calibration is launched.
- **Note:** The software is allowed to write these bits only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

### 26.6.23 ADC option register (ADC_OR)

Address offset: 0xC8

26.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs:

### 26.7.1 ADC common status register (ADC_CSR)

Address offset: 0x300
Reset value: 0x0000 0000

This register provides an image of the status bits of the different ADC. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADC_ISR register.

| Bit 31  | Bit 30  | Bit 29  | Bit 28  | Bit 27  | Bit 26  | Bit 25  | Bit 24  | Bit 23  | Bit 22  | Bit 21  | Bit 20  | Bit 19  | Bit 18  | Bit 17  | Bit 16  |

Bits 31:27 Reserved, must be kept at reset value.

- **Bit 26 JQOVF_SLV**: Injected Context Queue Overflow flag of the slave ADC
  - This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

- **Bit 25 AWD3_SLV**: Analog watchdog 3 flag of the slave ADC
  - This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

- **Bit 24 AWD2_SLV**: Analog watchdog 2 flag of the slave ADC
  - This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

- **Bit 23 AWD1_SLV**: Analog watchdog 1 flag of the slave ADC
  - This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

- **Bit 22 JEOS_SLV**: End of injected sequence flag of the slave ADC
  - This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.
Bit 21  **JEOC_SLV**: End of injected conversion flag of the slave ADC  
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 20  **OVR_SLV**: Overrun flag of the slave ADC  
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 19  **EOS_SLV**: End of regular sequence flag of the slave ADC. This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 18  **EOC_SLV**: End of regular conversion of the slave ADC  
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 17  **EOSMP_SLV**: End of Sampling phase flag of the slave ADC  
This bit is a copy of the EOSMP2 bit in the corresponding ADC_ISR register.

Bit 16  **ADRDY_SLV**: Slave ADC ready  
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 15:11  Reserved, must be kept at reset value.

Bit 10  **JQOVF_MST**: Injected Context Queue Overflow flag of the master ADC  
This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 9  **AWD3_MST**: Analog watchdog 3 flag of the master ADC  
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8  **AWD2_MST**: Analog watchdog 2 flag of the master ADC  
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7  **AWD1_MST**: Analog watchdog 1 flag of the master ADC  
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6  **JEOS_MST**: End of injected sequence flag of the master ADC  
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5  **JEOC_MST**: End of injected conversion flag of the master ADC  
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4  **OVR_MST**: Overrun flag of the master ADC  
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3  **EOS_MST**: End of regular sequence flag of the master ADC  
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2  **EOC_MST**: End of regular conversion of the master ADC  
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1  **EOSMP_MST**: End of Sampling phase flag of the master ADC  
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0  **ADRDY_MST**: Master ADC ready  
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.
### 26.7.2 ADC common control register (ADC_CCR)

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable  
This bit is set and cleared by software to control.  
0: VBAT channel disabled  
1: VBAT channel enabled

Bit 23 **TSEN**: VSENSE enable  
This bit is set and cleared by software to control VSENSE.  
0: Temperature sensor channel disabled  
1: Temperature sensor channel enabled

Bit 22 **VREFEN**: VREFINT enable  
This bit is set and cleared by software to enable/disable the VREFINT channel.  
0: VREFINT channel disabled  
1: VREFINT channel enabled

Bits 21:18 **PRESC[3:0]**: ADC prescaler  
These bits are set and cleared by software to select the frequency of the clock to the ADC.  
The clock is common for all the ADCs.  
0000: input ADC clock not divided  
0001: input ADC clock divided by 2  
0010: input ADC clock divided by 4  
0011: input ADC clock divided by 6  
0100: input ADC clock divided by 8  
0101: input ADC clock divided by 10  
0110: input ADC clock divided by 12  
0111: input ADC clock divided by 16  
1000: input ADC clock divided by 32  
1001: input ADC clock divided by 64  
1010: input ADC clock divided by 128  
1011: input ADC clock divided by 256  
other: reserved

*Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0). The ADC prescaler value is applied only when CKMODE[1:0] = 0b00.*
Bits 17:16 **CKMODE[1:0]: ADC clock mode**

These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):

- 00: adc_ker_ck (x = 1/2) (Asynchronous clock mode), generated at product level (refer to Section 6: Reset and clock control (RCC))
- 01: adc_hclk/1 (Synchronous clock mode). This configuration must be enabled only if the AHB clock prescaler is set to 1 (HPRE[3:0] = 0XXX in RCC_CFGR register) and if the system clock has a 50% duty cycle.
- 10: adc_hclk/2 (Synchronous clock mode)
- 11: adc_hclk/4 (Synchronous clock mode)

In all synchronous clock modes, there is no jitter in the delay from a timer trigger to the start of a conversion.

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).*

Bits 15:14 **MDMA[1:0]: Direct memory access mode for dual ADC mode**

This bitfield is set and cleared by software. Refer to the DMA controller section for more details.

- 00: MDMA mode disabled
- 01: Reserved
- 10: MDMA mode enabled for 12 and 10-bit resolution
- 11: MDMA mode enabled for 8 and 6-bit resolution

*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 13 **DMACFG: DMA configuration (for dual ADC mode)**

This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.

- 0: DMA One Shot mode selected
- 1: DMA Circular mode selected

For more details, refer to Section : Managing conversions using the DMA

*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 12 **Reserved, must be kept at reset value.**
Bits 11:8 **DELAY[3:0]**: Delay between 2 sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to Table 253 for the value of ADC resolution versus DELAY bits values.

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).*

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]**: Dual ADC mode selection

These bits are written by software to select the operating mode. 00000 corresponds to independent mode. Values 00001 to 01001 correspond to dual mode, master and slave ADCs working together.

- 00000: Independent mode
- 00001: Combined regular simultaneous + injected simultaneous mode
- 00010: Combined regular simultaneous + alternate trigger mode
- 00011: Combined interleaved mode + injected simultaneous mode
- 00100: Reserved
- 00101: Injected simultaneous mode only
- 00110: Regular simultaneous mode only
- 00111: Interleaved mode only
- 01001: Alternate trigger mode only
- Others: Reserved, must not be used

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).*

Bits 31:16 **RDATA_SLV[15:0]**: Regular data of the slave ADC
In dual mode, these bits contain the regular data of the slave ADC. Refer to Section 26.4.30: Dual ADC modes.
The data alignment is applied as described in Section : Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.
In dual mode, these bits contain the regular data of the master ADC. Refer to Section 26.4.30: Dual ADC modes.
The data alignment is applied as described in Section : Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)
In MDMA = 0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

Bits 31:0 **SID[31:0]**: Size Identification
SID[31:8]: fixed code that characterizes the ADC_SIDR register. This field is always read at 0xA3C5DD.
SID[7:0]: read-only numeric field that returns the address offset (in Kbytes) of the identification registers from the IP base address:
0x01: 1 Kbytes address offset
0x02: 2 Kbytes address offset
0x04: 4 Kbytes address offset
0x08: 8 Kbytes address offset
### 26.8 ADC register map

Refer to Section 2.3 on page 111 for the register boundary addresses.
27 Digital temperature sensor (DTS)

27.1 Introduction

The device embeds a sensor that converts the temperature into a square wave which frequency is proportional to the temperature. The frequency is measured either with the PCLK or the LSE clock.

27.2 DTS main features

The temperature sensor block main features are the following:

- Start of measurement triggered by software or 4 hardware sources
- Programmable sampling time to increase temperature measurement precision
- Counter synchronized on LSE or PCLK clock
- Temperature watchdog on low and high threshold
- Interrupt generation when the temperature is lower or higher than predefined thresholds and at the end of measurement.
- Asynchronous wakeup signal generation when the temperature is higher/lower than a predefined threshold (LSE mode only)
- Quick measurement using LSE clock
27.3  DTS functional description

27.3.1  DTS block diagram

The temperature sensor block diagram is shown in Figure 259.

Figure 259. Temperature sensor functional block diagram

27.3.3 DTS block operation

The analog part of the temperature sensor outputs a frequency that is proportional to the absolute temperature (CLK_PTAT). The frequency measurement is based on the PCLK or the LSE clock.

Before each measurement, the temperature sensor performs a calibration of the frequency generation blocks.

27.3.4 Operating modes

Several operating modes can be selected by setting the REFCLK_SEL bit in Temperature sensor configuration register 1 (DTS_CFGR1):

- PCLK only (REFCLK_SEL = 0)
  The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using PCLK clock

- PCLK and LSE (REFCLK_SEL = 1)
  The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using the LSE clock.

- LSE only (REFCLK_SEL = 1) and PCLK OFF
  The registers cannot be accessed. The measurement can be performed using the LSE clock. This mode is used to exit from Sleep mode by using hardware triggers and the asynchronous interrupt line.

27.3.5 Calibration

The temperature sensor must run the calibration prior to any frequency measurement. The calibration is performed automatically when the temperature measurement is triggered except for quick measurement mode (Q_MEAS_OPT set to 1 in DTS_CFGR1).

27.3.6 Prescaler

When a calibration is ongoing, the counter clock must be slower than 1 MHz. This is achieved by the PCLK clock prescaler embedded in the temperature sensor.

During the temperature measurement period, the prescaler is bypassed.

- When PCLK is used as reference clock (REFCLK_SEL set to 0 in DTS_CFGR1), a prescaler is used. Its division ratio must be configured up to 127 (refer to the HSREF_CLK_DIV[6:0] register definition for the divider setting).
- When LSE is used as reference clock (REFCLK_SEL set to 1 in DTS_CFGR1), the timebase is equal to 2 LSE periods. In this case, no prescaler is used.
27.3.7 Temperature measurement principles

The analog part of temperature sensor outputs a signal (CLK_PTAT) which FM(T) frequency is temperature-dependent.

Either PCLK or LSE can be selected as reference clock (REF_CLK) through the REFCLK_SEL bit in DTS_CFGR1.

The counting method depends on the REF_CLK frequency. This is due to the fact that two counters are implemented in the temperature sensor block:

- For low REF_CLK frequencies, a counting of FM(T) cycles is performed during one or several REF_CLK cycles.
- For high REF_CLK frequencies, a counting of REF_CLK cycles is performed during one or several FM(T) cycles.

This counter behavior is shown in *Figure 260* and *Figure 261*.

**Figure 260. Method for low REF_CLK frequencies**

![Figure 260. Method for low REF_CLK frequencies](image1)

1. To increase the precision, FM(T) measurement can be done on several LSE periods.

**Figure 261. Method for high REF_CLK frequencies**

![Figure 261. Method for high REF_CLK frequencies](image2)

1. To increase the precision, PCLK measurement can be done on several FM(T) periods.

The counting result is stored in the DTS_DR register (see *Temperature sensor data register (DTS_DR)*).

Once the FM(T) frequency has been obtained, the corresponding temperature can be calculated by software using the following formula:

- When PCLK is used:

\[
T = T_0 + \left( \frac{F_{PCLK}}{F_{PCLK}} \cdot \frac{TS1_{MFREQ}}{TS1_{SMP\_TIME}} \cdot 100 \cdot TS1_{FMT0} \right) \div TS1_{RAMP\_COEFF}
\]

where

- \( T_0 \) (factory calibration temperature) is equal to 30 °C.
- TS1_FMT0 is measured and stored in the DTS_T0VALR1 register. It is expressed in hundreds of Hertz.
TS1_RAMP_COEFF is measured during tests in factory and stored in DTS_RAMPVALR register. This value is expressed in Hz/°C.

- When the LSE clock is used

\[ T = T_0 + \left( F_{\text{LSE}} \times \text{TS1_MFREQ} / \text{TS1_SMP_TIME} - (100 \times \text{TS1_FMT0}) / \text{TS1_RAMP_COEFF} \right) \]

### 27.3.8 Sampling time

The sampling period can be increased to improve measurement accuracy. This is useful when the reference frequency (REF_CLK) is close to the FM(T) frequency. The default value is one REF_CLK cycle in LSE mode, and one FM(T) cycle in PCLK mode.

The sampling time is configured through TS1_SMP_TIME bits in DTS_CFGR1 register (see Table 258).

### 27.3.9 Quick measurement mode

If a high precision is not required, the calibration step included in each measurement sequence can be skipped by setting Q_MEAS_OPT to 1 in the DTS_CFGR1 register. This method must used only when the LSE clock is selected as reference clock (LSREF_CLK set to 1). This mode can reduce the measurement time.
27.3.10 Trigger input

The temperature measurement can be triggered either by software or by an external event. The trigger source can be selected through TS1_INTRIG[3:0] bits in DTS_CFRG1.

</table>

Note: Hardware triggers are active only on the rising edge.

The temperature sensor can only capture a hardware trigger rising edge when TS1_RDY bit is set (see Section 27.3.11: On-off control and ready flag, otherwise the trigger is ignored.

If a trigger source changes on-the-fly, the new trigger source signal should be low. If the new source signal is high, the temperature sensor detects a rising edge and start the measurement sequence.

27.3.11 On-off control and ready flag

The DTS block can be enabled by setting TS1_EN bit in DTS_CFRG1 register. The TS1_RDY flag in the Temperature sensor status register (DTS_SR) indicate that the DTS block is ready for temperature measurement: when TS1_RDY bit is set to 1, the measurement can be started. Once a measurement has started, TS1_RDY bit is reset. New measurement requests are then ignored. Once the measurement is finished, TS1_RDY bit is set again to indicate the sensor is ready to start a new measurement.
27.3.12 Temperature measurement sequence

Start of measurement can be triggered by software or hardware.

Software trigger

The software trigger is selected when TS1_INTRIG_SEL[3:0] is set to ‘0000’ in DTS_CFGR1.

If TS1_RDY is set to 1, writing TS1_START bit to 1 in DTS_CFGR1 starts the measurement.

If TS1_RDY equals 0, the software trigger does not start until TS1_RDY is set.

If TS1_START bit is kept at 1 once the measurement is finished, then the TS1_RDY flag becomes 1 and the measurement restarts.

Hardware trigger

TS1_INTRIG_SEL[3:0] bits allow selecting one hardware trigger out of 4. If TS1_RDY is set to 1, a rising edge on the trigger signal starts the measurement. When TS1_RDY is 0, the rising edge is ignored.

Temperature measurement sequence

One measurement contains two steps: the calibration of the analog blocks and the measurement. The calibration automatically starts when the measurement is triggered (see Section 27.3.5: Calibration). The measurement period depends on the following DTS_CFGR1 bits:

- the reference clock selected through REFCLK_SEL bit
- the divider ratio configured by HSREF_CLK_DIV bits
- the sampling time defined by TS1_SMP_TIME bits.

</tbody>
</table>

**Table 260. Temperature sensor behavior in low-power modes**

27.5 **DTS interrupts**

There are two ways to use the DTS block as an interrupt source. The DTS interrupt line can be connected to the EXTI controller (see *Section 27.5.3: Asynchronous wakeup*) or to the CPU NVIC (see *Section 27.5.2: Synchronous interrupt*).

27.5.1 **Temperature window comparator**

The DTS_ITR1 register allows defining the high and low threshold that are used for temperature comparison. If the temperature data is equal or higher than TS1_HITTHD, or equal or lower than TS1_LITTHD bit, an interrupt is generated and the corresponding flag, TS1_ITLF, TS1ITHF, TS1_AITLF and TS1_AITHF, is set in the DTS_SR register (see *Section 27.6.6*).

27.5.2 **Synchronous interrupt**

A global interrupt output line is available on the DTS block. The interrupt can be generated at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see *Section 27.5.1: Temperature window comparator*).

Three interrupt events can be select via 3 bits in DTS_ITENR register (see *Section 27.6.7*). All combinations of interrupts are allowed.

The TS1_ITEF, TS1 ITLF and TS1_ITHF flags in the DTS_SR register reflect the interrupt event. They can be reset with the correspond bits of the DTS_ICIFR register (see *Section 27.6.8*).

27.5.3 **Asynchronous wakeup**

The DTS block also provides an asynchronous interrupt line. It is used only when the LSE is selected as reference clock (REFCLK_SEL=1).

This line can generate a signal that wakes up the system from Sleep mode at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see *Section 27.5.1: Temperature window comparator*).

Three asynchronous wakeup events can be selected via 3 bits in DTS_ITENR register. All combination of interrupts are allowed.
The TS1_AITEF, TS1_AITLF and TS1_AITHF flags in the DTS_SR register reflect the interrupt status. They can be reset with the correspond bits of the DTS_ICIFR register.

The following table shows the interrupt bits an the their description.

### Table 261. Interrupt control bits

<table>

</table>

### 27.6 DTS registers

The registers of this peripheral can only be accessed by-word (32-bit).

#### 27.6.1 Temperature sensor configuration register 1 (DTS_CFRG1)

DTS_CFRG1 is the configuration register for temperature sensor 1.

Address offset: 0x00
Reset value: 0x0000 0000
Bit 31  Reserved, must be kept at reset value.

Bits 30:24  **HSREF_CLK_DIV[6:0]**: High speed clock division ratio
These bits are set and cleared by software. They can be used to define the division ratio for the main clock in order to obtain the internal frequency lower than 1 MHz required for the calibration. They are applicable only for calibration when PCLK is selected as reference clock (REFCLK_SEL=0).
- 0000000: No divider
- 0000001: No divider
- 0000010: 1/2 division ratio
- ...
- 1111111: 1/127 division ratio

Bits 23:22  Reserved, must be kept at reset value.

Bit 21  **Q_MEAS_OPT**: Quick measurement option bit
This bit is set and cleared by software. It is used to increase the measurement speed by suppressing the calibration step. It is effective only when the LSE clock is used as reference clock (REFCLK_SEL=1).
- 0: Measurement with calibration
- 1: Measurement without calibration

Bit 20  **REFCLK_SEL**: Reference clock selection bit
This bit is set and cleared by software. It indicates whether the reference clock is the high speed clock (PCLK) or the low speed clock (LSE).
- 0: High speed reference clock (PCLK)
- 1: Low speed reference clock (LSE)

Bits 19:16  **TS1_SMP_TIME[3:0]**: Sampling time for temperature sensor 1
These bits allow increasing the sampling time to improve measurement precision.
When the PCLK clock is selected as reference clock (REFCLK_SEL = 0), the measurement is performed at TS1_SMP_TIME period of CLK_PTAT.
When the LSE is selected as reference clock (REFCLK_SEL = 1), the measurement is performed at TS1_SMP_TIME period of LSE.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:8  **TS1_INTRIG_SEL[3:0]**: Input trigger selection bit for temperature sensor 1
These bits are set and cleared by software. They select which input triggers a temperature measurement. Refer to *Section 27.3.10: Trigger input*.

Bits 7:5  Reserved, must be kept at reset value.

Bit 4  **TS1_START**: Start frequency measurement on temperature sensor 1
This bit is set and cleared by software.
- 0: No software trigger.
- 1: Software trigger for a frequency measurement. (only if TS1 is ready).

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **TS1_EN**: Temperature sensor 1 enable bit
This bit is set and cleared by software.
- 0: Temperature sensor 1 disabled
- 1: Temperature sensor 1 enabled

*Note: Once enabled, the temperature sensor is active after a specific delay time. The TS1_RDY flag is set when the sensor is ready.*
27.6.2 Temperature sensor T0 value register 1 (DTS_T0VALR1)

DTS_T0VALR1 contains the value of the factory calibration temperature (T0) for temperature sensor 1. The reset value is factory trimmed.

Address offset: 0x08
Reset value: 0x000X XXXX

---

<table>

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **TS1_T0[1:0]**: Engineering value of the T0 temperature for temperature sensor 1.
- 00: 30 °C
- 01: 130 °C
- Others: Reserved, must not be used.

Bits 15:0 **TS1_FMT0[15:0]**: Engineering value of the frequency measured at T0 for temperature sensor 1.
This value is expressed in 0.1 kHz.

---

27.6.3 Temperature sensor ramp value register (DTS_RAMPVALR)

The DTS_RAMPVALR is the ramp coefficient for the temperature sensor. The reset value is factory trimmed.

Address offset: 0x10
Reset value: 0xXXXX XXXX

---

<table>

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TS1_RAMP_COEFF[15:0]**: Engineering value of the ramp coefficient for the temperature sensor 1.
This value is expressed in Hz/°C.
### 27.6.4 Temperature sensor interrupt threshold register 1 (DTS_ITR1)

DTS_ITR1 contains the threshold values for sensor 1.

Address offset: 0x14  
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:16 **TS1_HITTHD[15:0]**: High interrupt threshold for temperature sensor 1  
These bits are set and cleared by software. They indicate the highest value than can be reached before raising an interrupt signal.

Bits 15:0 **TS1_LITTHD[15:0]**: Low interrupt threshold for temperature sensor 1  
These bits are set and cleared by software. They indicate the lowest value than can be reached before raising an interrupt signal.

### 27.6.5 Temperature sensor data register (DTS_DR)

The DTS_DR contains the number of REF_CLK cycles used to compute the FM(T) frequency.

Address offset: 0x1C  
Reset value: 0x0000 0000

<table>
<thead>

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

- **Bit 15** **TS1_RDY**: Temperature sensor 1 ready flag
  - This bit is set and reset by hardware.
  - It indicates that a measurement is ongoing.
  - 0: Temperature sensor 1 busy
  - 1: Temperature sensor 1 ready

Bits 14:7 Reserved, must be kept at reset value.

- **Bit 6** **TS1_AITHF**: Asynchronous interrupt flag for high threshold on temperature sensor 1
  - This bit is set by hardware when the high threshold is reached.
  - It is cleared by software by writing 1 to the TS1_CAITHF bit in the DTS_ICIFR register.
  - 0: High threshold not reached on temperature sensor 1
  - 1: High threshold reached on temperature sensor 1
  - *Note: This bit is active only when the TS1_AITHFEN bit is set*

- **Bit 5** **TS1_AITLF**: Asynchronous interrupt flag for low threshold on temperature sensor 1
  - This bit is set by hardware when the low threshold is reached.
  - It is cleared by software by writing 1 to the TS1_CAITLF bit in the DTS_ICIFR register.
  - 0: Low threshold not reached on temperature sensor 1
  - 1: Low threshold reached on temperature sensor 1
  - *Note: This bit is active only when the TS1_AITLFEN bit is set*

- **Bit 4** **TS1_AITEF**: Asynchronous interrupt flag for end of measure on temperature sensor 1
  - This bit is set by hardware when a temperature measure is done.
  - It is cleared by software by writing 1 to the TS1_CAITEF bit in the DTS_ICIFR register.
  - 0: End of measure not detected on temperature sensor 1
  - 1: End of measure detected on temperature sensor 1
  - *Note: This bit is active only when the TS1_AITEFEN bit is set*

Bits 3 Reserved, must be kept at reset value.
Bit 2 **TS1ITHF**: Interrupt flag for high threshold on temperature sensor 1, synchronized on PCLK.
   This bit is set by hardware when the high threshold is set and reached.
   It is cleared by software by writing 1 to the TS1_CITHF bit in the DTS_ICIFR register.
   0: High threshold not reached on temperature sensor 1
   1: High threshold reached on temperature sensor 1
   *Note: This bit is active only when the TS1ITHFEN bit is set*

Bit 1 **TS1ITLF**: Interrupt flag for low threshold on temperature sensor 1, synchronized on PCLK.
   This bit is set by hardware when the low threshold is set and reached.
   It is cleared by software by writing 1 to the TS1_CITLF bit in the DTS_ICIFR register.
   0: Low threshold not reached on temperature sensor 1
   1: Low threshold reached on temperature sensor 1
   *Note: This bit is active only when the TS1ITLFEN bit is set*

Bit 0 **TS1ITEF**: Interrupt flag for end of measurement on temperature sensor 1, synchronized on PCLK.
   This bit is set by hardware when a temperature measure is done.
   It is cleared by software by writing 1 to the TS2_CITEF bit in the DTS_ICIFR register.
   0: No end of measurement detected on temperature sensor 1
   1: End of measure detected on temperature sensor 1
   *Note: This bit is active only when the TS1ITEFEN bit is set*

27.6.7 Temperature sensor interrupt enable register (DTS_ITENR)

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **TS1AITHEN**: Asynchronous interrupt enable flag on high threshold for temperature sensor 1.
   This bit are set and cleared by software.
   It enables the asynchronous interrupt when the temperature is above the high threshold
   (only when REFCLK_SEL = 1’b1)
   0: Asynchronous interrupt on high threshold disabled for temperature sensor 1
   1: Asynchronous interrupt on high threshold enabled for temperature sensor 1

Bit 5 **TS1AITLEN**: Asynchronous interrupt enable flag for low threshold on temperature sensor 1.
   This bit are set and cleared by software.
   It enables the asynchronous interrupt when the temperature is below the low threshold (only
   when REFCLK_SEL = 1)
   0: Asynchronous interrupt on low threshold disabled for temperature sensor 1
   1: Asynchronous interrupt on low threshold enabled for temperature sensor 1
Digital temperature sensor (DTS)  RM0481

27.6.8 Temperature sensor clear interrupt flag register (DTS_ICIFR)

DTS_ICIFR is the control register for the interrupt flags.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **TS1_CAITHF**: Asynchronous interrupt clear flag for high threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITHF flag in the DTS_SR register.

Bit 5 **TS1_CAITLF**: Asynchronous interrupt clear flag for low threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITLF flag in the DTS_SR register.
Bit 4 **TS1_CAITEF**: Write once bit. Clear the asynchronous IT flag for End Of Measure for thermal sensor 1.
   Writing 1 clears the TS1_AITEF flag of the DTS_SR register.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_CITHF**: Interrupt clear flag for high threshold on temperature sensor 1
   Writing this bit to 1 clears the TS1_ITHF flag in the DTS_SR register.

Bit 1 **TS1_CITLF**: Interrupt clear flag for low threshold on temperature sensor 1
   Writing 1 to this bit clears the TS1_ITLF flag in the DTS_SR register.

Bit 0 **TS1_CITEF**: Interrupt clear flag for end of measurement on temperature sensor 1
   Writing 1 to this bit clears the TS1_ITEF flag in the DTS_SR register.

### 27.6.9 Temperature sensor option register (DTS_OR)

The DTS_OR contains general-purpose option bits.

Address offset: 0x2C

Reset value: 0x0000 0000

28 Digital-to-analog converter (DAC)

28.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data can be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions can be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, \( V_{\text{REF}+} \) (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to voltage reference buffer (VREFBUF) section.

The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and hold mode.

28.2 DAC main features

The DAC main features are the following (see Figure 263: Dual-channel DAC block diagram)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- Double data DMA capability to reduce the bus activity
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference from \( V_{\text{REF}+} \) pin or internal VREFBUF reference

Figure 263 shows the block diagram of a DAC channel and Table 264 gives the pin description.

28.4 DAC functional description

28.4.1 DAC block diagram

Figure 263. Dual-channel DAC block diagram

1. MODEx bits in the DAC_MCR control the output mode and allow switching between the Normal mode in buffer/unbuffered configuration and the Sample and hold mode.

2. Refer to Section 28.3: DAC implementation for channel2 availability.
28.4.2 DAC pins and internal signals

The DAC includes:
- Up to two output channels
- DAC output channel buffered or non-buffered
- Sample and hold block and registers operational in Stop mode, using the LSI/LSE clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and hold block and its associated registers can run in Stop mode using the LSI/LSE clock source (dac_hold_ck).

28.4.3 DAC clocks

Two clock sources can be used to update the DAC:
- `dac_hclk`: DAC peripheral clock (AHB clock)
- `dac_ker_ck`: DAC kernel clock: this clock can be used to synchronize DAC and ADC.
- `dac_hold_ck`: low-power clock used in Sample and hold mode

The DAC clock is selected in the RCC.

28.4.4 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a tWAKEUP startup time.

DACxRDY bit is set in the DAC_SR register when the DAC interface is ready to accept data. Writing new data or asserting the trigger is not allowed when ENx bit is set while DACxRDY signal is reset.

*Note:* The ENx bit enables the analog DAC channelx only. The DAC channelx digital interface is enabled even if the ENx bit is reset.

28.4.5 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:
- **Single DAC channel**
  - There are three possibilities:
    - 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)
    - 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)
    - 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyxy register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

**Table 266. DAC interconnection (continued)**

</table>
Dual DAC channels (when available)

There are three possibilities:

- 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)

- 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)

- 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Signed/unsigned data

DAC input data are unsigned: 0x000 corresponds to the minimum value and 0xFFF to the maximum value for 12-bit mode.

The DAC can also handle signed input data in 2’s complement format. This is done by setting SINFORMATx bit in the DAC_MCR register.

When SINFORMATx bit is set, the MSB bit of the data written to DHRx registers is inverted when it is copied to the DAC_DORx register, and the DAC interface can accept signed data (Q1.15, Q1.11 or Q1.7 format). DAC_DHR12Lx register can be used to store 16-bit signed data in the data holding registers. The 12 MSBs of 16-bit data are used for the DAC output data and the MSB bit is inverted. The four LSBs are simply ignored.
28.4.6 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channel must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_hclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_hclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time \( t_{SETTLING} \) that depends on the power supply voltage and the analog output load.

To synchronize DAC and ADC, the same clock source can be used for both peripherals. This is done by selecting the dac_ker_ck clock instead of the dac_hclk clock (AHB clock) in the RCC.

HFSEL bits of DAC_MCR must be set when dac_hclk or dac_ker_ck clock speed is faster than 80 MHz. It adds an extra delay to the transfer from DAC_DHRx register to DAC_DORx register.

Refer to Table HFSEL description below for the limitation of the DAC_DORx update rate depending on HFSEL bits and dac_hclk clock frequency.

If the data is updated or a software/hardware trigger event occurs during the non-allowed period, the peripheral behavior is unpredictable.

The above timing is only related to the limitation of the DAC interface. Refer also to the \( t_{SETTLING} \) parameter value in the product datasheet.

**Figure 266. Timing diagram for conversion with trigger disabled TEN = 0**

![Timing diagram](image)

**28.4.7 DAC output voltage**

Digital inputs are converted to output voltages on a linear conversion between 0 and V\(\text{REF}^+\).

The analog output voltages on each DAC channel pin are determined by the following equation:

\[
\text{DACoutput} = \frac{\text{V}_{\text{REF}} \times \text{DOR}}{4096}
\]

**28.4.8 DAC trigger selection**

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to the interconnection table in Section 28.4.2: DAC pins and internal signals.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the
DAC_DORx register. The DAC_DORx register is updated three dac_hclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

**Note:**

TSELx[3:0] bit cannot be changed when the ENx bit is set.

When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_hclk clock cycle.

### 28.4.9 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

#### DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion can be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

#### DMA Double data mode

When the DMA controller is used in Normal mode, only 12-bit (or 8-bit) data are transferred by a DMA request. As the AHB width is 32 bits, two 12-bit data may be transferred simultaneously. To use this mode, set the DMADOUBLEx bit of DAC_MCR register.

A DAC DMA request is generated every two external triggers (except for software triggers) when the DMAENx bit is set:

1. When the first trigger is detected, the value of the DAC_DHRx and DAC_DHRBx registers are transferred into the DAC_DORx and DAC_DORBx registers. The actual
DAC data is loaded into the DAC_DORx register. A DMA request is then generated. The DMA writes the new data to the DAC_DHRx and DAC_DHRBx data registers.

2. When the next trigger is detected, the actual DAC data is loaded into the DAC_DHRBx register. This second trigger does not generate any DMA request. The DORSTATx bit indicates which DOR data is actually loaded into the analog DAC input.

DMA underrun function is also supported in DMA Double data mode.

In DMA Double mode, DMA requests can only handle one DAC channel. To use two channel outputs in DMA Double mode, each DMA channel has to be configured separately.

The following conditions must be met to change from Double data to single data mode or vice versa:
- The DAC must be disabled.
- DMAEN bit must be cleared (ENx = 0 and DMAEN = 0).

### 28.4.10 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_hclk clock cycles after each trigger event, following a specific calculation algorithm.

The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a ‘1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.
Note: The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.

28.4.11 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_hclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.
28.4.12 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In Normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 000: DAC is connected to the external pin

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 010: DAC is connected to the external pin

Sample and hold mode

In Sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI/LSE low-speed clock (dac_hold_ck) in addition to the dac_hclk clock, allowing using the DAC channels in deep low power modes such as Stop mode.

The LSI/LSE low-speed clock (dac_hold_ck) must not be stopped when the Sample and hold mode is enabled.
The sample/hold mode operations can be divided into 3 phases:

1. **Sample phase:** the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (AHB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation.

2. **Hold phase:** the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register.

3. **Refresh phase:** the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register.

The timings for the three phases above are in units of LSI/LSE clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI/LSE ~32 KHz is selected:

- 12 cycles are required for sample phase: TSAMPLEx[9:0] = 11,
- 62 cycles are required for hold phase: THOLDx[9:0] = 62,
- and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

### Table 269. Sample and refresh timings

<table>
<thead>
<tr>
<th>Buffer State</th>
<th>$t_{SAMP}$</th>
<th>$t_{REFRESH}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>$7 \mu s + (10*R_{BON}*C_{SH})$</td>
<td>$7 \mu s + (R_{BON}<em>C_{SH})</em>\ln(2*N_{LSB})$</td>
</tr>
<tr>
<td>Disable</td>
<td>$3 \mu s + (10*R_{BOFF}*C_{SH})$</td>
<td>$3 \mu s + (R_{BOFF}<em>C_{SH})</em>\ln(2*N_{LSB})$</td>
</tr>
</tbody>
</table>

1. In the above formula the settling to the desired code value with $\frac{1}{2}$ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.

2. $C_{SH}$ is the capacitor in Sample and hold mode.

3. The tolerated voltage drop during the hold phase “Vd” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with $\frac{1}{2}$ LSB error accuracy requires $\ln(2*N_{LSB})$ constant time of the DAC.

**Example of the sample and refresh time calculation with output buffer on**

The values used in the example below are provided as indication only. Refer to the product datasheet for product data.

- $C_{SH} = 100 \text{ nF}$
- $V_{REF+} = 3.0 \text{ V}$

Sampling phase:

$t_{SAMP} = 7 \mu s + (10 * 2000 * 100 * 10^{-9}) = 2.007 \text{ ms}$

(where $R_{BON} = 2 \text{ k\Omega}$)
Refresh phase:
\[ t_{\text{REFRESH}} = 7 \ \mu s + (2000 \cdot 100 \cdot 10^{-9}) \cdot \ln(2 \cdot 10) = 606.1 \ \mu s \]
(where \( N_{\text{LSB}} = 10 \) (10 LSB drop during the hold phase))

Hold phase:
\[ D_v = i_{\text{leak}} \cdot t_{\text{hold}} / C_{\text{SH}} = 0.0073 \ \text{V} \ (10 \ \text{LSB of 12bit at 3 \ \text{V}}) \]
\[ i_{\text{leak}} = 150 \ \text{nA} \ (\text{worst case on the IO leakage on all the temperature range}) \]
\[ t_{\text{hold}} = 0.0073 \cdot 100 \cdot 10^{-9} / (150 \cdot 10^{-9}) = 4.867 \ \text{ms} \]

Figure 271. DAC Sample and hold mode phase diagram

Like in Normal mode, the Sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 100: DAC is connected to the external pin

To disabled the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 110: DAC is connected to external pin

When MODEx[2:0] bits are equal to 111, an internal capacitor, \( C_{\text{Link}} \) holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All Sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.
The transfer function for an N-bit digital-to-analog converter (DAC) is:

\[ V_{\text{out}} = \left( \frac{D}{2^N} \right) \times G \times V_{\text{ref}} \times + V_{\text{OS}} \]

Where \( V_{\text{out}} \) is the analog output, \( D \) is the digital input, \( G \) is the gain, \( V_{\text{ref}} \) is the nominal full-scale voltage, and \( V_{\text{OS}} \) is the offset voltage. For an ideal DAC channel, \( G = 1 \) and \( V_{\text{OS}} = 0 \).

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the \( V_{\text{OS}} \), a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101). If applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to \( V_{\text{REF+}}/2 \) signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- **Factory trimming (default setting)**
  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.

- **User trimming**
  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when \( V_{\text{DDA}} \) voltage, temperature, \( V_{\text{REF+}} \) values change and can be done at any point during application by software.

**Note:** Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when \( V_{\text{DD}} \) is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

<table>
<thead>
<tr>
<th>MODEx[2:0]</th>
<th>Mode</th>
<th>Buffer</th>
<th>Output connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0 0</td>
<td>Normal mode</td>
<td>Enabled</td>
<td>Connected to external pin</td>
</tr>
<tr>
<td>0 1 0</td>
<td>Sample and hold mode</td>
<td>Disabled</td>
<td>Connected to external pin</td>
</tr>
<tr>
<td>1 0 0</td>
<td>Normal mode</td>
<td>Enabled</td>
<td>Connected to external pin</td>
</tr>
<tr>
<td>1 1 0</td>
<td>Sample and hold mode</td>
<td>Disabled</td>
<td>Connected to external pin and to on chip peripherals (such as comparators)</td>
</tr>
</tbody>
</table>
1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101.
3. Start the DAC channel calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 0b00000.
   b) Wait for tTRIM delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) If CAL_FLAGx is set to 1, the OTRIMx[4:0] trimming code is found and can be used during device operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

   The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

   The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC_CCR register.

   **Note:**
   A tTRIM delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value. This parameter is specified into datasheet electrical characteristics section.

   If VDDA, VREF+ and temperature conditions do not change during device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers, then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

   **When CENx bit is set, it is not allowed to set ENx bit.**

28.4.14 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

15 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

**Independent trigger without wave generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).
When a DAC channel 1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_hclk clock cycles later).

When a DAC channel 2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_hclk clock cycles later).

**Independent trigger with single LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVE[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel 1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel 2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

**Independent trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVE[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel 1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel 2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.
**Independent trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Independent trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous software start**

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_hclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

**Simultaneous trigger without wave generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_hclk clock cycles).

**Simultaneous trigger with single LFSR generation**

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three AHB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the DAC channel2 triangle counter is updated.

### 28.5 DAC in low-power modes

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CEN2**: DAC channel2 calibration enable

This bit is set and cleared by software to enable/disable DAC channel2 calibration, it can be written only if EN2 bit is set to 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel2 in Normal operating mode
1: DAC channel2 in calibration mode

*Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.*

Bit 29 **DMAUDR1E2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

0: DAC channel2 DMA underrun interrupt disabled
1: DAC channel2 DMA underrun interrupt enabled

*Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.*

Bit 28 **DMAEN2**: DAC channel2 DMA enable

This bit is set and cleared by software.

0: DAC channel2 DMA mode disabled
1: DAC channel2 DMA mode enabled

*Note: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.*
Bits 27:24  **MAMP2[3:0]**: DAC channel2 mask/amplitude selector  
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.  
0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1  
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3  
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7  
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15  
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31  
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63  
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127  
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255  
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511  
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023  
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047  
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095  

*Note:* These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bits 23:22  **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable  
These bits are set/reset by software.  
00: wave generation disabled  
01: Noise wave generation enabled  
1x: Triangle wave generation enabled  

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)  
These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bits 21:18  **TSEL2[3:0]**: DAC channel2 trigger selection  
These bits select the external event used to trigger DAC channel2  
0000: SWTRIG2  
0001: dac_ch2_trg1  
0010: dac_ch2_trg2  
...  
1111: dac_ch2_trg15  
Refer to the trigger selection tables in Section 28.4.2: DAC pins and internal signals for details on trigger configuration and mapping.  

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).  
These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 17  **TEN2**: DAC channel2 trigger enable  
This bit is set and cleared by software to enable/disable DAC channel2 trigger  
0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_hclk clock cycle later to the DAC_DOR2 register  
1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_hclk clock cycles later to the DAC_DOR2 register  

*Note:* When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_hclk clock cycle.  
These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.
Bit 16  **EN2**: DAC channel2 enable

This bit is set and cleared by software to enable/disable DAC channel2.
- 0: DAC channel2 disabled
- 1: DAC channel2 enabled

*Note:* These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 15  Reserved, must be kept at reset value.

Bit 14  **CEN1**: DAC channel1 calibration enable

This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled). Otherwise, the write operation is ignored.
- 0: DAC channel1 in Normal operating mode
- 1: DAC channel1 in calibration mode

Bit 13  **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable

This bit is set and cleared by software.
- 0: DAC channel1 DMA Underrun Interrupt disabled
- 1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12  **DMAEN1**: DAC channel1 DMA enable

This bit is set and cleared by software.
- 0: DAC channel1 DMA mode disabled
- 1: DAC channel1 DMA mode enabled

Bits 11:8  **MAMP1[3:0]**: DAC channel1 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
- 0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
- 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
- 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
- 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
- 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
- 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
- 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
- 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
- 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
- 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
- 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
- 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6  **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable

These bits are set and cleared by software.
- 00: wave generation disabled
- 01: Noise wave generation enabled
- 1x: Triangle wave generation enabled

Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).
Bits 5:2 **TSEL1[3:0]:** DAC channel1 trigger selection
These bits select the external event used to trigger DAC channel1
0000: SWTRIG1
0001: dac_ch1_trg1
0010: dac_ch1_trg2
...
1111: dac_ch1_trg15
Refer to the trigger selection tables in Section 28.4.2: DAC pins and internal signals for details on trigger configuration and mapping.

*Note:* Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bit 1 **TEN1:** DAC channel1 trigger enable
This bit is set and cleared by software to enable/disable DAC channel1 trigger.
0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_hclk clock cycle later to the DAC_DOR1 register
1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_hclk clock cycles later to the DAC_DOR1 register

*Note:* When software trigger is selected, the transfer from the DAC_DHR1 register to the DAC_DOR1 register takes only one dac_hclk clock cycle.

Bit 0 **EN1:** DAC channel1 enable
This bit is set and cleared by software to enable/disable DAC channel1.
0: DAC channel1 disabled
1: DAC channel1 enabled

### 28.7.2 DAC software trigger register (DAC_SWTRGR)

Address offset: 0x04
Reset value: 0x0000 0000
Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger
1: Trigger

*Note*: This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register.

This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 0 **SWTRIG1**: DAC channel1 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger
1: Trigger

*Note*: This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

### 28.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1)

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 DAC1DHRB[7:0]: DAC channel1 8-bit right-aligned data
These bits are written by software. They specify 8-bit data for DAC channel1 when the DAC operates in Double data mode.

Bits 7:0 DAC1DHR[7:0]: DAC channel1 8-bit right-aligned data
These bits are written by software. They specify 8-bit data for DAC channel1.
28.7.6 DAC channel2 12-bit right aligned data holding register (DAC_DHR12R2)

This register is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Address offset: 0x14
Reset value: 0x0000 0000

These bits are read-only, they contain data output for DAC channel2.
28.7.14  DAC status register (DAC_SR)

Address offset: 0x34
Reset value: 0x0000 0000

Bit 31  BWST2: DAC channel2 busy writing sample time flag
This bit is systematically set just after Sample and hold mode enable. It is set each time the software writes the register DAC_SHSR2. It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI/LSE periods of synchronization).
0: There is no write operation of DAC_SHSR2 ongoing: DAC_SHSR2 can be written
1: There is a write operation of DAC_SHSR2 ongoing: DAC_SHSR2 cannot be written

Notes: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 30  CAL_FLAG2: DAC channel2 calibration offset status
This bit is set and cleared by hardware.
0: Calibration trimming value is lower than the offset correction value
1: Calibration trimming value is equal or greater than the offset correction value

Notes: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 29  DMAUDR2: DAC channel2 DMA underrun flag
This bit is set by hardware and cleared by software (by writing it to 1).
0: No DMA underrun error condition occurred for DAC channel2
1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).

Notes: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 28  DORSTAT2: DAC channel2 output register status bit
This bit is set and cleared by hardware. It is applicable only when the DAC operates in Double data mode.
0: DOR[11:0] is used actual DAC output
1: DORB[11:0] is used actual DAC output

Notes: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bit 27  DAC2RDY: DAC channel2 ready status bit
This bit is set and cleared by hardware.
0: DAC channel2 is not yet ready to accept the trigger nor output data
1: DAC channel2 is ready to accept the trigger or output data

Notes: This bit is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

**Bits 15** `BWST1`: DAC channel1 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable and is set each time the software writes the register DAC_SHSR1. It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI/LSE periods of synchronization).

- 0: There is no write operation of DAC_SHSR1 ongoing: DAC_SHSR1 can be written
- 1: There is a write operation of DAC_SHSR1 ongoing: DAC_SHSR1 cannot be written

**Bit 14** `CAL_FLAG1`: DAC channel1 calibration offset status

This bit is set and cleared by hardware.

- 0: Calibration trimming value is lower than the offset correction value
- 1: Calibration trimming value is equal or greater than the offset correction value

**Bit 13** `DMAUDR1`: DAC channel1 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

- 0: No DMA underrun error condition occurred for DAC channel1
- 1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

**Bit 12** `DORSTAT1`: DAC channel1 output register status bit

This bit is set and cleared by hardware. It is applicable only when the DAC operates in Double data mode.

- 0: DOR[11:0] is used actual DAC output
- 1: DORB[11:0] is used actual DAC output

**Bit 11** `DAC1RDY`: DAC channel1 ready status bit

This bit is set and cleared by hardware.

- 0: DAC channel1 is not yet ready to accept the trigger nor output data
- 1: DAC channel1 is ready to accept the trigger or output data

**Bits 10:0** Reserved, must be kept at reset value.

**Bits 31:21** Reserved, must be kept at reset value.

**Bits 20:16** `OTRIM2[4:0]`: DAC channel2 offset trimming value

These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

**Bits 15:5** Reserved, must be kept at reset value.

**Bits 4:0** `OTRIM1[4:0]`: DAC channel1 offset trimming value
28.7.16 DAC mode control register (DAC_MCR)

Address offset: 0x3C
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:26</th>
<th>Reserved, must be kept at reset value.</th>

</tbody>
</table>

Bits 23:19 Reserved, must be kept at reset value.

Bits 18:16 MODE2[2:0]: DAC channel2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2 = 0 and bit CEN2 = 0 in the DAC_CR register). If EN2 = 1 or CEN2 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

- DAC channel2 in Normal mode
  - 000: DAC channel2 is connected to external pin with Buffer enabled
  - 001: Reserved
  - 010: DAC channel2 is connected to external pin with buffer disabled
  - 011: Reserved
- DAC channel2 in Sample and hold mode
  - 100: DAC channel2 is connected to external pin with Buffer enabled
  - 101: Reserved
  - 110: DAC channel2 is connected to external pin with Buffer disabled
  - 111: Reserved

Note: This register can be modified only when EN2 = 0. Refer to Section 28.3: DAC implementation for the availability of DAC channel2.
Bits 15:14 **HFSEL[1:0]**: High frequency interface mode selection
- 00: High frequency interface mode disabled
- 01: High frequency interface mode enabled for AHB clock frequency > 80 MHz
- 10: High frequency interface mode enabled for AHB clock frequency > 160 MHz
- 11: Reserved

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **SINFORMAT1**: Enable signed format for DAC channel1
This bit is set and cleared by software.
0: Input data is in unsigned format
1: Input data is in signed format (2’s complement). The MSB bit represents the sign.

Bit 8 **DMADouble1**: DAC channel1 DMA double data mode
This bit is set and cleared by software.
0: DMA Normal mode selected
1: DMA Double data mode selected

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE[2:0]**: DAC channel1 mode
These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.
They can be set and cleared by software to select the DAC channel1 mode:
- DAC channel1 in Normal mode
  000: DAC channel1 is connected to external pin with Buffer enabled
  001: Reserved
  010: DAC channel1 is connected to external pin with Buffer disabled
  011: Reserved
- DAC channel1 in sample & hold mode
  100: DAC channel1 is connected to external pin with Buffer enabled
  101: Reserved
  110: DAC channel1 is connected to external pin with Buffer disabled
  111: Reserved

Note: This register can be modified only when EN1 = 0.

28.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2)

This register is available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Address offset: 0x44
Reset value: 0x0000 0000

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE1[9:0]**: DAC channel1 sample time (only valid in Sample and hold mode)

These bits can be written when the DAC channel1 is disabled or also during normal operation. in the latter case, the write can be done only when BWST1 of DAC_SR register is low, if BWST1 = 1, the write operation is ignored.

Note: It represents the number of LSI/LSE clocks to perform a sample phase. Sampling time = (TSAMPLE1[9:0] + 1) x LSI/LSE clock period.

28.7.19 DAC sample and hold time register (DAC_SHHR)

Address offset: 0x48
Reset value: 0x0001 0001

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE2[9:0]**: DAC channel2 sample time (only valid in Sample and hold mode)

These bits can be written when the DAC channel2 is disabled or also during normal operation. in the latter case, the write can be done only when BWST2 of DAC_SR register is low, if BWST2 = 1, the write operation is ignored.

Note: It represents the number of LSI/LSE clocks to perform a sample phase. Sampling time = (TSAMPLE1[9:0] + 1) x LSI/LSE clock period.
Bits 31:26  Reserved, must be kept at reset value.

Bits 25:16  **THOLD2[9:0]**: DAC channel2 hold time (only valid in Sample and hold mode).
            Hold time = (THOLD[9:0]) x LSI/LSE clock period
            *Note:* This register can be modified only when EN2 = 0.
            *Note:* These bits are available only on dual-channel DACs. Refer to Section 28.3: DAC implementation.

Bits 15:10  Reserved, must be kept at reset value.

Bits 9:0   **THOLD1[9:0]**: DAC channel1 hold time (only valid in Sample and hold mode)
            Hold time = (THOLD[9:0]) x LSI/LSE clock period
            *Note:* This register can be modified only when EN1 = 0.

*Note:* These bits can be written only when the DAC channel is disabled and in Normal operating mode (when bit ENx = 0 and bit CENx = 0 in the DAC_CR register). If ENx = 1 or CENx = 1 the write operation is ignored.

### 28.7.20 DAC sample and hold refresh time register (DAC_SHRR)

Address offset: 0x4C

Reset value: 0x0001 0001

Table 273. DAC register map and reset values
Refer to *Section 2.3 on page 111* for the register boundary addresses.
29 Voltage reference buffer (VREFBUF)

29.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for ADCs and also as voltage reference for external components through the VREF+ pin.

29.2 VREFBUF implementation

The table below describes the VREFBUF voltages typical values:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>VREFBUF0</td>
<td>2.5 V</td>
</tr>
<tr>
<td>VREFBUF1</td>
<td>2.048 V</td>
</tr>
<tr>
<td>VREFBUF2</td>
<td>1.8 V</td>
</tr>
</tbody>
</table>

Note: Refer to the product datasheet for more details.

29.3 VREFBUF functional description

The internal voltage reference buffer is an operational amplifier, with programmable gain. The amplifier input is connected to the internal voltage reference \( V_{\text{REFINT}} \). The VREFBUF supports four voltages\(^8\), which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: VREFBUF0 voltage selected.
- VRS = 001: VREFBUF1 voltage selected.
- VRS = 010: VREFBUF2 voltage selected.

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:
After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

### 29.4 VREFBUF trimming

The VREFBUF output voltage is factory-calibrated by ST. At reset, and each time the VRS setting is changed, the calibration data is automatically loaded to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits directly. In this case, the VRS setting has no more effect on the TRIM register until the device is reset.

### 29.5 VREFBUF registers

#### 29.5.1 VREFBUF control and status register (VREFBUF_CSR)

Address offset: 0x00
Reset value: 0x0000 0002

<table>
<thead>
<tr>
<th>ENVR</th>
<th>HIZ</th>
<th>VREF buffer configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>VREFBUF buffer off mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– V\textsubscript{REF}+ pin pulled-down to V\textsubscript{SSA}</td>
</tr>
<tr>

</table>
a. The minimum \( V\text{\textsubscript{DDA}} \) voltage depends on VRS setting, refer to the product datasheet.
29.5.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04

Reset value: 0x0000 00XX

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 VRS[2:0]: Voltage reference scale

These bits select the value generated by the voltage reference buffer.

VRS = 000: VREFBUF0 voltage selected.
VRS = 001: VREFBUF1 voltage selected.
VRS = 010: VREFBUF2 voltage selected.
Others: Reserved

Note: Refer to the product datasheet for each VREFBUFx voltage setting value.
The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).

Bit 3 VRR: Voltage reference buffer ready

0: the voltage reference buffer output is not ready.
1: the voltage reference buffer output reached the requested level.

Bit 2 Reserved, must be kept at reset value.

Bit 1 HIZ: High impedance mode

This bit controls the analog switch to connect or not the VREF+ pin.
0: VREF+ pin is internally connected to the voltage reference buffer output.
1: VREF+ pin is high impedance.

Refer to Table 275: VREF buffer modes for the mode descriptions depending on ENVR bit configuration.

Bit 0 ENVR: Voltage reference buffer mode enable

This bit is used to enable the voltage reference buffer mode.
0: Internal voltage reference mode disable (external voltage reference mode).
1: Internal voltage reference mode (reference buffer enable or hold mode) enable.
Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 TRIM[5:0]: Trimming code

The TRIM code is a 6-bit unsigned data (minimum 000000, maximum 111111) that is set and updated according the mechanism described below.

- **Reset:**
  TRIM[5:0] is automatically initialized with the VRS = 0 trimming value stored in the flash memory during the production test.

- **VRS change:**
  TRIM[5:0] is automatically initialized with the trimming value (corresponding to VRS setting) stored in the flash memory during the production test.

- **Write in TRIM[5:0]:**
  User can modify the TRIM[5:0] with an arbitrary value. This is permanently disabling the control of the trimming value with VRS (until the device is reset).

*Note:* If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

### 29.5.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|---------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| 0x00   | VREFBUF_CSR   | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             |
|        | Reset value   | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 1             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             |
| 0x04   | VREFBUF_CCR   | TRIM[5:0]     | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             |
|        | Reset value   | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             | x             |

Refer to Section 2.3 for the register boundary addresses.
30 Digital camera interface (DCMI)

30.1 Introduction

The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

30.2 DCMI main features

- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw Bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

30.3 DCMI functional description

The digital camera interface is a synchronous parallel interface that can receive high-speed data flows. It consists of up to 14 data lines (DCMI_D[13:0]) and a pixel clock line (DCMI_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI_CR register) must be set.

The data flow is synchronized either by hardware using the optional DCMI_HSYNC (horizontal synchronization) and DCMI_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.
30.3.1 DCMI block diagram

*Figure 273* shows the DCMI block diagram.

<tr>
<td>dcmi_it</td>
<td>Output</td>
<td>DCMI interrupt request</td>
</tr>
<tr>
<td>dcmi_hclk</td>
<td>Input</td>
<td>DCMI interface clock</td>
</tr>
</tbody>
</table>
30.3.3 DCMI clocks

The digital camera interface uses two clock domains, DCMI_PIXCLK and HCLK. The signals generated with DCMI_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The maximum DCMI_PIXCLK period must be higher than 2.5 HCLK periods.

30.3.4 DCMI DMA interface

The DMA interface is active when the CAPTURE bit of the DCMI_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

30.3.5 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits of the DCMI_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.

DCMI pins are shown in Table 277.

The data are synchronous with DCMI_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI_HSYNC signal indicates the start/end of a line.

The DCMI_VSYNC signal indicates the start/end of a frame.

**Figure 274. DCMI signal waveforms**

![DCMI signal waveforms](ai15606c)

1. The capture edge of DCMI_PIXCLK is the falling edge, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.

2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

8-bit data

When EDM[1:0] = 00 in DCMI_CR the interface captures 8 LSBs at its input (DCMI_D[7:0]) and stores them as 8-bit data. The DCMI_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4th captured data byte is placed in the MSB position in the 32-bit word. The table below gives an example of the positioning of captured data bytes in two 32-bit words.
10-bit data

When EDM[1:0] = 01 in DCMI_CR, the camera interface captures 10-bit data at its input DCMI_D[9:0] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits of the DCMI_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

| Table 279. Positioning of captured data bytes in 32-bit words (8-bit width) |
|------------------|------------------|------------------|------------------|------------------|
| Byte address    | 31:24            | 23:16            | 15:8             | 7:0              |
| 0               | D_{n+3}[7:0]     | D_{n+2}[7:0]     | D_{n+1}[7:0]     | D_{n}[7:0]       |
| 4               | D_{n+7}[7:0]     | D_{n+6}[7:0]     | D_{n+5}[7:0]     | D_{n+4}[7:0]     |

12-bit data

When EDM[1:0] = 10 in DCMI_CR, the camera interface captures the 12-bit data at its input DCMI_D[11:0] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

| Table 280. Positioning of captured data bytes in 32-bit words (10-bit width) |
|------------------|------------------|------------------|------------------|------------------|
| Byte address    | 31:26            | 25:16            | 15:10            | 9:0              |
| 0               | 0                | D_{n+1}[9:0]     | 0                | D_{n}[9:0]       |
| 4               | 0                | D_{n+3}[9:0]     | 0                | D_{n+2}[9:0]     |

14-bit data

When EDM[1:0] = 11 in DCMI_CR, the camera interface captures the 14-bit data at its input DCMI_D[13:0] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

| Table 281. Positioning of captured data bytes in 32-bit words (12-bit width) |
|------------------|------------------|------------------|------------------|------------------|
| Byte address    | 31:28            | 27:16            | 15:12            | 11:0             |
| 0               | 0                | D_{n+1}[11:0]    | 0                | D_{n}[11:0]      |
| 4               | 0                | D_{n+3}[11:0]    | 0                | D_{n+2}[11:0]    |
30.3.6 DCMI synchronization

The digital camera interface supports embedded or hardware (DCMI_HSYNC and DCMI_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI_CR register, the EDM[1:0] bits must be cleared).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI_VSYNC is used as a start/end of the image, and DCMI_HSYNC is used as a Data Valid signal. Figure 275 shows the corresponding timing diagram.

Figure 275. Timing diagram

Hardware synchronization mode

In hardware synchronization mode, the two synchronization signals (DCMI_HSYNC/DCMI_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI_HSYNC/DCMI_VSYNC signals act like blanking signals since all the data received during DCMI_HSYNC/DCMI_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI_VSYNC signal. When the hardware synchronization mode is selected, and...
capture is enabled (CAPTURE bit set in DCMI_CR), data transfer is synchronized with the deactivation of the DCMI_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive buffers or the same/circular buffer. To allow the DMA management of successive frames, a VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

**Embedded data synchronization mode**

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in the data flow. These codes use the 0x00/0xFF values that are not used in data anymore. There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization codes are supported only in 8-bit parallel data width capture (in the DCMI_CR register, the EDM[1:0] bits must be cleared). For other data widths, this mode generates unpredictable results and must not be used.

*Note: Camera modules can have 8 such codes (in interleaved mode). For this reason, the interleaved mode is not supported by the camera interface (otherwise, every other half-frame would be discarded).*

- **Mode 2**
  - Four embedded codes signal the following events
    - Frame start (FS)
    - Frame end (FE)
    - Line start (LS)
    - Line end (LE)

  The XY values in the 0xFF0000XY format of the four codes are programmable (see Section 30.5.7: DCMI embedded synchronization code register (DCMI_ESCR)).

  A 0xFF value programmed as a "frame end" means that all the unused codes are interpreted as valid frame end codes.

  In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.

- **Mode 1**
  - An alternative coding is the camera mode 1. This mode is ITU656 compatible.

    The codes signal another set of events:
    - SAV (active line) - line start
    - EAV (active line) - line end
    - SAV (blanking) - end of line during interframe blanking period
    - EAV (blanking) - end of line during interframe blanking period

    This mode can be supported by programming the following codes:
    - FS ≤ 0xFF
    - FE ≤ 0xFF
    - LS ≤ SAV (active)
    - LE ≤ EAV (active)

    An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. A bit can therefore be selected to compare in the embedded code and
detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

**Example**

FS = 0xA5

Unmask code for FS = 0x10

In this case the frame start code is embedded in the bit 4 of the frame start code.

### 30.3.7 DCMI capture modes

This interface supports two types of capture: snapshot (single frame) and continuous grab.

**Snapshot mode (single frame)**

In this mode, a single frame is captured (CM = 1 of the DCMI_CR register). After the CAPTURE bit is set in DCMI_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI_CR) after receiving the first complete frame. An interrupt is generated (IT_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

![Figure 276. Frame capture waveforms in snapshot mode](image)

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

**Continuous grab mode**

In this mode (CM bit = 0 in DCMI_CR), once the CAPTURE bit has been set in DCMI_CR, the grabbing process starts on the next DCMI_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.
1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.

2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

In continuous grab mode, the FCRC[1:0] bits in DCMI_CR can be configured to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

**Note:** *In the hardware synchronization mode (ESS = 0 in DCMI_CR), the IT_VSYNC interrupt is generated (if enabled) even when CAPTURE = 0 in DCMI_CR so, to reduce the frame capture rate even further, the IT_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.*

### 30.3.8 DCMI crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI_CWSTRT and DCMI_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

**Figure 278. Coordinates and size of the window after cropping**

These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.
If the DCMI_VSYNC signal goes active before the number of lines is specified in the DCMI_CWSIZE register, then the capture stops and an IT_FRAME interrupt is generated when enabled.

**Figure 279. Data capture waveforms**

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

### 30.3.9 DCMI JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit of the DCMI_CR register. JPEG images are not stored as lines and frames, so the DCMI_VSYNC signal is used to start the capture while DCMI_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4. This case must be carefully handled since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with zeros and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in JPEG format.

### 30.3.10 DCMI FIFO

A 8-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.
30.3.11 DCMI data format description

Data formats

Three types of data are supported:

- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred.

Compressed data: JPEG

For B&W (black and white), YCbCr or RGB data, the maximum input size is 2048 × 2048 pixels. No limit in JPEG compressed mode.

For monochrome, RGB and YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little-endian format is supported.

![Figure 280. Pixel raster scan order](image)

Monochrome format

Characteristics:

- Raster format
- 8 bits per pixel

The table below shows how the data are stored.

| Table 283. Data storage in monochrome progressive video format |
|---|---|---|---|---|
| Byte address | 31:24 | 23:16 | 15:8 | 7:0 |
| 0 | n + 3 | n + 2 | n + 1 | n |
| 4 | n + 7 | n + 6 | n + 5 | n + 4 |

RGB format

Characteristics:

- Raster format
- RGB
- Interleaved: one buffer: R, G and B interleaved (such as BRGBRGBRG)
- Optimized for display output
The RGB planar format is compatible with standard OS frame buffer display formats. Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and gray-scale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

The table below shows how the data are stored.

**Table 284. Data storage in RGB progressive video format**

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:27</th>
<th>26:21</th>
<th>20:16</th>
<th>15:11</th>
<th>10:5</th>
<th>4:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Red n + 1</td>
<td>Green n + 1</td>
<td>Blue n + 1</td>
<td>Red n</td>
<td>Green n</td>
<td>Blue n</td>
</tr>
<tr>
<td>4</td>
<td>Red n + 4</td>
<td>Green n + 3</td>
<td>Blue n + 3</td>
<td>Red n + 2</td>
<td>Green n + 2</td>
<td>Blue n + 2</td>
</tr>
</tbody>
</table>

**YCbCr format**

Characteristics:
- Raster format
- YCbCr 4:2:2
- Interleaved: one buffer: Y, Cb and Cr interleaved (such as CbYCrYCbYCr)

Pixel components are Y (luminance or "luma"), Cb and Cr (chrominance or "chroma" blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in the table below.

**Table 285. Data storage in YCbCr progressive video format**

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Y n + 1</td>
<td>Cr n</td>
<td>Y n</td>
<td>Cb n</td>
</tr>
<tr>
<td>4</td>
<td>Y n + 3</td>
<td>Cr n + 2</td>
<td>Y n + 2</td>
<td>Cb n + 2</td>
</tr>
</tbody>
</table>

**YCbCr format - Y only**

Characteristics:
- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or "luma"), Cb and Cr (chrominance or "chroma" blue and red). In this mode, the chroma information is dropped. Only the luma component of each pixel, encoded in 8 bits, is stored as shown in Table 286.

The result is a monochrome image having the same resolution as the original YCbCr data.
Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode is used to only store a half resolution image. It is selected through OELS and LSM control bits.

### 30.4 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (dcmi_it) is the OR of all the individual interrupts. The table below gives the list of all interrupts.

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 OELS: Odd/Even Line Select (Line Select Start)
This bit works in conjunction with the LSM field (LSM = 1).
0: Interface captures first line after the frame start, second one being dropped.
1: Interface captures second line from the frame start, first one being dropped.

Bit 19 LSM: Line Select mode
0: Interface captures all received lines.
1: Interface captures one line out of two.

Bit 18 OEBS: Odd/Even Byte Select (Byte Select Start)
This bit works in conjunction with BSM field (BSM ≠ 00).
0: Interface captures first data (byte or double byte) from the frame/line start, second one being dropped.
1: Interface captures second data (byte or double byte) from the frame/line start, first one being dropped.

Bits 17:16 BSM[1:0]: Byte Select mode
00: Interface captures all received data.
01: Interface captures every other byte from the received data.
10: Interface captures one byte out of four.
11: Interface captures two bytes out of four.

Note: This mode only works for EDM[1:0] = 00. For all other EDM values, this field must be programmed to the reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 ENABLE: DCMI enable
0: DCMI disabled
1: DCMI enabled

Note: The DCMI configuration registers must be programmed correctly before enabling this bit.

Bits 13:12 Reserved, must be kept at reset value.
Bits 11:10 **EDM[1:0]**: Extended data mode
00: Interface captures 8-bit data on every pixel clock.
01: Interface captures 10-bit data on every pixel clock.
10: Interface captures 12-bit data on every pixel clock.
11: Interface captures 14-bit data on every pixel clock.

Bits 9:8 **FCRC[1:0]**: Frame capture rate control
These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.
00: All frames are captured.
01: Every alternate frame captured (50% bandwidth reduction)
10: One frame out of four captured (75% bandwidth reduction)
11: reserved

Bit 7 **VSPOL**: Vertical synchronization polarity
This bit indicates the level on the DCMI_VSYNC pin when the data are not valid on the parallel interface.
0: DCMI_VSYNC active low
1: DCMI_VSYNC active high

Bit 6 **HSPOL**: Horizontal synchronization polarity
This bit indicates the level on the DCMI_HSYNC pin when the data are not valid on the parallel interface.
0: DCMI_HSYNC active low
1: DCMI_HSYNC active high

Bit 5 **PCKPOL**: Pixel clock polarity
This bit configures the capture edge of the pixel clock.
0: Falling edge active
1: Rising edge active

Bit 4 **ESS**: Embedded synchronization select
0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the DCMI_HSYNC/DCMI_VSYNC signals.
1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.
*Note*: Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set. This bit is disabled in JPEG mode.

Bit 3 **JPEG**: JPEG format
0: Uncompressed video format
1: This bit is used for JPEG data transfers. The DCMI_HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bit 2 **CROP**: Crop feature
0: The full image is captured. In this case the total number of bytes in an image frame must be a multiple of four.
1: Only the data inside the window specified by the crop register is captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

Bit 1 **CM**: Capture mode
0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.
1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.
Bit 0  **CAPTURE**: Capture enable
   0: Capture disabled
   1: Capture enabled
The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.
In snapshot mode, the CAPTURE bit is automatically cleared at the end of the first frame received.
In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit is effectively cleared after the frame end.
*Note*: The DMA controller and all DCMI configuration registers must be programmed correctly before enabling this bit.

### 30.5.2  DCMI status register (DCMI_SR)

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  **FNE**: FIFO not empty
   This bit gives the status of the FIFO.
   1: FIFO contains valid data.
   0: FIFO empty

Bit 1  **VSYNC**: Vertical synchronization
   This bit gives the state of the DCMI_VSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
   0: active frame
   1: synchronization between frames
   In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

Bit 0  **HSYNC**: Horizontal synchronization
   This bit gives the state of the DCMI_HSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
   0: active line
   1: synchronization between lines
   In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.
30.5.3 DCMI raw interrupt status register (DCMI_RIS)

DCMI_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI_IER register value.

Address offset: 0x08

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

**Bit 4** **LINE_IE**: Line interrupt enable  
0: No interrupt generation when the line is received  
1: An interrupt is generated when a line has been completely received.

**Bit 3** **VSYNC_IE**: DCMI_VSYNC interrupt enable  
0: No interrupt generation  
1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state.  
The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

**Bit 2** **ERR_IE**: Synchronization error interrupt enable  
0: No interrupt generation  
1: An interrupt is generated if the embedded synchronization codes are not received in the correct order.  
*Note:* This bit is available only in embedded synchronization mode.

**Bit 1** **OVR_IE**: Overrun interrupt enable  
0: No interrupt generation  
1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received.

**Bit 0** **FRAME_IE**: Capture complete interrupt enable  
0: No interrupt generation  
1: An interrupt is generated at the end of each received frame/crop window (in crop mode).
### 30.5.5 DCMI masked interrupt status register (DCMI_MIS)

This DCMI_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI_IER is set and the corresponding bit in DCMI_RIS is set.

Note: The bit fields are defined as read-write (rw) or read-only (ro) depending on the register state.

STMicroelectronics
Bits 31:24 **FEC[7:0]**: Frame end delimiter code

This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.

If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code

This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code

This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code

This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.

If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the first occurrence of LSC after an FEC code is interpreted as a start of frame delimiter.

Refer to Section 2.3 for the register boundary addresses.
31 Parallel synchronous slave interface (PSSI)

The PSSI peripheral and the DCMI (digital camera interface) use the same circuitry. As a result, these two peripherals cannot be used at the same time: when using the PSSI, the DCMI registers cannot be accessed, and vice-versa.

In addition, the PSSI and the DCMI share the same alternate functions and interrupt vector (see Section 31.3.2: PSSI pins and internal signals).

31.1 Introduction

The PSSI is a generic synchronous 8/16-bit parallel data input/output slave interface. It enables the transmitter to send a data valid signal that indicates when the data is valid, and the receiver to output a flow control signal that indicates when it is ready to sample the data.

31.2 PSSI main features

The PSSI peripheral main features are the following:

- Slave mode operation
- 8-bit or 16-bit parallel data input or output
- 8-word (32-byte) FIFO
- Data enable (PSSI_DE) alternate function input and Ready (PSSI_RDY) alternate function output
  
  When selected, these signals can either enable the transmitter to indicate when the data is valid, allow the receiver to indicate when it is ready to sample the data, or both.

31.3 PSSI functional description

The PSSI is a synchronous parallel slave interface that can send or receive high-speed data flows. It consists of up to 16 data lines (PSSI_D[15:0]) plus a clock line (PSSI_PDCK). The clock polarity can be configured so that data can be captured or transmitted on either the clock rising or falling edge.

Usually, a general-purpose DMA channel is used to pass 32-bit packed data via the data register (PSSI_DR).

The data flow can either be continuous or synchronized by hardware using the optional PSSI_DE (Data enable), and PSSI_RDY (Ready) signals.

*Figure 281* shows the PSSI block diagram.
31.3.1 PSSI block diagram

![Figure 281. PSSI block diagram](MSv48844V3)

![Figure 282. Top-level block diagram](MSv48845V4)

31.3.2 PSSI pins and internal signals

The PSSI interface is composed of 19 pins, though nine signals are enough to transfer parallel data. Table 289 shows the PSSI pins.

When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, the alternate functions and the interrupt vector are associated with the PSSI. Otherwise, they are associated with the DCMI. The DCMI ENABLE bit (bit 15 of DCMI_CR) and the PSSI ENABLE bit (bit 14 of PSSI_CR) must not be set to 1 at the same time. As an example, if a GPIO is configured to use the alternate function PSSI_PDCK/DCMI_PIXCK, it is the PSSI_PDCK function which becomes active if PSSI_CR/ENABLE is set to 1.
### 31.3.3 PSSI clock

The AHB clock frequency must be at least 2.5 times higher than the PSSI_PDCK frequency. At frequency ratios lower than 2.5, data might be corrupted or lost during transfers.

Data transfers are synchronous with PSSI_PDCK. The PSSI_PDCK polarity can be configured as follows, through CKPOL bit (bit 5 of PSSI_CR):

- When CKPOL = 0
  - Input pins are sampled on PSSI_PDCK falling edge
  - Output pins are driven on PSSI_PDCK rising edge
- When CKPOL = 1
  - Input pins are sampled on PSSI_PDCK rising edge
  - Output pins are driven on PSSI_PDCK falling edge

### 31.3.4 PSSI data management

#### Data direction

The direction of data transfers is configured through the OUTEN control bit (bit 31 of PSSI_CR):

- When OUTEN is cleared to 0 (default setting), the PSSI operates in receive mode and the data is input on the data pins.
- When OUTEN is set to 1, the peripheral operates in transmit mode and the data is output on the data pins.

OUTEN can be modified only when the ENABLE bit is cleared to 0.
Data register and DMA

Data are transferred from/to the FIFO using the PSSI_DR data register:
- In receive mode, data must be read from the FIFO by reading PSSI_DR.
- In transmit mode, data must be written to the FIFO by writing into PSSI_DR.

Word (32-bit) accesses to PSSI_DR and half-word (16-bit) accesses to PSSI_DR[15:0] are permitted in all modes. Byte (8-bit) accesses to PSSI_DR[7:0] are permitted only when the PSSI is configured to transfer 8 bits at a time (EDM=00 in the PSSI_CR register).

To reduce the load on the CPU, it is recommended to use the DMA to transfer data from/to the PSSI FIFO. When it is used, the DMA must be configured to transfer data via the PSSI_DR register. Using 32-bit transfers optimizes bandwidth and reduces the bus load. However, 8-bit and 16-bit transfers are also permitted.

To use the DMA, set the PSSI DMA enable bit (DMAEN in PSSI_CR) to 1 (default setting). When DMAEN is set to 1, a DMA transfer is initiated when the FIFO is ready for a 32-bit transfer (four valid bytes in receive mode or four empty bytes in transmit mode). As a result, in receive mode, no DMA transfers are initiated if there are three bytes or fewer in the FIFO, even if the DMA is configured to perform 8-bit transfers.

The RTT4B and RTT1B status bits (PSSI_SR) are useful when the CPU directly performs transfers to and from the FIFO. RTT4B set to 1 indicates that the FIFO is ready to transfer four bytes: at least four valid bytes in the FIFO in receive mode or at least four free bytes in transmit mode. RTT1B set to 1 indicates that the FIFO is ready to transfer one byte: at least one valid byte in the FIFO in receive mode or at least one free byte in transmit mode.

8-bit data

The PSSI parallel interface can transfer either 8-bit (using D[7:0]) or 16-bit data (using D[15:0]) depending on the EDM[1:0] control bits (bits 11:10 of PSSI_CR). If the 8-bit configuration is selected (EDM[1:0] set to 00), the unused D[15:0] pins can be used for GPIO or other functions.

When EDM[1:0] in PSSI_CR are programmed to 00, the interface transfers 8 bits using the D[7:0] pins. In this case, D[15:8] are not used and four PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant byte (bits 7:0) correspond to the first byte transferred, and the most-significant byte (bits 31:24) corresponds to the forth byte transferred. Table 291 illustrates the positioning of the data bytes in two 32-bit words.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>D_{n+3}[7:0]</td>
<td>D_{n+2}[7:0]</td>
<td>D_{n+1}[7:0]</td>
<td>D_{n}[7:0]</td>
</tr>
<tr>
<td>4</td>
<td>D_{n+7}[7:0]</td>
<td>D_{n+6}[7:0]</td>
<td>D_{n+5}[7:0]</td>
<td>D_{n+4}[7:0]</td>
</tr>
</tbody>
</table>
16-bit data
When EDM[1:0] in PSSI_CR are programmed to 11, the interface transfers 16 bits using the D[15:0] pins. In this case, two PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant half word (bits 15:0) correspond to the first half word transferred, and the most-significant half-word (bits 31:16) corresponds to the second half word transferred. Table 292 illustrates the positioning of the data in two 32-bit words.

FIFO data buffer and error conditions
An eight-word FIFO helps improving performance and avoids overruns and underruns.

If the ready signal (PSSI_RDY) is disabled in receive mode, an overrun error is generated when a clock active edge occurs when the FIFO is full. In this case, the input data is lost.

If the data enable signal (PSSI_DE) is disabled in transmit mode, an underrun error is generated when a clock active edge occurs when the FIFO is empty. In this case, unpredictable data are output.

The OVR_RIS status bit indicates that either an overrun or an underrun occurred. An interrupt can be generated when these events occur.

31.3.5 PSSI optional control signals

Data Enable (PSSI_DE) alternate function input
The data enable signal, PSSI_DE, is an optional signal. It is driven by the data source/transmitter in order to indicate that the data is valid to be transferred during the current cycle. When PSSI_DE is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG (bits 20:18 of PSSI_CR) control bits. PSSI_DE polarity is configured through DEPOL control bit (bit 6 of PSSI_CR). PSSI_DE is active low when DEPOL is cleared to 0, and high when DEPOL is set to 1.

The direction of the PSSI_DE signal is defined by the OUTEN value. It is the same as the data direction.

If the PSSI_DE alternate function input is enabled (through DERDYCFG) in receive mode (OUTEN cleared to 0), the PSSI samples PSSI_DE on the same PSSI_PDCK edge as the one used for sampling the data (D[15:0]). If PSSI_DE is active, the sampled data is saved in the FIFO. Otherwise, the sampled data is considered invalid and discarded. The transmitting device can use PSSI_DE as a data valid signal, driving it inactive when the data in the current cycle is not valid. This flow control function allows avoiding underrun errors.
If the PSSI_DE alternate output function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI drives PSSI_DE on the same PSSI_PDCK edge that the one used to drive the data (D[15:0]). If a new 8 or 16-bit data (as programmed in the EDM[1:0] control bits in PSSI_CR) is available for transmission in the internal FIFO, this data is output on the data outputs (D[15:0]) and the PSSI_DE output becomes active on the current PSSI_PDCK edge. Otherwise (if the TX FIFO is empty), the D[15:0] outputs remains unchanged on the next clock edge and the PSSI_DE output becomes inactive.

**Figure 284. Data enable waveform diagram in transmit mode (CKPOL=0)**

If the PSSI_RDY alternate output function is enabled (through DERDYCFG) in receive mode (OUTEN=0), the PSSI drives PSSI_RDY one PSSI_PDCK half cycle after it samples.

**Ready (PSSI_RDY) alternate function output**

The ready signal, PSSI_RDY, is an optional signal. It is driven by the receiving device and indicates whether data is being accepted in the current cycle. When PSSI_RDY is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG control bits (bits 20:18 of PSSI_CR). PSSI_RDY polarity is configured through the RDYPOL control bit (bit 6 of PSSI_CR). PSSI_RDY is active low when RDYPOL is cleared to 0, and high when RDYPOL set to 1.

The direction of the PSSI_RDY signal is defined by the OUTEN (bit 31 of PSSI_CR). It is set in the opposite direction compared to the PSSI_DE and data signals.

If the PSSI_RDY alternate output function is enabled (through DERDYCFG) in receive mode (OUTEN=0), the PSSI drives PSSI_RDY one PSSI_PDCK half cycle after it samples.
the data \((D[15:0])\). If the FIFO has enough free space to receive more data, the PSSI drives
the PSSI\_RDY signal active. Otherwise, if the FIFO is full and cannot accept more data, the
PSSI drives the PSSI\_RDY signal inactive. The transmitting device must repeat the current
data in the next cycle when it detects that PSSI\_RDY is inactive. This flow control function
allows the PSSI to avoid overrun errors when the system (via the DMA) is unable to keep up
with the data flow.

**Figure 285. Ready in receive mode waveform diagram (CKPOL=0)**

![Waveform Diagram](MSv48848V2)

If the PSSI\_RDY alternate input function is enabled (through DERDYCFG) in transmit mode
\((OUTEN=1)\), the PSSI samples the PSSI\_RDY signal on the opposite PSSI\_PDCK edge to
the one at which \(D[15:0]\) are driven. If the PSSI\_RDY signal is inactive, the PSSI keeps the
same data \((D[15:0])\) and PSSI\_DE signals that valid data are available during the next
PSSI\_PDCK clock cycle. Otherwise, if PSSI\_RDY signal is sampled as active, the next data
from the TX FIFO (if available) is output on the data outputs \((D[15:0])\). If no new data are
available in the TX FIFO, the PSSI keeps the data output values and outputs the PSSI\_DE
signal as inactive (if enabled).

The receiving device uses the PSSI\_RDY to control the data flow and avoid overrun errors
when the system (via the DMA) is unable to keep up with the data flow.

**Bidirectional PSSI\_DE/PSSI\_RDY signal**

A single pin can be used for both data enable (PSSI\_DE) and ready (PSSI\_RDY) functions
if DEPOL and RDYPOL are both set to 1 and DERDYCFG is set to 111 or 100 in the
PSSI\_CR register. In this case, the GPIO corresponding to selected alternate function
(PSSI\_DE when DERDYCFG=111 or PSSI\_RDY when DERDYCFG=100) must be
configured as open-drain. The other device must also be configured to drive the line as
open-drain, and a weak pull-up must be applied to the line.

The signal thus becomes bidirectional. If either the sender drives the line low (to indicate
that the data is not valid) or the receiver drives the line low (to indicate that it is not sampling
the current data), then both devices know that the data is not being transferred in the current
cycle.
31.4 PSSI interrupts

The PSSI generates only one interrupt (IT_OVR). It is consequently equivalent to the global interrupt (pssi_it). Refer to Table 293 for the list of interrupts.

The PSSI and the DCMI share the same interrupt vector. When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, these interrupts are triggered by the PSSI. Otherwise, they are controlled by the DCMI.

The DCMI ENABLE bit (bit 14 of DCMI_CR) and PSSI ENABLE bit must not be set to 1 at the same time.

31.5 PSSI registers

An 8-bit write or a 16-bit write operation to any PSSI register besides PSSI_DR, results in a bus error. 32-bit read and write operations are permitted.

31.5.1 PSSI control register (PSSI_CR)

Address offset: 0x00
Reset value: 0x4000 0000

</tr>
</tbody>
</table>

Bit 31 OUTEN: Data direction selection bit
0: Receive mode: data is input synchronously with PSSI_PDCK
1: Transmit mode: data is output synchronously with PSSI_PDCK

Bit 30 DMAEN: DMA enable bit
0: DMA transfers are disabled. The user application can directly access the PSSI_DR register when DMA transfers are disabled.
1: DMA transfers are enabled (default configuration). A DMA channel in the general-purpose DMA controller must be configured to perform transfers from/to PSSI_DR.

Bits 29:21 Reserved, must be kept at reset value.

Bits 20:18 DERDYCFG[2:0]: Data enable and ready configuration
000: PSSI_DE and PSSI_RDY both disabled
001: Only PSSI_RDY enabled
010: Only PSSI_DE enabled
011: Both PSSI_RDY and PSSI_DE alternate functions enabled
100: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_RDY pin (see Bidirectional PSSI_DE/PSSI_RDY signal on page 1225)
101: Only PSSI_RDY function enabled, but mapped to PSSI_DE pin
110: Only PSSI_DE function enabled, but mapped to PSSI_RDY pin
111: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_DE pin (see Bidirectional PSSI_DE/PSSI_RDY signal on page 1225)

When the PSSI_RDY function is mapped to the PSSI_DE pin (settings 101 or 111), it is still the RDYPOL bit which determines its polarity. Similarly, when the PSSI_DE function is mapped to the PSSI_RDY pin (settings 110 or 111), it is still the DEPOL bit which determines its polarity.

Bits 17:15 Reserved, must be kept at reset value.
31.5.2 PSSI status register (PSSI_SR)

Bit 14 ENABLE: PSSI enable
0: PSSI disabled
1: PSSI enabled
The contents of the FIFO are flushed when ENABLE is cleared to 0.

Note: When ENABLE=1, the content of PSSI_CR must not be changed, except for the ENABLE bit itself. All configuration bits can change as soon as ENABLE changes from 0 to 1.
The DMA controller and all PSSI configuration registers must be programmed correctly before setting the ENABLE bit to 1.
The ENABLE bit and the DCMI ENABLE bit (bit 15 of DCMI_CR) must not be set to 1 at the same time.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 EDM[1:0]: Extended data mode
00: Interface captures 8-bit data on every parallel data clock
01: Reserved, must not be selected
10: Reserved, must not be selected
11: The interface captures 16-bit data on every parallel data clock

Bits 9 Reserved, must be kept at reset value.

Bit 8 RDYPOL: Ready (PSSI_RDY) polarity
This bit indicates the level on the PSSI_RDY pin when the data are not valid on the parallel interface.
0: PSSI_RDY active low (0 indicates that the receiver is ready to receive)
1: PSSI_RDY active high (1 indicates that the receiver is ready to receive)

Bits 7 Reserved, must be kept at reset value.

Bit 6 DEPOL: Data enable (PSSI_DE) polarity
This bit indicates the level on the PSSI_DE pin when the data are not valid on the parallel interface.
0: PSSI_DE active low (0 indicates that data is valid)
1: PSSI_DE active high (1 indicates that data is valid)

Bit 5 CKPOL: Parallel data clock polarity
This bit configures the capture edge of the parallel clock or the edge used for driving outputs, depending on OUTEN.
0: Falling edge active for inputs or rising edge active for outputs
1: Rising edge active for inputs or falling edge active for outputs.

Bits 4:0 Reserved, must be kept at reset value.
31.5.3 PSSI raw interrupt status register (PSSI_RIS)

Address offset: 0x08
Reset value: 0x0000 0000

PSSI_RIS gives the raw interrupt status. This register is read-only. When read, it returns the status of the corresponding interrupt before masking with the PSSI_IER register value.

| Bits 31:2 | Reserved, must be kept at reset value. |
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|           r               |

Bit 3 RTT1B: FIFO is ready to transfer one byte
1: FIFO is ready for a one byte (32-bit) transfer. In receive mode, this means that at least one valid data byte is in the FIFO. In transmit mode, this means that there is at least one byte free in the FIFO.
0: FIFO is not ready for a 1-byte transfer

Bit 2 RTT4B: FIFO is ready to transfer four bytes
1: FIFO is ready for a four-byte (32-bit) transfer. In receive mode, this means that at least four valid data bytes are in the FIFO. In transmit mode, this means that there are at least four bytes free in the FIFO.
0: FIFO is not ready for a four-byte transfer

Bits 1:0 Reserved, must be kept at reset value.
### 31.5.4 PSSI interrupt enable register (PSSI_IER)

Address offset: 0x0C  
Reset value: 0x0000 0000

The PSSI_IER register is used to enable interrupts. When one of the PSSI_IER bits is set, the corresponding interrupt is enabled. This register is accessible both in read and write modes.

<table>
<thead>
<tr>
<th>Address offset</th>
<th>Reset value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0C</td>
<td>0x0000 0000</td>
<td>PSSI_IER register</td>
</tr>
</tbody>
</table>

#### Bits 31:2

- **Bit 0** Reserved, must be kept at reset value.
- **Bit 1** OVR_IE: Data buffer overrun/underrun interrupt enable  
  0: No interrupt generation  
  1: An interrupt is generated if either an overrun or an underrun error occurred.

#### Bits 15:2

- **Bit 1** OVR_MIS: Data buffer overrun/underrun masked interrupt status  
  This bit is set to 1 only when PSSI_IER/OVR_IE and PSSI_RIS/OVR_RIS are both set to 1.  
  0: No interrupt is generated when an overrun/underrun error occurs  
  1: An interrupt is generated if there is either an overrun or an underrun error and the OVR_IE bit is set in PSSI_IER.

- **Bit 0** Reserved, must be kept at reset value.

---

### 31.5.5 PSSI masked interrupt status register (PSSI_MIS)

This PSSI_MIS register is read-only. When read, it returns the current masked status value of the corresponding interrupt (depending on the value in PSSI_IER). A bit in this register is set if the corresponding enable bit in PSSI_IER is set and the corresponding bit in PSSI_RIS is set.

Address offset: 0x10  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset</th>
<th>Reset value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x10</td>
<td>0x0000 0000</td>
<td>PSSI_MIS register</td>
</tr>
</tbody>
</table>

#### Bits 31:2

- **Bit 0** Reserved, must be kept at reset value.
- **Bit 1** OVR_MIS: Data buffer overrun/underrun masked interrupt status  
  This bit is set to 1 only when PSSI_IER/OVR_IE and PSSI_RIS/OVR_RIS are both set to 1.  
  0: No interrupt is generated when an overrun/underrun error occurs  
  1: An interrupt is generated if there is either an overrun or an underrun error and the OVR_IE bit is set in PSSI_IER.

- **Bit 0** Reserved, must be kept at reset value.
31.5.6 PSSI interrupt clear register (PSSI_ICR)

Address offset: 0x14
Reset value: 0x0000 0000

The PSSI_ICR register is write-only. Writing a 1 into a bit of this register clears the corresponding bit in the PSSI_RIS and PSSI_MIS registers. Writing a 0 has no effect. Reading this register always gives zeros.

31.5.7 PSSI data register (PSSI_DR)

Address offset: 0x28
Reset value: 0x0000 0000

In receive mode (OUTEN = 0), the DMA controller must read the received data from this register. Write operations to PSSI_DR result in an error response. When more bytes than the number of valid bytes are read in the FIFO, the invalid bytes return zeros.

In transmit mode (OUTEN = 1), the DMA controller must write the data to be transmitted into this register. Read operations to PSSI_DR result in an error response.

32-bit, 16-bit, and 8-bit accesses are all supported for PSSI_DR. For instance, 16-bit read/write operations remove/add two bytes from/to the FIFO. However, 8-bit accesses are permitted only when the PSSI is configured to transfer 8 data bits at a time (EDM=00 in PSSI_CR). 8-bit accesses to PSSI_DR when EDM is not set to 0 result in an error response.

All accesses must include byte 0: 8-bit accesses must be performed to bits 7 to 0 and 16-bit accesses from bits 15 to 0. Accesses that do not include byte 0 results in an error response.

Accessing PSSI_DR when ENABLE bit in PSSI_CR is set to 0 results in an error response.
31.5.8 PSSI register map

| Offset | Register name reset value | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|--------------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | PSSI_CR                  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | OUTEN                    | 0  | 1  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | DMAEN                    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | DERDCFG                  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | ENABLE[2:0]              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | EDM                      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | RDYPOL                   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | DEPOL                    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | OPOL                     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x04   | PSSI_SR                  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        |                          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x08   | PSSI_RIS                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        |                          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Refer to Section 2.3 for the register boundary addresses.
32 True random number generator (RNG)

32.1 Introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG is a NIST SP 800-90B compliant entropy source that can be used to construct a nondeterministic random bit generator (NDRBG).

The RNG true random number generator has been precertified NIST SP800-90B. It has also been tested using the German BSI statistical tests of AIS-31 (T0 to T8).

32.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source conditioned by a NIST SP800-90B approved conditioning stage.
- It can be used as the entropy source to construct a nondeterministic random bit generator (NDRBG).
- In the NIST configuration, it produces four 32-bit random samples every 412 AHB clock cycles if \( f_{\text{AHB}} < f_{\text{threshold}} \) (256 RNG clock cycles otherwise).
- It embeds startup and NIST SP800-90B approved continuous health tests (repetition count and adaptive proportion tests), associated with specific error management.
- It can be disabled to reduce power consumption, or enabled with an automatic low power mode (default configuration).
- It has an AMBA® AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).

32.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals.

Within its boundary RNG integrates all the required NIST components depicted on Figure 289. Those components are an analog noise source, a digitization stage, a conditioning algorithm, a health monitoring block and two interfaces that are used to interact with the entropy source: GetEntropy and HealthTest.

![Figure 289. NIST SP800-90B entropy source model](image)

The components pictured above are detailed hereafter.

Noise source

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. This noise source provides 1-bit samples. It is composed of:

- Multiple analog noise sources (x6), each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in Section 32.3.8: RNG low-power use.
- The XORing of all the noise sources into a single analog output.
- A sampling stage of this output clocked by a dedicated clock input (rng_clk with integrated divider), delivering a 1-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (rng_hclk), with a possibility for the software to decrease the sampling frequency by using the integrated divider.

Note: In Section 32.6: RNG entropy source validation the recommended RNG clock frequencies and associated divider value are given.
Post processing

In the NIST configuration no post-processing is applied to the sampled noise source. In non-NIST configuration B (as defined in Section 32.6.2) a normalization debiasing is applied, that is half of the bits are taken from the sampled noise source, half of the bits are taken from the inverted sampled noise source.

Conditioning

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bitstrings output (128-bit). The NIST SP800-90B target is full entropy on the output (128-bit).

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in Section 32.5: RNG processing time.

Output buffer

A data output buffer can store up to four 32-bit words that have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register after a number of clock cycles specified in Section 32.5: RNG processing time.

Whenever a random number is available through the RNG_DR register, the DRDY flag changes from 0 to 1. This flag remains high until the output buffer becomes empty after reading four words from the RNG_DR register.

Note: When interrupts are enabled an interrupt is generated when this data ready flag transitions from 0 to 1. Interrupt is then cleared automatically by the RNG as explained above.
Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features in accordance with NIST SP800-90B. The described thresholds correspond to the value recommended for register RNG_HTCR (configuration A in Section 32.6.2).

1. Startup health tests, performed after reset and before the first use of the RNG as entropy source:
   - Repetition count test, flagging an error when the noise source has provided more than 42 consecutive bits at a constant value (0 or 1).
   - Adaptive proportion test running on a window of 1024 consecutive bits: the RNG verifies that the first bit on the outputs of the noise source is not repeated more than 711 times.
   - Known-answer tests, to verify the conditioning stage.

2. Continuous health tests, running indefinitely on the outputs of the noise source:
   - Repetition count test, similar to the one running in startup tests.
   - Adaptive proportion test, similar to the one running in startup tests.

3. Vendor specific continuous tests
   - Transition count test, flagging an error when the noise source has delivered more than 32 consecutive occurrences of 2-bit patterns (01 or 10).
   - Real-time “too slow” sampling clock detector, flagging an error when one RNG clock cycle (before divider) is smaller than AHB clock cycle divided by 32.

4. On-demand test of digitized noise source (raw data)
   - Supported by restarting the entropy source and rerunning the startup tests (see software reset sequence in Section 32.3.4: RNG initialization). Other kinds of on-demand testing (software based) are not supported.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in Section 32.3.7: Error management.

Note: An interrupt can be generated when an error is detected.

Above the health test thresholds are modified by changing the value in the RNG_HTCR register. See Section 32.6: RNG entropy source validation for details.
32.3.4 RNG initialization

The RNG simplified state machine is pictured on Figure 290.

After enabling the RNG (RNGEN = 1 in RNG_CR), the following chain of events occurs:

1. The analog noise source is enabled, and by default the RNG waits 16 cycles of RNG clock cycles (before divider) before starting to sample the analog output and filling the 128-bit conditioning shift register.
2. The conditioning hardware initializes, automatically triggering startup behavior test on the raw data samples and known-answer tests.
3. When startup health tests are completed. During this time, three 128-bit noise source samples are used.
4. The conditioning stage internal input data buffer is filled again with 128-bit and a number of conditioning rounds defined by the RNG configuration (NIST or non-NIST) is performed. The output buffer is then filled with the post processing result.
5. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in Section 32.5: RNG processing time.

Figure 290. RNG initialization overview
Figure 290 also highlights a possible software reset sequence, implemented by:

1. Writing bits RNGEN = 0 and CONDRST = 1 in the RNG_CR register with the same RNG configuration and a new CLKDIV if needed.
2. Then writing RNGEN = 1 and CONDRST = 0 in the RNG_CR register.
3. Wait for random number to be ready, after initialization completes.

**Note:** When the RNG peripheral is reset through RCC (hardware reset), the RNG configuration for optimal randomness is lost in the RNG registers. Software reset with CONFIGLOCK set preserves the RNG configuration.

### 32.3.5 RNG operation

**Normal operations**

To run the RNG using interrupts, the following steps are recommended:

1. Consult Section 32.6: RNG entropy source validation and verify if a specific RNG configuration is required for the application.
   - If it is the case, write in the RNG_CR register the bit CONDRST = 1 together with the correct RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST = 0, the interrupt enable bit IE = 1 and the RNG enable bit RNGEN = 1.
   - If it is not the case perform a write to the RNG_CR register with the interrupt enable bit IE = 1 and the RNG enable bit RNGEN = 1.
2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore, at each interrupt, check that:
   - No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG_SR register.
   - A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   - If the above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data is available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in Section 32.3.7 must be used.

To run the RNG in polling mode following steps are recommended:

1. Consult Section 32.6: RNG entropy source validation and verify if a specific RNG configuration is required for the application.
   - If it is the case write in the RNG_CR register the bit CONDRST = 1 together with the correction RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST = 0 and the RNG enable bit RNGEN = 1.
   - If it is not the case only enable the RNG by setting the RNGEN bit to 1 in the RNG_CR register.
2. Read the RNG_SR register and check that:
   - No error occurred (the SEIS and CEIS bits must be set to 0)
   - A random number is ready (the DRDY bit must be set to 1)
3. If above conditions are true read the content of the RNG_DR register up to four consecutive times. If valid data is available in the conditioning output buffer four
additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in Section 32.3.7 must be used.

**Note:** When data is not ready (DRDY = 0) RNG_DR returns zero. It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

If the random number generation period is a concern to the application and if NIST compliance is not required it is possible to select a faster RNG configuration by using the RNG configuration “B”, described in Section 32.6: RNG entropy source validation. The gain in random number generation speed is summarized in Section 32.5: RNG processing time.

**Low-power operations**

If the power consumption is a concern to the application, low-power strategies can be used, as described in Section 32.3.8: RNG low-power use.

**Software post-processing**

No specific software post-processing/conditioning is expected to meet the AIS-31 or NIST SP800-90B approvals.

Built-in health check functions are described in Section 32.3.3: Random number generation.

### 32.3.6 RNG clocking

The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock. The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock, coupled with a programmable divider (see CLKDIV bitfield in the RNG_CR register) is used for noise source sampling. Recommended clock configurations are detailed in Section 32.6: RNG entropy source validation.

**Note:** When the CED bit in the RNG_CR register is set to 0, the RNG clock frequency before the internal divider must be higher than the AHB clock frequency divided by 32, otherwise the clock checker always flags a clock error (CECS = 1 in the RNG_SR register).

See Section 32.3.1: RNG block diagram for details (AHB and RNG clock domains).

### 32.3.7 Error management

In parallel to random number generation a health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

**Clock error detection**

When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application must check that the RNG clock is configured correctly (see Section 32.3.6: RNG clocking) and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when the clocking condition is normal.
Note: The clock error has no impact on generated random numbers that is the application can still read the RNG_DR register.  

CEIS is set only when CECS is set to 1 by RNG.

Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred. If a value is available in the RNG_DR register, it must not be used as it may not have enough entropy.

The following sequence must be used to fully recover from a seed error:

1. Software reset by writing CONDRST at 1 and at 0 (see bitfield description for details). This step is needed only if SECS is set. Indeed, when SEIS is set and SECS is cleared it means RNG performed the reset automatically (auto-reset). In this case application must clear the SEIS bit interrupt flag.
2. If SECS was set in step 1 (no auto-reset) wait for CONDRST to be cleared in the RNG_CR register, then confirm that SEIS is cleared in the RNG_SR register. Otherwise, just clear the SEIS bit in the RNG_SR register.
3. If SECS was set in step 1 (no auto-reset), wait for SECS to be cleared by RNG. The random number generation is now back to normal.

Note: After a seed error RNG restarts generating random numbers when SECS is cleared. When the application sets the ARDIS bit in the RNG_CR register, the auto-reset is disabled. CONDRST must be used in step 1.

RNG tamper errors

When an unexpected error is found by the RNG an internal tamper event is triggered in the TAMP peripheral, and the RNG stops delivering random data.

When this event occurs, the secure application needs to reset the RNG peripheral either using the central reset management or the global SoC reset. Then a proper initialization of the RNG is required, again.

32.3.8 RNG low-power use

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to 1 by setting the RNGEN bit to 0 in the RNG_CR register. As the post-processing logic and the output buffer remain operational while RNGEN = 0 following features are available to the software:

- If there are valid words in the output buffer four random numbers can still be read from the RNG_DR register.
- If there are valid bits in the conditioning output internal register four additional random numbers can be still be read from the RNG_DR register. If it is not the case RNG must be reenabled by the application until the expected new noise source bits threshold is reached (128-bit in NIST mode) and a complete conditioning round is done. Four new random words are then available only if the expected number of conditioning round is reached (two if NISTC = 0). The overall time can be found in Section 32.5: RNG processing time on page 1243.

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates
all the logic clocked by the RNG clock. Note that this strategy is adding latency before a 
random sample is available on the RNG_DR register, because of the RNG initialization time.

If the RNG block is disabled during initialization (that is well before the DRDY bit rises for the 
first time), the initialization sequence resumes from where it was stopped when RNGEN bit 
is set to 1, unless the application resets the conditioning logic using CONDRST bit in the 
RNG_CR register.

When the application wants to gate the RNG clock it is recommended to wait two RNG 
kernel clock cycles between clearing the RNGEN bit and gating the RNG kernel clock using 
the RCC.

Also, when application needs to enter a power mode where RNG is de-activated, it is 
recommended to wait two RNG kernel clock cycles between clearing the RNGEN bit and 
entering the low power mode using the PWR.

In the two cases above, to avoid unexpected consumption when RNG analog oscillators 
stay active, application can set the bit 13 in RNG_CR register. Setting this bit adds some 
marginal power consumption while RNGEN bit is set (RNG activated).

Note: The power modes where RNG is deactivated (that is retained or not available) can be found 
in the PWR section.

32.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:
- Data ready flag
- Seed error, see Section 32.3.7: Error management
- Clock error, see Section 32.3.7: Error management

Dedicated interrupt enable control bits are available as shown in Table 296.

Table 296. RNG interrupt requests

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>
<tr>
<td>RNG</td>
<td>Data ready flag</td>
<td>DRDY</td>
<td>IE</td>
<td>None (automatic)</td>
</tr>
<tr>
<td></td>
<td>Seed error flag</td>
<td>SEIS</td>
<td>IE</td>
<td>Write 0 to SEIS or write CONDRST to 1 then to 0</td>
</tr>
<tr>
<td></td>
<td>Clock error flag</td>
<td>CEIS</td>
<td>IE</td>
<td>Write 0 to CEIS</td>
</tr>
</tbody>
</table>

The user can enable or disable the above interrupt sources individually by changing the 
mask bits or the general interrupt control bit IE in the RNG_CR register. The status of the 
individual interrupt sources can be read from the RNG_SR register.

Note: Interrupts are generated only when RNG is enabled.
32.5 **RNG processing time**

In recommended configuration A described in Table 297, the time between two sets of four 32-bit data is either:

- 206 x N AHB cycles if $f_{AHB} < f_{\text{threshold}}$ (conditioning stage is limiting), or
- 128 x N RNG cycles $f_{AHB} \geq f_{\text{threshold}}$ (noise source stage is limiting).

With $f_{\text{threshold}} = 1.6 \times f_{\text{RNG}}$, for instance 77 MHz if $f_{\text{RNG}} = 48$ MHz. Value N is 2.

**Note:** When CLKDIV is different from zero, $f_{\text{RNG}}$ must take into account the internal divider ratio.

If configuration B is selected the performance figures become:

- 206 AHB cycles if $f_{AHB} < f_{\text{threshold}}$ or
- 32 RNG cycles $f_{AHB} \geq f_{\text{threshold}}$

with $f_{\text{threshold}} = 6.5 \times f_{\text{RNG}}$.

32.6 **RNG entropy source validation**

32.6.1 **Introduction**

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral using the German BSI AIS-31 statistical tests (T0 to T8), and NIST SP800-90B test suite. The results can be provided on demand or the customer can reproduce the tests.

32.6.2 **Validation conditions**

STMicroelectronics has tested the RNG true random number generator in the following conditions:

- RNG clock $\text{rng}_{\text{clk}} = 48$ MHz
- RNG configurations described in Table 297: RNG configurations. Note that only configuration A can be certified NIST SP800-90B.

<table>
<thead>
<tr>
<th>Table 297. RNG configurations</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>RNG Config.</strong></td>
</tr>
<tr>
<td><strong>NISTC bit</strong></td>
</tr>
<tr>
<td>A</td>
</tr>
<tr>
<td>B</td>
</tr>
</tbody>
</table>

1. For NIST certification the noise source sampling must be 48 MHz or less. Hence, if the RNG clock is different from 48 MHz, this value of CLKDIV must be adapted. See the CLKDIV bitfield description in Section 32.7.1 for details.
2. 0x1 value is recommended when RNG power consumption is critical. See the end of Section 32.3.8: RNG low-power use for details.
3. Corresponds to 42 for repetition tests and 711 for adaptive tests. See Health checks on page 1237 for details.
32.6.3 Data collection

In order to run statistical tests, it is required to collect samples from the entropy source at the raw data level as well as at the output of the entropy source. For details on data collection and the running of statistical test suites refer to “STM32 microcontrollers random number generation validation using NIST statistical test suite” application note (AN4230) available from www.st.com.

Contact STMicroelectronics if the above samples need to be retrieved for the product.

32.7 RNG registers

The RNG is associated with a control register, a data register and a status register.

32.7.1 RNG control register (RNG_CR)

Address offset: 0x000
Reset value: 0x0080 0D00

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>CONFGLOCK: RNG Config lock</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0: Writes to the RNG_HTCR and RNG_CR configuration bits [29:4] are allowed.</td>
</tr>
<tr>
<td></td>
<td>1: Writes to the RNG_HTCR and RNG_CR configuration bits [29:4] are ignored until the next RNG reset.</td>
</tr>
<tr>
<td></td>
<td>This bitfield is set once: if this bit is set it can only be reset to 0 if RNG is reset.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit 30</th>
<th>CONDRST: Conditioning soft reset</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Write 1 and then write 0 to reset the conditioning logic, clear all the FIFOs and start a new RNG initialization process, with RNG_SR cleared. Registers RNG_CR and RNG_HTCR are not changed by CONDRST.</td>
</tr>
<tr>
<td></td>
<td>This bit must be set to 1 in the same access that set any configuration bits [29:4]. In other words, when CONDRST bit is set to 1 correct configuration in bits [29:4] must also be written.</td>
</tr>
<tr>
<td></td>
<td>When CONDRST is set to 0 by the software, its value goes to 0 when the reset process is done. It takes about 2 AHB clock cycles + 2 RNG clock cycles.</td>
</tr>
</tbody>
</table>

| Bits 29:26 | Reserved, must be kept at reset value. |
| Bits 25:20 | RNG_CONFIG1[5:0]: RNG configuration 1 |
|           | Reserved to the RNG configuration (bitfield 1). Must be initialized using the recommended value documented in Section 32.6: RNG entropy source validation. |
|           | Writing any bit of RNG_CONFIG1 is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFGLOCK remains at 0. Writing to this bit is ignored if CONFGLOCK = 1. |
Bits 19:16 **CLKDIV[3:0]:** Clock divider factor
This value used to configure an internal programmable divider (from 1 to 16) acting on the incoming RNG clock. These bits can be written only when the core is disabled (RNGEN = 0).
0x0: Internal RNG clock after divider is similar to incoming RNG clock.
0x1: Two RNG clock cycles per internal RNG clock.
0x2: \(2^2 \approx 4\) RNG clock cycles per internal RNG clock.
... 
0xF: \(2^{15}\) RNG clock cycles per internal clock (for example, an incoming 48 MHz RNG clock becomes a 1.5 kHz internal RNG clock)
Writing these bits is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 15:13 **RNG_CONFIG2[2:0]:** RNG configuration 2
Reserved to the RNG configuration (bitfield 2). Bit 13 can be set when RNG power consumption is critical. See Section 32.3.8: RNG low-power use. Refer to the RNG_CONFIG1 bitfield for details.

Bit 12 **NISTC:** NIST custom
0: Hardware default values for NIST compliant RNG. In this configuration per 128-bit output two conditioning loops are performed and 256 bits of noise source are used.
1: Custom values for NIST compliant RNG. See Section 32.6: RNG entropy source validation for proposed configuration.
Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 11:8 **RNG_CONFIG3[3:0]:** RNG configuration 3
Reserved to the RNG configuration (bitfield 3). Refer to RNG_CONFIG1 bitfield for details. If the NISTC bit is cleared in this register RNG_CONFIG3 bitfield values are ignored by RNG.

Bit 7 **ARDIS:** Auto reset disable
0: When a noise source error occurs RNG performs an automatic reset to clear the SECS bit.
1: When a noise source error occurs the application must reset RNG by writing CONDRST to 1 then to 0, in order to restart random number generation.
When auto-reset is enabled the application still need to clear the SEIS bit after a noise source error.
Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CED:** Clock error detection
0: Clock error detection enabled
1: Clock error detection is disabled
The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, that is to enable or disable CED, the RNG must be disabled.
Writing this bit is taken into account only if the CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **IE:** Interrupt enable
0: RNG interrupt is disabled
1: RNG interrupt is enabled. An interrupt is pending as soon as DRDY = 1, SEIS = 1 or CEIS = 1 in the RNG_SR register.
Bit 2 **RNGEN**: True random number generator enable

0: True random number generator is disabled. Analog noise sources are powered off and logic clocked by the RNG clock is gated.

1: True random number generator is enabled.

Bits 1:0 Reserved, must be kept at reset value.
32.7.2 RNG status register (RNG_SR)

Address offset: 0x004
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 SEIS: Seed error interrupt status

This bit is set at the same time as SECS. It is cleared by writing 0 (unless CONDRST is used). Writing 1 has no effect.

0: No faulty sequence detected
1: At least one faulty sequence is detected. See SECS bit description for details.

An interrupt is pending if IE = 1 in the RNG_CR register.

Bit 5 CEIS: Clock error interrupt status

This bit is set at the same time as CECS. It is cleared by writing 0. Writing 1 has no effect.

0: The RNG clock is correct (f_{RNGCLK} > f_{HCLK}/32)
1: The RNG clock before the internal divider is detected too slow (f_{RNGCLK} < f_{HCLK}/32)

An interrupt is pending if IE = 1 in the RNG_CR register.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 SECS: Seed error current status

0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.
1: At least one of the following faulty sequences has been detected:
   - Runtime repetition count test failed (noise source has provided more than 24 consecutive bits at a constant value 0 or 1, or more than 32 consecutive occurrence of two bits patterns 01 or 10)
   - Startup or continuous adaptive proportion test on noise source failed.
   - Startup post-processing/conditioning sanity check failed.

Bit 1 CECS: Clock error current status

0: The RNG clock is correct (f_{RNGCLK} > f_{HCLK}/32). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.
1: The RNG clock is too slow (f_{RNGCLK} < f_{HCLK}/32).

Note: CECS bit is valid only if the CED bit in the RNG_CR register is set to 0.

Bit 0 DRDY: Data ready

0: The RNG_DR register is not yet valid, no random data is available.
1: The RNG_DR register contains valid random data.

Once the output buffer becomes empty (after reading the RNG_DR register), this bit returns to 0 until a new random value is generated.

Note: The DRDY bit can rise when the peripheral is disabled (RNGEN = 0 in the RNG_CR register).

If IE=1 in the RNG_CR register, an interrupt is generated when DRDY = 1.
32.7.3 RNG data register (RNG_DR)

Address offset: 0x008
Reset value: 0x0000 0000

The RNG_DR register is a read-only register that delivers a 32-bit random value when read. The content of this register is valid when the DRDY = 1 and the value is not 0x0, even if RNGEN = 0.

Bits 31:0 RNDATA[31:0]: Random data
32-bit random data, which are valid when DRDY = 1. When DRDY = 0, the RNDATA value is zero.
When DRDY is set, it is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

32.7.4 RNG health test control register (RNG_HTCR)

Address offset: 0x010
Reset value: 0x0000 72AC

Writing in RNG_HTCR is taken into account only if the CONDRST bit is set, and the CONFIGLOCK bit is cleared in the RNG_CR. Writing to this register is ignored if CONFIGLOCK=1.

Bits 31:0 HTCFCFG[31:0]: health test configuration
This configuration is used by RNG to configure the health tests. See Section 32.6: RNG entropy source validation for the recommended value.
Note: The RNG behavior, including the read to this register, is not guaranteed if a different value from the recommended value is written.
### 32.7.5 RNG register map

Refer to Section 2.3 for the register boundary addresses.
33 **AES hardware accelerator (AES)**

### 33.1 Introduction

The AES hardware accelerator (AES) encrypts or decrypts data in compliance with the advanced encryption standard (AES) defined by NIST.

AES supports ECB, CBC, CTR, GCM, GMAC, and CCM chaining modes for key sizes of 128 or 256 bits. AES has the possibility to load by hardware the key stored in SAES peripheral, under SAES control.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels are required).

### 33.2 AES main features

- Compliant with NIST FIPS publication 197 “*Advanced encryption standard (AES)*” (November 2001)
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- 128-bit data block processing, supporting cipher key lengths of 128-bit and 256-bit
  - 51 or 75 clock cycle latency in ECB mode for processing one 128-bit block with, respectively, 128-bit or 256-bit key
- Using dedicated key bus, optional key sharing with side-channel resistant SAES peripheral (Shared-key mode), controlled by SAES
- Integrated key scheduler to compute the last round key for ECB/CBC decryption
- 256-bit of write-only registers for storing cryptographic keys (eight 32-bit registers)
- 128-bit of registers for storing initialization vectors (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control supporting two direct memory access (DMA) channels, one for incoming data, one for processed data. Only single transfers are supported.
- Data-swapping logic to support 1-, 8-, 16-, or 32-bit data
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.
- Possibility for software to suspend a message if AES needs to process another message with a higher priority, then resume the original message
33.3 AES implementation

The devices have one AES peripheral, implemented as per the following table. It can use the key generated by the SAES peripheral. For comparison, the SAES peripheral is also included in the table.

</tr>
</tbody>
</table>

33.4.3 AES reset and clocks

The AES peripheral is clocked by the AHB bus clock. The AES has a dedicated reset bit in the RCC.

33.4.4 AES symmetric cipher implementation

The AES hardware accelerator (AES) is a 32-bit AHB peripheral that encrypts or decrypts 16-byte blocks of data using the advanced encryption standard (AES). It also implements a set of approved AES symmetric key security functions summarized in *Table 301*. Those functions can be certified NIST PUB 140-3.

AES can be used directly by the CPU, or indirectly, using two DMA channels (one for the plaintext, one for the ciphertext). It is possible to suspend then resume any AES processing, following the sequence described in Section 33.4.8.
33.4.5 AES encryption or decryption typical usage

The following figure shows a typical operation for encryption or decryption.

Figure 292. Encryption/decryption typical usage

Initialization

The AES peripheral is initialized according to the chaining mode. Refer to Section 33.4.9: AES basic chaining modes (ECB, CBC) and Section 33.4.10: AES counter (CTR) mode for details.

Data append

This section describes different ways of appending data for processing. For ECB or CBC chaining modes, refer to Section 33.4.7: AES ciphertext stealing and data padding if the size of data to process is not a multiple of 16 bytes. The last block management in these cases is more complex than what is described in this section.

Appending data using the CPU in polling mode

This method uses flag polling to control the data append through the following sequence:

1. When KEYVALID is set, enable the AES peripheral, by setting the EN bit of the AES_CR register (if not already done).
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the AES_DINR register.
   b) Wait until the status flag CCF is set in the AES_ISR register, then read the four data words from the AES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
   d) If the next processing block is the last block, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (using...
Note: Up to three wait cycles are automatically inserted between two consecutive writes to the AES_DINR register, to allow sending the key to the AES processor. NPBLB[3:0] bitfield is not used in header phase of GCM, GMAC and CCM chaining modes.

Appending data using the CPU in interrupt mode

The method uses interrupt from the AES peripheral to control the data append, through the following sequence:

1. Enable interrupts from AES, by setting the CCFIE bit of the AES_IER register.
2. When KEYVALID is set, enable the AES peripheral, by setting EN (if not already done).
3. Write first four input data words into the AES_DINR register.
4. Handle the data in the AES interrupt service routine. Upon each interrupt:
   a) Read four output data words from the AES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the AES_ICR register.
   c) If the next processing block is the last block of the message, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (through NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, optionally discard the data that are not part of the message/payload, then disable the AES peripheral by clearing EN and quit the interrupt service routine.
   e) Write next four input data words into the AES_DINR register and quit the interrupt service routine.

Note: AES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two AES computations. The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

Appending data using DMA

With this method, all the transfers and processing are managed by DMA and AES. Proceed as follows:

1. If the last block of the message to process is shorter than 16 bytes, prepare the last four-word data block by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the AES peripheral input and the processed data from the AES peripheral output to the memory, as described in Section 33.6: AES DMA requests. Configure the DMA controller so as to generate an interrupt on transfer completion. For GCM payload encryption or CCM payload decryption, the DMA transfer must not include the last four-word block if padded with zeros. The sequence described in Appending data using the CPU in polling mode must be used instead for this last block, because the
NPBLB[3:0] bitfield must be set up before processing the block, for AES to compute a correct tag.

3. When KEYVALID is set, enable the AES peripheral, by setting EN (if not already done).
4. Enable DMA requests, by setting DMAINEN and DMAOUTEN.
5. Upon DMA interrupt indicating the transfer completion, get the AES-processed data from the memory.

**Note:** The CCF flag has no use with this method because the reading of the AES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

### 33.4.6 AES authenticated encryption, decryption, and cipher-based message authentication

The following figure shows a typical operation for authenticated encryption or decryption, and for cipher-based message authentication.

![Figure 293. Typical operation with authentication](image)

Section 33.4.11: AES Galois/counter mode (GCM) and Section 33.4.13: AES counter with CBC-MAC (CCM) describe detailed sequences supported by AES.

Cipher-based message authentication flow omits the payload phase, as shown in the figure. Detailed sequence supported by AES is described in Section 33.4.12: AES Galois message authentication code (GMAC).

### 33.4.7 AES ciphertext stealing and data padding

When using AES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (16 bytes), the application must use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since
AES does not implement such techniques, the application must complete the last block of input data using data from the second last block.

*Note:* Ciphertext stealing techniques are not documented in this reference manual.

Similarly, in modes other than ECB or CBC, an incomplete input data block (that is, a block with input data shorter than 16 bytes) must be padded with zeros prior to encryption. That is, extra bits must be appended to the trailing end of the data string. After decryption, the extra bits must be discarded. Since AES does not implement automatic data padding operation to the last block, the application must follow the recommendation given in this document to manage messages the size of which is not a multiple of 16 bytes.

### 33.4.8 AES suspend and resume operations

A message can be suspended to process another message with a higher priority. When the higher-priority message is sent, the suspended message can resume. This applies to both encryption and decryption mode.

Suspend and resume operations do not break the chaining operation. The message processing can resume as soon as AES is enabled again, to receive a next data block.

*Figure 294* gives an example of suspend and resume operations: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

*Figure 294. Example of suspend mode management*

A detailed description of suspend and resume operations is in the sections dedicated to each chaining mode.

### 33.4.9 AES basic chaining modes (ECB, CBC)

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately. When decrypting in ECB, a special key scheduling is required before processing the first block.
Figure 295 and Figure 296 describe the electronic codebook (ECB) chaining implementation in encryption and in decryption, respectively. To select ECB chaining mode, write CHMOD[2:0] with 0x0.

In CBC encryption mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing. When decrypting in CBC, a special key scheduling is required before processing the first block.
**Figure 297** and **Figure 298** describe the cipher block chaining (CBC) implementation in encryption and in decryption, respectively. To select this chaining mode, write CHMOD[2:0] with 0x1.

**Figure 297. CBC encryption**

**Figure 298. CBC decryption**

For more details, refer to NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

**ECB and CBC encryption process**

This process is described in Section 33.4.5, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register as follows:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in encryption mode (write MODE[1:0] with 0x0).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
3. Write the initialization vector into the AES_IVRx registers if CBC mode is selected in the previous step.

4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see Section 33.4.14).

5. Wait until KEYVALID is set (the key loading completed).

6. Enable the AES peripheral, by setting EN.

7. Append cleartext data:
   a) If it is the second-last or the last block and the plaintext size of the message is not a multiple of 16 bytes, follow the guidance in Section 33.4.7.
   b) Append the cleartext block into AES as described in Section 33.4.5, then read the AES_DOUTR register four times to save the ciphertext block.
   c) Repeat the step b) until the third-last plaintext block is encrypted. For the last two blocks, follow the steps a) and b).

8. Finalize the sequence: disable the AES peripheral, by clearing EN.

**ECB/CBC decryption process**

This process is described in Section 33.4.5, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.

2. Initialize the AES_CR register as follows:
   - Select the key derivation mode (write MODE[1:0] with 0x1). The CHMOD[2:0] bitfield is not significant during this operation.
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.

3. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see Section 33.4.14).

4. Wait until KEYVALID is set (the key loading completed).

5. Enable the AES peripheral, by setting EN. The peripheral immediately starts an AES round for key preparation.

6. Wait until the CCF flag in the AES_ISR register is set.

7. Clear the CCF flag, by setting the CCF bit of the AES_ICR register. The decryption key is available in the AES core and AES is disabled automatically.

8. Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in decryption mode (write MODE[1:0] with 0x2). Do not change other parameters.

9. Write the initialization vector into the AES_IVRx registers if CBC mode is selected in the previous step.

10. Enable the AES peripheral, by setting EN.
11. Append encrypted data:
   a) If it is the second-last or the last block and the ciphertext size of the message is not a multiple of 16 bytes, follow the guidance in Section 33.4.7.
   b) Append the ciphertext block into AES as described in Section 33.4.5, then read the AES_DOUTR register four times to save the cleartext block (MSB first).
   c) Repeat the step b) until the third-last ciphertext block is decrypted. For the last two blocks, follow the steps a) and b).
12. Finalize the sequence: disable the AES peripheral, by clearing EN.

**Suspend/resume operations in ECB/CBC modes**

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the input FIFO, by clearing the DMAINEN bit of the AES_CR register.
2. If DMA is not used, read four times the AES_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the AES_ISR register then stop the DMA transfers from the output FIFO, by clearing the DMAOUTEN bit of the AES_CR register.
3. If DMA is not used, wait until the CCF flag in the AES_ISR register is set (computation completed).
4. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
5. Save initialization vector registers (only required in CBC mode as the AES_IVRx registers are altered during the data processing).
6. Disable the AES peripheral, by clearing EN.
7. Save the AES_CR register and clear the key registers if they are not needed, to process the higher-priority message.
8. If DMA is used, save the DMA controller status (pointers for AES input and output data transfers, number of remaining bytes, and so on).

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller so as to complete the remaining input FIFO and output FIFO transfers.
2. Disable the AES peripheral, by clearing EN.
3. Restore the AES_CR register (with correct KEYSIZE) then restore the AES_KEYRx registers. If KMOD[1:0] is at 0x2, the key must be transferred again from the SAES peripheral (see Section 33.4.14).
4. Prepare the decryption key, as described in ECB/CBC decryption process (only required for ECB or CBC decryption).
5. Restore the IVRx registers, using the saved configuration (only required in CBC mode).
6. Enable the AES peripheral, by setting EN.
7. If DMA is used, enable AES DMA transfers, by setting DMAINEN and DMAOUTEN.

*Note: It is not required to save the key registers as the application knows the original key.*

**33.4.10 AES counter (CTR) mode**

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext. Unlike with ECB and CBC modes, no key
scheduling is required for the CTR decryption since the AES core is always used in encryption mode.

A typical message construction in CTR mode is given in Figure 299.

Figure 299. Message construction in CTR mode

The structure of this message is:

- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector (IV)**: a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

For more details, refer to NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*.

**CTR encryption and decryption**

*Figure 300* describes the counter (CTR) chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x2.
Initialization vectors in AES must be initialized as shown in Table 302.

### Table 302. Counter mode initialization vector definition

### CTR encryption and decryption process

This process is described in Section 33.4.5, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select CTR chaining mode (write CHMOD[2:0] with 0x2) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
3. Write the initialization vector into the AES_IVRx registers according to Table 302.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see Section 33.4.14).
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the AES peripheral, by setting EN.
7. Append data:
   a) If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is less than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into AES as described in Section 33.4.5, then read the AES_DOUTR register four times to save the resulting block (MSB first).
   c) Repeat the step b) until the second-last block is processed. For the last block of plaintext (encryption only), follow the steps a) and b). For the last block, discard
the bits that are not part of the message when the last block is smaller than 16 bytes.

8. Finalize the sequence: disable the AES peripheral, by clearing EN.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher-priority message, then resume the interrupted message. Detailed CBC suspend and resume sequence is described in Section 33.4.9: AES basic chaining modes (ECB, CBC).

Note: Like for CBC mode, the IV registers must be reloaded during the resume operation.

33.4.11 AES Galois/counter mode (GCM)

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code).

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. The following figure shows a typical message construction in GCM mode.

**Figure 301. Message construction in GCM**

The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV)**: a 96-bit value that must be unique for each encryption cycle with a given key. The GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.
- **Authenticated header AAD** (also known as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} – 1$ bits. This part of the message is only authenticated, not encrypted.
- **Plaintext message** $P$ is both authenticated and encrypted as ciphertext $C$, with a known length $\text{Len}(P)$ that may be non-multiple of 16 bytes, and cannot exceed $2^{32} - 2$ 16-byte blocks.

- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in Table 304.

The GCM standard specifies that ciphertext $C$ has the same bit length as the plaintext $P$.

When a part of the message (AAD or $P$) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

For more details, refer to NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*.

*Figure 302* describes the GCM chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x3.

**Figure 302. GCM authenticated encryption**

The first counter block (CB1) is derived from the initial counter block ICB by the application software, as defined in Table 303.

---

1264/3119  RM0481 Rev 1
The last block of a GCM message contains the AAD header length and the payload length information, as shown in Table 304.

GCM encryption and decryption process

This process is described in Section 33.4.6, with the following sequence of events:

**GCM initialize**
1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select GCM chaining mode (write CHMOD[2:0] with 0x3) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
   - Select the GCM initialization phase, by writing GCMPH[1:0] with 0x0.
3. Write the initialization vector in AES_IVRx registers according to Table 303.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see Section 33.4.14).
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN to start the calculation of the hash key. EN is automatically cleared when the calculation is completed.
7. Wait until the CCF flag is set in the AES_ISR register, indicating that the GCM hash subkey (H) computation is completed.
8. Clear the CCF flag by setting the CCF bit of the AES_ICR register.

**GCM header phase**
9. Initialize header phase:
   a) Select the GCM header phase, by writing 0x1 to GCMPH[1:0]. Do not change the other configurations written during GCM initialization.
   b) Enable the AES peripheral, by setting EN.

### Table 304. GCM last block definition

<table>
<thead>
<tr>
<th>Word order to AES_DINR</th>
<th>First word</th>
<th>Second word</th>
<th>Third word</th>
<th>Fourth word</th>
</tr>
</thead>
</table>
10. Append header data:
   a) If it is the last block and the AAD in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into AES as described in Section 33.4.5.
   c) Repeat the step b) until the second-last AAD data block is processed. For the last block, follow the steps a) and b).

   **Note:** *This phase can be skipped if there is no AAD, that is, Len(A) = 0.*

   No data are read during header phase.

**GCM payload phase**

11. Initialize payload phase:
   a) Select the GCM payload phase, by writing GMCPH[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
   b) If the header phase is skipped, enable the AES peripheral by setting EN.

12. Append payload data:
   a) If it is the last block and the message in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into AES as described in Section 33.4.5, then read the AES_DOUTR register four times to save the resulting block.
   c) Repeat the step b) until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps a) and b). For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

   **Note:** *This phase can be skipped if there is no payload, that is, Len(C)=0 (see GMAC mode).*

**GCM finalization**

13. Select the GCM final phase, by writing GMCPH[1:0] with 0x3. Do not change the other configurations written during GCM initialization.

14. Write the final GCM block into the AES_DINR register. It is the concatenated AAD bit and payload bit lengths, as shown in Table 304.

15. Wait until the CCF flag in the AES_ISR register is set.

16. Get the GCM authentication tag, by reading the AES_DOUTR register four times.

17. Clear the CCF flag, by setting the CCF bit in AES_ICR register.

18. Disable the AES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

   **Note:** *In the final phase, data are written to AES_DINR normally (no swapping), while swapping is applied to tag data read from AES_DOUTR.*

   *When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.*
Suspend/resume operations in GCM mode

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the input FIFO, by clearing DMAINEN. If DMA is not used, wait until the CCF flag in the AES_ISR register is set (computation completed).
2. In the payload phase, if DMA is not used, read four times the AES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag in the AES_ISR register is set then stop the DMA transfers from the output FIFO, by clearing DMAOUTEN.
3. Clear the CCF flag of the AES_ISR register, by setting the CCF bit of the AES_ICR register.
4. Save the AES_SUSPRx registers in the memory.
5. In the payload phase, save the AES_IVRx registers as, during the data processing, they changed from their initial values. In the header phase, this step is not required.
6. Disable the AES peripheral, by clearing EN.
7. Save the current AES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.
8. If DMA is used, save the DMA controller status (pointer for AES input data transfers, number of remaining bytes, and so on). In the payload phase, also save the pointer for AES output data transfers.

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the remaining input FIFO transfers. In the payload phase, also configure the DMA controller for the remaining output FIFO transfers.
2. Disable the AES peripheral, by clearing EN.
3. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPRx registers.
4. In the payload phase, write the initialization vector register values, previously saved in the memory, back into their corresponding AES_IVRx registers. In the header phase, write initial setting values back into the AES_IVRx registers.
5. Restore the initial setting values in the AES_CR and AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see Section 33.4.14).
6. Enable the AES peripheral, by setting EN.
7. If DMA is used, enable AES DMA requests, by setting DMAINEN (and DMAOUTEN if in payload phase).

33.4.12 AES Galois message authentication code (GMAC)

The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code).

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload). The following figure shows typical message construction for GMAC.
For more details, refer to NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

Figure 304 describes the GMAC chaining implementation in the AES peripheral. To select this chaining mode, write CHMOD[2:0] with 0x3.

The GMAC algorithm corresponds to the GCM algorithm applied on a message that only contains a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

**Suspend/resume operations in GMAC**

In GMAC mode, the sequence described for the GCM applies except that only the header phase can be interrupted.
33.4.13 AES counter with CBC-MAC (CCM)

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES counter mode processing. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve CBC-MAC as an authentication mode outside the context of the CCM specification.

The following figure shows typical message construction for CCM.

Figure 305. Message construction in CCM mode

The structure of the message is:

- **16-byte first authentication block (B0)**, composed of three distinct fields:
  - Q: a bit string representation of the octet length of P (\(\text{Len}(P)\))
  - Nonce (N): a single-use value (that is, a new nonce must be assigned to each new communication) of \(\text{Len}(N)\) size. The sum \(\text{Len}(N) + \text{Len}(P)\) must be equal to 15 bytes.
  - Flags: most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values \(t\) (MAC length expressed in bytes) and \(Q\) (plaintext length such that \(\text{Len}(P) < 2^{8Q}\) bytes). The counter blocks range associated to \(Q\) is equal to \(2^{8Q-4}\), that is, if the maximum value of \(Q\) is 8, the counter blocks used in cipher must be on 60 bits.

- **16-byte blocks (B)** associated to the associated data (A). This part of the message is only authenticated, not encrypted. This section has a known length \(\text{Len}(A)\) that can be a non-multiple of 16 bytes (see Figure 305). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
  - If \(0 < a < 2^{16} - 2^5\), then it is encoded as \([a]_{16}\), that is, on two bytes.
  - If \(2^{16} - 2^8 < a < 2^{32}\), then it is encoded as \(0xff \| 0xfe \| [a]_{32}\), that is, on six bytes.
  - If \(2^{32} < a < 2^{64}\), then it is encoded as \(0xff \| 0xff \| [a]_{64}\), that is, on ten bytes.
• **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length Len(P). This length can be a non-multiple of 16 bytes (see Figure 305).

• **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

*Note:* CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

- N: 10111213 141516 (Len(N) = 56 bits or 7 bytes)
- A: 00010203 04050607 (Len(A) = 64 bits or 8 bytes)
- P: 20212223 (Len(P) = 32 bits or 4 bytes)
- T: 6084341B (Len(T) = 32 bits or t = 4)
- B0: 4F101112 13141516 00000000 00000004
- B1: 00080001 02030405 06070000 00000000
- B2: 20212223 00000000 00000000 00000000
- CTR0: 0710111213 141516 00000000 00000000
- CTR1: 0710111213 141516 00000000 00000001

For more details, refer to NIST Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality.
**Figure 306** describes the CCM chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x4.

The first block of a CCM message (B0) must be prepared by the application as defined in Table 305.

<td>B0[63:32]</td>
<td>B0[31:0]</td>
</tr>
</tbody>
</table>

1. The 5 most significant bits are cleared (flag bits).
2. Q length bits are cleared, except for the bit 0 that is set.

AES supports counters up to 64 bits, as specified by NIST.
CCM encryption and decryption process

This process is described in Section 33.4.6, with the following sequence of events:

CCM initialize
1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select CCM chaining mode (write CHMOD[2:0] with 0x4) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
   - Select the CCM initialization phase, by writing GCMPH[1:0] with 0x0.
3. Write the B0 data in AES_IVRx registers according to Table 305.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see Section 33.4.14).
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN to start the first mask calculation. The EN bit is automatically cleared when the calculation is completed.
7. Wait until the CCF flag in the AES_ISR register is set.
8. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.

CCM header phase
9. Initialize header phase:
   a) Prepare the first block of the (B1) data associated with the message, in accordance with CCM chaining rules.
   b) Select the CCM header phase, by writing GCMPH[1:0] with 0x1. Do not change the other configurations written during the CCM initialization.
   c) Enable the AES peripheral, by setting EN.
10. Append header data:
    a) If it is the last block and the associated data in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in Section 33.4.5.
    c) Repeat the step b) until the second-last associated data block is processed. For the last block, follow the steps a) and b).

Note: This phase can be skipped if there is no associated data, that is, Len(A) = 0
No data are read during the header phase.

CCM payload phase
11. Initialize payload phase:
    a) Select the CCM payload phase, by writing GCMPH[1:0] with 0x2. Do not change the other configurations written during the CCM initialization.
    b) If the header phase is skipped, enable the AES peripheral, by setting EN.
12. Append payload data:
   a) In encryption only, if it is the last block and the plaintext in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into AES as described in Section 33.4.5, then read the AES_DOUTR register four times to save the resulting block.
   c) Repeat the step b) until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps a) and b). For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

   Note: This phase can be skipped if there is no payload, that is, Len(P) = 0 or Len(C) = Len(T).

Remove LSB_{Len(T)} encrypted tag information when decrypting ciphertext C.

CCM finalization

13. Select the CCM final phase, by writing GCMPH[1:0] with 0x3. Do not change the other configurations written during the CCM initialization.

14. Wait until CCF flag in the AES_ISR register is set.

15. Get the CCM authentication tag, by reading the AES_DOUTR register four times.

16. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.

17. Disable the AES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message. Mask the authentication tag output with tag length to obtain a valid tag.

   Note: In the final phase, swapping is applied to tag data read from AES_DOUTR register.

When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.

Suspend and resume operations in CCM mode

To suspend the processing of a message in header or payload phase, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the input FIFO, by clearing DMAINEN. If DMA is not used, wait until the CCF flag of the AES_ISR register is set (computation completed).

2. In the payload phase, if DMA is not used, read four times the AES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag in the AES_ISR register is set, then stop the DMA transfers from the output FIFO, by clearing DMAOUTEN.

3. Clear the CCF flag in the AES_ISR register, by setting the CCF bit of the AES_ICR register.

4. Save the AES_SUSPRx registers in the memory.

5. Save the IV registers as they are altered during the data processing.

6. Disable the AES peripheral, by clearing EN.

7. Save the current AES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.

8. If DMA is used, save the DMA controller status (pointer for AES input data transfers, number of remaining bytes, and so on). In the payload phase, also save pointer for AES output data transfers.
To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the remaining input FIFO transfers. In the payload phase, also configure the DMA controller for the remaining output FIFO transfers.
2. Disable the AES peripheral, by clearing EN.
3. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPRx registers.
4. Restore AES_IVRx registers using the saved configuration.
5. Restore the initial setting values in the AES_CR and AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key must be transferred again from the SAES peripheral (see Section 33.4.14).
6. Enable the AES peripheral, by setting EN.
7. If DMA is used, enable AES DMA requests, by setting DMAINEN (and DMAOUTEN if in payload phase).

33.4.14 AES key sharing with secure AES co-processor

The AES peripheral can use the SAES peripheral as security co-processor. The secure application prepares the key in the robust SAES peripheral and when it is ready, the AES application can load this prepared key through a dedicated hardware key bus.

The recommended sequence is described hereafter and in the section SAES operations with shared keys in the SAES section of this document.

1. In SAES peripheral, the application encrypts (wraps) the key to share in Shared-key mode (KMOD[1:0] at 0x2).
2. Each time the shared key is required in AES peripheral, the application decrypts it in the SAES peripheral in Shared-key mode (KMOD[1:0] at 0x2).
3. Once the shared key is decrypted (unwrapped) and loaded in SAES_KEYRx registers it can be shared with AES. To load the shared key in AES, the application sets KEYSIZE as appropriate and writes KMOD[1:0] with 0x2. When KEYVALID is cleared, the key is automatically transferred by hardware into the AES_KEYRx registers and the BUSY flag in the AES_SR register set.
4. Once the key transfer is completed, the BUSY flag is cleared and the KEYVALID flag set in the AES_SR register. If KEYVALID is not set when BUSY bit is cleared, or if the KEIF flag is set in the AES_ISR register, either the KEYSIZE value is incorrect or an unexpected event occurred during the transfer (such as DPA error, tamper event or KEYVALID cleared before the end of the transfer). When such errors occur, reset both peripherals through their IPRST bits and restart the whole key sharing process.

When the key sharing sequence is completed, the AES is initialized with a valid, shared key. The application can then process data in normal key mode, by writing KMOD[1:0] with 0x0.

Note: This sequence in AES peripheral can be run multiple times (for example, to manage a suspend/resume situation), as long as SAES peripheral is unused and duly remains in key sharing state.
33.4.15 AES data registers and data swapping

Data input and output

A 16-byte data block enters the AES peripheral with four successive 32-bit word writes into the AES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 16-byte data block is retrieved from the AES peripheral with four successive 32-bit word reads of the AES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The four 32-bit words of a 16-byte data block must be stored in the memory consecutively and in big-endian order, that is, with the most significant word on the lowest address. See Table 306 "no swapping" option for details.

Data swapping

The AES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the AES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the AES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through DATATYPE[1:0]. The selection applies to both AES input and output.

Note: The data in AES key registers (AES_KEYRx) and initialization vector registers (AES_IVRx) are not sensitive to the swap mode selection.

The AES data swapping feature is summarized in Table 306 and Figure 307.

Table 306. AES data swapping example

Figure 307. 128-bit block construction according to the data type

**DATATYPE[1:0] = 00: no swapping**

**DATATYPE[1:0] = 01: 16-bit (half-word) swapping**

**DATATYPE[1:0] = 10: 8-bit (byte) swapping**

**DATATYPE[1:0] = 11: bit swapping**

Legend:  
- **Dx**: input/output data bit ‘x’  
- **↓**: Data swap  
- **↓↓**: Order of write to data input / read from data output register  
- **----**: Zero padding (example)  
- __AES core input/output data__
Data padding

*Figure 307* also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 84 message bits, with DATATYPE[1:0] = 0x0
- 48 message bits, with DATATYPE[1:0] = 0x1
- 56 message bits, with DATATYPE[1:0] = 0x2
- 34 message bits, with DATATYPE[1:0] = 0x3

### 33.4.16 AES key registers

The eight AES_KEYRx write-only registers store the encryption or decryption key information, as shown on Table 307. Reads are not allowed for security reason.

*Note:* In memory and in AES key registers, keys are stored in little-endian format, with most significant byte on the highest address.

*Table 307. Key endianness in AES_KEYRx registers (128/256-bit keys)*

<table>
<thead>
<tr>
<th>AES_KEYR7 [31:0]</th>
<th>AES_KEYR6 [31:0]</th>
<th>AES_KEYR5 [31:0]</th>
<th>AES_KEYR4 [31:0]</th>
<th>AES_KEYR3 [31:0]</th>
<th>AES_KEYR2 [31:0]</th>
<th>AES_KEYR1 [31:0]</th>
<th>AES_KEYR0 [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>KEY[127:96]</td>
<td>KEY[95:64]</td>
<td>KEY[63:32]</td>
<td>KEY[31:0]</td>
</tr>
</tbody>
</table>

The key registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield.

Write operations to the AES_KEYRx registers are ignored when AES peripheral is enabled (EN bit set). The application must check this before modifying key registers.

The entire key must be written before starting an AES computation. In normal key mode (KMOD[1:0] at 0x0), the key registers must always be written in either ascending or descending order. The write sequence becomes:

- AES_KEYRx (x = 0 to 3 or x=3 to 0) for KEYSIZE cleared
- AES_KEYRx (x = 0 to 7 or x=7 to 0) for KEYSIZE set

*Note:* KEYSIZE must be written before the key.

As soon as the first key register is written, the KEYVALID flag is cleared. Once the key registers writing sequence is completed, KEYVALID is set and EN becomes writable. If an error occurs, KEYVALID is cleared and KEIF set (see *Section 33.4.18*).

### 33.4.17 AES initialization vector registers

The four AES_IVRx registers store the initialization vector (IV) information, as shown in Table 308. They can only be written if the AES peripheral is disabled (EN cleared).

*Note:* In memory and in AES IV registers, initialization vectors are stored in little-endian format, with most significant byte on the highest address.
Initialization vector information depends on the chaining mode selected. When used, AES_IVRx registers are updated upon each AES computation cycle (useful for managing suspend mode).

The initialization vector registers are not affected by the data swapping feature controlled through DATATYPE[1:0].

33.4.18 AES error management

The AES peripheral manages the errors described in this section.

Read error flag (RDERRF)

Unexpected read attempt of the AES_DOUTR register returns zero, setting the RDERRF flag and the RWEIF flag. RDERRF is triggered during the computation phase or during the input phase.

Note: **AES is not disabled when RDERRF rises and it continues processing.**

An interrupt is generated if the RWEIE bit is set. For more details, refer to Section 33.5: AES interrupts.

The RDERRF and RWEIF flags are cleared by setting the RWEIF bit of the AES_ICR register.

Write error flag (WDERR)

Unexpected write attempt of the AES_DINR register is ignored, setting the WRERRF and the RWEIF flags. WRERRF is triggered during the computation phase or during the output phase.

Note: **AES is not disabled when WRERRF rises and it continues processing.**

An interrupt is generated if the RWEIE bit is set. For more details, refer to Section 33.5: AES interrupts.

The WRERRF and RWEIF flags are cleared by setting the RWEIF bit of the AES_ICR register.

Key error interrupt flag (KEIF)

There are multiple sources of errors that set the KEIF flag of the AES_ISR register and clear the KEYVALID bit of the AES_SR register:

- **Key writing sequence error:** triggered upon detecting an incorrect sequence of writing key registers. See Section 33.4.16: AES key registers for details.
- **Key sharing size mismatch error:** triggered when KMOD[1:0] is at 0x2 and KEYSIZE in AES peripheral does not match KEYSIZE in SAES peripheral.

<table>
<thead>
<tr>
<th>AES_IVR3[31:0]</th>
<th>AES_IVR2[31:0]</th>
<th>AES_IVR1[31:0]</th>
<th>AES_IVR0[31:0]</th>
</tr>
</thead>
</table>

Table 308. IVI bitfield spread over AES_IVRx registers
• **Key sharing error**: triggered upon failing transfer of SAES shared key to AES peripheral. See Section 33.4.14: AES key sharing with secure AES co-processor for details.

The KEIF flag is cleared with corresponding bit of the AES_ICR register. An interrupt is generated if the KEIE bit of the AES_IER register is set. For more details, refer to Section 33.5: AES interrupts.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

*Note:* *For any key error, clear KEIF flag prior to disabling and re-configuring AES.*

### 33.5 AES interrupts

There are multiple individual maskable interrupt sources generated by the AES peripheral to signal the following events:

- computation completed (CCF)
- read error (RDERRF)
- write error (WRERRF)
- key error (KEIF)

See Section 33.4.18: AES error management for details on AES errors.

These sources are combined into a common interrupt signal from the AES peripheral that connects to the Cortex® CPU interrupt controller. Application can enable or disable AES interrupt sources individually by setting/clearing the corresponding enable bit of the AES_IER register.

The status of the individual maskable interrupt sources can be read from the AES_ISR register. They are cleared by setting the corresponding bit of the AES_ICR register.

*Table 309* gives a summary of the available features.

<table>

1. Bit of the AES_ICR register.
2. Flag of the AES_SR register, mirrored by the flag RWEIF of the AES_ISR register.

### 33.6 AES DMA requests

The AES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the DMAINEN and DMAOUTEN bits of the AES_CR register. When key derivation is selected (MODE[1:0] is at 0x1), setting those bits has no effect.
AES only supports single DMA requests.

Detailed usage of DMA with AES can be found in **Appending data using DMA** subsection of **Section 33.4.5: AES encryption or decryption typical usage**.

**Data input using DMA**

Setting DMAINEN enables DMA writing into AES. AES then initiates, during the input phase, a set of single DMA requests for each 16-byte data block to write to the AES_DINR register (quadruple 32-bit word, MSB first).

*Note:* According to the algorithm and the mode selected, special padding / ciphertext stealing might be required (see **Section 33.4.7**).

**Data output using DMA**

Setting DMAOUTEN enables DMA reading from AES. AES then initiates, during the output phase, a set of single DMA requests for each 16-byte data block to read from the AES_DOUTR register (quadruple 32-bit word, MSB first).

After the output phase, at the end of processing of a 16-byte data block, AES switches automatically to a new input phase for the next data block, if any.

In DMA mode, the CCF flag has no use because the reading of the AES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to managing the data transfers by software.

*Note:* According to the message size, extra bytes might need to be discarded by application in the last block.

**Stopping DMA transfers**

All DMA request signals are de-asserted when AES is disabled (EN cleared) or the DMA enable bit (DMAINEN for input data, DMAOUTEN for output data) is cleared.

### 33.7 AES processing latency

The following tables provide the 16-byte data block processing latency per operating mode.

Bit 17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **GCMPTH[1:0]**: GCM or CCM phase selection
- This bitfield selects the phase, applicable only with GCM, GMAC or CCM chaining modes.
  0x0: Initialization phase
  0x1: Header phase
  0x2: Payload phase
  0x3: Final phase

Bit 12 **DMAOUTEN**: DMA output enable
- This bit enables automatic generation of DMA requests during the data phase, for outgoing data transfers from AES via DMA.
  0: Disable
  1: Enable
  Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bit 11 **DMAINEN**: DMA input enable
- This bit enables automatic generation of DMA requests during the data phase, for incoming data transfers to AES via DMA.
  0: Disable
  1: Enable
  Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bits 10:7 Reserved, must be kept at reset value.

Bits 16, 6:5 **CHMOD[2:0]**: Chaining mode
- This bitfield selects the AES chaining mode:
  0x0: Electronic codebook (ECB)
  0x1: Cipher-block chaining (CBC)
  0x2: Counter mode (CTR)
  0x3: Galois counter mode (GCM) and Galois message authentication code (GMAC)
  0x4: Counter with CBC-MAC (CCM)
  others: Reserved
  Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 4:3 **MODE[1:0]**: Operating mode
- This bitfield selects the AES operating mode:
  0x0: Encryption
  0x1: Key derivation (or key preparation), for ECB/CBC decryption only
  0x2: Decryption
  0x3: Reserved
  Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.
33.8.2 AES status register (AES_SR)

Address offset: 0x004
Reset value: 0x0000 0000

<table>

<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 KEYVALID: Key valid flag
This bit is set by hardware when the key of size defined by KEYSIZE is loaded in AES_KEYRx key registers.
0: Key not valid
1: Key valid
The EN bit can only be set when KEYVALID is set.
In normal mode when KMOD[1:0] is at zero, the key must be written in the key registers in the correct sequence, otherwise the KEIF flag is set and KEYVALID remains cleared.
When KMOD[1:0] is different from zero, the BUSY flag is automatically set by AES. When the key is loaded successfully, BUSY is cleared and KEYVALID set. Upon an error, KEIF is usually set, BUSY cleared and KEYVALID remains cleared.
If set, KEIF must be cleared through the AES_ICR register, otherwise KEYVALID cannot be set. See the KEIF flag description for more details.
For further information on key loading, refer to Section 33.4.16: AES key registers.

Bits 6:4 Reserved, must be kept at reset value.
Bit 3  **BUSY**: Busy  
This flag indicates whether AES is idle or busy.  
0: Idle  
1: Busy  
AES is flagged as idle when disabled (when EN is low) or when the last processing is completed.  
AES is flagged as busy when processing a block data, preparing a key (ECB or CBC decryption only), or transferring a shared key from the SAES peripheral.  
When GCM encryption is selected, this flag must be at zero before suspending current process to manage a higher-priority message.

Bit 2  **WRERRF**: Write error flag  
This bit is set when an unexpected write to the AES_DINR register occurred. When set WRERRF bit has no impact on the AES operations.  
0: No error  
1: Unexpected write to AES_DINR register occurred during computation or data output phase.  
The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.  
The flag is cleared by setting the RWEIF bit of the AES_ICR register.

Bit 1  **RDERRF**: Read error flag  
This bit is set when an unexpected read to the AES_DOUTR register occurred. When set RDERRF bit has no impact on the AES operations.  
0: No error  
1: Unexpected read to AES_DOUTR register occurred during computation or data input phase.  
The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.  
The flag is cleared by setting the RWEIF bit of the AES_ICR register.

Bit 0  Reserved, must be kept at reset value.

### 33.8.3  AES data input register (AES_DINR)

**DIN[31:16]**

**DIN[15:0]**

Bits 31:0  **DIN[31:0]**: Data input  
A four-fold sequential write to this bitfield during the Input phase results in writing a complete 16-bytes block of input data to the AES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 16-bytes input buffer.  
Reads return zero.
33.8.4 AES data output register (AES_DOUTR)

Address offset: 0x00C

</tr>
</tbody>
</table>

Bits 31:0 **DOUT[31:0]:** Data output
This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF flag set), virtually reads a complete 16-byte block of output data from the AES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

</tr>
</tbody>
</table>

Bits 31:0 **KEY[31:0]:** Cryptographic key, bits [31:0]
These are bits [31:0] of the write-only bitfield KEY[255:0] AES encryption or decryption key, depending on the MODE[1:0] bitfield of the AES_CR register.

Writes to AES_KEYRx registers are ignored when AES is enabled (EN bit set). When the key comes from the SAES peripheral (KMOD[1:0] at 0x2), writes to key registers are also ignored and they result in setting the KEIF bit of the AES_ISR register.

With KMOD[1:0] at 0x0, a special writing sequence is required. In this sequence, any valid write to AES_KEYRx register clears the KEYVALID flag except for the sequence-completing write that sets it. Also refer to the description of the KEYVALID flag in the AES_SR register.
33.8.6 AES key register 1 (AES_KEYR1)

Address offset: 0x014
Reset value: 0x0000 0000

Bits 31:0 KEY[63:32]: Cryptographic key, bits [63:32]
Refer to the AES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing AES_KEYRx registers.

33.8.7 AES key register 2 (AES_KEYR2)

Address offset: 0x018
Reset value: 0x0000 0000

Bits 31:0 KEY[95:64]: Cryptographic key, bits [95:64]
Refer to the AES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing AES_KEYRx registers.

33.8.8 AES key register 3 (AES_KEYR3)

Address offset: 0x01C
Reset value: 0x0000 0000

Bits 31:0 KEY[127:96]: Cryptographic key, bits [127:96]
Refer to the AES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing AES_KEYRx registers.
### 33.8.9 AES initialization vector register 0 (AES_IVR0)

Address offset: 0x020  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:16</th>

</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:0 **IVI[31:0]**: Initialization vector input, bits [31:0]

AES_IVRx registers store the 128-bit initialization vector or the nonce, depending on the chaining mode selected. This value is updated by hardware after each computation round (when applicable). Write to this register is ignored when EN bit is set in AES_SR register.

### 33.8.10 AES initialization vector register 1 (AES_IVR1)

1290/3119    RM0481 Rev 1
Bits 31:0 **SUSP[31:0]:** Suspend data

AES_SUSPRx registers contain the complete internal register states of the AES when the GCM, GMAC or CCM processing of the current task is suspended to process a higher-priority task. Refer to Section 33.4.8: AES suspend and resume operations for more details.

Read to this register returns zero when EN bit is cleared in AES_SR register.

AES_SUSPRx registers are not used in other chaining modes than GCM, GMAC or CCM.

### 33.8.18 AES interrupt enable register (AES_IER)

|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

| Bit 31:3 Reserved, must be kept at reset value. |
| Bit 2 KEIF: Key error interrupt flag |
| This read-only bit is set by hardware when the key information fails to load into key registers. |
| 0: No key error detected |
| 1: Key information failed to load into key registers |
| The flag setting generates an interrupt if the KEIE bit of the AES_IER register is set. |
| The flag is cleared by setting the corresponding bit of the AES_ICR register. |
| KEIF is raised upon any of the following events: |
| –AES_KEYRx register write does not respect the correct order. (For KEYSIZE cleared, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 register, or reverse. For KEYSIZE set, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 then AES_KEYR4 then AES_KEYR5 then AES_KEYR6 then AES_KEYR7, or reverse). |
| –AES fails to load the key shared by the SAES peripheral (KMOD[1:0] = 0x2). |
| KEIF must be cleared by the application software, otherwise KEYVALID cannot be set. |

| Bit 1 RWEIF: Read or write error interrupt flag |
| This read-only bit is set by hardware when a RDERRF or a WRERRF error flag is set in the AES_SR register. |
| 0: No read or write error detected |
| 1: Read or write error detected |
| The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set. |
| The flag is cleared by setting the corresponding bit of the AES_ICR register. |
| The flags has no meaning when key derivation mode is selected. |
| See the AES_SR register for details. |

| Bit 0 CCF: Computation complete flag |
| This flag indicates whether the computation is completed. It is significant only when the DMAOUTEN bit is cleared, and it may stay high when DMAOUTEN is set. |
| 0: Not completed |
| 1: Completed |
| The flag setting generates an interrupt if the CCFIE bit of the AES_IER register is set. |
| The flag is cleared by setting the corresponding bit of the AES_ICR register. |
33.8.20  AES interrupt clear register (AES_ICR)

Address offset: 0x308
Reset value: 0x0000 0000

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  KEIF: Key error interrupt flag clear
   Setting this bit clears the KEIF status bit of the AES_ISR register.

Bit 1  RWEIF: Read or write error interrupt flag clear
   Setting this bit clears the RWEIF status bit of the AES_ISR register, and clears both RDERRF and
   WRERRF flags in the AES_SR register.

Bit 0  CCF: Computation complete flag clear
   Setting this bit clears the CCF status bit of the AES_ISR register.

33.8.21  AES register map

34  Secure AES coprocessor (SAES)

34.1 Introduction

The secure AES coprocessor (SAES) encrypts or decrypts data in compliance with the advanced encryption standard (AES) defined by NIST. It incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3.

SAES supports ECB, CBC, CTR, GCM, GMAC, and CCM chaining modes for key sizes of 128 or 256 bits, as well as special modes such as hardware secret key encryption/decryption (Wrapped-key mode) and key sharing with faster AES peripheral (Shared-key mode).

SAES has the possibility to load by hardware STM32 hardware secret master keys (boot hardware key BHK and derived hardware unique key DHUK), usable but not readable by application.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels are required). It is hardware-linked with the true random number generator (TRNG) and with the AES peripheral.
34.2 SAES main features

- Compliant with NIST FIPS publication 197 “Advanced encryption standard (AES)” (November 2001)
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- Protection against side-channel attacks (SCA), incl. differential power analysis (DPA), certified SESIP and PSA security assurance level 3
- 128-bit data block processing, supporting cipher key lengths of 128-bit and 256-bit
  - 480 or 680 clock cycle latency in ECB mode for processing one 128-bit block with, respectively, 128-bit or 256-bit key
- Hardware secret key encryption/decryption (Wrapped-key mode)
- Using dedicated key bus, optional key sharing with faster AES peripheral (Shared-key mode), controlled by SAES
- Integrated key scheduler to compute the last round key for ECB/CBC decryption
- 256-bit of write-only registers for storing cryptographic keys (eight 32-bit registers)
  - Optional 128-bit or 256-bit hardware loading of two hardware secret keys (BHK, DHUK) that can be XOR-ed together
- Security context enforcement for keys
- 128-bit of registers for storing initialization vectors (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control supporting two direct memory access (DMA) channels, one for incoming data, one for processed data. Only single transfers are supported.
- Data-swapping logic to support 1-, 8-, 16-, or 32-bit data
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.
- Possibility for software to suspend a message if SAES needs to process another message with a higher priority, then resume the original message

34.3 SAES implementation

The devices have one SAES peripheral, implemented as per the following table. It shares the key with the AES peripheral. For comparison, the AES peripheral is also included in the table.

34.4 SAES functional description

34.4.1 SAES block diagram

*Figure 308* shows the block diagram of SAES.

![SAES Block Diagram](figure308.png)

**Figure 308. SAES block diagram**

Note: AES represents the AES peripheral.

34.4.2 SAES internal signals

*Table 314* describes the user relevant internal signals interfacing the SAES peripheral.
### RM0481

**Secure AES coprocessor (SAES)**

#### 34.4.3 SAES reset and clocks

The SAES peripheral is clocked by the AHB bus clock. The SAES instance has also a dedicated kernel clock programmed in the RCC.

The SAES has a dedicated reset bit in the RCC.

#### 34.4.4 SAES symmetric cipher implementation

The secure AES coprocessor (SAES) is a 32-bit AHB peripheral that encrypts or decrypts 16-byte blocks of data using the advanced encryption standard (AES). It also implements a set of approved AES symmetric key security functions summarized in Table 315. Those functions can be certified NIST PUB 140-3.

SAES can be used directly by the CPU, or indirectly, using two DMA channels (one for the plaintext, one for the ciphertext).

It is possible to suspend then resume any SAES processing, following the sequence described in Section 34.4.8.

### 34.4.5 SAES encryption or decryption typical usage

The following figure shows a typical operation for encryption or decryption.

**Figure 309. Encryption/decryption typical usage**

![SAES Encryption/Decryption Diagram](diagram)

**Initialization**

The SAES peripheral is initialized according to the chaining mode. Refer to Section 34.4.9: SAES basic chaining modes (ECB, CBC) and Section 34.4.10: SAES counter (CTR) mode for details.

**Data append**

This section describes different ways of appending data for processing. For ECB or CBC chaining modes, refer to Section 34.4.7: SAES ciphertext stealing and data padding if the size of data to process is not a multiple of 16 bytes. The last block management in these cases is more complex than what is described in this section.
Appending data using the CPU in polling mode

This method uses flag polling to control the data append through the following sequence:

1. When KEYVALID is set, enable the SAES peripheral, by setting the EN bit of the SAES_CR register (if not already done).
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the SAES_DINR register.
   b) Wait until the status flag CCF is set in the SAES_ISR register, then read the four data words from the SAES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
   d) If the next processing block is the last block, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (using NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong).
3. As the data block just processed is the last block of the message, optionally discard the data that is not part of the message/payload, then disable the SAES peripheral by clearing EN.

Note: Up to three wait cycles are automatically inserted between two consecutive writes to the SAES_DINR register, to allow sending the key to the AES co-processor.

NPBLB[3:0] bitfield is not used in header phase of GCM, GMAC and CCM chaining modes.

Appending data using the CPU in interrupt mode

The method uses interrupt from the SAES peripheral to control the data append, through the following sequence:

1. Enable interrupts from SAES, by setting the CCFIE bit of the SAES_IER register.
2. When KEYVALID is set, enable the SAES peripheral, by setting EN (if not already done).
3. Write first four input data words into the SAES_DINR register.
4. Handle the data in the SAES interrupt service routine. Upon each interrupt:
   a) Read four output data words from the SAES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the SAES_ICR register.
   c) If the next processing block is the last block of the message, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (through NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, optionally discard the data that are not part of the message/payload, then disable the SAES peripheral by clearing EN and quit the interrupt service routine.
   e) Write next four input data words into the SAES_DINR register and quit the interrupt service routine.

Note: SAES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two SAES computations.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.
Appending data using DMA

With this method, all the transfers and processing are managed by DMA and SAES. Proceed as follows:

1. If the last block of the message to process is shorter than 16 bytes, prepare the last four-word data block by padding the remainder of the block with zeros.

2. Configure the DMA controller so as to transfer the data to process from the memory to the SAES peripheral input and the processed data from the SAES peripheral output to the memory, as described in Section 34.6: SAES DMA requests. Configure the DMA controller so as to generate an interrupt on transfer completion. For GCM payload encryption or CCM payload decryption, the DMA transfer must not include the last four-word block if padded with zeros. The sequence described in Appending data using the CPU in polling mode must be used instead for this last block, because the NPBLB[3:0] bitfield must be set up before processing the block, for SAES to compute a correct tag.

3. When KEYVALID is set, enable the SAES peripheral, by setting EN (if not already done).

4. Enable DMA requests, by setting DMAINEN and DMAOUTEN.

5. Upon DMA interrupt indicating the transfer completion, get the SAES-processed data from the memory.

Note: The CCF flag has no use with this method because the reading of the SAES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.
34.4.6 SAES authenticated encryption, decryption, and cipher-based message authentication

The following figure shows a typical operation for authenticated encryption or decryption, and for cipher-based message authentication.

**Figure 310. Typical operation with authentication**

---

Section 34.4.11: SAES Galois/counter mode (GCM) and Section 34.4.13: SAES counter with CBC-MAC (CCM) describe detailed sequences supported by SAES.

Cipher-based message authentication flow omits the payload phase, as shown in the figure. Detailed sequence supported by SAES is described in Section 34.4.12: SAES Galois message authentication code (GMAC).

34.4.7 SAES ciphertext stealing and data padding

When using SAES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (16 bytes), the application must use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since SAES does not implement such techniques, the application must complete the last block of input data using data from the second last block.

*Note:* **Ciphertext stealing techniques are not documented in this reference manual.**

Similarly, in modes other than ECB or CBC, an incomplete input data block (that is, a block with input data shorter than 16 bytes) must be padded with zeros prior to encryption. That is, extra bits must be appended to the trailing end of the data string. After decryption, the extra bits must be discarded. Since SAES does not implement automatic data padding operation to the last block, the application must follow the recommendation given in this document to manage messages the size of which is not a multiple of 16 bytes.
34.4.8 SAES suspend and resume operations

A message can be suspended to process another message with a higher priority. When the higher-priority message is sent, the suspended message can resume. This applies to both encryption and decryption mode.

Suspend and resume operations do not break the chaining operation. The message processing can resume as soon as SAES is enabled again, to receive a next data block. 

*Figure 311* gives an example of suspend and resume operations: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

*Figure 311. Example of suspend mode management*

A detailed description of suspend and resume operations is in the sections dedicated to each chaining mode.

34.4.9 SAES basic chaining modes (ECB, CBC)

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately. When decrypting in ECB, a special key scheduling is required before processing the first block.

*Figure 312* and *Figure 313* describe the electronic codebook (ECB) chaining implementation in encryption and in decryption, respectively. To select ECB chaining mode, write CHMOD[2:0] with 0x0.
In CBC encryption mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing. When decrypting in CBC, a special key scheduling is required before processing the first block.

Figure 314 and Figure 315 describe the cipher block chaining (CBC) implementation in encryption and in decryption, respectively. To select this chaining mode, write CHMOD[2:0] with 0x1.
**For more details, refer to NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.**

### ECB and CBC encryption process

This process is described in Section 34.4.5, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follows:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in encryption mode (write MODE[1:0] with 0x0).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit must also be set.
   - Select normal key mode by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to Section 34.4.14 (wrapped keys) and Section 34.4.15 (shared keys).
4. Write the initialization vector into the SAES_IVRx registers if CBC mode is selected in the previous step.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to Section 34.4.17: SAES key registers for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Append cleartext data:
   a) If it is the second-last or the last block and the plaintext size of the message is not a multiple of 16 bytes, follow the guidance in Section 34.4.7.
   b) Append the cleartext block into SAES as described in Section 34.4.5, then read the SAES_DOUTR register four times to save the ciphertext block.
   c) Repeat the step b) until the third-last plaintext block is encrypted. For the last two blocks, follow the steps a) and b).
9. Finalize the sequence: disable the SAES peripheral, by clearing EN.
ECB/CBC decryption process

This process is described in Section 34.4.5, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follows:
   - Select the key derivation mode (write MODE[1:0] with 0x1). The CHMOD[2:0] bitfield is not significant during this operation.
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit must also be set.
   - Select normal key mode by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to Section 34.4.14 (wrapped keys) and Section 34.4.15 (shared keys).
4. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to Section 34.4.17: SAES key registers for details.
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the SAES peripheral, by setting EN. The peripheral immediately starts an AES round for key preparation.
7. Wait until the CCF flag in the SAES_ISR register is set.
8. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register. The decryption key is available in the AES core and SAES is disabled automatically.
9. Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in decryption mode (write MODE[1:0] with 0x2). Do not change other parameters.
10. Write the initialization vector into the SAES_IVRx registers if CBC mode is selected in the previous step.
11. Enable the SAES peripheral, by setting EN.
12. Append encrypted data:
   a) If it is the second-last or the last block and the ciphertext size of the message is not a multiple of 16 bytes, follow the guidance in Section 34.4.7.
   b) Append the ciphertext block into SAES as described in Section 34.4.5, then read the SAES_DOUTR register four times to save the cleartext block (MSB first).
   c) Repeat the step b) until the third-last ciphertext block is decrypted. For the last two blocks, follow the steps a) and b).
13. Finalize the sequence: disable the SAES peripheral, by clearing EN.

Suspend/resume operations in ECB/CBC modes

The following sequences are valid for normal key mode (KMOD[1:0] at 0x0).

To suspend the processing of a message, proceed as follows:
1. If DMA is used, stop the SAES DMA transfers to the input FIFO, by clearing the DMAINEN bit of the SAES_CR register.
2. If DMA is not used, read four times the SAES_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the SAES_ISR
register then stop the DMA transfers from the output FIFO, by clearing the
DMAOUTEN bit of the SAES_CR register.
3. If DMA is not used, wait until the CCF flag in the SAES_ISR register is set (computation
completed).
4. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
5. Save initialization vector registers (only required in CBC mode as the SAES_IVRx
registers are altered during the data processing).
6. Disable the SAES peripheral, by clearing EN.
7. Save the SAES_CR register and clear the key registers if they are not needed, to
process the higher-priority message.
8. If DMA is used, save the DMA controller status (pointers for SAES input and output
data transfers, number of remaining bytes, and so on).

To resume the processing of a message, proceed as follows:
1. If DMA is used, configure the DMA controller so as to complete the remaining input
FIFO and output FIFO transfers.
2. Disable the SAES peripheral, by clearing EN.
3. Restore the SAES_CR register (with correct KEYSIZE) then restore the SAES_KEYRx
registers. Alternatively, select a key source different from key registers, using
KEYSEL[2:0]. Refer to Section 34.4.17: SAES key registers for details.
4. Prepare the decryption key, as described in ECB/CBC decryption process (only
required for ECB or CBC decryption).
5. Restore the SAES_IVRx registers, using the saved configuration (only required in CBC
mode).
6. Enable the SAES peripheral, by setting EN.
7. If DMA is used, enable SAES DMA transfers, by setting DMAINEN and DMAOUTEN.

Note: It is not required to save the key registers as the application knows the original key.

34.4.10 SAES counter (CTR) mode

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed
with the plaintext to obtain the ciphertext. Unlike with ECB and CBC modes, no key
scheduling is required for the CTR decryption since the AES core is always used in
encryption mode.
A typical message construction in CTR mode is given in Figure 316.

**Figure 316. Message construction in CTR mode**

The structure of this message is:

- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector** (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.

- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

For more details, refer to NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*.

**CTR encryption and decryption**

*Figure 317* describes the counter (CTR) chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x2.

**Figure 317. CTR encryption**
Initialization vectors in SAES must be initialized as shown in Table 316.

</tbody>
</table>

CTR encryption and decryption process

This process is described in Section 34.4.5, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select CTR chaining mode (write CHMOD[2:0] with 0x2) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit must also be set.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to Section 34.4.14 (wrapped keys) and Section 34.4.15 (shared keys).
4. Write the initialization vector into the SAES_IVRx registers according to Table 316.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to Section 34.4.17: SAES key registers for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Append data:
   a) If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is less than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into SAES as described in Section 34.4.5, then read the SAES_DOUTR register four times to save the resulting block (MSB first).
   c) Repeat the step b) until the second-last block is processed. For the last block of plaintext (encryption only), follow the steps a) and b). For the last block, discard the bits that are not part of the message when the last block is smaller than 16 bytes.
9. Finalize the sequence: disable the SAES peripheral, by clearing EN.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher-priority message, then resume the interrupted message. Detailed CBC suspend and resume sequence is described in Section 34.4.9: SAES basic chaining modes (ECB, CBC).

Note: Like for CBC mode, the IV registers must be reloaded during the resume operation.
34.4.11 SAES Galois/counter mode (GCM)

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code).

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. The following figure shows a typical message construction in GCM mode.

![Figure 318. Message construction in GCM](image)

The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV)**: a 96-bit value that must be unique for each encryption cycle with a given key. The GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.

- **Authenticated header AAD** (also knows as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} - 1$ bits. This part of the message is only authenticated, not encrypted.

- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed $2^{32} - 2$ 16-byte blocks.

- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in Table 318.

The GCM standard specifies that ciphertext C has the same bit length as the plaintext P. When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

For more details, refer to NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*
Figure 319 describes the GCM chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x3.

The first counter block (CB1) is derived from the initial counter block ICB by the application software, as defined in Table 317.

<table>
<thead>

GCM encryption and decryption process

This process is described in Section 34.4.6, with the following sequence of events:

**GCM initialize**

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select GCM chaining mode (write CHMOD[2:0] with 0x3) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (such as secure, non-secure, specific CPU), also set KEYPROT.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to Section 34.4.14 (wrapped keys) and Section 34.4.15 (shared keys).
   - Select the GCM initialization phase, by writing GCMPH[1:0] with 0x0.
4. Write the initialization vector in SAES_IVRx registers according to Table 317.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to Section 34.4.17: SAES key registers for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Set EN to start the calculation of the hash key. EN is automatically cleared when the calculation is completed.
8. Wait until the CCF flag is set in the SAES_ISR register, indicating that the GCM hash subkey (H) computation is completed.
9. Clear the CCF flag by setting the CCF bit of the SAES_ICR register.

**GCM header phase**

10. Initialize header phase:
   a) Select the GCM header phase, by writing 0x1 to GCMPH[1:0]. Do not change the other configurations written during GCM initialization.
   b) Enable the SAES peripheral, by setting EN.
11. Append header data:
   a) If it is the last block and the AAD in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into SAES as described in Section 34.4.5.
   c) Repeat the step b) until the second-last AAD data block is processed. For the last block, follow the steps a) and b).

**Note:** This phase can be skipped if there is no AAD, that is, Len(A) = 0.
No data are read during header phase.
GCM payload phase
12. Initialize payload phase:
   a) Select the GCM payload phase, by writing GCMPH[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
   b) If the header phase is skipped, enable the SAES peripheral by setting EN.
13. Append payload data:
   a) If it is the last block and the message in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into SAES as described in Section 34.4.5, then read the SAES_DOUTR register four times to save the resulting block
   c) Repeat the step b) until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps a) and b). For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(C)=0 (see GMAC mode).

GCM finalization
14. Encryption only: wait until the BUSY flag in the SAES_SR register is cleared.
15. Select the GCM final phase, by writing GCMPH[1:0] with 0x3. Do not change the other configurations written during GCM initialization.
16. Write the final GCM block into the SAES_DINR register. It is the concatenated AAD bit and payload bit lengths, as shown in Table 318.
17. Wait until the CCF flag in the SAES_ISR register is set.
18. Get the GCM authentication tag, by reading the SAES_DOUTR register four times.
19. Clear the CCF flag, by setting the CCF bit in SAES_ICR register.
20. Disable the SAES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data are written to SAES_DINR normally (no swapping), while swapping is applied to tag data read from SAES_DOUTR.

When transiting from the header or the payload phase to the final phase, the SAES peripheral must not be disabled, otherwise the result is wrong.

Suspend/resume operations in GCM mode
Suspend/resume operations are not supported in GCM mode.

34.4.12 SAES Galois message authentication code (GMAC)
The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code).

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload). The following figure shows typical message construction for GMAC.
For more details, refer to NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC. Figure 321 describes the GMAC chaining implementation in the SAES peripheral. To select this chaining mode, write CHMOD[2:0] with 0x3.

**Figure 321. GMAC authentication mode**

The GMAC algorithm corresponds to the GCM algorithm applied on a message that only contains a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

**Suspend/resume operations in GMAC**

Suspend/resume operations are not supported in GMAC mode.
34.4.13 SAES counter with CBC-MAC (CCM)

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES counter mode processing. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve CBC-MAC as an authentication mode outside the context of the CCM specification.

The following figure shows typical message construction for CCM.

**Figure 322. Message construction in CCM mode**

The structure of the message is:

- **16-byte first authentication block (B0),** composed of three distinct fields:
  - Q: a bit string representation of the octet length of P (Len(P))
  - Nonce (N): a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - Flags: most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values t (MAC length expressed in bytes) and Q (plaintext length such that Len(P) < 2^Q bytes). The counter blocks range associated to Q is equal to 2^Q-4, that is, if the maximum value of Q is 8, the counter blocks used in cipher must be on 60 bits.

- **16-byte blocks (B) associated to the associated data (A).**

  This part of the message is only authenticated, not encrypted. This section has a known length Len(A) that can be a non-multiple of 16 bytes (see Figure 322). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
  - If 0 < a < 2^16 - 2^5, then it is encoded as [a]16, that is, on two bytes.
  - If 2^16 - 2^8 < a < 2^32, then it is encoded as 0xff || 0xfe || [a]32, that is, on six bytes.
  - If 2^32 < a < 2^64, then it is encoded as 0xff || 0xff || [a]64, that is, on ten bytes.
- **16-byte blocks (B)** associated to the plaintext message \( P \), which is both authenticated and encrypted as ciphertext \( C \), with a known length \( \text{Len}(P) \). This length can be a non-multiple of 16 bytes (see Figure 322).

- **Encrypted MAC (T)** of length \( \text{Len}(T) \) appended to the ciphertext \( C \) of overall length \( \text{Len}(C) \).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

*Note:* CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

- \( N: 10111213\ 141516 \) (Len(N) = 56 bits or 7 bytes)
- \( A: 00010203\ 04050607 \) (Len(A) = 64 bits or 8 bytes)
- \( P: 20212223 \) (Len(P) = 32 bits or 4 bytes)
- \( T: 6084341B \) (Len(T) = 32 bits or \( t = 4 \))
- \( B0: 4F101112\ 13141516\ 00000000\ 00000004 \)
- \( B1: 00080001\ 02030405\ 06070000\ 00000000 \)
- \( B2: 20212223\ 00000000\ 00000000\ 00000000 \)
- \( \text{CTR}0: 0710111213\ 141516\ 00000000\ 00000000 \)
- \( \text{CTR}1: 0710111213\ 141516\ 00000000\ 00000001 \)

For more details, refer to NIST Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality.
Figure 323 describes the CCM chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x4.

The first block of a CCM message (B0) must be prepared by the application as defined in Table 319.

Table 319. Initialization of IV registers in CCM mode

<table>
<thead>

</tbody>
</table>

1. The 5 most significant bits are cleared (flag bits).
2. Q length bits are cleared, except for the bit 0 that is set.

SAES supports counters up to 64 bits, as specified by NIST.
CCM encryption and decryption process

This process is described in Section 34.4.6, with the following sequence of events:

**CCM initialize**

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select CCM chaining mode (write CHMOD[2:0] with 0x4) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context, also set the KEYPROT bit.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to Section 34.4.14 (wrapped keys) and Section 34.4.15 (shared keys).
   - Select the CCM initialization phase, by writing GCMPH[1:0] with 0x0.
4. Write the B0 data in SAES_IVRx registers according to Table 319.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to Section 34.4.17: SAES key registers for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Set EN to start the first mask calculation. The EN bit is automatically cleared when the calculation is completed.
8. Wait until the CCF flag in the SAES_ISR register is set.
9. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.

**CCM header phase**

10. Initialize header phase:
    a) Prepare the first block of the (B1) data associated with the message, in accordance with CCM chaining rules.
    b) Select the CCM header phase, by writing GCMPH[1:0] with 0x1. Do not change the other configurations written during the CCM initialization.
    c) Enable the SAES peripheral, by setting EN.
11. Append header data:
    a) If it is the last block and the associated data in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in Section 34.4.5.
    c) Repeat the step b) until the second-last associated data block is processed. For the last block, follow the steps a) and b).

*Note:* This phase can be skipped if there is no associated data, that is, Len(A) = 0

No data are read during the header phase.
CCM payload phase

12. Initialize payload phase:
   a) Select the CCM payload phase, by writing GCMPH[1:0] with 0x2. Do not change the other configurations written during the CCM initialization.
   b) If the header phase is skipped, enable the SAES peripheral, by setting EN.

13. Append payload data:
   a) In encryption only, if it is the last block and the plaintext in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into SAES as described in Section 34.4.5, then read the SAES_DOUTR register four times to save the resulting block.
   c) Repeat the step b) until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps a) and b). For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(P) = 0 or Len(C) = Len(T).
Remove LSB_{Len(T)}(C) encrypted tag information when decrypting ciphertext C.

CCM finalization

14. Select the CCM final phase, by writing GCMPH[1:0] with 0x3. Do not change the other configurations written during the CCM initialization.

15. Wait until CCF flag in the SAES_ISR register is set.

16. Get the CCM authentication tag, by reading the SAES_DOUTR register four times.

17. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.

18. Disable the SAES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message. Mask the authentication tag output with tag length to obtain a valid tag.

Note: In the final phase, swapping is applied to tag data read from SAES_DOUTR register.
When transiting from the header or the payload phase to the final phase, the SAES peripheral must not be disabled, otherwise the result is wrong.

Suspend and resume operations in CCM mode

To suspend the processing of a message in header or payload phase, proceed as follows:

1. If DMA is used, stop the SAES DMA transfers to the input FIFO, by clearing DMAINEN. If DMA is not used, wait until the CCF flag of the SAES_ISR register is set (computation completed).

2. In the payload phase, if DMA is not used, read four times the SAES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag in the SAES_ISR register is set, then stop the DMA transfers from the output FIFO, by clearing DMAOUTEN.

3. Clear the CCF flag in the SAES_ISR register, by setting the CCF bit of the SAES_ICR register.

4. Save the SAES_SUSPRx registers in the memory.

5. Save the IV registers as they are altered during the data processing.

6. Disable the SAES peripheral, by clearing EN.
7. Save the current SAES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.

8. If DMA is used, save the DMA controller status (pointer for SAES input data transfers, number of remaining bytes, and so on). In the payload phase, also save pointer for SAES output data transfers.

To resume the processing of a message, proceed as follows:
1. If DMA is used, configure the DMA controller in order to complete the remaining input FIFO transfers. In the payload phase, also configure the DMA controller for the remaining output FIFO transfers.
2. Disable the SAES peripheral, by clearing EN.
3. Write the suspend register values, previously saved in the memory, back into their corresponding SAES_SUSPRx registers.
4. Restore SAES_IVRx registers using the saved configuration.
5. Restore the initial setting values in the SAES_CR and SAES_KEYRx registers. Alternatively, select a key source different from the key registers, by setting KEYSEL[2:0] to a value different from 0x0. Refer to Section 34.4.17: SAES key registers for details.
6. Enable the SAES peripheral, by setting EN.
7. If DMA is used, enable SAES DMA requests, by setting DMAINEN (and DMAOUTEN if in payload phase).

34.4.14 SAES operation with wrapped keys

SAES peripheral can wrap (encrypt) and unwrap (decrypt) application keys using hardware-secret key DHUK, XOR-ed or not with application key BHK. With this feature, AES keys can be made usable by application software without being exposed in clear-text (unencrypted).

Wrapped key sequences are too small to be suspended/resumed. SAES cannot unwrap a key using an unwrapped key.

Operation with wrapped keys for SAES in ECB and CBC modes

*Figure 324* summarizes how to wrap or unwrap keys for SAES in ECB and CBC modes. To protect the wrapped key, select DHUK by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.
The recommended sequence to wrap (that is, encrypt) a key is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in encryption mode (MODE[1:0] at 0x0)
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size with KEYSIZE. This information is used both for the encryption key and for the key to be encrypt.
   - Select wrapped key mode by writing KMOD[1:0] with 0x1
4. Write the initialization vector in SAES_IVRx registers if CBC mode has been selected in previous step.
5. Select the DHUK key source by writing KEYSEL[2:0] with 0x1 or 0x4. Refer to Section 34.4.17 for details on the use of KEYSEL[2:0] at 0x4.
6. Wait until KEYVALID is set (DHUK loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Write the SAES_DINRx register four times to input the key to encrypt (MSB first, see Table 321 on page 1329).
9. Wait until CCF flag is set in the SAES_ISR register.
10. Get the encrypted key (MSB first) by reading the SAES_DOUTRx register four times. Then clear the CCF flag, by setting the CCF bit in SAES_ICR register.
11. Repeat steps 8. to 10. if KEYSIZE is set.
12. Disable the SAES peripheral, by clearing EN.

Note: Encryption in Wrapped-key mode is only supported when ECB or CBC is selected.
Key unwrapping for SAES

The recommended sequence to unwrap (or decrypt) a wrapped (encrypted) key using ECB/CBC is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select the chaining mode used during the wrapping process (CHMOD[2:0] at 0x0 or 0x1) in key derivation mode (MODE[1:0] at 0x1)
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size used during the wrapping process, with KEYSIZE. This information is used both for the decryption key and for the key to decrypt.
   - Select wrapped key mode, by writing KMOD[1:0] with 0x1.
4. Select the DHUK key source, by writing KEYSEL[2:0] with 0x1 or 0x4. Refer to Section 34.4.17 for details on the use of KEYSEL[2:0] at 0x4.
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN bit in SAES_CR to enable the peripheral
7. Wait until CCF flag is set in the SAES_ISR register.
8. Clear the CCF flag, by setting the CCF bit in SAES_ICR register. The decryption key is available in the AES core, and SAES is disabled automatically.
9. Select the decryption mode (MODE[1:0] at 0x2). Other parameters are unchanged.
10. Write the initialization vector in SAES_IVRx registers if CBC mode has been selected in previous step.
11. Enable the SAES peripheral, by setting EN.
12. Write the SAES_DINR register four times to input the key to decrypt (MSB first, see Table 321 on page 1329).
13. Wait until CCF flag is set in the SAES_ISR register. Then clear the CCF flag by setting the CCF bit in SAES_ICR register. Reading SAES_DOUTR returns zero and triggers a read error (RDERR).
15. Disable the SAES peripheral, by clearing EN.

At the end of this sequence, the decrypted wrapped key is immediately usable by the application for any AES operation (normal key mode). Decrypted wrapped key can be shared with an application running in a different security context (different security or Compartment ID attribute) if KEYPROT bit was cleared during step 3.

Note: When KMOD[1:0] = 0x1 (wrapped key) and MODE[1:0] = 0x2 (decryption) a read access to SAES_DOUTR register triggers a read error (RDERR).

When KEYSEL[2:0] is at 0x1 (DHUK) or 0x4 (DHUK XOR BHK), the application software must use the same privilege, security, KMOD[1:0], CHMOD[2:0] and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

Operation with wrapped keys for SAES in CTR mode

Figure 325 summarizes how to unwrap keys for SAES in CTR mode. To protect the derived key, select DHUK by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.
The recommended sequence for SAES wrapped key mode using CTR is as follows:
1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select the CTR chaining mode (CHMOD[2:0] at 0x2) in decryption mode (MODE[1:0] at 0x2). Other MODE[1:0] values are not supported.
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size with KEYSIZE. It is used for encryption key and for the key to share.
   - Select wrapped key mode, by writing KMOD[1:0] with 0x1.
4. Write the initialization vector in SAES_IVRx registers, keeping the two least significant bits of SAES_IVR0 at zero.
5. Select the DHUK key source by writing KEYSEL[2:0] with 0x1 or 0x4. Refer to Section 34.4.17 for details on the use of KEYSEL[2:0] at 0x4.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Wait until CCF flag is set in the SAES_ISR register.
9. Clear the CCF flag, by setting the CCF bit in SAES_ICR register. The derived hardware secret key is available in SAES_KEYRx registers.
10. Repeat steps 8. and 9. if KEYSIZE is set.
11. Disable the SAES peripheral, by clearing EN.

At the end of this sequence, the hardware secret key derived from the public data in the SAES_IVRx registers is then immediately usable by the application for any AES operation (normal key mode).
**Note:** The configuration KMOD[1:0] at 0x1 (wrapped key), CHMOD[2:0] at 0x2 (CTR chaining), and MODE at 0x0 (encryption) disables the peripheral, by automatically clearing the EN bit of the SAES_CR register.

### 34.4.15 SAES operation with shared keys

SAES peripheral can share application keys wrapped with hardware-secret key DHUK, XOR-ed or not with application key BHK. With this feature, the application software can make the AES keys available to the AES peripheral, without exposing them in clear-text (unencrypted).

Shared key sequences are too small to be suspended/resumed. SAES cannot unwrap a shared key using an unwrapped key.

**Note:** When a key stored in SAES is shared with AES, the protection given by KEYPROT bit is lost. The protection is detailed in Section 34.4.17: SAES key registers.

*Figure 326* summarizes how to wrap or unwrap keys to share with AES peripheral. To protect the shared key, DHUK must be selected, by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.

</tr>
<tr>
<td><strong>MODE</strong> = 00 (encryption)</td>
<td><strong>MODE</strong> = 10 (decryption)</td>
<td><strong>MODE</strong> = any value</td>
</tr>
</tbody>
</table>

**Note:** DHUK value depends on privilege, KMOD[1:0], KSHAREID, KEYSEL[2:0], CHMOD[2:0], and on whether SAES peripheral is secure or non-secure.

In the step 3, AES represents the AES peripheral.

### Key wrapping for AES peripheral

Before SAES can share a key with the AES peripheral, the key must be encrypted (wrapped) once. The encryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] at 0x2 (shared key) and KSHAREID[1:0] kept at 0x0 in the step 3 in *Figure 326*. See Key wrapping for SAES for details.

**Note:** Encryption in Shared-key mode is only supported when ECB or CBC is selected.
Key unwrapping for AES peripheral (shared key)

Each time SAES needs to share a key with the AES peripheral, shared encrypted key must be decrypted (unwrapped) in SAES, then loaded by AES. The overall sequence is described next.

Sequence in the SAES peripheral

The decryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] at 0x2 (shared key) and KSHAREID[1:0] kept at 0x0 in the step 3 in Figure 326. See Key unwrapping for SAES for details.

In shared key mode when decryption mode is selected (MODE[1:0] at 0x2), a read access to the SAES_DOUTR register triggers a read error (RDERR).

Note: Instead of being shared, a decrypted shared key can be used directly in SAES as the KEYSEL[2:0] bitfield is automatically cleared. In this case, KMOD[1:0] must be written with 0x0 (normal key mode).

Sequence in the AES peripheral

Once the shared key is decrypted in SAES key registers, it can be shared with the AES peripheral, while SAES peripheral remains in key sharing state, that is, with KMOD[1:0] at 0x2 and KEYVALID set. The sequence in the AES key share target peripheral is described in AES key sharing with secure AES co-processor of the corresponding section in this document. It can be run multiple times (for example, to manage a suspend/resume situation) as long as SAES is unused and duly remains in key sharing state.

Note: When KMOD[1:0] is at 0x2 and BUSY set in the AES peripheral, and KEYSIZE value of AES and SAES differs, the key sharing fails and the KEIF flag is raised in both peripherals.

When KEYSEL[2:0] is at 0x1 (DHUK) or 0x4 (DHUK XOR BHK), the application software must use the same privilege, security, KMOD[1:0] / KSHAREID[1:0], CHMOD[2:0], and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

34.4.16 SAES data registers and data swapping

Data input and output

A 16-byte data block enters the SAES peripheral with four successive 32-bit word writes into the SAES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 16-byte data block is retrieved from the SAES peripheral with four successive 32-bit word reads of the SAES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The four 32-bit words of a 16-byte data block must be stored in the memory consecutively and in big-endian order, that is, with the most significant word on the lowest address. See Table 320 “no swapping” option for details.

Data swapping

The SAES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the SAES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the SAES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.
The data swap type is selected through DATATYPE[1:0]. The selection applies to both SAES input and output.

Note: The data in SAES key registers (SAES_KEYRx) and initialization vector registers (SAES_IVRx) are not sensitive to the swap mode selection.

The SAES data swapping feature is summarized in Table 320 and Figure 327.

</tbody>
</table>
Data padding

Figure 327 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 84 message bits, with DATATYPE[1:0] = 0x0
- 48 message bits, with DATATYPE[1:0] = 0x1
- 56 message bits, with DATATYPE[1:0] = 0x2
- 34 message bits, with DATATYPE[1:0] = 0x3
34.4.17 SAES key registers

The eight SAES_KEYR[0] write-only registers store the encryption or decryption key information, as shown on Table 321. Reads are not allowed for security reason.

**Note:** In memory and in SAES key registers, keys are stored in little-endian format, with most significant byte on the highest address.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>

<td>-</td>
<td>KEY[127:96]</td>
<td>KEY[95:64]</td>
<td>KEY[63:32]</td>
<td>KEY[31:0]</td>
</tr>
</tbody>
</table>

The key registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield.

Write operations to the SAES_KEYR[0] registers are ignored when SAES peripheral is enabled (EN bit set) and KEYSEL[2:0] is different from zero. The application must check this before modifying key registers.

The entire key must be written before starting an AES computation. In normal key mode (KMOD[1:0] at 0x0), with KEYSEL[2:0] at 0x0, the key registers must always be written in either ascending or descending order. The write sequence becomes:

- SAES_KEYR[0] (x = 0 to 3 or x=3 to 0) for KEYSIZE cleared
- SAES_KEYR[0] (x = 0 to 7 or x=7 to 0) for KEYSIZE set

**Note:** KEYSIZE must be written before the key.

As soon as the first key register is written, the KEYVALID flag is cleared. Once the key registers writing sequence is completed, KEYVALID is set and EN becomes writable. If an error occurs, KEYVALID is cleared and KEIF set (see Section 34.4.19).

**Key selection**

With KEYSEL[2:0] at 0x0, the application must write the key in the SAES_KEYR[0] registers.

With KEYSEL[2:0] at 0x1, a derived hardware unique key (DHUK), computed inside SAES from a non-volatile and secret root hardware unique key, is loaded directly into key registers, based on KEYSIZE information. Thanks to the key derivation function, a secure SAES uses a secure DHUK, while a non-secure SAES uses a non-secure DHUK.

With KEYSEL[2:0] at 0x2, the boot hardware key (BHK), stored in tamper-resistant secure backup registers, is entirely transferred into key registers upon a secure application performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE cleared, x = 0 to 7 for KEYSIZE set) in either ascending or descending order. Refer to Table 321.

With KEYSEL[2:0] at 0x4, the XOR combination of DHUK and BHK is entirely transferred into key registers upon a secure application performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE cleared, x = 0 to 7 for KEYSIZE set) in either ascending or descending order. Refer to Table 321.
Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK if KEYVALID is set. The recommended method to clear KEYVALID is to set IPRST. Such method is required for example when switching from ECB decryption to ECB encryption, selecting the same BHK (KEYSEL[2:0] at 0x2).

For all KEYSEL[2:0] values, initiating the key-loading sequence sets the BUSY flag and clears the KEYVALID flag. Once the amount of bits defined by KEYSIZE is transferred to the SAES_KEYRx registers, BUSY is cleared, KEYVALID set and the EN bit becomes writable. If an error occurs, BUSY and KEYVALID are cleared and KEIF set (see Section 34.4.19).

**Key protection**

As depicted in Figure 328, when an application sets the KEYPROT bit before writing a key in SAES_KEYRx, any application executing in a different security context (that is, different security attribute) triggers a KEIF error flag upon access to any SAES register when KEYVALID is set.

**Note:** KEYSEL[2:0] values different from zero (normal key) automatically protect the key registers.

**Figure 328. Key protection mechanisms**

![Key protection mechanisms](image)

34.4.18 SAES initialization vector registers

The four SAES_IVRx registers store the initialization vector (IV) information, as shown in Table 322. They can only be written if the SAES peripheral is disabled (EN cleared).

**Note:** In memory and in SAES IV registers, initialization vectors are stored in little-endian format, with most significant byte on the highest address.

<table>
<thead>
<tr>
<th>SAES_IVR3[31:0]</th>
<th>SAES_IVR2[31:0]</th>
<th>SAES_IVR1[31:0]</th>
<th>SAES_IVR0[31:0]</th>
</tr>
</thead>
</table>
Initialization vector information depends on the chaining mode selected. When used, SAES_IVRx registers are updated upon each AES computation cycle (useful for managing suspend mode).

The initialization vector registers are not affected by the data swapping feature controlled through DATATYPE[1:0].

### 34.4.19 SAES error management

The SAES peripheral manages the errors described in this section.

**Read error flag (RDERRF)**

Unexpected read attempt of the SAES_DOUTR register returns zero, setting the RDERRF flag and the RWEIF flag. RDERRF is triggered during the computation phase or during the input phase.

*Note:* Unless otherwise indicated, **SAES is not disabled when RDERRF rises and it continues processing.**

An interrupt is generated if the RWEIE bit is set. For more details, refer to [Section 34.5: SAES interrupts](#).

The RDERRF and RWEIF flags are cleared by setting the RWEIF bit of the SAES_ICR register.

**Write error flag (WDERR)**

Unexpected write attempt of the SAES_DINR register is ignored, setting the WRERRF and the RWEIF flags. WRERRF is triggered during the computation phase or during the output phase.

*Note:* Unless otherwise indicated, **SAES is not disabled when WRERRF rises and it continues processing.**

An interrupt is generated if the RWEIE bit is set. For more details, refer to [Section 34.5: SAES interrupts](#).

The WRERRF and RWEIF flags are cleared by setting the RWEIF bit of the SAES_ICR register.

**Key error interrupt flag (KEIF)**

There are multiple sources of errors that set the KEIF flag of the SAES_ISR register and clear the KEYVALID bit of the SAES_SR register:

- **Key protection error:** while KEYVALID is set, then if KEYPROT is set or KEYSEL[2:0] is different from zero, this error is triggered when an application executing in a security context different from the one used to load the key (that is, different security attribute) accesses SAES.

- **Key writing sequence error:** triggered upon detecting an incorrect sequence of writing key registers. See [Section 34.4.17: SAES key registers](#) for details.

- **Key sharing size mismatch error:** triggered when KMOD[1:0] is at 0x2 and KEYSIZE in AES peripheral does not match KEYSIZE in SAES peripheral.
Secure AES coprocessor (SAES)

- **Key sharing error**: triggered upon failing transfer of SAES shared key to AES peripheral. See Section 34.4.15: SAES operation with shared keys for details.

- **Hardware secret key loading error**: triggered upon failing load of DHUK or BHK into SAES. KEYSEL[2:0] at 0x1 (DHUK), 0x2 (BHK) or 0x4 (DHUK XOR BHK) is not functional.

The KEIF flag is cleared with corresponding bit of the SAES_ICR register. An interrupt is generated if the KEIE bit of the SAES_IER register is set. For more details, refer to Section 34.5: SAES interrupts.

Upon a key selection error, clearing the KEIF flag automatically restarts the key selection process. Persisting problems (for example, RHUK load failing) may require a power-on reset.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

**Note:** For any key error, clear KEIF flag prior to disabling and re-configuring SAES.

### RNG error interrupt flag (RNGEIF)

SAES fetches random numbers from the RNG peripheral automatically after an IP reset triggered in the RCC. SAES cannot be used when RNGEIF is set.

An error detected while fetching a random number from RNG peripheral (due to, for example, bad entropy) sets the RNGEIF flag of the SAES_ISR register. The flag is cleared by setting the corresponding bit of the SAES_ICR register. An interrupt is generated if the RNGEIF bit of the SAES_IER register is set. For more details, refer to Section 34.5: SAES interrupts.

Upon an RNG error:

- Verify that the RNG peripheral AHB clock is enabled and no noise source (or seed) error is pending in this peripheral.
- Clear RNGEIF or reset the peripheral by setting IPRST. The clearance of the BUSY flag then indicates the completion of the random number fetch from RNG.

**Note:** To avoid RNGEIF errors, it is recommended to activate the RNG AHB clock each time SAES AHB clock is activated.

### About DPA errors

An unexpected error triggers an SAES internal tamper event in the TAMP peripheral, and stops any SAES co-processor processing.

To resume normal operation, reset the SAES peripheral through RCC or global reset.
34.5 **SAES interrupts**

There are multiple individual maskable interrupt sources generated by the SAES peripheral to signal the following events:

- computation completed (CCF)
- read error (RDERRF)
- write error (WRERRF)
- key error (KEIF)
- RNG error (RNGEIF)

See Section 34.4.19: SAES error management for details on SAES errors.

These sources are combined into a common interrupt signal from the SAES peripheral that connects to the Cortex® CPU interrupt controller. Application can enable or disable SAES interrupt sources individually by setting/clearing the corresponding enable bit of the SAES_IER register.

The status of the individual maskable interrupt sources can be read from the SAES_ISR register. They are cleared by setting the corresponding bit of the SAES_ICR register.

Table 323 gives a summary of the available features.

<table>

1. Bit of the SAES_ICR register.
2. Flag of the SAES_SR register, mirrored by the flag RWEIF of the SAES_ISR register.

34.6 **SAES DMA requests**

The SAES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the DMAINEN and DMAOUTEN bits of the SAES_CR register. When key derivation is selected (MODE[1:0] is at 0x1), setting those bits has no effect.

SAES only supports single DMA requests.

Detailed usage of DMA with SAES can be found in Appending data using DMA subsection of Section 34.4.5: SAES encryption or decryption typical usage.

**Data input using DMA**

Setting DMAINEN enables DMA writing into SAES. SAES then initiates, during the input phase, a set of single DMA requests for each 16-byte data block to write to the SAES_DINR register (quadruple 32-bit word, MSB first).
Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required (see Section 34.4.7).

Data output using DMA

Setting DMAOUTEN enables DMA reading from SAES. SAES then initiates, during the output phase, a set of single DMA requests for each 16-byte data block to read from the SAES_DOUTR register (quadruple 32-bit word, MSB first).

After the output phase, at the end of processing of a 16-byte data block, SAES switches automatically to a new input phase for the next data block, if any.

In DMA mode, the CCF flag has no use because the reading of the SAES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to managing the data transfers by software.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.

Stopping DMA transfers

All DMA request signals are de-asserted when SAES is disabled (EN cleared) or the DMA enable bit (DMAINEN for input data, DMAOUTEN for output data) is cleared.

34.7 SAES processing latency

The following tables provide the 16-byte data block processing latency per operating mode.

<table>
<thead>

<td>GCM</td>
<td>650</td>
<td>72(2)</td>
<td>690(3)</td>
<td>650</td>
</tr>
<tr>
<td></td>
<td>Mode 3: Decryption</td>
<td>CCM</td>
<td>650</td>
<td>680</td>
<td>1350</td>
<td>650</td>
</tr>
</tbody>
</table>

1. Data insertion can include wait states forced by SAES on the AHB bus (maximum 3 cycles, typical 1 cycle).
2. SAES AHB clock cycles instead of kernel clock cycle (Galois multiplier only).
3. As a worst case in encryption mode, add extra 72 AHB clock cycles for the last block computation.
34.8 SAES registers

The registers are accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

34.8.1 SAES control register (SAES_CR)

Address offset: 0x000

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>IPRST: SAES peripheral software reset</td>
</tr>
<tr>
<td>Setting the bit resets the SAES peripheral, putting all registers to their default values, except the IPRST bit itself. Hence, any key-relative data are lost. For this reason, it is recommended to set the bit before handing over the SAES to a less secure application. The bit must be kept low while writing any configuration registers.</td>
<td></td>
</tr>
<tr>
<td>30:28</td>
<td>KEYSEL[2:0]: Key selection</td>
</tr>
<tr>
<td>The bitfield defines the source of the key information to use in the AES cryptographic core.</td>
<td></td>
</tr>
<tr>
<td>0x0: Software key, loaded in key registers SAES_KEYx</td>
<td></td>
</tr>
<tr>
<td>0x1: Derived hardware unique key (DHUK)</td>
<td></td>
</tr>
<tr>
<td>0x2: Boot hardware key (BHK)</td>
<td></td>
</tr>
<tr>
<td>0x4: XOR of DHUK and BHK</td>
<td></td>
</tr>
<tr>
<td>Others: Reserved (if used, unfreeze SAES with IPRST)</td>
<td></td>
</tr>
<tr>
<td>When KEYSEL[2:0] is different from zero, selected key value is available in key registers when BUSY bit is cleared and KEYVALID is set in the SAES_SR register. Otherwise, the key error flag KEIF is set. Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK when KEYVALID is cleared.</td>
<td></td>
</tr>
<tr>
<td>When the application software changes the key selection by writing the KEYSEL[2:0] bitfield, the key registers are immediately erased and the KEYVALID flag cleared.</td>
<td></td>
</tr>
<tr>
<td>At the end of the decryption process, if KMOD[1:0] is other than zero, KEYSEL[2:0] is cleared.</td>
<td></td>
</tr>
<tr>
<td>With the bitfield value other than zero and KEYVALID set, the application cannot transfer the ownership of SAES with a loaded key to an application running in another security context (such as secure, non-secure). More specifically, when security of an access to any register does not match the information recorded by SAES, the KEIF flag is set. Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.</td>
<td></td>
</tr>
</tbody>
</table>
Bits 27:26 **KSHAREID[1:0]**: Key share identification

This bitfield defines, at the end of a decryption process with KMOD[1:0] at 0x2 (shared key), which target can read the SAES key registers using a dedicated hardware bus.

0x0: AES peripheral

Others: Reserved

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 25:24 **KMOD[1:0]**: Key mode selection

The bitfield defines how the SAES key can be used by the application. KEYSIZE must be correctly initialized when setting KMOD[1:0] different from zero.

0x0: Normal key mode. Key registers are freely usable and no specific use or protection applies to SAES_DINR and SAES_DOUTR registers.

0x1: Wrapped key for SAES mode. Key loaded in key registers can only be used to encrypt or decrypt AES keys. Hence, when a decryption is selected, read-as-zero SAES_DOUTR register is automatically loaded into SAES key registers after a successful decryption process.

0x2: Shared key mode. After a successful decryption process (unwrapping), SAES key registers are shared with the peripheral described in KSHAREID[1:0] bitfield. This sharing is valid only while KMOD[1:0] at 0x2 and KEYVALID=1. When a decryption is selected, read-as-zero SAES_DOUTR register is automatically loaded into SAES key registers after a successful decryption process.

Others: Reserved

With KMOD[1:0] other than zero, any attempt to configure the SAES peripheral for use by an application belonging to a different security domain (such as secure or non-secure) results in automatic key erasure and setting of the KEIF flag.

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 23:20 **NPBLB[3:0]**: Number of padding bytes in last block

This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.

0x0: All bytes are valid (no padding)

0x1: Padding for the last LSB byte

... 0xF: Padding for the 15 LSB bytes of last block.

Bit 19 **KEYPROT**: Key protection

When set, hardware-based key protection is enabled.

0: When KEYVALID is set and KEYSEL[2:0]=0 application can transfer the ownership of the SAES, with its loaded key, to an application running in another security context (such as non-secure, secure).

1: When KEYVALID is set, key error flag (KEIF) is set when an access to any registers is detected, this access having a security context (for example, secure, non-secure) that does not match the one of the application that loaded the key.

Attempts to write the bit are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bit 18 **KEYSIZE**: Key size selection

This bitfield defines the key length in bits of the key used by SAES.

0: 128-bit

1: 256-bit

When KMOD[1:0] is at 0x1 or 0x2, KEYSIZE also defines the length of the key to encrypt or decrypt. Attempts to write the bit are ignored when BUSY is set, as well as when the EN is set before the write access and it is not cleared by that write access.

Bit 17 Reserved, must be kept at reset value.
Bit 15  Reserved, must be kept at reset value.

Bits 14:13  **GCMPH[1:0]**  GCM or CCM phase selection
   This bitfield selects the phase, applicable only with GCM, GMAC or CCM chaining modes.
   0x0: Initialization phase
   0x1: Header phase
   0x2: Payload phase
   0x3: Final phase

Bit 12  **DMAOUTEN**: DMA output enable
   This bit enables automatic generation of DMA requests during the data phase, for outgoing data transfers from SAES via DMA.
   0: Disable
   1: Enable
   Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bit 11  **DMAINEN**: DMA input enable
   This bit enables automatic generation of DMA requests during the data phase, for incoming data transfers to SAES via DMA.
   0: Disable
   1: Enable
   Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bits 10:7  Reserved, must be kept at reset value.

Bits 16, 6:5  **CHMOD[2:0]**  Chaining mode
   This bitfield selects the AES chaining mode:
   0x0: Electronic codebook (ECB)
   0x1: Cipher-block chaining (CBC)
   0x2: Counter mode (CTR)
   0x3: Galois counter mode (GCM) and Galois message authentication code (GMAC)
   others: Reserved
   Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 4:3  **MODE[1:0]**  Operating mode
   This bitfield selects the SAES operating mode:
   0x0: Encryption
   0x1: Key derivation (or key preparation), for ECB/CBC decryption only
   0x2: Decryption
   0x3: Reserved
   Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 2:1  **DATATYPE[1:0]**  Data type
   This bitfield defines the format of data written in the SAES_DINR register or read from the SAES_DOUTR register, through selecting the mode of data swapping. This swapping is defined in Section 34.4.16: SAES data registers and data swapping.
   0x0: No swapping (32-bit data).
   0x1: Half-word swapping (16-bit data)
   0x2: Byte swapping (8-bit data)
   0x3: Bit-level swapping
   Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.
Bit 0  **EN**: Enable
This bit enables/disables the SAES peripheral.
0: Disable
1: Enable
At any moment, clearing then setting the bit re-initializes the SAES peripheral. When KMOD[1:0] is different from 0x0, using IPRST bit is recommended instead.
This bit is automatically cleared by hardware upon the completion of the key preparation (MODE[1:0] at 0x1) and upon the completion of GCM/GMAC/CCM initialization phase.
The bit cannot be set as long as KEYVALID is cleared, or when SAES is in one of the following configurations:
– KMOD[1:0] at 0x1 (wrap), CHMOD[2:0] at 0x3 (GCM)
– KMOD[1:0] at 0x1 (wrap), CHMOD[2:0] at 0x2 (CTR), MODE[1:0] at 0x0 (encryption).

**RES.** Reserved, must be kept at reset value.

**Bit 7** **KEYVALID**: Key valid flag
This bit is set by hardware when the key of size defined by KEYSIZE is loaded in SAES_KEYRx key registers.
0: Key not valid
1: Key valid
The EN bit can only be set when KEYVALID is set.
In normal mode when KEYSEL[2:0] is at zero, the key must be written in the key registers in the correct sequence, otherwise the KEIF flag is set and KEYVALID remains cleared.
When KEYSEL[2:0] is different from zero, the BUSY flag is automatically set by SAES. When the key is loaded successfully, BUSY is cleared and KEYVALID set. Upon an error, KEIF is set, BUSY cleared and KEYVALID remains cleared.
If set, KEIF must be cleared through the SAES_ICR register, otherwise KEYVALID cannot be set.
See the KEIF flag description for more details.
For further information on key loading, refer to Section 34.4.17: SAES key registers.

**Bits 6:4** Reserved, must be kept at reset value.
### Bit 3 BUSY: Busy
This flag indicates whether SAES is idle or busy.
0: Idle
1: Busy
SAES is flagged as idle when disabled (when EN is low) or when the last processing is completed. SAES is flagged as busy when processing a block data, preparing a key (ECB or CBC decryption only), fetching random number from the RNG, or transferring a shared key to the target peripheral. When GCM encryption is selected, this flag must be at zero before suspending current process to manage a higher-priority message. BUSY must also be cleared before selecting the GCM final phase.

### Bit 2 WRERRF: Write error flag
This bit is set when an unexpected write to the SAES_DINR register occurred. When set WRERRF bit has no impact on the SAES operations.
0: No error
1: Unexpected write to SAES_DINR register occurred during computation or data output phase.
The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.
The flag is cleared by setting the RWEIF bit of the SAES_ICR register.

### Bit 1 RDERRF: Read error flag
This bit is set when an unexpected read to the SAES_DOUTR register occurred. When set RDERRF bit has no impact on the SAES operations.
0: No error
1: Unexpected read to SAES_DOUTR register occurred during computation or data input phase.
The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.
The flag is cleared by setting the RWEIF bit of the SAES_ICR register.

### Bit 0 Reserved, must be kept at reset value.

### 34.8.3 SAES data input register (SAES_DINR)

### DIN[15:0]: Data input
A four-fold sequential write to this bitfield during the Input phase results in writing a complete 16-bytes block of input data to the SAES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 16-bytes input buffer.
Reads return zero.
34.8.4 SAES data output register (SAES_DOUTR)
Address offset: 0x00C
Reset value: 0x0000 0000
Read when KMOD[1:0] is at 0x1 or 0x2 while MODE[1:0] is at 0x2 and EN is set triggers a read error.

Bits 31:0 DOUT[31:0]: Data output
This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF flag set), virtually reads a complete 16-byte block of output data from the SAES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.
Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

Bits 31:0 KEY[31:0]: Cryptographic key, bits [31:0]
These are bits [31:0] of the write-only bitfield KEY[255:0] AES encryption or decryption key, depending on the MODE[1:0] bitfield of the SAES_CR register.
Writes to SAES_KEYRx registers are ignored when SAES is enabled (EN bit set). When KEYSEL[2:0] is different from 0 and KEYVALID is 0, writes to key registers are also ignored and they result in setting the KEIF bit of the SAES_ISR register.
With KMOD[1:0] at 0x0, a special writing sequence is required. In this sequence, any valid write to AES_KEYRx register clears the KEYVALID flag except for the sequence-completing write that sets it. Also refer to the description of the KEYVALID flag in the AES_SR register.
34.8.6 SAES key register 1 (SAES_KEYR1)

Address offset: 0x014
Reset value: 0x0000 0000

Bits 31:0 KEY[63:32]: Cryptographic key, bits [63:32]
Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.

34.8.7 SAES key register 2 (SAES_KEYR2)

Address offset: 0x018
Reset value: 0x0000 0000

Bits 31:0 KEY[95:64]: Cryptographic key, bits [95:64]
Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.

34.8.8 SAES key register 3 (SAES_KEYR3)

Address offset: 0x01C
Reset value: 0x0000 0000

Bits 31:0 KEY[127:96]: Cryptographic key, bits [127:96]
Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.
### 34.8.9 SAES initialization vector register 0 (SAES_IVR0)

Bits 31:0 IV[31:0]: Initialization vector input, bits [31:0]  
SAES_IVRx registers store the 128-bit initialization vector or the nonce, depending on the chaining mode selected. This value is updated by hardware after each computation round (when applicable).  
Write to this register is ignored when EN bit is set in SAES_SR register.

### 34.8.10 SAES initialization vector register 1 (SAES_IVR1)

### Bits 31:4
Reserved, must be kept at reset value.

**Bit 3** **RNGEIE**: RNG error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when RNGEIF (RNG error flag) is set.

0: Disabled (masked)
1: Enabled (not masked)

**Bit 2** **KEIE**: Key error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when KEIF (key error flag) is set.

0: Disabled (masked)
1: Enabled (not masked)

**Bit 1** **RWEIE**: Read or write error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when RWEIF (read and/or write error flag) is set.

0: Disabled (masked)
1: Enabled (not masked)

**Bit 0** **CCFIE**: Computation complete flag interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when CCF (computation complete flag) is set.

0: Disabled (masked)
1: Enabled (not masked)
34.8.19  SAES interrupt status register (SAES_ISR)

Address offset: 0x304

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31-4</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

Bit 3 **RNGEIF**: RNG error interrupt flag

This read-only bit is set by hardware when an error is detected on RNG bus interface (for example bad entropy).

0: RNG bus is functional
1: Error detected on RNG bus interface (random seed fetching error)

The flag setting generates an interrupt if the RNGEIF bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register. The clear action triggers the reload of a new random number from the RNG peripheral.

Bit 2 **KEIF**: Key error interrupt flag

This read-only bit is set by hardware when the key information fails to load into key registers or when the key register use is forbidden.

0: No key error detected
1: Key information failed to load into key registers or the key register use is forbidden

The flag setting generates an interrupt if the KEIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register.

KEIF is raised upon any of the following events:
- SAES fails to load the DHUK (KEYSEL[2:0] = 0x1 or 0x4).
- SAES fails to load the BHK (KEYSEL[2:0] = 0x2 or 0x4).
- AES fails to load the key shared by SAES peripheral (KMOD[1:0] = 0x2).
- KEYVALID is set and either KEYPROT is set or KEYSEL[2:0] is other than 0x0. The security context of the application that loads the key (secure or non-secure) does not match the security attribute of the access to SAES_CR or SAES_DOUT. In this case, KEYVALID and EN bits are cleared.
- SAES_KEYRx register write does not respect the correct order. (For KEYSIZE cleared, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 register, or reverse. For KEYSIZE set, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 then SAES_KEYR4 then SAES_KEYR5 then SAES_KEYR6 then SAES_KEYR7, or reverse). KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.
Bit 1 **RWEIF**: Read or write error interrupt flag
- This read-only bit is set by hardware when a RDERRF or a WRERRF error flag is set in the SAES_SR register.
  - 0: No read or write error detected
  - 1: Read or write error detected
- The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.
- The flag is cleared by setting the corresponding bit of the SAES_ICR register.
- The flags has no meaning when key derivation mode is selected.
  See the SAES_SR register for details.

Bit 0 **CCF**: Computation complete flag
- This flag indicates whether the computation is completed. It is significant only when the DMAOUTEN bit is cleared, and it may stay high when DMAOUTEN is set.
  - 0: Not completed
  - 1: Completed
- The flag setting generates an interrupt if the CCFIE bit of the SAES_IER register is set.
- The flag is cleared by setting the corresponding bit of the SAES_ICR register.

### 34.8.20 SAES interrupt clear register (SAES_ICR)

Address offset: 0x308
Reset value: 0x0000 0000

</table>

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIF**: RNG error interrupt flag clear
- Application must set this bit to clear the RNGEIF status bit in SAES_ISR register.

Bit 2 **KEIF**: Key error interrupt flag clear
- Setting this bit clears the KEIF status bit of the SAES_ISR register.

Bit 1 **RWEIF**: Read or write error interrupt flag clear
- Setting this bit clears the RWEIF status bit of the SAES_ISR register, and clears both RDERRF and WRERRF flags in the SAES_SR register.

Bit 0 **CCF**: Computation complete flag clear
- Setting this bit clears the CCF status bit of the SAES_ISR register.

Refer to Section 2.3 on page 111 for the register boundary addresses.
35 Hash processor (HASH)

35.1 Introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA-2 family) and the HMAC (keyed-hash message authentication code) algorithm. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of any length less than $2^{64}$ bits (for SHA-1, SHA-224 and SHA-256) or less than $2^{128}$ bits (for SHA-384, SHA-512).

35.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, Secure Hash Standard (SHA-1 and SHA-2 family)
  - Federal Information Processing Standards Publication FIPS PUB 186-4, Digital Signature Standard (DSS)
- Fast computation of SHA-1, SHA2-224, SHA2-256, SHA2-384, and SHA2-512
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA-256) algorithm
  - 98 clock cycles for processing one 1024-bit block of data using either SHA2-384 or SHA2-512 algorithm
  - Support for SHA-2 truncated outputs (SHA2-512/224, SHA2-512/256)
- Support for HMAC mode with all supported algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Supported word swapping format: bits, bytes, half-words and 32-bit words
- Single 32-bit, write-only, input register associated to an internal input FIFO, corresponding to a 64-byte block size (16 x 32 bits)
- Automatic padding to complete the input bit string to fit digest minimum block size
- AHB slave peripheral, accessible by 32-bit words only (else an AHB error is generated)
  - 8 x 32-bit words (H0 to H15) for output message digest
  - Automatic data flow control supporting direct memory access (DMA) using one channel.
  - Support for both single and fixed DMA burst transfers of four words.
  - Interruptible message digest computation, on a per-block basis
    - Re-loadable digest registers
    - Hashing computation suspend/resume mechanism, including DMA
35.3 HASH implementation

The devices have a single instance of HASH peripheral.

35.4.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard.

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message is presented on the input, the HASH processing core produces a fixed-length output string called a message digest (see Table 328).

</tbody>
</table>

1. Block size = (NBWE-1) * 4 bytes. NBWE[4:0] bitfield can be read from the HASH_SR register after ALGO and INIT bits are written in the HASH_CR register.
2. Digest size is 224 bits for SHA2-512/224 and 256 bits for SHA2-512/256 (truncated modes).

The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process since the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” by NIST because it is computationally infeasible to find a message that corresponds to a given message digest, or to find two different messages that produce the same message digest (SHA-1 does not qualify as secure since February 2017). Any change to a message in transit results, with very high probability, in a different message digest, and the signature fails to verify.

35.4.4 Message data feeding

The message (or data file) to be processed by the HASH must be considered as a bit string. Per FIPS PUB 180-4 standard this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of “01100001 01100010 01100011” is represented by a 32-bit word 0x00636261, and 8-bit words 0x61626300.

Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH_DIN register. The current contents of the HASH_DIN register are transferred to the 16 words input FIFO each time the register is written with new data. Hence HASH_DIN and the FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).

In accordance to the kind of data to be processed (for example byte swapping when data are ASCII text stream) there must be a bit, byte, half-word or no swapping operation to be
performed on data from the input FIFO before entering the little-endian hash processing core. Figure 330 shows how the hash processing core 32-bit data block M0...31 is constructed from one 32-bit words popped into input FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH_CR)

HASH_DIN data endianness when bit swapping is disabled (DATATYPE = 00) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

Figure 330. Message data swapping feature
35.4.5 Message digest computing

The hash processor sequentially processes several blocks when computing the message digest. Block sizes can be found in Table 328: Information on supported hash algorithms.

Each time the DMA or the CPU writes a block to the hash processor, the HASH automatically starts computing the message digest. This operation is known as partial digest computation.

As described in Section 35.4.4: Message data feeding, the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH_DIN register to fill the input FIFO. In order to perform the hash computation on this data the application must follow below sequence.

1. Initialize the hash processor using the HASH_CR register:
   - Write to the HASH_CR register to select the right algorithm using the ALGO bitfield, and set the INIT bit (other bits are kept at zero). Then read the NBWE bitfield from the HASH_SR register to deduce the algorithm block size, which equals \((\text{NBWE} - 1) \times 4\). This step is not required if the block size is already known (see Table 328 for details).
   - Select the right algorithm using the ALGO[3:0] field. If needed, program the correct swapping operation on the message input words using the DATATYPE[1:0] bitfield.
   - When HMAC mode is required, set the MODE bit as well as the LKEY bit if the HMAC key size is greater than the known block size of the algorithm (otherwise keep LKEY cleared). Refer to Section 35.4.7: HMAC operation for details.
   - Update NBLW[4:0] in the HASH_STR register to define the number of valid bits in the last word of the message if it is different from 32 bits. NBLW information are used to correctly perform the automatic message padding before the final message digest computation.

2. Complete the initialization by setting the INIT bit in HASH_CR register. Also set the DMAE bit if data are transferred via DMA.

Caution: When programming step 2, it is important that the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW) are set up before or at the same time.

3. Start filling data by writing to the HASH_DIN register, unless data are automatically transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the input FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
   - Data are filled by software:
     Partial digest computations are triggered each time the application writes the first word of the next block, the block size being defined by NBWE bits in HASH_SR. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write new data to HASH_DIN. This mechanism avoids the introduction of wait states by the HASH.
     The final digest computation is triggered when the last block is entered and the software sets the DCAL bit. If the message length is not an exact multiple of the
block size, the NBLW field in HASH_STR register must be written prior to writing DCAL bit (see Section 35.4.6 for details).

- Data are filled as a single DMA transfer (MDMAT = 0):
  Partial digest computations are triggered automatically each time the FIFO is full.
  The final digest computation is triggered automatically when the last block has
  been transferred to the HASH_DIN register by DMA (DCAL bit is set by hardware).
  If the message length is not an exact multiple of the block size, the NBLW field in
  HASH_STR register must be written prior to enabling the DMA (see
  Section 35.4.6 for details).

- Data are filled using multiple DMA transfers (MDMAT = 1):
  Partial digest computations are triggered as for single DMA transfers (refer to the
  above description). However the final digest computation is not triggered
  automatically when the last block has been transferred by DMA to the HASH_DIN
  register (DCAL bit is not set by hardware). It enables the hash processor to
  receive a new DMA transfer as part of this digest computation. To launch the final
  digest computation, the software must clear MDMAT bit before the last DMA
  transfer in order to trigger the final digest computation as it is done for single DMA
  transfers.

4. Once the digest calculation is completed (DCIS = 1), the resulting digest can be read
   from the output registers, as described in Table 329.

<table>

1. Digest size is 224 bits for SHA2-512/224 and 256 bits for SHA2-512/256 (truncated modes)

For more information about HMAC detailed instructions, refer to Section 35.4.7: HMAC operation.

### 35.4.6 Message padding

#### Overview

When computing a condensed representation of a message, the process of feeding data
into the hash processor (with automatic partial digest computation every block size transfer)
loops until the last bits of the original message are written to the HASH_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written
to the hash processor may have a valid number of bits between 1 and 32. This number of
valid bits in the last word, NBLW, has to be written to the HASH_STR register, so that
message padding is correctly performed before the final message digest computation.
Padding processing

Detailed padding sequences, with DMA enabled or disabled, are described in Section 35.4.5: Message digest computing.

Padding example

As specified by Federal Information Processing Standards PUB 180-4, message padding consists in appending a “1” followed by \( k \) “0”s, itself followed by a 64-bit integer that is equal to the length \( L \) in bits of the message. These three padding operations generate a padded message of length \( L + 1 + k + 64 \), which by construction is a multiple of 512 bits.

For the hash processor, the “1” is added to the last word written to the HASH_DIN register at the bit position defined by the NBLW bitfield, and the remaining upper bits are cleared (“0”s).

Example from FIPS PUB180-4

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length \( L = 24 \):

```
byte 0  byte 1  byte 2  byte 3
01100001 01100010 01100011 UUUUUUU
<--- 1st word written to HASH_DIN -->
```

NBLW has to be loaded with the value 24: a “1” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH_DIN register (little-endian convention):

```
01100001 01100010 01100011 IUUUUUUU
```

Since \( L = 24 \), the number of bits in the above bit string is 25, and 423 “0” bits are appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000
```

The message length value, \( L \), in two-word format (that is 00000000 00000018) is appended. Hence the final padded message in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
```

If the hash processor is programmed to swap byte within HASH_DIN input register (DATATYPE = 10 in HASH_CR), the above message has to be entered using following sequence:

1. \texttt{0xUU636261} is written to the HASH_DIN register (where ‘U’ means don’t care)
2. \texttt{0x18} is written to the HASH_STR register (the number of valid bits in the last word written to the HASH_DIN register is 24, as the original message length is 24 bits)
3. \texttt{0x10} is written to the HASH_STR register to start the message padding (described above) and then perform the digest computation.
4. The hash computing is complete with the message digest available in the HASH_HRx registers (x = 0...4) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

   \begin{align*}
   \text{HASH_HR0} &= \texttt{0xA9993E36} \\
   \text{HASH_HR1} &= \texttt{0x4706816A} \\
   \text{HASH_HR2} &= \texttt{0xBA3E2571} \\
   \text{HASH_HR3} &= \texttt{0x7850C26C} \\
   \text{HASH_HR4} &= \texttt{0x9CD0D89D}
   \end{align*}

### 35.4.7 HMAC operation

#### Overview

As specified by Internet Engineering Task Force RFC2104 and NIST FIPS PUB 198-1, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

\[
\text{HMAC(}\text{message}\text{)} = \text{Hash}(\text{Key} \ | \ \text{pad}) \text{ XOR opad} \ | \\
\text{Hash}(\text{Key} \ | \ \text{pad}) \text{ XOR ipad} \ | \ \text{message})
\]

where:

- \text{opad} = [0x5C]_n (outer pad) and \text{ipad} = [0x36]_n (inner pad)
- \([X]_n\) represents a repetition of \(X\) \(n\) times, where \(n\) equal to the byte size of the underlying hash function data block (\(n = 64\) when block size is \(512\) bits).
- \text{pad} is a sequence of zeroes needed to extend the key to the length \(n\) defined above. If the key length is greater than \(n\), the application must first hash the key using Hash() function and then use the resultant byte string as the actual key to HMAC.
- \(\mid\) represents the concatenation operator.

\textbf{Note:} \textit{HMAC mode of the hash processor can be used with all supported algorithms.}

#### HMAC processing

Four different steps are required to compute the HMAC:

1. The software sets the INIT bit, with the MODE bit set and the ALGO bits selecting the desired algorithm. The LKEY bit must also be set if the key being used is longer than the block size. In this case, as required by HMAC specifications, the hash processor uses the hash of the key instead of the real key.
2. The software provides the key to be used for the inner hash function, using the same mechanism as the message string loading, that is by writing the key data into
HASH_DIN register and then completing the transfer by setting DCAL bit and the correct NBLW to HASH_STR register.

3. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write the message string to HASH_DIN. When the last word of the last block is entered and the software sets DCAL bit in HASH_STR register, the NBLW bitfield must be programmed at the same time to a value different from zero if the message length is not an exact multiple of the block size. Note that the DMA can also be used to feed the message string, as described in Section 35.4.5: Message digest computing.

4. Once the processor is ready again (DINIS = 1 in HASH_SR), the software provides the key to be used for the outer hash function, writing the key data into HASH_DIN register, and then completing the transfer by setting DCAL bit and programming the correct NBLW to HASH_STR register. The HMAC result can be found in the valid output registers (HASH_HRx) as soon as DCIS bit is set.

Note: The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in Section 35.6: HASH processing time.

Endianness management details can be found in Section 35.4.4: Message data feeding.

HMAC example

Below is an example of HMAC SHA-1 algorithm (ALGO = 00 and MODE = 1 in HASH_CR) as specified by NIST. SHA-1 block size is 64 bytes.

Let us assume that the original message is the ASCII binary-coded form of "Sample message for keylen = blocklen", of length L = 34 bytes. If the HASH is programmed in no swapping mode (DATATYPE = 00 in HASH_CR), the following data must be loaded sequentially into HASH_DIN register:

1. **Inner hash key** input (length = 64, i.e. no padding), specified by NIST. As key length = 64, LKEY bit is cleared in HASH_CR register
   
   00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617
   18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F
   30313233 34353637 38393A3B 3C3D3E3F

2. **Message** input (length = 34, i.e. padding required). HASH_STR must be set to 0x20 to start message padding and inner hash computation (see 'U' as don’t care)
   
   53616D70 6C65206D 65737361 67652066 6F722065
   73696C65 53616D70 6C65206D 65737361 67652066 6F722065
   73696C65 53616D70 6C65206D 65737361 67652066 6F722065
   73696C65

3. **Outer hash key** input (length = 64, i.e. no padding). A key identical to the inner hash key is entered here.

4. **Final outer hash computing** is then performed by the HASH. The HMAC-SHA1 digest result is available in the HASH_HRx registers, as shown below:

   HASH_HR0 = 0xF5FD596EE
   HASH_HR1 = 0x78D5555C
   HASH_HR2 = 0x8FF4E72D
   HASH_HR3 = 0x266DFD19
   HASH_HR4 = 0x2366DA29
35.4.8 HASH suspend/resume operations

Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in Figure 331.

Figure 331. HASH suspend/resume mechanism

To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described hereafter.
Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing.

To suspend the processing of a message, proceed as follows after writing the number of words defined in NBWE:

1. In Polling mode, wait for BUSY = 0 then poll if the DINIS status bit is set.
   In Interrupt mode, implement the next step in DINIS interrupt handler (recommended).
2. Store the contents of the following registers into memory:
   - HASH_IMR
   - HASH_STR
   - HASH_CR
   - HASH_CSR0 to HASH_CSR37, when SHA-1 or SHA2-256 is selected, plus HASH_CSR38 to HASH_CSR53 if an HMAC operation was ongoing
   - HASH_CSR0 to HASH_CSR90, when SHA2-384 or SHA2-512 (truncated or not) is selected, plus HASH_CSR91 to HASH_CSR102 if an HMAC operation was ongoing.

To resume the processing of a message, proceed as follows:

1. Write the following registers with the values saved in memory: HASH_IMR, HASH_STR, HASH_CR.
2. Initialize the hash processor by setting the INIT bit in the HASH_CR register
3. Write the HASH_CSRx registers with the values saved in memory.
4. Restart the processing from the point where it has been interrupted.

Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is recommended to suspend and then restore a secure digest computing as described below.

In this sequence the DMA channel allocated to the hash peripheral remains allocated to the processing of message 1 (see Figure 331).

To suspend the processing of a message using DMA, proceed as follows:

1. Clear the DMAE bit to disable the DMA interface. The hash peripheral automatically fetches enough data via the DMA to complete the current burst transfer.
2. Wait until the last DMA transfer is complete (DMAS = 0 in HASH_SR).
3. Disable the DMA channel.
4. In Polling or Interrupt mode (recommended), wait until the hash processor is ready (no block is being processed), that is wait for DINIS = 1 in HASH_SR. If DCIS is also set in HASH_SR, the hash result is available and the context swapping is useless. Else go to step 5.
5. Save HASH_IMR, HASH_STR and HASH_CR registers. Also save a number of HASH_CSRx registers depending on the SHA algorithm that is used:
   - When SHA-1 or SHA2-256 is selected, save HASH_CSR0 to HASH_CSR37, plus HASH_CSR38 to HASH_CSR53 if an HMAC operation was ongoing.
   - When SHA2-384 or SHA2-512 is selected, save HASH_CSR0 to HASH_CSR90, plus HASH_CSR91 to HASH_CSR102 if an HMAC operation was ongoing.
To resume the processing of a message using DMA, proceed as follows:

1. Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again.
2. Program the values saved in memory to HASH_IMR, HASH_STR and HASH_CR registers.
3. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
4. Program the values saved in memory to the HASH_CSRx registers.
5. Restart the processing from the point where it was interrupted by setting the DMAE bit.

35.4.9 HASH DMA interface

The HASH supports both single and fixed DMA burst transfers of four words.

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH_CR register. When this bit is set, the HASH initiates a DMA request each time a block has to be written to the HASH_DIN register.

Once four 32-bit words have been received, the HASH automatically triggers a new request to the DMA. For more information refer to Section 35.4.5: Message digest computing.

Before starting the DMA transfer, the software must program the number of valid bits in the last word that is copied into HASH_DIN register. This is done by writing in HASH_STR register the following value:

\[ NBLW = \text{Len(Message)} \mod 32 \]

where \( x \mod 32 \) gives the remainder of \( x \) divided by 32.

The DMAS bit of the HASH_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared and no DMA transfer is ongoing.

**Note:** No interrupt is associated to DMAS bit.

*When MDMAT is set, the size of the transfer must be a multiple of four words.*

35.4.10 HASH error management

No error flags are generated by the hash processor.

35.5 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal (hash_it), which is in turn connected to the device interrupt controller. Each interrupt source can individually be enabled or disabled by changing the mask bits in the HASH_IMR register. Setting the appropriate mask bit enables the interrupt.

The status of each maskable interrupt sources can be read from the HASH_SR register.

*Table 330* gives a summary of the available features.
35.6 HASH processing time

Table 331 summarizes the time required to process an intermediate block for each mode of operation.

<table>
<thead>
<tr>
<th>Mode of operation</th>
<th>Block size (in bytes)</th>
<th>FIFO load</th>
<th>Computation phase</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHA-1</td>
<td>64</td>
<td>16</td>
<td>66</td>
<td>82</td>
</tr>
<tr>
<td>SHA2-224</td>
<td></td>
<td>16</td>
<td>50</td>
<td>66</td>
</tr>
<tr>
<td>SHA2-256</td>
<td></td>

<tr>
<td>SHA2-384</td>
<td>128</td>
<td>32</td>
<td>66</td>
<td>98</td>
</tr>
<tr>
<td>SHA2-512(2)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. Add the time required to load the block into the processor.
2. SHA2-512 includes SHA2-512/224 and SHA2-512/256 modes.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:
- 1 to 2.5 for a hash message
- ~2.5 for an HMAC input-key
- 1 to 2.5 for an HMAC message
- ~2.5 for an HMAC output key in case of a short key
- 3.5 to 5 for an HMAC output key in case of a long key

35.7 HASH registers

The hash core is associated with several control and status registers and several message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB error is generated.

35.7.1 HASH control register (HASH_CR)

Address offset: 0x00
Reset value: 0x0000 0000
Bits 31:21 Reserved, must be kept at reset value.

Bits 20:17 **ALGO[3:0]: Algorithm selection**

These bits select the hash algorithm:

- 0000: SHA-1
- 0001: reserved
- 0010: SHA2-224
- 0011: SHA2-256
- 1100: SHA2-384
- 1101: SHA2-512/224
- 1110: SHA2-512/256
- 1111: SHA2-512

This selection is only taken into account when the INIT bit is set. Changing this bitfield during a computation has no effect.

When the ALGO bitfield is updated and INIT bit is set, NBWE in HASH_SR is automatically updated to 0x11.

Bit 16 **LKEY**: Long key selection

The application must set this bit if the HMAC key is greater than the block size corresponding to the hash algorithm (see Table 328: Information on supported hash algorithms for details). For example the block size is 64 bytes for SHA2-256.

- 0: HMAC key is shorter or equal to the block size (short key). The actual key value written in HASH_DIN is used during the HMAC computation.
- 1: HMAC key is longer than the block size (long key). The hash of the key is used instead of the real key during the HMAC computation.

This selection is only taken into account when the INIT and MODE bits are set (HMAC mode selected). Changing this bit during a computation has no effect.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **MDMAT**: Multiple DMA transfers

This bit is set when hashing large files when multiple DMA transfers are needed.

- 0: DCAL is automatically set at the end of a DMA transfer.
- 1: DCAL is not automatically set at the end of a DMA transfer.

Bit 12 **DINNE**: DIN not empty

Refer to DINNE bit of HASH_SR for a description of DINNE bit.

This bit is read-only.

Bits 11:8 **NBW[3:0]: Number of words already pushed**

This bit is read-only.

Bit 7 Reserved, must be kept at reset value.
Bit 6 **MODE:** Mode selection
This bit selects the normal or the keyed HMAC mode for the selected algorithm:
0: Hash mode selected
1: HMAC mode selected. LKEY bit must be set if the key being used is longer than the algorithm block size.
This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.

Bits 5:4 **DATATYPE[1:0]:** Data type selection
This bitfield defines the format of the data entered into the HASH_DIN register:
00: 32-bit data. The data written into HASH_DIN are directly used by the HASH processing, without reordering.
01: 16-bit data or half-word. The data written into HASH_DIN are considered as two half-words, and are swapped before being used by the HASH processing.
10: 8-bit data or bytes. The data written into HASH_DIN are considered as four bytes, and are swapped before being used by the HASH processing.
11: bit data or bit string. The data written into HASH_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the HASH processing (1st bit of the string at position 31).

Bit 3 **DMAE:** DMA enable
0: DMA transfers disabled
1: DMA transfers enabled. A DMA request is sent as soon as the hash core is ready to receive data.
After this bit is set, it is cleared by hardware while the last data of the message is written into the hash processor.
Clearing this bit while a DMA transfer is ongoing does not abort the current transfer. Instead, the DMA interface of the HASH remains internally enabled until the transfer is complete or INIT is set.
Setting INIT bit does not clear DMAE bit.

Bit 2 **INIT:** Initialize message digest calculation
Setting this bit resets the hash processor core, so that the HASH is ready to compute the message digest of a new message.
Clearing this bit has no effect. Reading this bit always returns 0.

Bits 1:0 Reserved, must be kept at reset value.

### 35.7.2 HASH data input register (HASH_DIN)

**Address offset:** 0x04

**Reset value:** 0x0000 0000

HASH_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks defined by the hash algorithm (see Table 328: Information on supported hash algorithms for details). For example the block size is 64 bytes for SHA2-256.

When the HASH_DIN register is programmed, the value presented on the AHB bus is ‘pushed’ into the hash core and the register takes the new value presented on the AHB bus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH_CR register.
When a complete block has been written to the HASH_DIN register, an intermediate digest calculation is launched:
- by writing first data of the next block into the HASH_DIN register, if the DMA is not used
- automatically, if the DMA is used

When the last block has been written to the HASH_DIN register, the final digest calculation (including padding) is launched by setting the DCAL bit in the HASH_STR register (final digest calculation). This operation is automatic if the DMA is used and MDMAT bit is cleared.

Reading the HASH_DIN register returns zeros.

Note: When the HASH is busy, a write access to the HASH_DIN register might stall the AHB bus if the digest calculation (intermediate or final) is not complete.

35.7.3 HASH start register (HASH_STR)

Address offset: 0x08

Reset value: 0x0000 0000

The HASH_STR register has two functions:
- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH_DIN register)
- It is used to start the processing of the last block in the message by setting the DCAL bit.
Bits 31:9  Reserved, must be kept at reset value.

Bit 8  **DCAL**: Digest calculation
Setting this bit starts the message padding using the previously written value of NBLW, and starts the calculation of the final message digest with all the data words written to the input FIFO since the INIT bit was last set.
Reading this bit returns 0.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **NBLW[4:0]**: Number of valid bits in the last word
When the last word of the message bit string is written to HASH_DIN register, the hash processor takes only the valid bits, specified as below, after internal data swapping:
0x00: All the 32 bits of the last data written are valid message bits, that is M[31:0]
0x01: Only one bit of the last data written (after swapping) is valid, that is M[0]
0x02: Only two bits of the last data written (after swapping) are valid, that is M[1:0]
0x03: Only three bits of the last data written (after swapping) are valid that is M[2:0]
...
0x1F: Only 31 bits of the last data written (after swapping) are valid that is M[30:0]
The above mechanism is valid only if DCAL = 0. If NBLW bits are written while DCAL is set, the NBLW bitfield remains unchanged. In other words it is not possible to configure NBLW and set DCAL at the same time.
Reading NBLW bits returns the last value written to NBLW.

### 35.7.4 HASH digest registers

These registers contain the message digest result defined as follows:
- HASH_HR0, HASH_HR1, HASH_HR2, HASH_HR3 and HASH_HR4 registers return the SHA-1 digest result.
- HASH_HR0 to HASH_HR6 registers return the SHA2-224, SHA2-512/224 digest result.
- HASH_HR0 to HASH_HR7 registers return the SHA2-256, SHA2-512/256 digest result.
- HASH_HR0 to HASH_HR11 registers return the SHA2-384 digest result.
- HASH_HR0 to HASH_HR15 registers return the SHA2-512 digest result

In all cases, the digest most significant bit is stored in HASH_HR0[31], and unused HASH_HRx registers reads as zero.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (DCIS bit equals 0), then the read operation returns zeros.

**Note:** When starting a digest computation for a new message (by setting the INIT bit), HASH_HRx registers are forced to their reset values.

**HASH_HR0 to HASH_HR4 registers can be accessed through two different addresses (register aliasing).**
**HASH aliased digest register x (HASH_HRAx)**

Address offset: 0x0C + x * 0x4, (x = 0 to 4)
Reset value: 0x0000 0000

The content of the HASH_HRAx registers is identical to the one of the HASH_HRx registers located at address offset 0x310.

0: Data input interrupt disabled  
1: Data input interrupt enabled

### 35.7.6 HASH status register (HASH_SR)

Address offset: 0x24  
Reset value: 0x0011 0001

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **NBWE[4:0]**: Number of words expected  
This bitfield reflects the number of words in the message that must be pushed into the FIFO to trigger a partial computation. NBWE is decremented by 1 when a write access is performed to the HASH_DIN register. NBWE is set to the expected block size +1 in words (0x11) when INIT bit is set in HASH_CR. It is set to the expected block size (0x10) when the partial digest calculation ends.

Bit 15 **DINNE**: DIN not empty  
This bit is set when the HASH_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is set.  
0: No data are present in the data input buffer  
1: The input buffer contains at least one word of data

Bit 14 Reserved, must be kept at reset value.
35.7.7 HASH context swap registers

These registers contain the complete internal register states of the hash processor. They are useful when a suspend/resume operation has to be performed because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task. When the hash computation is complete, the saved context can be read from memory and written back into the HASH_CSRx registers.

HASH_CSRx registers can be read only when DINIS equals to 1, otherwise zeros are returned.

36 Public key accelerator (PKA)

36.1 Introduction

PKA (public key accelerator) is intended for the computation of cryptographic public key primitives, specifically those related to RSA, Diffie-Hellmann or ECC (elliptic curve cryptography) over GF(p) (Galois fields). To achieve high performance at a reasonable cost, these operations are executed in the Montgomery domain.

For a given operation, all needed computations are performed within the accelerator, so no further hardware/software elaboration is needed to process the inputs or the outputs.

When manipulating secrets, the PKA incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3.

36.2 PKA main features

- Acceleration of RSA, DH and ECC over GF(p) operations, based on the Montgomery method for fast modular multiplications. More specifically:
  - RSA modular exponentiation, RSA chinese remainder theorem (CRT) exponentiation
  - ECC scalar multiplication, point on curve check, complete addition, double base ladder, projective to affine
  - ECDSA signature generation and verification
- Capability to handle operands up to 4160 bits for RSA/DH and 640 bits for ECC
- When manipulating secrets: protection against side-channel attacks (SCA), including differential power analysis (DPA), certified SESIP and PSA security assurance level 3
  - Applicable to modular exponentiation, ECC scalar multiplication and ECDSA signature generation
- Arithmetic and modular operations such as addition, subtraction, multiplication, modular reduction, modular inversion, comparison, and Montgomery multiplication
- Built-in Montgomery domain inward and outward transformations
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
36.3 PKA functional description

<td>PKA internal tamper event signal to TAMP (XOR-ed), triggered when an unexpected fault occurs while PKA manipulates secrets, or when the programmed input point is not found on the input curve (ECDSA signature and ECC scalar multiplication only). This signal is asserted as soon as a fault is detected. When asserted, read access to PKA registers are reset to 0 and writes are ignored. The signal is de-asserted when PKA memory is cleared.</td>
</tr>
</tbody>
</table>

36.3.3 PKA reset and clocks

PKA is clocked on the AHB bus clock. When the PKA peripheral reset signal is released PKA_RAM is cleared automatically, taking 667 clock cycles. During this time the setting of bit EN in PKA_CR register is ignored.

According to the security policy applied to the device, PKA RAM can also be reset following a tamper event. Refer to *Tamper detection and response* in the System security section (if applicable to this product).
36.3.4 PKA public key acceleration

Overview
Public key accelerator (PKA) is used to accelerate Rivest, Shamir and Adleman (RSA), Diffie-Hellman (DH) as well as ECC over prime field operations. Supported operand sizes is up to 4160 bits for RSA and DH, and up to 640 bits for ECC.

The PKA supports all non-singular elliptic curves defined over prime fields, that can be described with a short Weierstrass equation $y^2 = x^3 + ax + b \pmod{p}$. More information can be found in Section 36.5.1: Supported elliptic curves.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

A memory of 5336 bytes (667 words of 64 bits) called PKA RAM is used to provide initial data to the PKA, and to hold the results after computation is completed. Access is done through the PKA AHB interface.

PKA operating modes
The list of operations the PKA can perform is detailed in Table 334 and Table 335, respectively, for integer arithmetic functions and prime field (Fp) elliptic curve functions.

</tbody>
</table>
Each of these operating modes has an associated code that has to be written to the MODE field in the PKA_CR register. If the application selects any value that is not documented below the write to MODE bitfield is ignored, and an operation error (OPERRF) is triggered. When this happens, a new operation must be selected after the error is cleared.

Some operations in Table 334 and Table 335 are indicated as protected. Those operations are used when manipulating secret keys (modular exponentiation for RSA decryption, scalar multiplication and signature for ECC). Those secrets (protected against side channel attacks) are automatically erased from PKA RAM at the end of the protected operations (BUSY goes low). They are also protected against side channel attacks.

**Caution:** For security reason it is very important to select protected modular exponentiation (MODE = 0x3) when performing RSA decryption.

### Montgomery space and fast mode operations

For efficiency reason the PKA internally performs modular multiply operations in the Montgomery domain, automatically performing inward and outward transformations.

As Montgomery parameter computation is time consuming the application can decide to use a faster mode of operation, during which the precomputed Montgomery parameter is supplied before starting the operation. Performance improvement is detailed in Section 36.5.2: Computation times.

The only operation using fast mode is modular exponentiation (MODE = 0x02).

### 36.3.5 Typical applications for PKA

**Introduction**

The PKA can be used to accelerate a number of public key cryptographic functions. In particular:

- RSA encryption and decryption
- RSA key finalization
- CRT-RSA decryption
- DSA and ECDSA signature generation and verification
- DH and ECDH key agreement
Specifications of the above functions are given in following publications:

- FIPS PUB 186-4, Digital Signature Standard (DSS), July 2013 by NIST
- PKCS #1, RSA Cryptography Standard, v1.5, v2.1 and v2.2. by RSA Laboratories

The principles of the main functions are described in this section, for a more detailed description refer to the above cited documents.

**RSA key pair**

For the following RSA operations a public key and a private key information are defined as below:

- Alice transmits her public key \((n, e)\) to Bob. Numbers \(n\) and \(e\) are very large positive integers.
- Alice keeps secret her private key \(d\), also a very large positive integer. Alternatively this private key can also be represented by a quintuple \((p, q, dp, dq, qInv)\).

For more information on the above representations refer to the RSA specification.

**RSA encryption/decryption principle**

As recommended by the PKCS#1 specification, Bob, to encrypt message \(M\) using Alice’s public key \((n, e)\) must go through the following steps:

1. Compute the encoded message \(EM = ENCODE(M)\), where ENCODE is an encoding method.
2. Turn \(EM\) into an integer \(m\), with \(0 \leq m < n\) and \((m, n)\) being coprimes.
3. Compute ciphertext \(c = m^e \mod n\).
4. Convert the integer \(c\) into a string ciphertext \(C\).

Alice, to decrypt ciphertext \(C\) using her private key \(d\), follows the steps indicated below:

1. Convert the ciphertext \(C\) to an integer ciphertext representative \(c\).
2. If necessary, retrieve the prime factors \((p, q)\) using \((n, e, d)\) information, then compute \(\phi = (p - 1) \times (q - 1)\). Refer to NIST SP800-56B Appendix C for details.
3. Recover plaintext \(m = c^d \mod n = (m^e)^d \mod n\). If the private key is the quintuple \((p, q, dp, dq, qInv)\), then plaintext \(m\) is obtained by performing the operations:
   a) \(m_1 = c^{dp} \mod p\)
   b) \(m_2 = c^{dq} \mod q\)
   c) \(h = qInv \times (m_1 - m_2) \mod p\)
   d) \(m = m_2 + h \times q\)
4. Convert the integer message representative \(m\) to an encoded message \(EM\).
5. Recover message \(M = DECODE(EM)\), where DECODE is a decoding method.

Above operations can be accelerated by PKA using Modular exponentiation \(A^e \mod n\) if the private key is \(d\), or RSA CRT exponentiation if the private key is the quintuple \((p, q, dp, dq, qInv)\).

*Note:* The decoding operation and the conversion operations between message and integers are specified in PKCS#1 standard.
Note: For the decryption process protected version of modular exponentiation (MODE = 0x3) is strongly recommended for security reason. For encryption process MODE = 0x3 cannot be used, as it requires the knowledge of the private key.

Elliptic curve selection

For following ECC operations curve parameters are defined as below:
- Curve corresponds to the elliptic curve field agreed among actors (Alice and Bob). Supported curves parameters are summarized in Section 36.5.1: Supported elliptic curves.
- G is the chosen elliptic curve base point (also known as generator), with a large prime order n (i.e. \( n \times G = \text{identity element } O \)).

ECDSA message signature generation

ECDSA (elliptic curve digital signature algorithm) signature generation function principle is the following: Alice, to sign a message \( m \) using her private key integer \( d_A \), goes through the following steps.
1. Calculate \( e = \text{HASH}(m) \), where \( \text{HASH} \) is a cryptographic hash function.
2. Let \( z \) be the \( L_n \) leftmost bits of \( e \), where \( L_n \) is the bit length of the group order \( n \).
3. Select a cryptographically secure random integer \( k \) where \( 0 < k < n \).
4. Calculate the curve point \( (x_1, y_1) = k \times G \).
5. Calculate \( r = x_1 \mod n \). If \( r = 0 \) go back to step 3.
6. Calculate \( s = k^{-1} (z + rd_A) \mod n \). If \( s = 0 \) go back to step 3.
7. The signature is the pair \((r, s)\).

Steps 4 to 7 are accelerated by PKA using:
- \textit{ECDSA sign}
or
- All of the operations below:
  - \textit{ECC Fp scalar multiplication} \( k \times P \)
  - \textit{Modular reduction} \( A \mod n \)
  - \textit{Modular inversion} \( A^{-1} \mod n \)
  - \textit{Modular addition} and \textit{Modular and Montgomery multiplication}

ECDSA signature verification

ECDSA (elliptic curve digital signature algorithm) signature verification function principle is the following: Bob, to authenticate Alice’s signature, must have a copy of her public key curve point \( Q_A \).

Bob can verify that \( Q_A \) is a valid curve point going through the following steps:
1. check that \( Q_A \) is not equal to the identity element \( O \)
2. check that \( Q_A \) is on the agreed curve
3. check that \( n \times Q_A = O \).

Then Bob follows the procedure detailed below:
1. verify that $r$ and $s$ are integer in $[1, n-1]$
2. calculate $e = \text{HASH}(m)$, where $\text{HASH}$ is the agreed cryptographic hash function
3. let $z$ be the $L_n$ leftmost bits of $e$
4. calculate $w = s^{-1} \mod n$
5. calculate $u_1 = zw \mod n$ and $u_2 = rw \mod n$
6. calculate the curve point $(x_1, y_1) = u_1 \times G + u_2 \times Q_A$
7. the signature is valid if $r = x_1 \mod n$, it is invalid otherwise.

Steps 4 to 7 are accelerated by PKA using ECDSA verification.

36.3.6 PKA procedure to perform an operation

Enabling/disabling PKA

Setting the EN bit to 1 in PKA_CR register enables the PKA peripheral. The PKA becomes available when INITOK bit is set in PKA_SR. When EN = 0, the PKA peripheral is kept under reset, with PKA memory still accessible by the application through the AHB interface.

Note: When PKA is in the process of clearing its memory EN bit cannot be set.

Note: When setting EN bit in PKA_CR make sure that the value of MODE bitfield corresponds to an authorized PKA operation (see OPERRF in Section 36.3.7).

Clearing EN bit to 0 while a calculation is in progress causes the operation to be aborted. In this case, the content of the PKA memory is not guaranteed, with the exception of the PKA modes 0x03, 0x20 and 0x24. For these operations, the PKA memory is cleared after abort, making the memory unavailable for 667 cycles. During this clearing time only PKA registers can be accessed, with writes to EN bits ignored.

If INITOK bit stays at 0, make sure that the RNG peripheral is clocked and properly initialized, then try to enable PKA again.

Data formats

The format of the input data and the results in the PKA RAM are specified, for each operation, in Section 36.4.

Executing a PKA operation

Each of the supported PKA operation is executed using the following procedure:

1. Load initial data into the PKA internal RAM, which is located at address offset 0x400.
2. Write in the MODE field of PKA_CR register, specifying the operation which is to be executed and then assert the START bit, also in PKA_CR register.
3. Wait until the PROCENDF bit in the PKA_SR register is set to 1, indicating that the computation is complete.
4. Read the result data from the PKA internal RAM, then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.

Note: When PKA is busy (BUSY = 1) any access by the application to PKA RAM is ignored, and the flag RAMERRF is set in PKA_SR.

Selecting an illegal or unknown operation in step 2 triggers an OPERRF error, and step 3 (PROCENDF = 1) never happens. See Section 36.3.7 for details.
Using precomputed Montgomery parameters (PKA Fast mode)

As explained in Section 36.3.4, when computing many operations with the same modulus it can be beneficial for the application to compute only once the corresponding Montgomery parameter (see, for example, Section 36.4.5). This is known as “Fast mode”.

To manage the usage of Fast mode it is recommended to follow the procedure described below:

1. Load in PKA RAM the modulus size and value information. Such information is compiled in Section 36.5.1.
2. Program in PKA_CR register the PKA in Montgomery parameter computation mode (MODE=“0x1”) then assert the START bit.
3. Wait until the PROCENDF bit in the PKA_SR register is set to 1, then read back from PKA memory the corresponding Montgomery parameter, and then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.
4. Proceed with the required PKA operation, loading on top of regular input data the Montgomery information R2 mod m. All addresses are indicated in Section 36.4.

36.3.7 PKA error management

When PKA is used some errors can occur:

- The access to PKA RAM falls outside the expected range. In this case the Address Error flag (ADDRERRF) is set in the PKA_SR register.
- An AHB access to the PKA RAM occurred while the PKA core was using it. In this case the RAM Error Flag (RAMERRF) is set in the PKA_SR register, reads to PKA RAM return zero, while writes are ignored.
- The selected operating mode using MODE bitfield is not listed in PKA operating modes (or in bitfield description), or PKA is running in limited mode (see LMF bit in PKA_SR). In this case the operation error flag (OPERRF) is set in the PKA_SR register, and write to MODE bitfield is ignored.

For each error flag above PKA generates an interrupt if the application sets the corresponding bit in PKA_CR register (see Section 36.6 for details).

ADDRERRF, OPERRF and RAMERRF errors are cleared by setting the corresponding bit in PKA_CLRFR.

The PKA can be re-initialized at any moment by resetting the EN bit in the PKA_CR register.

OPERRF error must be cleared using OPERRFC bit in PKA_CLRFR before a new operation is written in PKA_CR register.

36.4 PKA operating modes

36.4.1 Introduction

The various operations supported by PKA are described in the following subsections, defining the format of the input data and of the results, both stored in the PKA RAM.
Warning: The validity of all input parameters to the PKA must be checked before starting any operation, as PKA assumes that all of them are valid and consistent with each other. Input parameters must not exceed the operand size specified in the operation tables.

The following information applies to all PKA operations.

- PKA core processes 64-bit words in its RAM. Hence hereafter all word size is 64-bit.
- When an element is written as input in the PKA RAM, an additional word with all bits equal to zero has to be added after the most significant input word. This rule does not apply if the operand has a fixed size of 1.
- All reported RAM storage addresses refer to the least significant word of the data, and to obtain the actual address to use application must add to the indicated offset the base address of the PKA.
- Supported operand "Size" are:
  - ROS (RSA operand Size): data size is \( \frac{\text{rsa\_size}}{64} + 1 \) words, with \( \text{rsa\_size} \) equal to the chosen modulus length in bits. For example, when computing RSA with an operand size of 1024 bits, ROS is equal to 17 words, or 1088 bits.
  - EOS (ECC operand Size): data size is \( \frac{\text{ecc\_size}}{64} + 1 \) words, with \( \text{ecc\_size} \) equal to the chosen prime modulus length in bits. For example, when computing ECC with an operand size of 192 bits, EOS is equal to 4 words, or 256 bits.
  - ROS and EOS values include the required additional all 0 word.
- Unless indicated otherwise, all operands in the tables are integers.

Note: Fractional results for above formulas must be rounded up to the nearest integer since PKA core processes 64-bit words.

Note: The maximum ROS is 66 words (4160-bit max exponent size), while the maximum EOS is 11 words (640-bit max operand size).

As a first example (and to better understand the endianess in PKA memory), to prepare the operation \textbf{ECC Fp scalar multiplication}, when the application writes the \( x \) coordinate of point \( P \) for an ECC P256 curve (EOS = 5 words), the least significant bit must be placed in bit 0 at address offset 0x578, and the most significant bit in bit 63 at address offset 0x590. Then, as mentioned above, the application must write the empty word 0x0000000000000000 at address offset 0x598.

As a second example, still to prepare the operation ECC Fp scalar multiplication, when the application need to write the information \( a = -3 \), on a curve with a modulus length of 224 bits (i.e. four 64-bit words, rounded up, plus one) following data must be written in PKA memory:

\[
\begin{align*}
\text{\@RAM}+410 &\quad 0x0000000000000001 & \quad /* \text{curve coefficient 'a' sign without extra word} */ \\
\text{\@RAM}+418 &\quad 0x0000000000000011 & \quad /* \text{value of |a| LSB} */ \\
\text{\@RAM}+420 &\quad 0x0000000000000000 & \quad ... \\
\text{\@RAM}+428 &\quad 0x0000000000000000 & \quad ...
\end{align*}
\]
36.4.2 Montgomery parameter computation

This function is used to compute the Montgomery parameter \( R^2 \mod n \) used by PKA to convert operands into the Montgomery residue system representation. This operation can be very useful when fast mode operation is used, because in this case the Montgomery parameter is passed as input, saving the time for its computation.

Note: This operation can also be used with ECC curves. In this case prime modulus length and EOS size must be used.

Operation instructions for Montgomery parameter computation are summarized in Table 336.

36.4.5 Modular and Montgomery multiplication

To be more efficient when performing a sequence of multiplications the PKA accelerates multiplication which has at least one input in the Montgomery domain. The two main uses of this operation are:

- Map a value from natural domain to Montgomery domain and vice-versa
- Perform a modular multiplication \( A \times B \mod n \)

The method to perform above operations are described below. Note that “x” function is this operation, and \( A, B, C \) operands are in the natural domain.

1. Inward (or outward) conversion into (or from) Montgomery domain
   a) Assuming that \( A \) is an integer in the natural domain:
      - Compute \( r^2 \mod n \) using Montgomery parameter computation.
      - Result \( AR = A \times r^2 \mod n \) is \( A \) in the Montgomery domain.
   b) Assuming that \( BR \) is an integer in the Montgomery domain:
      - Result \( B = BR \times 1 \mod n \) is \( B \) in the natural domain.
      - Similarly, above value \( AR \) computed in a) can be converted into the natural domain by computing \( A = AR \times 1 \mod n \).

2. Simple modular multiplication \( A \times B \mod n \)
   a) Compute \( r^2 \mod n \) using Montgomery parameter computation.
   b) Compute \( AR = A \times r^2 \mod n \). Output is in the Montgomery domain.
   c) Compute \( AB = AR \times B \mod n \). Output is in natural domain.

3. Multiple modular multiplication \( A \times B \times C \mod n \)
   a) Compute \( r^2 \mod n \) using Montgomery parameter computation.
   b) Compute \( AR = A \times r^2 \mod n \). Output is in the Montgomery domain.
   c) Compute \( BR = B \times r^2 \mod n \). Output is in the Montgomery domain.
   d) Compute \( ABR = AR \times BR \mod n \). Output is in the Montgomery domain.
   e) Compute \( CR = C \times r^2 \mod n \). Output is in the Montgomery domain.
   f) Compute \( ABCR = ABR \times CR \mod n \). Output is in the Montgomery domain.
   g) (optional) Repeat the two steps above if more operands need to be multiplied.
   h) Compute \( ABC = ABCR \times 1 \mod n \) to retrieve the result in natural domain.

Operation instructions for Montgomery multiplication are summarized in Table 339.

**36.4.6 Modular exponentiation**

Modular exponentiation operation is commonly used to perform a single-step RSA operation. It consists in the computation of \( a^b \mod n \).

RSA operation involving public information (RSA encryption) can use the normal or fast mode detailed on Table 340 and Table 341. RSA operation involving secret information (RSA decryption) must use the protected mode detailed on Table 342, for security reason.

*Note:* Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware.

*Note:* When \( \text{MODE} = 0x03 \), if the error output is different from 0xD60D all the memory content is cleared by PKA to avoid leaking information about the private key.

Operation instructions for modular exponentiation are summarized in Table 340 (normal mode), Table 341 (fast mode) and in Table 342 (protected mode). Fast mode usage is explained in Section 36.3.6.

Modular inversion

Modular inversion operation consists in the computation of multiplicative inverse $A^{-1} \mod n$. If the modulus $n$ is prime, for all values of $A$ (1 ≤ $A < n$) modular inversion output is valid. If the modulus $n$ is not prime, $A$ has an inverse only if the greatest common divisor between $A$ and $n$ is 1.

If the operand $A$ is a divisor of the modulus $n$ the result is a multiple of a factor of $n$.

Operation instructions for modular inversion are summarized in Table 343.

---

(1) Euler totient function of $n^1$ with $phi = (p - 1) \times (q - 1)$, where $p$ and $q$ are prime factors of modulus $n$ (see NIST SP800-56B Appendix C or RSA encryption/decryption principle for details). As optimization it is recommended to keep phi information as part of the key pair generation. Alternative is to store the key as $(p, q, e, d)$ instead of $(N, e, d, phi)$; in this case, to derive $N$ and phi using PKA arithmetic multiplier:

$$N = p \times q,$$

and

$$phi = (p - 1) \times (q - 1).$$
36.4.8 Modular reduction

Modular reduction operation consists in the computation of the remainder of $A$ divided by $n$. Operation instructions are summarized in Table 344.

<table>

<td>RAM@0xE78</td>
</tr>
</tbody>
</table>

36.4.10 Arithmetic subtraction

Arithmetic subtraction operation consists in the following computations:

- If $A \geq B$ result equals $A - B$
- If $A < B$ and $M/32$ residue is $> 0$ result equals $A + 2^{\text{int}(M/32)^*32+1} - B$
- If $A < B$ and $M/32$ residue is $0$ result equals $A + 2^{\text{int}(M/32)^*32} - B$
For the last two bullets the 32-bit word following the most significant word of the output equals 0xFFFF FFFF, as result is negative.

Operation instructions are summarized in Table 346.

**36.4.11 Arithmetic multiplication**

Arithmetic multiplication operation consists in the computation of AxB. Operation instructions are summarized in Table 347.

36.4.13 RSA CRT exponentiation

For efficiency many popular crypto libraries such as OpenSSL RSA use the following optimization for decryption and signing based on the chinese remainder theorem (CRT):

- $p$ and $q$ are precomputed primes, stored as part of the private key
- $d_P = d \mod (p - 1)$
- $d_Q = d \mod (q - 1)$ and
- $q_{inv} = q^{-1} \mod p$

These values allow the recipient to compute the exponentiation $m = A^d \mod pq$ more efficiently as follows:

- $m_1 = A^{d_P} \mod p$
- $m_2 = A^{d_Q} \mod q$
- $h = q_{inv} (m_1 - m_2) \mod p$, with $m_1 > m_2$
- $m = m_2 + hq \mod pq$

Operation instructions for computing CRT exponentiation $A^d \mod pq$ are summarized in Table 349.

36.4.14 Point on elliptic curve Fp check

This operation consists in checking whether a given point $P(x, y)$ satisfies or not the curves over prime fields equation $y^2 = (x^3 + ax + b) \mod p$, where $a$ and $b$ are elements of the curve.

Operation instructions for point on elliptic curve Fp check are summarized in Table 350.
36.4.15  ECC Fp scalar multiplication

This operation consists in the computation of a k x P (x_P, y_P), where P is a point on a curve over prime fields and “x” is the elliptic curve scalar point multiplication. Result of the computation is a point that belongs to the same curve or a point at infinity.

Operation instructions for ECC Fp scalar multiplication are summarized in Table 351.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events, a PKA tamper event is triggered to TAMPER peripheral, and access to PKA RAM becomes blocked until erased by hardware. PKA tamper is also triggered when the programmed input point is not found on the input ECC curve. PKA operation "Point on elliptic curve" can be used to avoid this.

When performing this operation the following special cases must be noted:

- For \( k = 0 \) this function returns a point at infinity \((0, 0)\) if curve parameter \( b \) is nonzero, \((0, 1)\) otherwise. For \( k \) different from 0 it might happen that a point at infinity is returned. When the application detects this behavior a new computation must be carried out.

- For \( k < 0 \) (i.e. a negative scalar multiplication is required) the multiplier absolute value \( k = |-k| \) must be provided to the PKA. After the computation completion, the formula \(-P = (x, -y)\) can be used to compute the \( y \) coordinate of the effective final result (the \( x \) coordinate remains the same).

Note: If the error output is different from 0xD60D all the memory content is cleared by PKA to avoid leaking information about the private key.

### 36.4.16 ECDSA sign

ECDSA signing operation (outlined in Section 36.3.5) is summarized in Table 352 (input parameters) and in Table 353 (output parameters).

The application has to check if the output error is equal to 0xD60D, if it is different a new \( k \) must be generated and the ECDSA sign operation must be repeated.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware. PKA tamper is also triggered when the programmed input point is not found on the input ECC curve. PKA operation "Point on elliptic curve" can be used to avoid this.
Public key accelerator (PKA) RM0481

1. **Note:** If the error output equals 0xD60D or 0xCBC9 all the memory content is cleared by PKA to avoid leaking information about the private key. If error output equals 0xA3B7 or 0xF946 PKA memory content is partially erased, keeping the error code readable.

### Extended ECDSA support

PKA also supports extended ECDSA signature, for which the inputs and the outputs are the same as ECDSA signature (Table 352 and Table 353, respectively), with the addition of the coordinates of the point kG. This extra output is defined in Table 354.

---

### Table 352. ECDSA sign - Inputs

**Note:** If the error output equals 0xD60D or 0xCBC9 all the memory content is cleared by PKA to avoid leaking information about the private key. If error output equals 0xA3B7 or 0xF946 PKA memory content is partially erased, keeping the error code readable.
ECDSA verification

ECDSA verification operation (outlined in Section 36.3.5) is summarized in Table 355 (input parameters) and Table 356 (output parameters).

The application has to check if the output error is equal to 0xD60D, if different the signature is not verified.

¹. Padding with zeroes or hash truncation must be used to have the hash parameter size equal to the curve prime order n length.
36.4.18 **ECC complete addition**

ECC complete addition computes the addition of two given points on an elliptic curve.

Operation instructions are summarized in **Table 357**.

*Note:* The two input points and the resulting point are represented in Jacobian coordinates \((X,Y,Z)\). To input a point in affine coordinates \((x,y)\) conversion \((X,Y,Z) = (x,y,1)\) can be used. To convert resulting point to Jacobian coordinates conversion \((x,y) = (X/Z^2, Y/Z^3)\) can be used.

</tbody>
</table>
Note: The two input points are represented in Jacobian coordinates \((X, Y, Z)\). To input a point in affine coordinates \((x, y)\) conversion \((X, Y, Z) = (x, y, 1)\) can be used. The result is represented in affine coordinates \((x, y)\).

### ECC projective to affine

ECC projective to affine operation computes the conversion between the representation of a point \(P\) in homogeneous projective coordinates and the representation of the point \(P\) in affine coordinates. Namely, if the point is represented by the triple \((X, Y, Z)\), it computes the affine coordinates \((x, y) = (X/Z, Y/Z)\).

All the operations are performed modulo the modulus \(p\) of the curve, which the point belongs to. If the resulting point is the point at infinity (error code 0xA3B7), the resulting coordinate equals \((0, 0)\).

Operation instructions are summarized in Table 359.
36.5 Example of configurations and processing times

36.5.1 Supported elliptic curves

The PKA supports all non-singular elliptic curves defined over prime fields. Those curves can be described with a short Weierstrass equation, \( y^2 = x^3 + ax + b \ (\text{mod} \ p) \).

**Note:** Binary curves, Edwards curves and Curve25519 are not supported by the PKA. The maximum supported operand size for ECC operations is 640 bits.

When publishing the ECC domain parameters of those elliptic curves, standard bodies define the following parameters:

- the prime integer \( p \), used as the modulus for all point arithmetic in the finite field \( \text{GF}(p) \)
- the (usually prime) integer \( n \), the order of the group generated by \( G \), defined below
- the base point of the curve \( G \), defined by its coordinates \((G_x, G_y)\)
- the integers \( a \) and \( b \), coefficients of the short Weierstrass equation.

For the last bullet, when standard bodies define \( a \) as negative, PKA supports two representations:

1. **a defined as \( p-a \)** in the finite field \( \text{GF}(p) \), for example \( p-3 \):
   - Curve coefficient \( p = 0xFFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF \)
   - Curve coefficient \( a \) sign= 0x0 (positive)
   - Curve coefficient \( a = 0xFFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF \)

2. **a defined as negative**, for example \(-3\):
   - Curve coefficient \( p = 0xFFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF \)
   - Curve coefficient \( a \) sign= 0x1 (negative)
   - Curve coefficient \( a = 0x00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 \)

1. These values are average execution times of random moduli of given length, as they depend upon the length and the value of the modulus.
2. The execution time for the moduli that define the finite field of NIST elliptic curves is shorter than that needed for the moduli used for Brainpool elliptic curves or for random moduli of the same size.

There are four individual maskable interrupt sources generated by the public key accelerator, signaling the following events:

1. PKA unsupported operation error (OPERRF), see Section 36.3.7
2. Access to unmapped address (ADDRERRF), see Section 36.3.7
3. PKA RAM access while PKA operation is in progress (RAMERRF), see Section 36.3.7
4. PKA end of operation (PROCENDF)

The interrupt sources are connected to the same global interrupt request signal pka_it.

The user can enable or disable above interrupt sources individually by changing the mask bits in the PKA control register (PKA_CR). Setting the appropriate mask bit to 1 enables the interrupt. The status of the individual interrupt events can be read from the PKA status register (PKA_SR), and it is cleared in PKA_CLRFR register.

Table 370 gives a summary of the available features.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRIE**: Operation error interrupt enable
- 0: No interrupt is generated when OPERRF flag is set in PKA_SR.
- 1: An interrupt is generated when OPERRF flag is set in PKA_SR.

Bit 20 **ADDRERRIE**: Address error interrupt enable
- 0: No interrupt is generated when ADDRERRF flag is set in PKA_SR.
- 1: An interrupt is generated when ADDRERRF flag is set in PKA_SR.

Bit 19 **RAMERRIE**: RAM error interrupt enable
- 0: No interrupt is generated when RAMERRF flag is set in PKA_SR.
- 1: An interrupt is generated when RAMERRF flag is set in PKA_SR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDIE**: End of operation interrupt enable
- 0: No interrupt is generated when PROCENDF flag is set in PKA_SR.
- 1: An interrupt is generated when PROCENDF flag is set in PKA_SR.

Bits 16:14 Reserved, must be kept at reset value.
Bits 13:8 **MODE[5:0]**: PKA operation code

- 000000: Montgomery parameter computation then modular exponentiation
- 000001: Montgomery parameter computation only
- 000010: Modular exponentiation only (Montgomery parameter must be loaded first)
- 000011: Modular exponentiation (protected, used when manipulating secrets)
- 100000: Montgomery parameter computation then ECC scalar multiplication (protected)
- 100100: ECDSA sign (protected)
- 100110: ECDSA verification
- 101000: Point on elliptic curve Fp check
- 000111: RSA CRT exponentiation
- 001000: Modular inversion
- 001001: Arithmetic addition
- 001010: Arithmetic subtraction
- 001011: Arithmetic multiplication
- 001100: Arithmetic comparison
- 001101: Modular reduction
- 001110: Modular addition
- 001111: Modular subtraction
- 010000: Montgomery multiplication
- 100011: ECC complete addition
- 100111: ECC double base ladder
- 101111: ECC projective to affine

When an operation not listed here is written by the application with EN bit set, OPERRF bit is set in PKA_SR register, and the write to MODE bitfield is ignored. When PKA is configured in limited mode (LMF = 1 in PKA_SR), writing a MODE different from 0x26 with EN bit to 1 triggers OPERRF bit to be set and write to MODE bit is ignored.

Bits 7:2 Reserved, must be kept at reset value.

**Bit 1** START: start the operation

Writing 1 to this bit starts the operation which is selected by MODE[5:0], using the operands and data already written to the PKA RAM. This bit is always read as 0.

When an illegal operation is selected while START bit is set no operation is started, and OPERRF bit is set in PKA_SR.

*Note: START is ignored if PKA is busy.*

**Bit 0** EN: PKA enable

- 0: Disable PKA
- 1: Enable PKA. PKA becomes functional when INITOK is set by hardware in PKA_SR.

When an illegal operation is selected while EN = 1, OPERRF bit is set in PKA_SR. See PKA_CR.MODE bitfield for details.

*Note: When EN = 0, PKA RAM can still be accessed by the application.*
### 36.7.2 PKA status register (PKA_SR)

Address offset: 0x04
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>PKA end of operation flag</td>
</tr>
<tr>
<td>BUSY</td>
<td>Busy flag</td>
</tr>
<tr>
<td>LMF</td>
<td>Limited mode flag</td>
</tr>
</tbody>
</table>

Bits 31:22 Reserved, must be kept at reset value.

- **Bit 21** **OPERRF**: Operation error flag
  - 0: No event error
  - 1: An illegal or unknown operation has been selected in PKA_CR register

- **Bit 20** **ADDRERRF**: Address error flag
  - 0: No address error
  - 1: Address access is out of range (unmapped address)

- **Bit 19** **RAMERRF**: PKA RAM error flag
  - 0: No PKA RAM access error
  - 1: An AHB access to the PKA RAM occurred while the PKA core was computing and using its internal RAM (AHB PKA_RAM access are not allowed while PKA operation is in progress).

- **Bit 18** Reserved, must be kept at reset value.

- **Bit 17** **PROCENDF**: PKA end of operation flag
  - 0: Operation in progress
  - 1: PKA operation is completed. This flag is set when the BUSY bit is deasserted.

- **Bit 16** **BUSY**: Busy flag
  - 0: No operation is in progress (default)
  - 1: An operation is in progress

  If PKA is started with a wrong opcode, it stays busy for a couple of cycles, then it aborts automatically the operation and goes back to ready (BUSY = 0).

- **Bits 15:2** Reserved, must be kept at reset value.

- **Bit 1** **LMF**: Limited mode flag
  - 0: All values documented in MODE bitfield can be used.
  - 1: Only ECDSA verification (MODE = 0x26) is supported by the PKA.
36.7.3 **PKA clear flag register (PKA_CLRFR)**

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRFC**: Clear operation error flag
0: No action
1: Clear the OPERRF flag in PKA_SR

Bit 20 **ADDRERRFC**: Clear address error flag
0: No action
1: Clear the ADDRERRF flag in PKA_SR

Bit 19 **RAMERRFC**: Clear PKA RAM error flag
0: No action
1: Clear the RAMERRF flag in PKA_SR

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDFC**: Clear PKA end of operation flag
0: No action
1: Clear the PROCENDF flag in PKA_SR

Bits 16:0 Reserved, must be kept at reset value.

**Note:** Reading PKA_CLRFR returns all 0s.

36.7.4 **PKA RAM**

The PKA RAM is mapped at the offset address of 0x0400 compared to the PKA base address. Only 32-bit word single accesses are supported, through PKA_AHB interface.

RAM size is 5336 bytes (max word offset: 0x14D0)

**Note:** PKA RAM cannot be used just after a PKA reset or a product reset, as described in Section 36.3.3: PKA reset and clocks.
### PKA register map

Refer to **Section 2.3 on page 111** for the register boundary addresses.
37 On-the-fly decryption engine (OTFDEC)

37.1 Introduction

OTFDEC allows on-the-fly decryption of the AHB traffic based on the read request address information. Four independent and non-overlapping encrypted regions can be defined in OTFDEC.

OTFDEC uses AES-128 in counter mode to achieve the lowest possible latency. As a consequence, each time the content of one encrypted region is changed, the entire region must be re-encrypted with a different cryptographic context (key or initialization vector). This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR flash.

Note: When OTFDEC is used in conjunction with OCTOSPI, it is mandatory to access the flash memory using the memory-mapped mode of the flash memory controller.

When security is enabled in the product, OTFDEC can be programmed only by a secure host.

37.2 OTFDEC main features

- On-the-fly 128-bit decryption during the OCTOSPI Memory-mapped read operations (single or multiple).
  - Use of AES in counter (CTR) mode, with two 128-bit keystream buffers
  - Support for any read size
  - Physical address of the reads used for the encryption/decryption
- Up to four independent encrypted regions
  - Granularity of the region definition: 4096 bytes
  - Region configuration write-locking mechanism
  - Each region has its own 128-bit key, two bytes firmware version, and eight bytes application-defined nonce. At least one of those must be changed each time an encryption is performed by the application.
- Encryption keys confidentiality and integrity protection
  - Write-only registers, with software locking mechanism
  - Availability of 8-bit CRC as public key information
- Support for OCTOSPI pre-fetching mechanism
- Possibility to select an enhanced encryption mode to add a proprietary layer of protection on top of AES stream cipher (execute only)
- Privileged-aware AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
- Secure only programming if TrustZone security is enabled in the product
- Encryption mode
37.3 OTFDEC functional description

37.3.1 OTFDEC block diagram

</tr>
</tbody>
</table>
On-the-fly decryption engine (OTFDEC) RM0481

The TZEN option bit in FLASH is used to activate TrustZone in the device.
- TZEN = 1: TrustZone security is enabled in the product.
- TZEN = 0: TrustZone security is disabled in the product.

37.3.3 OTFDEC on-the-fly decryption

Introduction

Typical usage for OTFDEC is shown on Figure 334.

Figure 334. Typical OTFDEC use in a SoC

Original purpose of OTFDEC is to protect the confidentiality of read-only firmware libraries stored in external SPI NOR flash devices.

A special locking scheme is available in OTFDEC in order to protect the integrity of the decryption keys and also to protect the other configurations against software denial of services attacks. OTFDEC access to most registers can be made privileged-only by setting PRIV bit in OTFDEC_PRIVCFGR register. OTFDEC is only writeable by TrustZone CPU, when TrustZone security is activated.

When OTFDEC is used in conjunction with OCTOSPI, it is mandatory to read the flash memory using the Memory-mapped mode of the flash controller.

On top of decrypting on-the-fly, OTFDEC can also encrypt 32-bit word at a time (see Section 37.5.3: Encrypting for OTFDEC for more details).

OTFDEC architecture

OTFDEC analyzes all AHB read transfers on the associated AHB bus. If the read request is within one of the four regions programmed in OTFDEC, the control logic triggers a keystream computation based on AES algorithm in counter mode. This keystream is then used to decrypt on-the-fly the data present in the read transfer from the OCTOSPI AHB master, tying low the HREADYOUT signal of this master while the keystream information is being computed (this takes up to 11 cycles). Any accesses outside the enabled OTFDEC regions belong to a non-encrypted region.

Each OTFDEC region is programmed through OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR, OTFDEC_RxNONCER and
OTFDEC_RxKEYR registers, where x = 1 to 4. In OTFDEC_RxCFGR, the MODE bits define the OTFDEC operating mode (standard or enhanced encryption).

Granularity for the region determination is 4096 bytes.

**Note:** Although OTFDEC does not prevent region overlapping, it is not a valid programming and it must be avoided by application software.

OTFDEC can decrypt incremental or wrap bursts only if they do not cross the 4096-byte aligned address boundaries.

### 37.3.4 OTFDEC usage of AES in counter mode decryption

Figure 335 shows how OTFDEC uses industry standard Advanced Encryption Standard (AES) algorithm in counter chaining mode. This mode is specified by NIST in *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*.

**Figure 335. AES CTR decryption flow**

Every 128-bit data block, a special keystream information is computed using AES block cipher, as defined below:

- initialization vector \( AES\_IV[127:0] = RxNONCER1[31:0] || RxNONCER0[31:0] || 0b0000 0000 0000 0000 || RxCFGR[31:16] || 0b00 || (x-1) || ReadAddress[31:4] \)
- key material \( AES\_KEY[127:0] = RxKEYR3[31:0] || RxKEYR2[31:0] || RxKEYR1[31:0] || RxKEYR0[31:0] \)

**Note:** Above x is the RegionID of the selected encrypted region (x=1 to 4), ReadAddress is the AHB address of the encrypted data block, modulo 128-bit.

Resulting 128-bit keystream is XORed with 128-bit cipher text data to produce the 128-bit clear text data.

- \( AES\_DIN \) and \( AES\_DOUT \) data blocks are constructed following the rule below ("||" represents a binary concatenation):
  \[
  AES\_Dx[127:0] = AHB\_word(@ | 0xC)[31:0] || AHB\_word(@ | 0x8)[31:0] || AHB\_word(@ | 0x4)[31:0] || AHB\_word(@ | 0x0)[31:0], \]
  where @ is the hexadecimal address used to compute the keystream (ReadAddress[31:4] above).
When the read request is not within an encrypted region, or the decryption is not enabled in this region, the AHB data is not changed.

Note: When the application sets the MODE bitfield to 11 in OTFDEC_RxCFGR, an additional layer of protection is added on top of the AES stream cipher. This enhanced encryption mode can only be used with instructions (execute-only region).

37.3.5 Flow control management

Figure 336 shows how OTFDEC manages one INCR4 AHB burst that corresponds to one 128-bit AES data block.

Figure 336. OTFDEC flow control overview (dual burst read request)

with the following notes:
1. OTFDEC enforces HREADY signal from the AHB master low as it is not ready to decrypt data (keystream computation).
2. Thanks to the keystream buffer, OTFDEC can be ready to process a new batch of data within 12 cycles in this configuration (120 MHz AHB clock, 104 MHz SPI bus delivering 2 bytes per SPI clock).

37.3.6 OTFDEC error management

OTFDEC automatically manages errors defined as below:
- Illegal read to OTFDEC_RxKEYR registers
- Illegal write to OTFDEC_RxKEYR registers while CONFIGLOCK or KEYLOCK = 1 in OTFDEC_RxCFGR, while the access is secure. If the security is disabled in the product, the same error occurs when the access is nonsecure.
- Illegal write to OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR or OTFDEC_RxNONCER registers while CONFIGLOCK = 1 in OTFDEC_RxCFGR (x = 1 to 4), while the access is secure. If the security is disabled in the product the same error occurs when the access is nonsecure.
- Illegal read to an execute-only region (MODE[1:0] = 11). Such illegal request returns 0x0, without bus error.
- Execution request to a region while encryption is enabled (ENC = 1). The request returns 0x0, without bus error.
- Key error: read request to an encrypted region while its key registers are null or not properly initialized (KEYCRC = 0x0). Source of the error can be an incorrect key loading sequence (see KEYCRC in OTFDEC_RxCFGR) or it can be an abort event.
(tamper detection, unauthorized debug connection, untrusted boot, RDP level regression). Such read request returns 0x0, without bus error.

- Write to any registers while the access is nonsecure, if TrustZone security is enabled in the product.

  This last error is managed and cleared through TrustZone interrupt controller, as described in the GTZC section of the product reference manual.

For these errors (except the last one), an interrupt can be generated if the SEIE, XONEIE or KEIE bit is set in OTFDEC_IER register (see Section 37.4).

**Note:** After a key error, OTFDEC keys must be properly initialized again, and a reset of OTFDEC may be needed if registers are locked.

### 37.4 OTFDEC interrupts

There are three independent maskable interrupt sources generated by the OTFDEC, signaling following security events:

- Illegal read or write access to keys (SEIF flag), see Section 37.3.6
- Illegal write to a region configuration while CONFIGLOCK = 1 (SEIF flag), see Section 37.3.6
- Read access to an execute-only region (MODE[1:0] = 11), triggering the XONEIF flag
- Executing while encryption is enabled (XONEIF flag)
- Key error (encrypted regions read as zero) triggering the KEIF flag, see Section 37.3.6.

Interrupt sources are connected to the same global interrupt request signal.

OTFDEC interrupt sources can be enabled/disabled by setting the corresponding SEIE, XONEIE or KEIE bit in OTFDEC_IER, as described in Table 373. Status of the interrupt event is found in OTFDEC_ISR, and this event can be cleared using OTFDEC_ICR.

### Table 373. OTFDEC interrupt requests

1. The event flags are found in the OTFDEC_ISR register.

### 37.5 OTFDEC application information

#### 37.5.1 OTFDEC initialization process

**Introduction**

One key aspect of OTFDEC is the trusted initialization of its registers, as it involves secret keys. Two trusted initialization schemes are recommended here below.
Note: Those sequences are for production code, as during firmware development, it is not always recommended to lock the key or the region configuration. Writes to configuration registers are effective when the configuration locks allow it, even if the region is enabled.

Initialization scheme 1: one key for all regions

In this scheme, one entity owns the secret key used to decrypt the four protected regions. The recommended OTFDEC configuration sequence is described below:

1. For \( x = 1 \) to \( 4 \), write the correct \( \text{MODE}[1:0] \) value in OTFDEC\_RxCFGFR.
2. For \( x = 1 \) to \( 4 \), program OTFDEC\_RxKEYR registers using the sequence described in KEYCRC (to have a valid CRC). Warning as key registers are write only.
3. For \( x = 1 \) to \( 4 \), check the key CRC. If OK, set KEYLOCK bit in OTFDEC\_RxCFGFR. This bit cannot be cleared (key registers in this region \( x \) are no more writable).
4. To do to decrypt a region \( x \) (task that does not necessarily have to be performed by the entity that owns the decryption keys):
   a) Verify if the key CRC corresponds to the encrypted binary stored in the region.
   b) Fill the detailed information corresponding to this binary (nonce, start address, end address, version number).
   c) Enable decryption of this region using REG\_EN.
   d) Set CONFIGLOCK bit in OTFDEC\_RxCFGFR. This bit cannot be cleared (the region configuration is no more writable).

Caution: For a given region, when \( \text{MODE} \) bits are changed, the key registers and associated CRC are cleared by hardware. As a consequence, step 1 above must be done before step 2, and \( \text{MODE} \) bits must not be modified after step 2.

Initialization scheme 2: one key per region

In this scheme, one entity can own the secret used to decrypt one (or more) protected region. The recommended OTFDEC configuration sequence is described below:

1. To do to decrypt a region \( x \) (this task must be performed by the entity that owns the corresponding key):
   a) Write the correct \( \text{MODE}[1:0] \) value in OTFDEC\_RxCFGFR.
   b) Program OTFDEC\_RxKEYR registers using the sequence described in KEYCRC (to have a valid CRC). Warning as key registers are write only.
   c) Check the key CRC. If OK, set KEYLOCK bit in OTFDEC\_RxCFGFR. This bit cannot be cleared (key registers are no more writable).
   d) Fill the detailed information corresponding to the protected firmware (nonce, start address, end address, version number).
   e) Enable decryption of this region using REG\_EN.
   f) Set CONFIGLOCK bit in OTFDEC\_RxCFGFR. This bit cannot be cleared (the region configuration is no more writable).

Caution: For a given region, when \( \text{MODE} \) bits are changed, the key registers and associated CRC are cleared by hardware. As a consequence step a) above must be done before step b), and \( \text{MODE} \) bits must not be modified after step b).
37.5.2 OTFDEC and power management

Each time OTFDEC is reset, the correct key loading sequence described in Section 37.5.1 must be performed (in this case KEYCRC = 0 in OTFDEC_RxCFGR).

It is recommended for application software to verify this point each time OTFDEC is reset by hardware.

37.5.3 Encrypting for OTFDEC

Code and data standard encryption

OTFDEC uses standard AES in counter mode when processing a binary stored in a protected region with MODE[1:0] = 10. When this mode is selected, any AES compatible hardware accelerator or library can be used to encrypt those protected libraries. OTFDEC can be used as well, as described in enhanced encryption section below (with MODE[1:0] = 10).

Definition and endianness of the AES inputs and outputs are defined in Section 37.3.4: OTFDEC usage of AES in counter mode decryption.

Enhanced encryption with OTFDEC

OTFDEC uses a proprietary layer of protection on top of the standard AES in counter mode when processing a code stored in a protected region with MODE[1:0] = 11.

Enhanced encryption mode can be used to increase the robustness against tampering.

Recommended sequence to encrypt using OTFDEC is described below:

1. The application in charge of the encryption sets the ENC bit in OTFDEC_CR. This application must run in TrustZone secure mode when TrustZone security is enabled in the product. If PRIV bit is set in OTFDEC_PRIVCFGR, this application must be privileged.

2. Encryption application initializes OTFDEC as described in Section 37.5.1: OTFDEC initialization process. OCTOSPI must also be properly clocked, so that OTFDEC is fully functional in encryption mode. This step can also be done before step 1.

3. Encryption application writes 32-bit of clear-text data at the expected protected address, then reads it back encrypted at the same address to store it in RAM. Note that this data stays inside the device, as it is intercepted by OTFDEC in encryption mode.

4. Encryption application goes back to previous step (changing the address) until the whole binary is processed.

5. Encryption application clears the ENC bit in OTFDEC_CR. Another application can then take the encrypted binary and flash it to the correct address in external flash.

There are few important notes about this procedure:

• Encryption granularity is 32-bit (single 32-bit access is mandatory).

• While ENC bit is set, reads to non-encrypted regions return normal data (such as no encryption nor decryption). While in encryption mode, no access to OCTOSPI (including registers) must be done. This is because the OTFDEC cuts the communication with OCTOSPI while ENC bit is set.

• OTFDEC does not support execution while ENC = 1 (only encrypted data reads). Upon illegal execution detection a XONEIF flag is raised and zero is returned.
37.5.4 OTFDEC key CRC source code

Below is the CRC source code that can be used to compare with the result of the computation provided by OTFDEC in KEYCRC bitfield after loading the keys in OTFDEC_RxKEYR registers.

```c
uint8_t getCRC(uint32_t * keyin)
{
    const uint8_t CRC7_POLY = 0x7;
    const uint32_t key_strobe[4] = {0xAA55AA55, 0x3, 0x18, 0xC0};
    uint8_t  i, j, k, crc = 0x0;
    uint32_t  keyval;

    for (j = 0; j < 4; j++)
    {
        keyval = *(keyin+j);
        if (j == 0)
        {
            keyval ^= key_strobe[0];
        }
        else
        {
            keyval ^= (key_strobe[j] << 24) | (crc << 16) | (key_strobe[j] << 8) | crc;
        }

        for (i = 0, crc = 0; i < 32; i++)
        {
            k = (((crc >> 7) ^ (keyval >> (31-i))&0xF)) & 1;
            crc <<= 1;
            if (k)
            {
                crc ^= CRC7_POLY;
            }
        }
        crc^=0x55;
    }
    return crc;
}
```
# OTFDEC registers

## OTFDEC control register (OTFDEC_CR)

Address offset: 0x0  
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>

<td></td>
<td></td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:1 Reserved, must be kept at reset value.

**Bit 0 ENC:** Encryption mode bit

When this bit is set, OTFDEC is used in encryption mode, during which application can write clear text data then read back encrypted data. When this bit is cleared (default), OTFDEC is used in decryption mode, during which application only read back decrypted data. For both modes, cryptographic context (keys, nonces, firmware versions) must be properly initialized. When this bit is set, only data accesses are allowed (zeros are returned otherwise, and XONEIF is set). When MODE = 11, enhanced encryption mode is automatically selected.

0: OTFDEC working in decryption mode  
1: OTFDEC working in encryption mode

**Note:** When ENC bit is set, no access to OCTOSPI must be done (registers and Memory-mapped region).
### 37.6.2 OTFDEC privileged access control configuration register (OTFDEC_PRIVCFGR)

Address offset: 0x10  
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>

<td>This bit can only be written in privileged mode. There is no limitations on reads.</td>
<td></td>
</tr>
</tbody>
</table>

### 37.6.3 OTFDEC region x configuration register (OTFDEC_RxCFGR)

Address offset: 0x20 + 0x30 * (x - 1), (x = 1 to 4)  
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Writes are ignored if CONFIGLOCK bit is set to 1.
Bits 31:16 **REG_VERSION[15:0]:** region firmware version
   This 16-bit bitfield must be correctly initialized before the region corresponding REG_EN bit is set in OTFDEC_RxCFGR.

Bits 15:8 **KEYCRC[7:0]:** region key 8-bit CRC
   When KEYLOCK = 0, KEYCRC bitfield is automatically computed by hardware while loading the key of this region in this exact sequence: KEYR0 then KEYR1 then KEYR2 then finally KEYR3 (all written once). A new computation starts as soon as a new valid sequence is initiated, and KEYCRC is read as zero until a valid sequence is completed.
   When KEYLOCK = 1, KEYCRC remains unchanged until the next reset.
   CRC computation is an 8-bit checksum using the standard CRC-8-CCITT algorithm $x^8 + x^2 + x + 1$ (according the convention). Source code is available in Section 37.5.4.
   This field is read only.
   Note: CRC information is updated only after the last bit of the key has been written.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **MODE[1:0]:** operating mode
   This bitfield selects the OTFDEC operating mode for this region:
   10: All read accesses are decrypted (instruction or data).
   11: Enhanced encryption mode is activated, and only instruction accesses are decrypted
   Others: Reserved
   When MODE $\neq$ 11, the standard AES encryption mode is activated.
   When either of the MODE bits are changed, the region key and associated CRC are zeroed.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **KEYLOCK:** region key lock
   0: Writes to this region KEYRx registers are allowed.
   1: Writes to this region KEYRx registers are ignored until next OTFDEC reset. KEYCRC bitfield is locked.
   Note: This bit is set once: if this bit is set, it can only be reset to 0 if the OTFDEC is reset.

Bit 1 **CONFIGLOCK:** region config lock
   0: Writes to this region OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR and OTFDEC_RxNONCERy registers are allowed.
   1: Writes to this region OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR and OTFDEC_RxNONCERy registers are ignored until next OTFDEC reset.
   Note: This bit is set once. If this bit is set, it can only be reset to 0 if OTFDEC is reset. Setting this bit forces KEYLOCK bit to 1.

Bit 0 **REG_EN:** region on-the-fly decryption enable
   0: On-the-fly decryption is disabled for this region.
   1: On-the-fly decryption is enabled for this region. Data are XORed with the corresponding keystream.
   Note: Garbage is decrypted if region context (version, key, nonce) is not valid when this bit is set.
37.6.4 OTFDEC region x start address register (OTFDEC_RxSTARTADDR)

Address offset: 0x24 + 0x30 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Bits 31:0 REG_START_ADDR[31:0]: Region AHB start address
This register must be written before the region corresponding REG_EN bit in the OTFDEC_RxCFGR register is set.
Writing to this register is discarded if performed while the region CONFIGLOCK bit in the OTFDEC_RxCFGR register is set.

Note: When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.
When this register is accessed in read the 4 MSB bits and the 12 LSB bits return zeros.

37.6.5 OTFDEC region x end address register (OTFDEC_RxENDADDR)

Address offset: 0x28 + 0x30 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0FFF

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Bits 31:0 REG_NONCE[31:0]: Region nonce, bits [31:0]

This register must be written before the region corresponding REG_EN bit in OTFDEC_RxCFGR is set.

Writing is discarded in this register if performed while the region CONFIGLOCK bit in the OTFDEC_RxCFGR is set.
37.6.7 OTFDEC region x nonce register 1 (OTFDEC_RxNONCER1)

Address offset: 0x30 + 0x30 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

 Bits 31:0 REG_NONCE[63:32]: Region nonce, bits [63:32]
Refer to the OTFDEC_RxNONCER0 register for description of the NONCE[63:0] bitfield.

37.6.8 OTFDEC region x key register 0 (OTFDEC_RxKEYR0)

Address offset: 0x34 + 0x30 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

 Bits 31:0 REG_KEY[31:16]: Region key, bits [31:16]
This register must be written before the region corresponding REG_EN bit in OTFDEC_RxCFGR is set.
Reading this register returns a zero value. Writing to this register is discarded if performed while the region CONFIGLOCK or KEYLOCK bit is set in the OTFDEC_RxCFGR.
Note: When application successfully changes MODE bits in OTFDEC_RxCFGR and OTFDEC_RxKEYR, and associated KEYCRC are erased.
37.6.9 **OTFDEC region x key register 1 (OTFDEC_RxKEYR1)**

Address offset: 0x38 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

**REG_KEY[95:64]**

Bits 31:0 **REG_KEY[95:64]**: Region key, bits [95:64]

Refer to the OTFDEC_RxKEYR0 register for description of the KEY[127:0] bitfield.
37.6.11  **OTFDEC region x key register 3 (OTFDEC_RxKEYR3)**

Address offset: 0x40 + 0x30 * (x - 1), (x = 1 to 4)
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Bits 31:0  **REG_KEY[127:96]**: Region key, bits [127:96]

Refer to the OTFDEC_RxKEYR0 register for description of the KEY[127:0] bitfield.

37.6.12  **OTFDEC interrupt status register (OTFDEC_ISR)**

Address offset: 0x300
Reset value: 0x0000 0000

Unprivileged reads return zero if PRIV bit is set in OTFDEC_PRIVCFGR.

</tr>
</tbody>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  **KEIF**: Key error interrupt flag status

This bit is set by hardware and read only by application. The bit is set when a read access occurs on an encrypted region, while its key registers is null or not properly initialized (KEYCRC = 0x0).

This bit is cleared when the application sets in OTFDEC_ICR the corresponding bit to 1.

0: OTFDEC operates properly.
1: Read access detected on an enabled encrypted region with its key registers null or not properly initialized (KEYCRC = 0x0). OTFDEC returns a zeroed value for the read, and an optional interrupt is generated if bit KEIE is set to 1 in OTFDEC_IER.

After KEIF is set any subsequent read to the region with bad key registers returns a zeroed value. This state remains until those key registers are properly initialized (KEYCRC not zero).
Bit 1 **XONEIF**: Execute-only execute-never error interrupt flag status

This bit is set by hardware and read only by application. This bit is set when a read access and not an instruction fetch is detected on any encrypted region with MODE bits set to 11. Lastly, XONEIF is also set when an execute access is detected while encryption mode is enabled.
This bit is cleared when application sets in OTFDEC_ICR the corresponding bit to 1.
0: No execute-only error status. No interrupt pending.
1: Read access detected on one region with MODE bits set to 11 or execute access detected while ENC = 1. OTFDEC returns a zeroed value for the illegal access, and an optional interrupt is generated if bit XONEIE is set to 1 in OTFDEC_IER.

Bit 0 **SEIF**: Security error interrupt flag status

This bit is set by hardware and read only by application. This bit is set when at least one security error has been detected.
This bit is cleared when application sets in OTFDEC_ICR the corresponding bit to 1.
0: No security error status. No interrupt pending.
1: Security error flag status, with interrupt pending. Actual interrupt generation is dependent on OTFDEC_IER corresponding bit SEIE.

### 37.6.13 OTFDEC interrupt clear register (OTFDEC_ICR)

Address offset: 0x304
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.
Bit 2 **KEIF:** Key error interrupt flag clear
This bit is written by application, and always read as 0.
0: KEIF flag status is not affected.
1: KEIF flag status is cleared in OTFDEC_ISR.

*Note:* Clearing KEIF does not solve the source of the problem (bad key registers). To be able to access again any encrypted region, OTFDEC key registers must be properly initialized again.

Bit 1 **XONEIF:** Execute-only execute-never error interrupt flag clear
This bit is written by application, and always read as 0.
0: XONEIF flag status is not affected.
1: XONEIF flag status is cleared in OTFDEC_ISR.

Bit 0 **SEIF:** Security error interrupt flag clear
This bit is written by application, and always read as 0.
0: SEIF flag status is not affected.
1: SEIF flag status is cleared in OTFDEC_ISR.

### 37.6.14 OTFDEC interrupt enable register (OTFDEC_IER)

Address offset: 0x308
Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Bits 31:3 Reserved, must be kept at reset value.
Bit 2 **KEIE**: Key error interrupt enable
This bit is read and written by application. It controls the OTFDEC interrupt generation when KEIF flag status is set.
0: Interrupt generation on key error flag KEIF is disabled (masked).
1: Interrupt generation on key error flag KEIF is enabled (not masked).

Bit 1 **XONEIE**: Execute-only execute-never error interrupt enable
This bit is read and written by application. It controls the OTFDEC interrupt generation when XONEIF flag status is set.
0: Interrupt generation on execute-only error XONEIF is disabled (masked).
1: Interrupt generation on execute-only error XONEIF is enabled (not masked).

Bit 0 **SEIE**: Security error interrupt enable
This bit is read and written by application. It controls the OTFDEC interrupt generation when SEIF flag status is set.
0: Interrupt generation on security error SEIF is disabled (masked).
1: Interrupt generation on security error SEIF is enabled (not masked).

Advanced-control timers (TIM1/TIM8)

TIM1/TIM8 introduction

The advanced-control timers (TIM1/TIM8) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 38.3.30: Timer synchronization.

TIM1/TIM8 main features

TIM1/TIM8 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 6 independent channels for:
  - Input capture (but channels 5 and 6)
  - Output compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and Hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

38.3.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software, even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

*Note:* The counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler divides the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 338* and *Figure 339* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 338. Counter timing diagram with prescaler division change from 1 to 2

Figure 339. Counter timing diagram with prescaler division change from 1 to 4
38.3.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):
- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Write a new value in TIMx_ARR
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-
reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.
1. Here, center-aligned mode 1 is used (for more details refer to Section 38.6: TIM1/TIM8 registers).

Figure 351. Counter timing diagram, internal clock divided by 1, TIMx_ARR = 0x6

Figure 352. Counter timing diagram, internal clock divided by 2
Figure 353. Counter timing diagram, internal clock divided by 4, TIMx_ARR=0x36

Note: Here, center_aligned mode 2 or 3 is updated with an UIF on overflow
Figure 355. Counter timing diagram, update event with ARPE=1 (counter underflow)
38.3.5 Repetition counter

Section 38.3.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:
- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode.

Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is $2\times T_{ck}$, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 357). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

**Figure 357. Update rate examples depending on mode and TIMx_RCR register settings**

![Diagram showing update rate examples](image)

**38.3.6 External trigger input**

The timer features an external trigger input tim_etr_in. It can be used as:
- external clock (external clock mode 2, see *Section 38.3.7*)
- trigger for the slave mode (see *Section 38.3.30*)
- PWM reset input for cycle-by-cycle current regulation (see *Section 38.3.9*)

*Figure 358* below describes the tim_etr_in input conditioning. The input polarity is defined with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield. The resulting signal (tim_etrf) is available for three purposes: as an external clock, to condition...
the output (typically to reset a PWM output for a current limitation), and as a trigger for the Slave mode controller.

**Figure 358. External trigger input block**

The `tim_etr_in` input comes from multiple sources: input pins (default configuration), or internal sources. The selection is done with the ETRSEL[3:0] bitfield in the TIMx_AF1 register.

Refer to [Section 38.3.2: TIM1/TIM8 pins and internal signals](#) for the list of sources connected to the `etr_in` input in the product.

### 38.3.7 Clock selection

The counter clock can be provided by the following clock sources:

- **Internal clock** (`tim_ker_ck`)
- **External clock mode1**: external input pin (`tim_ti1` or `tim_ti2`)
- **External clock mode2**: external trigger input (`tim_etr_in`)
- **Encoder mode**

#### Internal clock source (`tim_ker_ck`)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock `tim_ker_ck`.

**Figure 359** shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

1. Codes ranging from 0100 to 1111 are reserved.
For example, to configure the upcounter to count in response to a rising edge on the `tim_ti2` input, use the following procedure:

1. Configure channel 2 to detect rising edges on the `tim_ti2` input by writing `CC2S = '01'` in the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the `IC2F[3:0]` bits in the TIMx_CCMR1 register (if no filter is needed, keep `IC2F=0000`).
3. Select rising edge polarity by writing `CC2P=0` and `CC2NP=0` in the TIMx_CCER register.
4. Configure the timer in external clock mode 1 by writing `SMS=111` in the TIMx_SMCR register.
5. Select `tim_ti2` as the trigger input source by writing `TS=00110` in the TIMx_SMCR register.
6. Enable the counter by writing `CEN=1` in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on `tim_ti2`, the counter counts once and the TIF flag is set. The delay between the rising edge on `tim_ti2` and the actual clock of the counter is due to the resynchronization circuit on `tim_ti2` input.

**Figure 361. Control circuit in external clock mode 1**

![Control circuit in external clock mode 1](image)

**External clock source mode 2**

This mode is selected by writing `ECE=1` in the TIMx_SMCR register. The counter counts at each rising or falling edge on the external trigger input `tim_etr_in`. The Figure 362 gives an overview of the external trigger input block.
Figure 362. External trigger input block

1. Refer to Section 38.3.2: TIM1/TIM8 pins and internal signals.

For example, to configure the upcounter to count each 2 rising edges on `tim_etrin`, use the following procedure:

1. As no filter is needed in this example, write `ETF[3:0]=0000` in the TIMx_SMCR register.
2. Set the prescaler by writing `ETPS[1:0]=01` in the TIMx_SMCR register.
3. Select rising edge detection on the `tim_etrin` input by writing `ETP=0` in the TIMx_SMCR register.
4. Enable external clock mode 2 by writing `ECE=1` in the TIMx_SMCR register.
5. Enable the counter by writing `CEN=1` in the TIMx_CR1 register.

The counter counts once each 2 `tim_etrin` rising edges.

The delay between the rising edge on `tim_etrin` and the actual clock of the counter is due to the resynchronization circuit on the `tim_etrp` signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most $\frac{1}{4}$ of `tim_ker_ck` frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.
38.3.8 Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

*Figure 364 to Figure 367* give an overview of one capture/compare channel.

The input stage samples the corresponding TIM_tix input to generate a filtered signal TIM_tixf. Then, an edge detector with polarity selection generates a signal (TIM_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

*Figure 364. Capture/compare channel (example: channel 1 input stage)*
The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

**Figure 365. Capture/compare channel 1 main circuit**
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.
In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 38.3.9 Input capture mode

In Input capture mode, the capture/compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_t1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the tim_t1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.

- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_t1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

- Select the edge of the active transition on the tim_t1 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).

- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).

- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.

- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.
Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

38.3.10 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIMx_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tixfp1 input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two tim_tixfp signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulsewidth of a PWM signal applied on tim_t1 can be measured using the following procedure:

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_t1 selected).
- Select the active polarity for tim_t1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_t1 selected).
- Select the active polarity for tim_t1fp2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP=’10’ (active on falling edge).
- Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_t1fp1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.
38.3.11 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_OCCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 0100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

38.3.12 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while channel 5 and 6 are only available inside the microcontroller (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM=0000), be set
active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.
• Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
• Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
• Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure
1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 369.
38.3.13 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
**PWM edge-aligned mode**

- **Upcounting configuration**
  
  Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to the *Upcounting mode on page 1435.*

  In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1’. If the compare value is 0 then tim_ocxref is held at ‘0’. *Figure 370* shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

</tbody>
</table>

- **Downcounting configuration**
  
  Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to the *Downcounting mode on page 1439.*

  In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then tim_ocxref is held at ‘1’. 0% PWM is not possible in this mode.

**PWM center-aligned mode**

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit...
(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to the Center-aligned mode (up/down counting) on page 1442.

Figure 371 shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Figure 371. Center-aligned PWM waveforms (ARR=8)

Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit.
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT > TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

### Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The **Figure 372** below presents the dithering principle applied to 4 consecutive PWM cycles.

![Figure 372. Dithering principle](MSv45752V1)

When the dithering mode is enabled, the register coding is changed as follows (see **Figure 373** for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value
Note: The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The DITHEN bit must be reset
3. The CCIF flags must be cleared
4. The CEN bit can be set (eventually with ARPE = 1).

Figure 373. Data format and register coding in dithering mode

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = F_{\text{Tim}} \cdot F_{\text{Max Resolution}}
\]

Dithering mode disabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode enabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

Note: The maximum TIMx ARR and TIMxCCRy values are limited to 0xFFFFE in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 374 below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.
The duty cycle and/or period changes are spread over 16 consecutive periods, as described in the Figure 375 below.
The auto-reload and compare values increments are spread following specific patterns described in the Table 386 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

The dithering mode is also available in center-aligned PWM mode (CMS bits in TIMx_CR1 register are not equal to '00'). In this case, the dithering pattern is applied over 8 consecutive PWM periods, considering the up and down counting phases as shown in the Figure 376 below.

#### 38.3.14 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- `tim_oc1refc` (or `tim_oc2refc`) is controlled by TIMx_CCR1 and TIMx_CCR2
- `tim_oc3refc` (or `tim_oc4refc`) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channel (one `tim_ocx` output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an `tim_oc1refc` signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the `tim_oc2refc` signal on channel 2, or an `tim_oc2refc` signal resulting from asymmetric PWM mode 1.

*Figure 377* represents an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 2). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.
38.3.15 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 378 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1.
38.3.16 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The tim_oc5ref signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx_CCR5 allow selection on which reference signal the tim_oc5ref is combined. The resulting signals, tim_ocxrefc, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, tim_oc1refc is controlled by TIMx_CCR1 and TIMx_CCR5
- If GC5C2 is set, tim_oc2refc is controlled by TIMx_CCR2 and TIMx_CCR5
- If GC5C3 is set, tim_oc3refc is controlled by TIMx_CCR3 and TIMx_CCR5

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].
The `tim_trgo2` waveform shows how the ADC can be synchronized on given 3-phase PWM signals. Refer to Section 38.3.31: ADC triggers for more details.

### 38.3.17 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...).

The polarity of the outputs (main output `tim_ocx` or complementary `tim_ocxn`) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals `tim_ocx` and `tim_ocxn` are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 395: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature on page 1544 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a
reference waveform `tim_ocxref`, it generates 2 outputs `tim_ocx` and `tim_ocxn`. If `tim_ocx` and `tim_ocxn` are active high:

- The `tim_ocx` output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The `tim_ocxn` output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (`tim_ocx` or `tim_ocxn`) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal `tim_ocxref`. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 380. Complementary output with symmetrical dead-time insertion**

![Diagram showing complementary output with symmetrical dead-time insertion](MSv62332V1)

The DTAE bit in the TIMx_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on Figure 381.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must not be modified while CEN=1.

It is possible to have the deadtime value updated on-the-fly during PWM operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMx_DTR2 register. The preload value is loaded in the active register on the next update event.

**Note:** *If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.*
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 38.6.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8) for delay calculation.
Re-directing tim_ocxref to tim_ocx or tim_ocxn

In output mode (forced, output compare or PWM), tim_ocxref can be re-directed to the tim_ocx output or to tim_ocxn output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** When only tim_ocxn is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as tim_ocxref is high. For example, if CCxNP=0 then tim_ocxref=tim_ocxn. On the other hand, when both tim_ocx and tim_ocxn are enabled (CCxE=CCxNE=1) tim_ocx becomes active when tim_ocxref is high whereas tim_ocxn is complemented and becomes active when tim_ocxref is low.

38.3.18 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, ECC / parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register is used to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shut-down level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 395: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature on page 1544 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIMx_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKEx and BKPx can be modified at the same time. When the BKEx and BKPx bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous
and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (tim_brk) channel are:

- External sources connected to one of the TIMx_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to Section 38.3.2: TIM1/TIM8 pins and internal signals for product specific implementation)
  - coming from a system break request (refer to Section 38.3.2: TIM1/TIM8 pins and internal signals for product specific implementation)

The sources for break2 (tim_brk2) are:

- External sources connected to one of the TIMx_BKIN2 pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources coming from a tim_brk2_cmpx input (refer to Section 38.3.2: TIM1/TIM8 pins and internal signals for product specific implementation)

Break events can also be generated by software using BG and B2G bits in the TIMx_EGR register.

All sources are ORed before entering the timer tim_brk or tim_brk2 inputs, as per Figure 384 below.
Note: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to...
their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 Tim_ker_ck clock cycles).

– If OSSi=0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

• The break status flag (SBIF, BIF and B2IF bits in the TIMx_SR register) is set. An interrupt is generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.

• If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to ‘1’ again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSi value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

Note: The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable and polarity). The application can choose from 3 levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to Section 38.6.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8). The LOCK bits can be written only once after an MCU reset.

Figure 385 shows an example of behavior of the outputs in response to a break.
The two break inputs have different behaviors on timer outputs:

- The `tim_brk` input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- `tim_brk2` can only disable (inactive state) the PWM outputs.
The `tim_brk` has a higher priority than `tim_brk2` input, as described in Table 388.

*Note:* `tim_brk2` must only be used with `OSSR = OSSI = 1`.

### Table 388. Behavior of timer outputs versus `tim_brk/tim_brk2` inputs

</tbody>
</table>

*Figure 386* gives an example of `tim_ocx` and `tim_ocxn` output behavior in case of active signals on `tim_brk` and `tim_brk2` inputs. In this case, both outputs have active high polarities (`CCxP = CCxNP = 0` in TIMx_CCER register).

*Figure 386. PWM output state following `tim_brk` and `tim_brk2` assertion (OSSI=1)*
38.3.19 Bidirectional break inputs

The TIM1/TIM8 are featuring bidirectional break I/Os, as represented on Figure 388.

This provides support for:

- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged

The tim_brk and tim_brk2 inputs are configured in bidirectional mode using the BKBID and BK2BID bits in the TIMxBDTR register. The BKBID programming bits can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode is available for both the tim_brk and tim_brk2 inputs, and require the I/O to be configured in open-drain mode with active low polarity (using BKINP, BKP, BK2INP and BK2P bits). Any break request coming either from system (for example CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software events (BG and B2G) also cause the break I/O to be forced to '0' to indicate to the external components that the timer is entered in break state. However, this is valid only if the break is enabled (BKE or B2KE = 1). When a software break event is generated with BKE or B2KE = 0, the outputs are put in safe state and the break flag is set, but there is no effect on the TIMx_BKin and TIMx_BKin2 I/Os.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM (BK2DSRM) bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:

- The break input path is always active: a break event is active even if the BKDSRM (BK2DSRM) bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM (BK2DSRM) bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 389).
Arming and re-arming break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).

The following procedure must be followed to re-arm the protection after a break (break2) event:

- The BKDSRM (BK2DSRM) bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM (BK2DSRM) bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

38.3.20 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocxref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM
cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode. tim_ocref_clr_int input can be selected between the tim_ocref_clr input and tim_etrf (tim_etrf_in after the filter) by configuring the OCCS bit in the TIMx_SMCR register.

The tim_ocref_clr input can be selected among several inputs, using the OCRSEL[2:0] bitfield in the TIMx_AF2 register, as shown on the Figure 389 below. Refer to Section 38.3.2: TIM1/TIM8 pins and internal signals for a list of sources available in the product.

**Figure 389. tim_ocref_clr input selection multiplexer**

When tim_etrf is chosen, tim_etrf_in must be configured as follows:

1. The External Trigger Prescaler must be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to ‘00’.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to ‘0’.
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to application needs (as per polarity of the source connected to the trigger and eventual need to remove noise using the filter).

*Figure 390* shows the behavior of the tim_ocxref signal when the tim_etrf Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.
Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), then tim_ocxref is enabled again at the next counter overflow.

38.3.21 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 391 describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.
38.3.22 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: $\text{CNT} < \text{CCRx} \leq \text{ARR}$ (in particular, $0 < \text{CCRx}$)
- In downcounting: $\text{CNT} > \text{CCRx}$
For example one may want to generate a positive pulse on `tim_oc1` with a length of `tPULSE` and after a delay of `tDELAY` as soon as a positive edge is detected on the `tim_ti2` input pin.

Let's use `tim_ti2fp2` as trigger 1:
- Map `tim_ti2fp2` to `tim_ti2` by writing `CC2S='01'` in the `TIMx_CCMR1` register.
- `tim_ti2fp2` must detect a rising edge, write `CC2P='0'` and `CC2NP='0'` in the `TIMx_CCER` register.
- Configure `tim_ti2fp2` as trigger for the slave mode controller (`tim_trgi`) by writing `TS=00110` in the `TIMx_SMCR` register.
- `tim_ti2fp2` is used to start the counter by writing `SMS to '110'` in the `TIMx_SMCR` register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).
- The `tDELAY` is defined by the value written in the `TIMx_CCR1` register.
- The `tPULSE` is defined by the difference between the auto-reload value and the compare value (`TIMx_ARR - TIMx_CCR1`).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing `OC1M=111` in the `TIMx_CCMR1` register. Optionally the preload registers can be enabled by writing `OC1PE='1'` in the `TIMx_CCMR1` register and ARPE in the `TIMx_CR1` register. In this case one has to write the compare value in the `TIMx_CCR1` register, the auto-reload value in the `TIMx_ARR` register, generate an update by setting the UG bit and wait for external trigger event on `tim_ti2`. `CC1P` is written to '0' in this example.

In our example, the DIR and CMS bits in the `TIMx_CR1` register must be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the `TIMx_CR1` register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the `TIMx_CR1` register is set to '0', so the Repetitive Mode is selected.
Particular case: tim_ocx fast enable:

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 38.3.23 Retriggerable One-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one-pulse mode described in Section 38.3.22:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
38.3.24 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulsewidth generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on the Figure 394 below.

Figure 394. Pulse generator circuitry

The Figure 395 below shows how the pulse is generated for edge-aligned and encoder operating modes.
This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bit fields in TIMx_CCMR2 register.

The pulselength is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

where \( t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim\_ker\_ck} \).

This gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

**Note:** If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the 1st arriving trigger is extended (because of the re-trigger), while the pulse width of the last arriving trigger is correct (as shown on the Figure 396 below).
38.3.25 Encoder interface mode

**Quadrature encoder**

To select Encoder Interface mode write SMS='0001' in the TIMx_SMCR register if the counter is counting on tim_t1 edges only, SMS='0010' if it is counting on tim_t2 edges only and SMS='0011' if it is counting on both tim_t1 and tim_t2 edges.

Select the tim_t1 and tim_t2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs tim_t1 and tim_t2 are used to interface to a quadrature encoder. Refer to Table 390. The counter is clocked by each valid transition on tim_t1fp1 or tim_t2fp2 (tim_t1 and tim_t2 after input filter and polarity selection, tim_t1fp1=tim_t1 if not filtered and not inverted, tim_t2fp2=tim_t2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_t1 or tim_t2), whatever the counter is counting on tim_t1 only, tim_t2 only or both tim_t1 and tim_t2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx.ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_t1 and tim_t2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

The Figure 397 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1).
- CC2S='01' (TIMx_CCMR2 register, tim_ti1fp2 mapped on tim_ti2).
- CC1P='0' and CC1NP='0' (TIMx_CCER register, tim_ti1fp1 non-inverted, tim_ti1fp1=tim_ti1).
- CC2P='0' and CC2NP='0' (TIMx_CCER register, tim_ti1fp2 non-inverted, tim_ti1fp2=tim_ti2).
- SMS='0011' (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- CEN='1' (TIMx_CR1 register, Counter enabled).

Figure 397. Example of counter operation in encoder interface mode.

Figure 398 gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P='1').

Figure 398. Example of encoder interface mode with tim_ti1fp1 polarity inverted.

The Figure 399 below shows the timer counter value during a speed reversal, for various counting modes.
The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

Clock plus direction encoder mode

In addition to the quadrature encoder mode, the timer offers support other types of encoders.

In the “clock plus direction” mode shown on Figure 400, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1010: x2 mode, the counter is updated on both rising and falling edges of the clock
- 1011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity
The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

**Figure 400. Direction plus clock encoder mode**

<table>
<thead>
<tr>
<th>Directional Clock encoder mode</th>
</tr>
</thead>
</table>

In the “directional clock” mode on Figure 401, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- **1100:** x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to Figure 401 below) and CCxP = 1 corresponds to low-level idle state (refer to Figure 402 below).

- **1101:** x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to Figure 401 below), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to Figure 402 below).

**Figure 401. Directional clock encoder mode (CC1P = CC2P = 0)**

**Index Input**

The counter can be reset by an index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMX_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.
Commercially available encoders are proposed with several options for index pulse conditioning, as per the Figure 403 below:

- gated with A and B: the pulsewidth is $1/4$ of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulsewidth is $1/2$ of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulsewidth is up to one channel period, without any alignment to the edges

**Figure 403. Index gating options**

The circuitry tolerates jitter on index signal, whatever the gating mode, as shown on Figure 404 below.

In ungated mode, the signal must be strictly below 2 encoder periods. If the pulsewidth is greater or equal to 2 encoder period, the counter is reset multiple times.

**Figure 404. Jittered Index signals**

The timer supports the 3 gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (i.e. channel A and channel B
state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The Index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0).
- The counter is set to TIMx_ARR when down counting.

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. The Figure 405 below shows at which position is the index generated, for a simplistic example (an encoder providing 4 edges par mechanical rotation).

**Figure 405. Index generation for IPOS[1:0] = 11**

The Figure 406 below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is ‘11’ (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the ‘11’ state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.
Figure 406. Counter reading with index gated on channel A (IPOS[1:0] = 11)

The Figure 407. below presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.

Figure 407. Counter reading with index ungated (IPOS[1:0] = 00)

The Figure 408. below shows how the ‘gated on A & B’ mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.
The *Figure 409* and *Figure 410* detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.
Figure 409. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)
The Figure 411 below shows how the index is managed in x1 and x2 modes.
**Figure 411. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)**

![Diagram](image)

**Directional index sensitivity**

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

The *Figure 412* below shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

**Figure 412. Directional index sensitivity**

![Diagram](image)
**Special first index event management**

The FIDX bit in the TIMx_ECR register allows the Index to be taken only once, as shown on the *Figure 413* below. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be re-armed by writing the FIDX bit to 0 and setting it again to 1.

*Figure 413. Counter reset as function of FIDX bit setting*

---

**Index blanking**

The Index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the *Figure 414* below.

This mode is enabled using the IBLK[1:0] bitfield in the TIMx_ECR register, as following:

- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input

*Figure 414. Index blanking*
Index management in non-quadrature mode

The Figure 415 and Figure 416 below detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:
- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

**Figure 415. Index behavior in clock + direction mode, IPOS[0] = 1**

**Figure 416. Index behavior in directional clock mode, IPOS[0] = 1**

Encoder error management

For encoder configurations where 2 quadrature signals are available, it is possible to detect transition errors. The reading on the 2 inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on the Figure 417. below. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR status.
register. A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.

**Figure 417. State diagram for quadrature encoded signals**

For encoder having an Index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The Index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an Index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 418 below.

**Figure 418. Up-counting encoder error detection**
In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 419 below, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

Figure 419. Down-counting encode error detection

An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

Functional encoder Interrupts

The following interrupts are also available in encoder mode

- Direction change: any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.
- Index event: the Index event sets the IDXF interrupt flag in the TIMx_SR status register. An Index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the Update interrupt rate, by switching from x4 to x2 to x1 mode, as show on the Figure 420 below.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMSPS bit in the TIMx_SMCR register.

- **SMSPS = 0**: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting.
- **SMSPS = 1**: the transfer is triggered by the Index event.

![Figure 420. Encoder mode change with preload transferred on update (SMSPS = 0)](image)

**Encoder clock output**

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register. It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

38.3.26 Direction bit output

It is possible to output a direction signal out of the timer, on the tim_oc3n and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bit field to 1011 in the TIMx_CCMR2 register.
This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

### 38.3.27 UIF bit remapping

The UIFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register's bit 31 (TIMx_CNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the UIF and UIFCPY flags assertion.

### 38.3.28 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3. The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per Figure 421 below.

**Figure 421. Measuring time interval between edges on 3 signals**

![Figure 421](MSv62359V2)

### 38.3.29 Interfacing with Hall sensors

This is done using the advanced-control timers to generate PWM signals to drive the motor and another timer TIMx referred to as “interfacing timer” in Figure 422. The “interfacing timer” captures the 3 timer input pins (tim_ti1, tim_ti2 and tim_ti3) connected through a XOR to the tim_ti1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is tim_ti1f_ed. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is tim_trc (See Figure 364: Capture/compare channel (example: channel 1...
The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (by triggering a COM event). The advanced-control timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer through the tim_trgo output.

Example: one wants to change the PWM configuration of the advanced-control timer after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the tim_ti1 input channel by writing the TI1S bit in the TIMx_CR2 register to ‘1’,
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the tim_ti1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program the channel 1 in capture mode (tim_trc selected): write the CC1S bits in the TIMx_CCMR1 register to ‘01’. The digital filter can also be programmed if needed,
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to ‘111’ and the CC2S bits to ‘00’ in the TIMx_CCMR1 register,
- Select tim_oc2ref as trigger output on tim_trgo: write the MMS bits in the TIMx_CR2 register to ‘101’.

In the advanced-control timer, the right tim_itrx input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of tim_oc2ref).

The Figure 422 describes this example.
38.3.30 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 39.4.23: Timer synchronization for details. They can be synchronized in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.
In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

- Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Figure 423. Control circuit in reset mode**

Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

- Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).
The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

- Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.
Slave mode: Combined reset + trigger mode
In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.
This mode is used for One-pulse mode.

Slave mode: Combined gated + reset mode
The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode: external clock mode 2 + trigger mode
The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.
In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_tr1 occurs:
1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on tim_etr_in and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

   A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

   The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.

**Figure 426. Control circuit in external clock mode 2 + trigger mode**

### Note:
The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
38.3.31 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the tim_trgo2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx_CR2 register.

An example of an application for 3-phase motor drives is given in Figure 379 on page 1471.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

38.3.32 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR register define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see Section 38.6.29: TIMx DMA control register (TIMx_DCR)(x = 1, 8) for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:
1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address.
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (see note below).
   - Circular mode disabled.

2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE and DBSS = 1.

3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).

4. Enable TIMx.

5. Enable the DMA channel.

This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

38.3.33 TIM1/TIM8 DMA requests

The TIM1/TIM8 can generate a DMA request, as shown in the table below.

<table>
<thead>
<tr>
<th>DMA request signal</th>
<th>DMA request</th>
<th>Enable control bit</th>
</tr>
</thead>
<tbody>

<td>TDE</td>
</tr>
</tbody>
</table>

38.3.34 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or stop, depending on DBG_TIMx_STOP configuration bit in DBG module.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.
For more details, refer to section Debug support (DBG).

### 38.4 TIM1/TIM8 low-power modes

**Table 393. Effect of low-power modes on TIM1/TIM8**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The timer operation is stopped and the register content is kept. No interrupt can be generated.</td>
</tr>
<tr>
<td>Standby</td>
<td>The timer is powered-down and must be reinitialized after exiting the Standby mode.</td>
</tr>
</tbody>
</table>

### 38.5 TIM1/TIM8 interrupts

The TIM1/TIM8 can generate multiple interrupts, as shown in **Table 394**.

**Table 394. Interrupt requests**

<table>

<td>00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).</td>
</tr>
<tr>
<td></td>
<td>01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down.</td>
</tr>
<tr>
<td></td>
<td>10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up.</td>
</tr>
<tr>
<td></td>
<td>11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)</td>
</tr>
</tbody>
</table>
Bit 4 **DIR**: Direction
0: Counter used as upcounter
1: Counter used as downcounter

*Note:* This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value
(ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is
set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note:* External clock, gated mode and encoder mode can work only if the CEN bit has been
previously set by software. However trigger mode can set the CEN bit automatically by
hardware.

### 38.6.2 TIMx control register 2 (TIMx_CR2)(x = 1, 8)

Address offset: 0x004
Reset value: 0x0000 0000
Bits 31:26  Reserved, must be kept at reset value.
Bit 24  Reserved, must be kept at reset value.

Bits 23:20  **MMS2[3:0]**: Master mode selection 2

These bits allow the information to be sent to ADC for synchronization (tim_trgo2) to be selected. The combination is as follows:

0000:  **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on tim_trgo2 is delayed compared to the actual reset.
0001:  **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx_SMCR register).
0010:  **Update** - the update event is selected as trigger output (tim_trgo2). For instance, a master timer can then be used as a prescaler for a slave timer.
0011:  **Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (tim_trgo2).
0100:  **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo2)
0101:  **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo2)
0110:  **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo2)
0111:  **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo2)
1000:  **Compare** - tim_oc5refc signal is used as trigger output (tim_trgo2)
1001:  **Compare** - tim_oc6refc signal is used as trigger output (tim_trgo2)
1010:  **Compare Pulse** - tim_oc4refc rising or falling edges generate pulses on tim_trgo2
1011:  **Compare pulse** - tim_oc6refc rising or falling edges generate pulses on tim_trgo2
1100:  **Compare pulse** - tim_oc4refc or tim_oc6refc rising edges generate pulses on tim_trgo2
1101:  **Compare pulse** - tim_oc4refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2
1110:  **Compare pulse** - tim_oc5refc or tim_oc6refc rising edges generate pulses on tim_trgo2
1111:  **Compare pulse** - tim_oc5refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 19  Reserved, must be kept at reset value.

Bit 18  **OIS6**: Output idle state 6 (tim_oc6 output)
Refer to OIS1 bit

Bit 17  Reserved, must be kept at reset value.

Bit 16  **OIS5**: Output idle state 5 (tim_oc5 output)
Refer to OIS1 bit

Bit 15  **OIS4N**: Output idle state 4 (tim_oc4n output)
Refer to OIS1N bit

Bit 14  **OIS4**: Output idle state 4 (tim_oc4 output)
Refer to OIS1 bit
Bit 13  **OIS3N**: Output idle state 3 (tim_oc3n output)
        Refer to OIS1N bit

Bit 12  **OIS3**: Output idle state 3 (tim_oc3n output)
        Refer to OIS1 bit

Bit 11  **OIS2N**: Output idle state 2 (tim_oc2n output)
        Refer to OIS1N bit

Bit 10  **OIS2**: Output idle state 2 (tim_oc2 output)
        Refer to OIS1 bit

Bit 9   **OIS1N**: Output idle state 1 (tim_oc1n output)
        0: tim_oc1n=0 after a dead-time when MOE=0
        1: tim_oc1n=1 after a dead-time when MOE=0
        **Note**: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8   **OIS1**: Output idle state 1 (tim_oc1 output)
        0: tim_oc1=0 (after a dead-time) when MOE=0
        1: tim_oc1=1 (after a dead-time) when MOE=0
        **Note**: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7   **TI1S**: tim_ti1 selection
        0: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input
        1: tim_ti1_in[15:0], tim_ti2_in[15:0] and tim_ti3_in[15:0] multiplexers outputs are XORed and connected to the tim_ti1 input
Bits 25, 6:4 **MMS[3:0]**: Master mode selection

These bits select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

- **0000**: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

- **0001**: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

- **0010**: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

- **0011**: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).

- **0100**: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)

- **0101**: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)

- **0110**: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)

- **0111**: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

- **1000**: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

Other codes reserved

**Note:** The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3 **CCDS**: Capture/compare DMA selection

- 0: CCx DMA request sent when CCx event occurs
- 1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

- 0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only
- 1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi

**Note:** This bit acts only on channels that have a complementary output.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

- 0: CCxE, CCxNE and OCxM bits are not preloaded
- 1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

**Note:** This bit acts only on channels that have a complementary output.
### 38.6.3 TIMx slave mode control register (TIMx_SMCR)(x = 1, 8)

Address offset: 0x008  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:26</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 25</td>
<td><strong>SMSPS</strong>: SMS preload source</td>
</tr>
<tr>
<td></td>
<td>This bit selects whether the events that triggers the SMS[3:0] bitfield transfer from preload to active</td>
</tr>
<tr>
<td></td>
<td>0: The transfer is triggered by the Timer’s Update event</td>
</tr>
<tr>
<td></td>
<td>1: The transfer is triggered by the Index event</td>
</tr>
<tr>
<td>Bit 24</td>
<td><strong>SMSPE</strong>: SMS preload enable</td>
</tr>
<tr>
<td></td>
<td>This bit selects whether the SMS[3:0] bitfield is preloaded</td>
</tr>
<tr>
<td></td>
<td>0: SMS[3:0] bitfield is not preloaded</td>
</tr>
<tr>
<td></td>
<td>1: SMS[3:0] preload is enabled</td>
</tr>
<tr>
<td>Bit 23:22</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bit 21:20</td>
<td><strong>TS[4:3]</strong>: Trigger selection - bit 4:3</td>
</tr>
<tr>
<td></td>
<td>Refer to TS[2:0] description - bits 6:4</td>
</tr>
<tr>
<td>Bit 19:17</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bit 15</td>
<td><strong>ETP</strong>: External trigger polarity</td>
</tr>
<tr>
<td></td>
<td>This bit selects whether tim_etr_in or tim_etr_in is used for trigger operations</td>
</tr>
<tr>
<td></td>
<td>0: tim_etr_in is non-inverted, active at high level or rising edge.</td>
</tr>
<tr>
<td></td>
<td>1: tim_etr_in is inverted, active at low level or falling edge.</td>
</tr>
<tr>
<td>Bit 14</td>
<td><strong>ECE</strong>: External clock enable</td>
</tr>
<tr>
<td></td>
<td>This bit enables External clock mode 2.</td>
</tr>
<tr>
<td></td>
<td>0: External clock mode 2 disabled</td>
</tr>
<tr>
<td></td>
<td>1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.</td>
</tr>
</tbody>
</table>

**Note:** Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etr (SMS=111 and TS=00111).  
It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etr in this case (TS bits must not be 0011).  
If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etr.
Bits 13:12 ETPS[1:0]: External trigger prescaler
   External trigger signal tim_etrp frequency must be at most 1/4 of TIMxCLK frequency. A
   prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast
   external clocks on tim_etrl_in.
   00: Prescaler OFF
   01: tim_etrl_in frequency divided by 2
   10: tim_etrl_in frequency divided by 4
   11: tim_etrl_in frequency divided by 8

Bits 11:8 ETF[3:0]: External trigger filter
   This bit-field then defines the frequency used to sample tim_etrp signal and the length of the
   digital filter applied to tim_etrp. The digital filter is made of an event counter in which N
   consecutive events are needed to validate a transition on the output:
   0000: No filter, sampling is done at fDTS
   0001: fSAMPLING=ftim_ker_ck, N=2
   0010: fSAMPLING=ftim_ker_ck, N=4
   0011: fSAMPLING=ftim_ker_ck, N=8
   0100: fSAMPLING=fDTS/2, N=6
   0101: fSAMPLING=fDTS/2, N=8
   0110: fSAMPLING=fDTS/4, N=6
   0111: fSAMPLING=fDTS/4, N=8
   1000: fSAMPLING=fDTS/8, N=6
   1001: fSAMPLING=fDTS/8, N=8
   1010: fSAMPLING=fDTS/16, N=5
   1011: fSAMPLING=fDTS/16, N=6
   1100: fSAMPLING=fDTS/32, N=5
   1101: fSAMPLING=fDTS/32, N=6
   1110: fSAMPLING=fDTS/32, N=8
   1111: fSAMPLING=fDTS/32, N=8

Bit 7 MSM: Master/slave mode
   0: No action
   1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect
      synchronization between the current timer and its slaves (through tim_trgo). It is useful if
      we want to synchronize several timers on a single external event.
Bits 6:4 **TS[2:0]: Trigger selection**

This bitfield is combined with TS[4:3] bits. This bit-field selects the trigger input to be used to synchronize the counter.

- **00000**: Internal Trigger 0 (tim_itr0)
- **00001**: Internal Trigger 1 (tim_itr1)
- **00010**: Internal Trigger 2 (tim_itr2)
- **00011**: Internal Trigger 3 (tim_itr3)
- **00100**: tim_ti1 Edge Detector (tim_ti1f_ed)
- **00101**: Filtered Timer Input 1 (tim_ti1fp1)
- **00110**: Filtered Timer Input 2 (tim_ti2fp2)
- **00111**: External Trigger input (tim_etrf)
- **01000**: Internal Trigger 4 (tim_itr4)
- **01001**: Internal Trigger 5 (tim_itr5)
- **01010**: Internal Trigger 6 (tim_itr6)
- **01011**: Internal Trigger 7 (tim_itr7)
- **01100**: Internal Trigger 8 (tim_itr8)
- **01101**: Internal Trigger 9 (tim_itr9)
- **01110**: Internal Trigger 10 (tim_itr10)
- **01111**: Internal trigger 11 (tim_itr11)
- **10000**: Internal trigger 12 (tim_itr12)
- **10001**: Internal trigger 13 (tim_itr13)
- **10010**: Internal trigger 14 (tim_itr14)
- **10011**: Internal trigger 15 (tim_itr15)
- **Others**: Reserved

See [Table 381: Internal trigger connection](#) for more details on tim_itrx meaning for each Timer.

**Note:** These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3 **OCCS**: OREF clear selection

This bit is used to select the OCREF clear source.

- **0**: tim_ocref_clr_int is connected to the tim_ocref_clr input
- **1**: tim_ocref_clr_int is connected to tim_etrf
Bits 16, 2:0  **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.

0001: Quadrature encoder mode 1, x2 mode - Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

0010: Quadrature encoder mode 2, x2 mode - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

0011: Quadrature encoder mode 3, x4 mode - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

1010: Encoder mode: Clock plus direction, x2 mode.

1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P.

1100: Encoder mode: Directional Clock, x2 mode.

1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

**Note**: The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS=00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

**Note**: The clock of the slave peripherals (timer, ADC, …) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
### 38.6.4 TIMx DMA/interrupt enable register (TIMx_DIER) (x = 1, 8)

Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **TERRF**: Transition error interrupt flag
This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to '0'.
0: No encoder transition error has been detected.
1: An encoder transition error has been detected

Bit 22  **IERRF**: Index error interrupt flag
This flag is set by hardware when an index error is detected. It is cleared by software by writing it to '0'.
0: No index error has been detected.
1: An index error has been detected

Bit 21  **DIRF**: Direction change interrupt flag
This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to '0'.
0: No direction change
1: Direction change

Bit 20  **IDXF**: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to '0'.
0: No index event occurred.
1: An index event has occurred

Bits 19:18  Reserved, must be kept at reset value.

Bit 17  **CC6IF**: Compare 6 interrupt flag
Refer to CC1IF description

*Note: Channel 6 can only be configured as output.*

Bit 16  **CC5IF**: Compare 5 interrupt flag
Refer to CC1IF description

*Note: Channel 5 can only be configured as output.*

Bits 15:14  Reserved, must be kept at reset value.

Bit 13  **SBIF**: System break interrupt flag
This flag is set by hardware as soon as the system break input goes active. It can be cleared by software if the system break input is not active.
This flag must be reset to re-start PWM operation.
0: No break event occurred.
1: An active level has been detected on the system break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 12  **CC4OF**: Capture/compare 4 overcapture flag
Refer to CC1OF description

Bit 11  **CC3OF**: Capture/compare 3 overcapture flag
Refer to CC1OF description

Bit 10  **CC2OF**: Capture/compare 2 overcapture flag
Refer to CC1OF description
Bit 9  **CC1OF**: Capture/compare 1 overcapture flag
   - This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
   - 0: No overcapture has been detected.
   - 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.

Bit 8  **B2IF**: Break 2 interrupt flag
   - This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.
   - 0: No break event occurred.
   - 1: An active level has been detected on the break 2 input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 7  **BIF**: Break interrupt flag
   - This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
   - 0: No break event occurred.
   - 1: An active level has been detected on the break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 6  **TIF**: Trigger interrupt flag
   - This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
   - 0: No trigger event occurred.
   - 1: Trigger interrupt pending.

Bit 5  **COMIF**: COM interrupt flag
   - This flag is set by hardware on COM event (when capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.
   - 0: No COM event occurred.
   - 1: COM interrupt pending.

Bit 4  **CC4IF**: Capture/compare 4 interrupt flag
   - Refer to CC1IF description

Bit 3  **CC3IF**: Capture/compare 3 interrupt flag
   - Refer to CC1IF description
38.6.6 TIMx event generation register (TIMx_EGR)(x = 1, 8)

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **B2G**: Break 2 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

Bit 7 **BG**: Break generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.
Bit 6  **TG**: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5  **COMG**: Capture/compare control update generation
This bit can be set by software, it is automatically cleared by hardware
0: No action
1: CCxE, CCxNE and OCxM bits update (providing CCPC bit is set)
*Note*: This bit acts only on channels having a complementary output.

Bit 4  **CC4G**: Capture/compare 4 generation
Refer to CC1G description

Bit 3  **CC3G**: Capture/compare 3 generation
Refer to CC1G description

Bit 2  **CC2G**: Capture/compare 2 generation
Refer to CC1G description

Bit 1  **CC1G**: Capture/compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
*If channel CC1 is configured as output:*
CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
*If channel CC1 is configured as input:*
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0  **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

### 38.6.7  TIMx capture/compare mode register 1 (TIMx_CCMR1)  
(*x = 1, 8*)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).
### Input capture mode:

Bits 31:16  **Reserved, must be kept at reset value.**

Bits 15:12  **IC2F[3:0]:** Input capture 2 filter

Bits 11:10  **IC2PSC[1:0]:** Input capture 2 prescaler

Bits 9:8   **CC2S[1:0]:** Capture/compare 2 selection
- This bit-field defines the direction of the channel (input/output) as well as the used input.
  - 00: CC2 channel is configured as output
  - 01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
  - 10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
  - 11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).
Advanced-control timers (TIM1/TIM8) RM0481

Bits 7:4 IC1F[3:0]: Input capture 1 filter
This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
- 0000: No filter, sampling is done at fDTS
- 0001: fSAMPLING=fTim_ker_ck, N=2
- 0010: fSAMPLING=fTim_ker_ck, N=4
- 0011: fSAMPLING=fTim_ker_ck, N=8
- 0100: fSAMPLING=fDTS/2, N=6
- 0101: fSAMPLING=fDTS/2, N=8
- 0110: fSAMPLING=fDTS/4, N=6
- 0111: fSAMPLING=fDTS/4, N=8
- 1000: fSAMPLING=fDTS/8, N=6
- 1001: fSAMPLING=fDTS/8, N=8
- 1010: fSAMPLING=fDTS/16, N=5
- 1011: fSAMPLING=fDTS/16, N=6
- 1100: fSAMPLING=fDTS/16, N=8
- 1101: fSAMPLING=fDTS/32, N=5
- 1110: fSAMPLING=fDTS/32, N=6
- 1111: fSAMPLING=fDTS/32, N=8

Bits 3:2 IC1PSC[1:0]: Input capture 1 prescaler
This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).
- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0 CC1S[1:0]: Capture/compare 1 Selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
- 10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
- 11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

38.6.8 TIMx capture/compare mode register 1 [alternate]
(TIMx_CCMR1)(x = 1, 8)
Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).
Output compare mode:

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15   \textbf{OC2CE}: Output compare 2 clear enable

Bits 24, 14:12  \textbf{OC2M[3:0]}: Output compare 2 mode

Bit 11   \textbf{OC2PE}: Output compare 2 preload enable

Bit 10   \textbf{OC2FE}: Output compare 2 fast enable

Bits 9:8   \textbf{CC2S[1:0]}: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC2 channel is configured as output
- 01: CC2 channel is configured as input, tim\_ic2 is mapped on tim\_ti2
- 10: CC2 channel is configured as input, tim\_ic2 is mapped on tim\_ti1
- 11: CC2 channel is configured as input, tim\_ic2 is mapped on tim\_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

\textbf{Note}: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx\_CCER).

Bit 7   \textbf{OC1CE}: Output compare 1 clear enable

0: tim\_oc1ref is not affected by the tim\_ocref\_clr\_int signal
1: tim\_oc1ref is cleared as soon as a High level is detected on tim\_ocref\_clr\_int signal (tim\_ocref\_clr input or tim\_etrf input)
Bits 16, 6:4 **OC1M[3:0]: Output compare 1 mode**

These bits define the behavior of the output reference signal `tim_oc1ref` from which `tim_oc1` and `tim_oc1n` are derived. `tim_oc1ref` is active high whereas `tim_oc1` and `tim_oc1n` active level depends on `CC1P` and `CC1NP` bits.

0000: Frozen - The comparison between the output compare register `TIMx_CCR1` and the counter `TIMx_CNT` has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. `tim_oc1ref` signal is forced high when the counter `TIMx_CNT` matches the capture/compare register 1 (`TIMx_CCR1`).

0010: Set channel 1 to inactive level on match. `tim_oc1ref` signal is forced low when the counter `TIMx_CNT` matches the capture/compare register 1 (`TIMx_CCR1`).

0011: Toggle - `tim_oc1ref` toggles when `TIMx_CNT=TIMx_CCR1`.

0100: Force inactive level - `tim_oc1ref` is forced low.

0101: Force active level - `tim_oc1ref` is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as `TIMx_CNT<TIMx_CCR1` else inactive. In downcounting, channel 1 is inactive (`tim_oc1ref='0'`) as long as `TIMx_CNT>TIMx_CCR1` else active (`tim_oc1ref='1'`).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as `TIMx_CNT<TIMx_CCR1` else active. In downcounting, channel 1 is active as long as `TIMx_CNT>TIMx_CCR1` else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - `tim_oc1ref` has the same behavior as in PWM mode 1. `tim_oc1refc` is the logical OR between `tim_oc1ref` and `tim_oc2ref`.

1101: Combined PWM mode 2 - `tim_oc1ref` has the same behavior as in PWM mode 2. `tim_oc1refc` is the logical AND between `tim_oc1ref` and `tim_oc2ref`.

1110: Asymmetric PWM mode 1 - `tim_oc1ref` has the same behavior as in PWM mode 1. `tim_oc1refc` outputs `tim_oc1ref` when the counter is counting up, `tim_oc2ref` when it is counting down.

1111: Asymmetric PWM mode 2 - `tim_oc1ref` has the same behavior as in PWM mode 2. `tim_oc1refc` outputs `tim_oc1ref` when the counter is counting up, `tim_oc2ref` when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and `CC1S='00'` (the channel is configured in output).

**Note:** In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from "frozen" mode to "PWM" mode and when the output compare mode switches from "force active/inactive" mode to "PWM" mode.

**Note:** On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.
38.6.9 TIMx capture/compare mode register 2 (TIMx_CCMR2) (x = 1, 8)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

Input capture mode

**Bit 3 OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

*Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output).*

**Bit 2 OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

**Bits 1:0 CC1S[1:0]**: Capture/compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2

11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCER).*
Bits 31:16: Reserved, must be kept at reset value.

Bits 15:12: **IC4F[3:0]:** Input capture 4 filter

Bits 11:10: **IC4PSC[1:0]:** Input capture 4 prescaler

Bits 9:8: **CC4S[1:0]:** Capture/compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00:** CC4 channel is configured as output
- **01:** CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
- **10:** CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
- **11:** CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx_CCER).

Bits 7:4: **IC3F[3:0]:** Input capture 3 filter

Bits 3:2: **IC3PSC[1:0]:** Input capture 3 prescaler

Bits 1:0: **CC3S[1:0]:** Capture/compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00:** CC3 channel is configured as output
- **01:** CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
- **10:** CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
- **11:** CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx_CCER).

### 38.6.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 1, 8)

**Address offset:** 0x01C

**Reset value:** 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

**Output compare mode**

Bits 31:25: Reserved, must be kept at reset value.

Bits 23:17: Reserved, must be kept at reset value.

Bit 15: **OC4CE:** Output compare 4 clear enable
Bits 24, 14:12 **OC4M[3:0]**: Output compare 4 mode
   Refer to OC3M[3:0] bit description

   Bit 11 **OC4PE**: Output compare 4 preload enable

   Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection
   This bit-field defines the direction of the channel (input/output) as well as the used input.
   - 00: CC4 channel is configured as output
   - 01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
   - 10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
   - 11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

   *Note:* **CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx_CCER).**

   Bit 7 **OC3CE**: Output compare 3 clear enable
Bits 16, 6:4 **OC3M[3:0]:** Output compare 3 mode

1540/3119 RM0481 Rev 1

These bits define the behavior of the output reference signal `tim_oc3ref` from which `tim_oc3` and `tim_oc3n` are derived. `tim_oc3ref` is active high whereas `tim_oc3` and `tim_oc3n` active level depends on `CC3P` and `CC3NP` bits.

- **0000:** Frozen - The comparison between the output compare register `TIMx_CCR3` and the counter `TIMx_CNT` has no effect on the outputs. (This mode is used to generate a timing base).
- **0001:** Set channel 3 to active level on match. `tim_oc3ref` signal is forced high when the counter `TIMx_CNT` matches the capture/compare register 3 (`TIMx_CCR3`).
- **0010:** Set channel 3 to inactive level on match. `tim_oc3ref` signal is forced low when the counter `TIMx_CNT` matches the capture/compare register 3 (`TIMx_CCR3`).
- **0011:** Toggle - `tim_oc3ref` toggles when `TIMx_CNT=TIMx_CCR3`.
- **0100:** Force inactive level - `tim_oc3ref` is forced low.
- **0101:** Force active level - `tim_oc3ref` is forced high.
- **0110:** PWM mode 1 - In up-counting, channel 3 is active as long as `TIMx_CNT<TIMx_CCR3` else inactive. In down-counting, channel 3 is inactive as long as `TIMx_CNT>TIMx_CCR3` else active (`tim_oc3ref='1'`).
- **0111:** PWM mode 2 - In up-counting, channel 3 is inactive as long as `TIMx_CNT<TIMx_CCR3` else active. In down-counting, channel 3 is active as long as `TIMx_CNT>TIMx_CCR3` else inactive.
- **1000:** Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.
- **1001:** Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.
- **1010:** Pulse on compare: a pulse is generated on `tim_oc3ref` upon `CCR3` match event, as per `PWPRSC[2:0]` and `PW[7:0]` bitfields programming in `TIMxECR`.
- **1011:** Direction output. The `tim_oc3ref` signal is overridden by a copy of the DIR bit.
- **1100:** Combined PWM mode 1 - `tim_oc3ref` has the same behavior as in PWM mode 1. `tim_oc3refc` is the logical OR between `tim_oc3ref` and `tim_oc4ref`.
- **1101:** Combined PWM mode 2 - `tim_oc3ref` has the same behavior as in PWM mode 2. `tim_oc3refc` is the logical AND between `tim_oc3ref` and `tim_oc4ref`.
- **1110:** Asymmetric PWM mode 1 - `tim_oc3ref` has the same behavior as in PWM mode 1. `tim_oc3refc` outputs `tim_oc3ref` when the counter is counting up, `tim_oc4ref` when it is counting down.
- **1111:** Asymmetric PWM mode 2 - `tim_oc3ref` has the same behavior as in PWM mode 2. `tim_oc3refc` outputs `tim_oc3ref` when the counter is counting up, `tim_oc4ref` when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and `CC1S='00'` (the channel is configured in output).

**Note:** In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC3M active bits take the new value from the preloaded bits only when a COM event is generated.

Refer to CC1NE description

Bit 5 **CC2P**: Capture/compare 2 output polarity  
Refer to CC1P description

Bit 4 **CC2E**: Capture/compare 2 output enable  
Refer to CC1E description

Bit 3 **CC1NP**: Capture/compare 1 complementary output polarity  

**CC1 channel configured as output:**  
0: tim_oc1n active high.  
1: tim_oc1n active low.

**CC1 channel configured as input:**  
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1 and tim_ti2fp1.  
Refer to CC1P description.

*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (channel configured as output).

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2 **CC1NE**: Capture/compare 1 complementary output enable  
0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.  
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.
Bit 1 **CC1P**: Capture/compare 1 output polarity  
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)  
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)  
When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.  
CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).  
CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).  
CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.  
CC1NP=1, CC1P=0: the configuration is reserved, it must not be used.  
**Note:** This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).  
**Note:** On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 **CC1E**: Capture/compare 1 output enable  
0: Capture mode disabled / OC1 is not active (see below)  
1: Capture mode enabled / OC1 signal is output on the corresponding output pin  
When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 395 for details.  
**Note:** On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.

<td>Asynchronously: tim_ocx=CCxP, tim_ocxn=CCxNP (if tim_brk or tim_brk2 is triggered).</td>
</tr>
<tr>
<td>1</td>
<td>Then (this is valid only if tim_brk is triggered), if the clock is present: tim_ocx=OISx and tim_ocxn=OISxN after a dead-time, assuming that OISx and OISxN do not correspond to OCX and tim_ocxn both in active state (may cause a short circuit when driving switches in half-bridge configuration). Note: tim_brk2 can only be used if OSSI = OSSR = 1.</td>
</tr>
</tbody>
</table>

---

1. When both outputs of a channel are not used (control taken over by GPIO), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

**Note:** The state of the external I/O pins connected to the complementary tim_ocx and tim_ocxn channels depends on the tim_ocx and tim_ocxn channel state and the GPIO registers.
38.6.12  TIMx counter (TIMx_CNT)(x = 1, 8)

Address offset: 0x024
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>UIFCPY: UIF copy</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in the TIMxCR1 is reset, bit 31 is reserved and read at 0.</td>
</tr>
</tbody>
</table>

| Bits 30:16 | Reserved, must be kept at reset value. |

<table>
<thead>
<tr>
<th>Bits 15:0</th>

</tr>
</tbody>
</table>

38.6.13  TIMx prescaler (TIMx_PSC)(x = 1, 8)

Address offset: 0x028
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit 15:0</th>
<th>PSC[15:0]: Prescaler value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The counter clock frequency (f_{tim_cnt_clk}) is equal to ( \frac{f_{tim_psc_clk}}{PSC[15:0] + 1} ).</td>
</tr>
<tr>
<td></td>
<td>PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).</td>
</tr>
</tbody>
</table>
38.6.14  TIMx auto-reload register (TIMx_ARR)(x = 1, 8)

Address offset: 0x02C
Reset value: 0x0000 FFFF

Bits 31:20  Reserved, must be kept at reset value.
Bits 19:0  **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.
Refer to the Section 38.3.3: Time-base unit on page 1433 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
Non-dithering mode (DITHEN = 0)
The register holds the auto-reload value.
Dithering mode (DITHEN = 1)
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

38.6.15  TIMx repetition counter register (TIMx_RCR)(x = 1, 8)

Address offset: 0x030
Reset value: 0x0000

Bits 15:0  **REP[15:0]**: Repetition counter reload value

This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable.
When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIMx_RCR register is not taken in account until the next repetition update event.
It means in PWM mode (REP+1) corresponds to:
– the number of PWM periods in edge-aligned mode
– the number of half PWM period in center-aligned mode.
38.6.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 1, 8)

Address offset: 0x034
Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.
Bits 19:0 **CCR1[19:0]**: Capture/compare 1 value

If channel CC1 is configured as output: CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.
Non-dithering mode (DITHEN = 0):
The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1):
The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input: CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0):
The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1):
The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

38.6.17 TIMx capture/compare register 2 (TIMx_CCR2)(x = 1, 8)

Address offset: 0x038
Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.
Bits 19:0 **CCR2[19:0]**: Capture/compare 2 value

If channel CC1 is configured as output: CCR2 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.
Non-dithering mode (DITHEN = 0):
The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.
Dithering mode (DITHEN = 1):
The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input: CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0):
The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.
Dithering mode (DITHEN = 1):
The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR2[19:0]: Capture/compare 2 value**

*If channel CC2 is configured as output*: CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

**Non-dithering mode (DITHEN = 0)**
The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

*If channel CC2 is configured as input*: CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

**Non-dithering mode (DITHEN = 0)**
The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**
The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

### 38.6.18  TIMx capture/compare register 3 (TIMx_CCR3)(x = 1, 8)

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  CCR3[19:0]: Capture/compare value

If channel CC3 is configured as output: CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).
   It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.
   The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on TIM_OC3 output.
   Non-dithering mode (DITHEN = 0)
   The register holds the compare value in CCR3[15:0]. The CCR3[19:16] bits are reset.
   Dithering mode (DITHEN = 1)
   The register holds the integer part in CCR3[19:4]. The CCR3[3:0] bitfield contains the dithered part.

If channel CC3 is configured as input: CCR3 is the counter value transferred by the last input capture 3 event (TIM_IC3). The TIMx_CCR3 register is read-only and cannot be programmed.
   Non-dithering mode (DITHEN = 0)
   The register holds the capture value in CCR3[15:0]. The CCR3[19:16] bits are reset.
   Dithering mode (DITHEN = 1)
   The register holds the capture in CCR3[19:4]. The CCR3[3:0] bits are reset.

Note: As the bits BK2BID/BK2BID/BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKP, BKE, OSSR, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.
Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **BK2BID**: Break2 bidirectional
Refer to BKBID description

Bit 28  **BKBID**: Break bidirectional
0: Break input tim_brk in input mode
1: Break input tim_brk in bidirectional mode
In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27  **BK2DSRM**: Break2 disarm
Refer to BKDSRM description

Bit 26  **BKDSRM**: Break disarm
0: Break input tim_brk is armed
1: Break input tim_brk is disarmed
This bit is cleared by hardware when no break source is active.
The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 25  **BK2P**: Break 2 polarity
0: Break input tim_brk2 is active low
1: Break input tim_brk2 is active high

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 24  **BK2E**: Break 2 enable
This bit enables the complete break 2 protection (including all sources connected to bk_acth and BKIN sources, as per Figure 384: Break and Break2 circuitry overview).
0: Break2 function disabled
1: Break2 function enabled

*Note:* The BKIN2 must only be used with OSSR = OSSI = 1.

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bits 23:20 \textbf{BK2F}[3:0]: Break 2 filter
This bit-field defines the frequency used to sample \textit{tim\_brk2} input and the length of the digital filter applied to \textit{tim\_brk2}. The digital filter is made of an event counter in which \( N \) consecutive events are needed to validate a transition on the output:

- 0000: No filter, \textit{tim\_brk2} acts asynchronously
- 0001: \( f_{\text{SAMPLING}} = f_{\text{tim\_ker\_ck}} \), \( N=2 \)
- 0010: \( f_{\text{SAMPLING}} = f_{\text{tim\_ker\_ck}} \), \( N=4 \)
- 0011: \( f_{\text{SAMPLING}} = f_{\text{tim\_ker\_ck}} \), \( N=8 \)
- 0100: \( f_{\text{SAMPLING}} = f_{\text{DTS}/2} \), \( N=6 \)
- 0101: \( f_{\text{SAMPLING}} = f_{\text{DTS}/2} \), \( N=8 \)
- 0110: \( f_{\text{SAMPLING}} = f_{\text{DTS}/4} \), \( N=6 \)
- 0111: \( f_{\text{SAMPLING}} = f_{\text{DTS}/4} \), \( N=8 \)
- 1000: \( f_{\text{SAMPLING}} = f_{\text{DTS}/8} \), \( N=6 \)
- 1001: \( f_{\text{SAMPLING}} = f_{\text{DTS}/8} \), \( N=8 \)
- 1010: \( f_{\text{SAMPLING}} = f_{\text{DTS}/16} \), \( N=6 \)
- 1011: \( f_{\text{SAMPLING}} = f_{\text{DTS}/16} \), \( N=8 \)
- 1100: \( f_{\text{SAMPLING}} = f_{\text{DTS}/32} \), \( N=6 \)
- 1101: \( f_{\text{SAMPLING}} = f_{\text{DTS}/32} \), \( N=8 \)
- 1110: \( f_{\text{SAMPLING}} = f_{\text{DTS}/32} \), \( N=8 \)

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in \textit{TIMx\_BDTR} register).

Bits 19:16 \textbf{BKF}[3:0]: Break filter
This bit-field defines the frequency used to sample \textit{tim\_brk} input and the length of the digital filter applied to \textit{tim\_brk}. The digital filter is made of an event counter in which \( N \) consecutive events are needed to validate a transition on the output:

- 0000: No filter, \textit{tim\_brk} acts asynchronously
- 0001: \( f_{\text{SAMPLING}} = f_{\text{tim\_ker\_ck}} \), \( N=2 \)
- 0010: \( f_{\text{SAMPLING}} = f_{\text{tim\_ker\_ck}} \), \( N=4 \)
- 0011: \( f_{\text{SAMPLING}} = f_{\text{tim\_ker\_ck}} \), \( N=8 \)
- 0100: \( f_{\text{SAMPLING}} = f_{\text{DTS}/2} \), \( N=6 \)
- 0101: \( f_{\text{SAMPLING}} = f_{\text{DTS}/2} \), \( N=8 \)
- 0110: \( f_{\text{SAMPLING}} = f_{\text{DTS}/4} \), \( N=6 \)
- 0111: \( f_{\text{SAMPLING}} = f_{\text{DTS}/4} \), \( N=8 \)
- 1000: \( f_{\text{SAMPLING}} = f_{\text{DTS}/8} \), \( N=6 \)
- 1001: \( f_{\text{SAMPLING}} = f_{\text{DTS}/8} \), \( N=8 \)
- 1010: \( f_{\text{SAMPLING}} = f_{\text{DTS}/16} \), \( N=6 \)
- 1011: \( f_{\text{SAMPLING}} = f_{\text{DTS}/16} \), \( N=8 \)
- 1100: \( f_{\text{SAMPLING}} = f_{\text{DTS}/32} \), \( N=6 \)
- 1101: \( f_{\text{SAMPLING}} = f_{\text{DTS}/32} \), \( N=8 \)
- 1110: \( f_{\text{SAMPLING}} = f_{\text{DTS}/32} \), \( N=8 \)

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in \textit{TIMx\_BDTR} register).
Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (tim_brk or tim_brk2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: In response to a break 2 event. OC and OCN outputs are disabled

In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.

1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register).

See OC/OCN enable description for more details (Section 38.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if none of the break inputs tim_brk and tim_brk2 is active)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKP**: Break polarity

0: Break input tim_brk is active low

1: Break input tim_brk is active high

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

This bit enables the complete break protection (including all sources connected to bk_acth and BKIN sources, as per Figure 384: Break and Break2 circuitry overview).

0: Break function disabled

1: Break function enabled

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 38.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).

1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10 **OSSI**: Off-state selection for idle mode
This bit is used when MOE=0 due to a break event or by a software write, on channels configured as outputs.

See OC/OCN enable description for more details (Section 38.6.11: TIMx capture/compare enable register (TIMx_CCRER)(x = 1, 8)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).
1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

**Note**: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration
These bits offer a write protection against software errors.
00: LOCK OFF - No bit is write protected.
01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKBED/BK2BED/BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCRER register, as well as OSSR and OSSI bits can no longer be written.
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

**Note**: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup
This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5]=0xx => DT=DTG[7:0]x t\_d\_tg with t\_d\_tg=\_D\_T\_S.
DTG[7:5]=10x => DT=(64+DTG[5:0])xT\_d\_tg with T\_d\_tg=2xT\_D\_T\_S.
DTG[7:5]=110 => DT=(32+DTG[4:0])xT\_d\_tg with T\_d\_tg=8xT\_D\_T\_S.
DTG[7:5]=111 => DT=(32+DTG[4:0])xT\_d\_tg with T\_d\_tg=16xT\_D\_T\_S.

Example if T\_D\_T\_S=125ns (8MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 us to 31750 ns by 250 ns steps,
32 us to 63 us by 1 us steps,
64 us to 126 us by 2 us steps

**Note**: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

### 38.6.21 TIMx capture/compare register 5 (TIMx_CCR5)(x = 1, 8)

Address offset: 0x048

Reset value: 0x0000 0000

1554/3119
38.6.22 TIMx capture/compare register 6 (TIMx_CCR6)(x = 1, 8)

Address offset: 0x04C
Reset value: 0x0000 0000
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR6[19:0]: Capture/compare 6 value**

CCR6 is the value to be loaded in the actual capture/compare 6 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register
(bit OC6PE). Else the preload value is copied in the active capture/compare 6 register when
an update event occurs.
The active capture/compare register contains the value to be compared to the counter
TIMx_CNT and signaled on tim_oc6 output.

**Non-dithering mode (DITHEN = 0)**
The register holds the compare value in CCR6[15:0]. The CCR6[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR6[19:4]. The CCR6[3:0] bitfield contains the
dithered part.

### 38.6.23  TIMx capture/compare mode register 3 (TIMx_CCMR3)  
(x = 1, 8)

Address offset: 0x050
Reset value: 0x0000 0000

Refer to the above CCMR1 register description. Channels 5 and 6 can only be configured in output.

Bits 31:18  Reserved, must be kept at reset value.

Bit 17  **DTPE**: Deadtime preload enable
0: Deadtime value is not preloaded
1: Deadtime value preload is enabled

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 16  **DTAE**: Deadtime asymmetric enable
0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register
1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **DTGF[7:0]**: Dead-time falling edge generator setup
This bit-field defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.

DTGF[7:5]=0xx => DTF=DTGF[7:0]x T_{dtg} with T_{dtg}=T_{DTS}.
DTGF[7:5]=10x => DTF=(64+DTGF[5:0])x T_{dtg} with T_{dtg}=2x T_{DTS}.
DTGF[7:5]=110 => DTF=(32+DTGF[4:0])x T_{dtg} with T_{dtg}=8x T_{DTS}.
DTGF[7:5]=111 => DTF=(32+DTGF[4:0])x T_{dtg} with T_{dtg}=16x T_{DTS}.

Example if T_{DTS}=125ns (8MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 us to 31750 ns by 250 ns steps,
32 us to 63us by 1 us steps,
64 us to 126 us by 2 us steps

*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*
38.6.25 TIMx timer encoder control register (TIMx_ECR)(x = 1, 8)

Address offset: 0x058
Reset value: 0x0000 0000

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **PWPRSC[2:0]**: Pulse width prescaler

This bitfield sets the clock prescaler for the pulse generator, as following:

\[ t_{PWG} = (2^{PWPRSC[2:0]}) \times t_{tim.ker.ck} \]

Bits 23:16 **PW[7:0]**: Pulse width

This bitfield defines the pulse duration, as following:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:6 **IPOS[1:0]**: Index positioning

In quadrature encoder mode (SMS[3:0] = 0001, 0010, 0011, 1110, 1111), this bit indicates in which AB input configuration the Index event resets the counter.

00: Index resets the counter when AB = 00
01: Index resets the counter when AB = 01
10: Index resets the counter when AB = 10
11: Index resets the counter when AB = 11

In directional clock mode or clock plus direction mode (SMS[3:0] = 1010, 1011, 1100, 1101), these bits indicates on which level the Index event resets the counter. In bidirectional clock mode, this applies for both clock inputs.

x0: Index resets the counter when clock is 0
x1: Index resets the counter when clock is 1

*Note: IPOS[1] bit is not significant*

Bit 5 **FIDX**: First index

This bit indicates if the first index only is taken into account

0: Index is always active
1: the first Index only resets the counter
Bits 4:3 **IBLK[1:0]**: Index blanking
This bit indicates if the Index event is conditioned by the `tim_ti3` or `tim_ti4` input
00: Index always active
01: Index disabled when `tim_ti3` input is active, as per CC3P bitfield
10: Index disabled when `tim_ti4` input is active, as per CC4P bitfield
11: Reserved

Bits 2:1 **IDIR[1:0]**: Index direction
This bit indicates in which direction the Index event resets the counter.
00: Index resets the counter whatever the direction
01: Index resets the counter when up-counting only
10: Index resets the counter when down-counting only
11: Reserved

Bit 0 **IE**: Index enable
This bit indicates if the Index event resets the counter.
0: Index disabled
1: Index enabled

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:14 ETRSEL[3:0]: etr_in source selection
These bits select the etr_in input source.
0000: tim_etr0: TIMx_ETR input
0001: tim_etr1
...
1111: tim_etr15
Refer to Section 38.3.2: TIM1/TIM8 pins and internal signals for product specific implementation.

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 BKCMP4P: tim_brk_cmp4 input polarity
This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp4 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp4 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 12 **BKCMP3P**: tim_brk_cmp3 input polarity

- This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.
  - 0: tim_brk_cmp3 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
  - 1: tim_brk_cmp3 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 11 **BKCMP2P**: tim_brk_cmp2 input polarity

- This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.
  - 0: tim_brk_cmp2 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
  - 1: tim_brk_cmp2 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10 **BKCMP1P**: tim_brk_cmp1 input polarity

- This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.
  - 0: tim_brk_cmp1 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
  - 1: tim_brk_cmp1 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 9 **BKINP**: TIMx_BKIN input polarity

- This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.
  - 0: TIMx_BKIN input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
  - 1: TIMx_BKIN input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable

- This bit enables the tim_brk_cmp8 for the timer’s tim_brk input. tim_brk_cmp8 output is 'ORed' with the other tim_brk sources.
  - 0: tim_brk_cmp8 input disabled
  - 1: tim_brk_cmp8 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable

- This bit enables the tim_brk_cmp7 for the timer’s tim_brk input. tim_brk_cmp7 output is 'ORed' with the other tim_brk sources.
  - 0: tim_brk_cmp7 input disabled
  - 1: tim_brk_cmp7 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable

- This bit enables the tim_brk_cmp6 for the timer’s tim_brk input. tim_brk_cmp6 output is 'ORed' with the other tim_brk sources.
  - 0: tim_brk_cmp6 input disabled
  - 1: tim_brk_cmp6 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 5 **BKCMP5E**: tim_brk_cmp5 enable
- This bit enables the tim_brk_cmp5 for the timer’s tim_brk input. tim_brk_cmp5 output is ‘ORed’ with the other tim_brk sources.
  - 0: tim_brk_cmp5 input disabled
  - 1: tim_brk_cmp5 input enabled

  **Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 4 **BKCMP4E**: tim_brk_cmp4 enable
- This bit enables the tim_brk_cmp4 for the timer’s tim_brk input. tim_brk_cmp4 output is ‘ORed’ with the other tim_brk sources.
  - 0: tim_brk_cmp4 input disabled
  - 1: tim_brk_cmp4 input enabled

  **Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 3 **BKCMP3E**: tim_brk_cmp3 enable
- This bit enables the tim_brk_cmp3 for the timer’s tim_brk input. tim_brk_cmp3 output is ‘ORed’ with the other tim_brk sources.
  - 0: tim_brk_cmp3 input disabled
  - 1: tim_brk_cmp3 input enabled

  **Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 2 **BKCMP2E**: tim_brk_cmp2 enable
- This bit enables the tim_brk_cmp2 for the timer’s tim_brk input. tim_brk_cmp2 output is ‘ORed’ with the other tim_brk sources.
  - 0: tim_brk_cmp2 input disabled
  - 1: tim_brk_cmp2 input enabled

  **Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 1 **BKCMP1E**: tim_brk_cmp1 enable
- This bit enables the tim_brk_cmp1 for the timer’s tim_brk input. tim_brk_cmp1 output is ‘ORed’ with the other tim_brk sources.
  - 0: tim_brk_cmp1 input disabled
  - 1: tim_brk_cmp1 input enabled

  **Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 0 **BKINE**: TIMx_BKIN input enable
- This bit enables the TIMx_BKIN alternate function input for the timer’s tim_brk input. TIMx_BKIN input is ‘ORed’ with the other tim_brk sources.
  - 0: TIMx_BKIN input disabled
  - 1: TIMx_BKIN input enabled

  **Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Note**: Refer to Section 38.3.2: TIM1/TIM8 pins and internal signals for product specific implementation.
38.6.28 TIMx alternate function register 2 (TIMx_AF2)(x = 1, 8)

Address offset: 0x064
Reset value: 0x0000 0001

| Bit 31:19 | Reserved, must be kept at reset value. |
| Bit 18:16 | OCRSEL[2:0]: ocref_clr source selection |
|           | These bits select the ocref_clr input source. |
|           | 000: tim_ocref_clr0 |
|           | 001: tim_ocref_clr1 |
|           | ... |
|           | 111: tim_ocref_clr7 |
|           | Refer to Section 38.3.2: TIM1/TIM8 pins and internal signals for product specific information. |
| Note:     | These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). |

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 BK2CMP4P: tim_brk2_cmp4 input polarity
This bit selects the tim_brk2_cmp4 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp4 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp4 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 12 BK2CMP3P: tim_brk2_cmp3 input polarity
This bit selects the tim_brk2_cmp3 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp3 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp3 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 11 BK2CMP2P: tim_brk2_cmp2 input polarity
This bit selects the tim_brk2_cmp2 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp2 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp2 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10 **BK2CMP1**: tim_brk2_cmp1 input polarity

This bit selects the tim_brk2_cmp1 input sensitivity. It must be programmed together with the BK2P polarity bit.

- 0: tim_brk2_cmp1 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
- 1: tim_brk2_cmp1 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9 **BK2INP**: TIMx_BKIN2 input polarity

This bit selects the TIMx_BKIN2 alternate function input sensitivity. It must be programmed together with the BK2P polarity bit.

- 0: TIMx_BKIN2 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
- 1: TIMx_BKIN2 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **BK2CMP8**: tim_brk2_cmp8 enable

This bit enables the tim_brk2_cmp8 for the timer’s tim_brk2 input. tim_brk2_cmp8 output is 'ORed' with the other tim_brk2 sources.

- 0: tim_brk2_cmp8 input disabled
- 1: tim_brk2_cmp8 input enabled

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **BK2CMP7**: tim_brk2_cmp7 enable

This bit enables the tim_brk2_cmp7 for the timer’s tim_brk2 input. tim_brk2_cmp7 output is 'ORed' with the other tim_brk2 sources.

- 0: tim_brk2_cmp7 input disabled
- 1: tim_brk2_cmp7 input enabled

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 6 **BK2CMP6**: tim_brk2_cmp6 enable

This bit enables the tim_brk2_cmp6 for the timer’s tim_brk2 input. tim_brk2_cmp6 output is 'ORed' with the other tim_brk2 sources.

- 0: tim_brk2_cmp6 input disabled
- 1: tim_brk2_cmp6 input enabled

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 5 **BK2CMP5**: tim_brk2_cmp5 enable

This bit enables the tim_brk2_cmp5 for the timer’s tim_brk2 input. tim_brk2_cmp5 output is 'ORed' with the other tim_brk2 sources.

- 0: tim_brk2_cmp5 input disabled
- 1: tim_brk2_cmp5 input enabled

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 4 **BK2CMP4**: tim_brk2_cmp4 enable

This bit enables the tim_brk2_cmp4 for the timer’s tim_brk2 input. tim_brk2_cmp4 output is 'ORed' with the other tim_brk2 sources.

- 0: tim_brk2_cmp4 input disabled
- 1: tim_brk2_cmp4 input enabled

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 3 **BK2CMP3**: tim_brk2_cmp3 enable  
This bit enables the tim_brk2_cmp3 for the timer’s tim_brk2 input. tim_brk2_cmp3 output is 'ORed' with the other tim_brk2 sources.  
0: tim_brk2_cmp3 input disabled  
1: tim_brk2_cmp3 input enabled  
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 2 **BK2CMP2**: tim_brk2_cmp2 enable  
This bit enables the tim_brk2_cmp2 for the timer’s tim_brk2 input. tim_brk2_cmp2 output is 'ORed' with the other tim_brk2 sources.  
0: tim_brk2_cmp2 input disabled  
1: tim_brk2_cmp2 input enabled  
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 1 **BK2CMP1**: tim_brk2_cmp1 enable  
This bit enables the tim_brk2_cmp1 for the timer’s tim_brk2 input. tim_brk2_cmp1 output is 'ORed' with the other tim_brk2 sources.  
0: tim_brk2_cmp1 input disabled  
1: tim_brk2_cmp1 input enabled  
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 0 **BK2INE**: TIMx_BKIN2 input enable  
This bit enables the TIMx_BKIN2 alternate function input for the timer’s tim_brk2 input. TIMx_BKIN2 input is 'ORed' with the other tim_brk2 sources.  
0: TIMx_BKIN2 input disabled  
1: TIMx_BKIN2 input enabled  
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

*Note: Refer to Section 38.3.2: TIM1/TIM8 pins and internal signals for product specific implementation.*

### 38.6.29 TIMx DMA control register (TIMx_DCR)(x = 1, 8)

Address offset: 0x3DC  
Reset value: 0x0000 0000

</tbody>
</table>
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:16  **DBSS[3:0]: DMA burst source selection**
This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).

- 0000: Reserved
- 0001: Update
- 0010: CC1
- 0011: CC2
- 0100: CC3
- 0101: CC4
- 0110: COM
- 0111: Trigger
- Others: reserved

Bits 15:13  Reserved, must be kept at reset value.

Bits 12:8  **DBL[4:0]: DMA burst length**
This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

- 00000: 1 transfer
- 00001: 2 transfers
- 00010: 3 transfers
- ...
- 11010: 26 transfers

Example: Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2_CR1.

- If DBL = 7 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation:
  \[(\text{TIMx\_CR1 address}) + \text{DBA} + (\text{DMA index})\]
  where DMA index = DBL

In this example, 7 bytes are added to (TIMx\_CR1 address) + DBA, which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx\_CR1 address) + DBA

According to the configuration of the DMA Data Size, several cases may occur:

- If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.
- If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on.

So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **DBA[4:0]: DMA base address**
This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:
- 00000: TIMx\_CR1
- 00001: TIMx\_CR2
- 00010: TIMx\_SMCR
- ...

38.6.30  **TIMx DMA address for full transfer (TIMx_DMAR)(x = 1, 8)**

Address offset: 0x3E0  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>DMAB[31:16]</th>
<th>DMAB[15:0]</th>
</tr>
</thead>

<td>7  6  5  4</td>
</tr>
<tr>
<td>19 18 17 16</td>
<td>3  2  1  0</td>
</tr>
</tbody>
</table>

Bits 31:0 **DMAB[31:0]:** DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address (TIMx_CR1 address) + (DBA + DMA index) x 4 where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

38.6.31  **TIMx register map**

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

<table>

39 General-purpose timers (TIM2/TIM3/TIM4/TIM5)

39.1 TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit or 32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 39.4.23: Timer synchronization.

39.2 TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

- 16-bit or 32-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

### 39.4.3 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.
**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 428* and *Figure 429* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

**Figure 428. Counter timing diagram with prescaler division change from 1 to 2**

![Counter timing diagram with prescaler division change from 1 to 2](image-url)
### 39.4.4 Counter modes

#### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.
Figure 430. Counter timing diagram, internal clock divided by 1

Figure 431. Counter timing diagram, internal clock divided by 2
Figure 432. Counter timing diagram, internal clock divided by 4

Figure 433. Counter timing diagram, internal clock divided by N
Figure 434. Counter timing diagram, Update event when ARPE=0 (TIMx_ARR not preloaded)

- **tim_psc_ck**
- **CEN**
- **tim_cnt_ck**
- **Counter register**: 31 32 33 34 35 36 00 01 02 03 04 05 06 07
- **Counter overflow**
- **Update event (UEV)**
- **Update interrupt flag (UIF)**
- **Auto-reload preload register**: FF 36

Write a new value in TIMx_ARR
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0.

However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

**Figure 436. Counter timing diagram, internal clock divided by 1**
**Figure 437. Counter timing diagram, internal clock divided by 2**

- `tim_psc_ck`
- `CEN`
- `tim_cnt_ck`
- Counter register: 0002 0001 0000 0036 0035 0034 0033
- Counter underflow
- Update event (UEV)
- Update interrupt flag (UIF)

**Figure 438. Counter timing diagram, internal clock divided by 4**

- `tim_psc_ck`
- `CEN`
- `tim_cnt_ck`
- Counter register: 0001 0000 0000 0001
- Counter underflow
- Update event (UEV)
- Update interrupt flag (UIF)
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-
reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.
Figure 441. Counter timing diagram, internal clock divided by 1, TIMx_ARR=0x6

1. Here, center-aligned mode 1 is used (for more details refer to Section 39.5.1: TIMx control register 1 (TIMx_CR1)(x = 2 to 5) on page 1648).

Figure 442. Counter timing diagram, internal clock divided by 2
Figure 443. Counter timing diagram, internal clock divided by 4, TIMx_ARR=0x36

1. Center-aligned mode 2 or 3 is used with an UIF on overflow.

Figure 444. Counter timing diagram, internal clock divided by N
Figure 445. Counter timing diagram, Update event with ARPE=1 (counter underflow)
39.4.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Internal trigger inputs (tim_itr): using one timer as prescaler for another timer, for example, Timer 1 can be configured to act as a prescaler for Timer 2. Refer to "Using one timer as prescaler for another timer on page 1640" for more details.

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 447 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 448. tim_ti2 external clock connection example

1. Codes ranging from 01000 to 11111: tim_itr[15:0].

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:
1. Select the proper `ti2_in[15:0]` source (internal or external) with the `TI2SEL[3:0]` bits in the `TIMx_TISEL` register.
2. Configure channel 2 to detect rising edges on the `ti2_in` input by writing `CC2S= '01` in the `TIMx_CCMR1` register.
3. Configure the input filter duration by writing the `IC2F[3:0]` bits in the `TIMx_CCMR1` register (if no filter is needed, keep `IC2F=0000`).

**Note:** The capture prescaler is not used for triggering, so it does not need to be configured.
4. Select rising edge polarity by writing `CC2P=0` and `CC2NP=0` and `CC2NP=0` in the `TIMx_CCER` register.
5. Configure the timer in external clock mode 1 by writing `SMS=111` in the `TIMx_SMCR` register.
6. Select `ti2` as the input source by writing `TS=00110` in the `TIMx_SMCR` register.
7. Enable the counter by writing `CEN=1` in the `TIMx_CR1` register.

When a rising edge occurs on `ti2`, the counter counts once and the `TIF` flag is set.

The delay between the rising edge on `ti2` and the actual clock of the counter is due to the resynchronization circuit on `ti2` input.

**Figure 449. Control circuit in external clock mode 1**

External clock source mode 2

This mode is selected by writing `ECE=1` in the `TIMx_SMCR` register.

The counter can count at each rising or falling edge on the external trigger input `etr_in`.

**Figure 450** gives an overview of the external trigger input block.
For example, to configure the upcounter to count each 2 rising edges on tim_etr_in, use the following procedure:

1. Select the proper tim_etr_in source (internal or external) with the ETRSEL[3:0] bits in the TIMx_AF1 register.
2. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
3. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
4. Select rising edge detection on the tim_etr_in by writing ETP=0 in the TIMx_SMCR register.
5. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 tim_etr_in rising edges.

The delay between the rising edge on tim_etr_in and the actual clock of the counter is due to the resynchronization circuit on the tim_etrf signal. As a consequence, the maximum frequency that can be correctly captured by the counter is at most ¼ of TIMxCLK frequency.

When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.
39.4.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: `tim_ocxref` (active high). The polarity acts at the end of the chain.

**Figure 453. Capture/compare channel 1 main circuit**

**Figure 454. Output stage of capture/compare channel (channel 1, idem ch.2, 3 and 4)**

1. Available on some instances only. If not available, `tim_etrf` is directly connected to `tim_ocref_clr_int`.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.
In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 39.4.7 Input capture mode

In input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_t1 input rises. To do this, use the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_t1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the needed input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_t1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_t1 channel by writing the CC1P and CC1NP and CC1NP bits to 000 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCR register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

**Note:** IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
39.4.8 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIM_CCR2 register holds the pulse width (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tix input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two T1xFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulse width of a PWM signal applied on tim_t1 can be measured using the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TIMx_TISEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_t1 selected).
3. Select the active polarity for tim_t1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P to ‘0’ and the CC1NP bit to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_t1 selected).
5. Select the active polarity for tim_t1fp2 (used for capture in TIMx_CCR2): write the CC2P bit to ‘1’ and the CC2NP bit to ‘0’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_t1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.
39.4.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

39.4.10 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:
- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP)
bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example:
   a) Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   b) Write OCxPE = 0 to disable preload register
   c) Write CCxP = 0 to select active high polarity
   d) Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 456.
39.4.11 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per TIMx output) by writing 110 (PWM mode 1) or ‘111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter). The tim_ocref_clr can be cleared by an external event through the tim_etr_in or the tim_ocref_clr signals. In this case the tim_ocref_clr signal is asserted only:

- After a compare match event
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM=’000) to one of the PWM modes (OCxM=’110 or ‘111). This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
**PWM edge-aligned mode**

**Upcounting configuration**

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to *Upcounting mode on page 1578*.

In the following example, we consider PWM mode 1. The reference PWM signal `tim_ocxref` is high as long as `TIMx_CNT < TIMx_CCRx` else it becomes low. If the compare value in `TIMx_CCRx` is greater than the auto-reload value (in `TIMx_ARR`) then `tim_ocxref` is held at '1'. If the compare value is 0 then `tim_ocxref` is held at '0'. *Figure 457* shows some edge-aligned PWM waveforms in an example where `TIMx_ARR`=8.

*Figure 457. Edge-aligned PWM waveforms (ARR=8)*

![Counter register diagram](diagram)

**Downcounting configuration**

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to *Downcounting mode on page 1582*.

In PWM mode 1, the reference signal `tim_ocxref` is low as long as `TIMx_CNT > TIMx_CCRx` else it becomes high. If the compare value in `TIMx_CCRx` is greater than the auto-reload value in `TIMx_ARR`, then `tim_ocxref` is held at 100%. PWM is not possible in this mode.

**PWM center-aligned mode**

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00 (all the remaining configurations having the same effect on the `tim_ocxref`/`tim_ocx` signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit
(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to Center-aligned mode (up/down counting) on page 1585.

Figure 458 shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Figure 458. Center-aligned PWM waveforms (ARR=8)

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The Figure 459 below presents the dithering principle applied to 4 consecutive PWM cycles.

![Figure 459. Dithering principle](MS45752V1)

When the dithering mode is enabled, the register coding is changed as following (see Figure 460 for example):

- The 4 LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted by 4 places and are coding for the base value. In 16-bit mode, the 16-bit format is maintained.
Note: The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset.
2. The DITHEN bit must be reset.
3. The CCIF flags must be cleared.
4. The CEN bit can be set (eventually with ARPE = 1).

Figure 460. Data format and register coding in dithering mode

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{pwm}}}{F_{\text{Tim}}} \Rightarrow F_{\text{pwmMin}} = F_{\text{Tim}} \cdot \frac{\text{Max Resolution}}{\text{Resolution}}
\]

Dithering mode disabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode (16-bit timer): \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

Dithering mode (32-bit timer): \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{268435454 + \frac{15}{16}} \)

Note: For 16-bit timers, the maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).
For 32-bit timers, the maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFFEF.
0xFFFFFFFFF in dithering mode (corresponds to 264435454 for the integer part and 15 for the dithered part).

As shown on the Figure 461 and Figure 462 below, the dithering mode is used to increase the PWM resolution.

Figure 461. PWM resolution vs frequency (16-bit mode)

![Figure 461](image1)

Figure 462. PWM resolution vs frequency (32-bit mode)

![Figure 462](image2)

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in the Figure 463 below.
The auto-reload and compare values increments are spread following specific patterns described in the Table 406 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.
The dithering mode is also available in center-aligned PWM mode (CMS bits in TIMx_CR1 register are not equal to '00'). In this case, the dithering pattern is applied over 8 consecutive PWM periods, considering the up and down counting phases as shown in the Figure 464 below.

**Figure 464. Dithering effect on duty cycle in center-aligned PWM mode**

The dithering pattern is added in center-aligned PWM mode. The specific pattern for each LSB value is shown in the Table 406 below.

**Table 406. CCR and ARR register change dithering pattern**

*Note: Table 407 below shows how the dithering pattern is added in center-aligned PWM mode.*
49.4.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx registers. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- \text{tim\_oc1refc} (or \text{tim\_oc2refc}) is controlled by TIMx_CCR1 and TIMx_CCR2
- \text{tim\_oc3refc} (or \text{tim\_oc4refc}) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channels (one \text{tim\_ocx} output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

\textbf{Note:} The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an \text{tim\_oc1refc} signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the \text{tim\_oc2ref} signal on channel 2, or an \text{tim\_oc2refc} signal resulting from asymmetric PWM mode 2.
Figure 465 shows an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 2).

**Figure 465. Generation of 2 phase-shifted PWM signals with 50% duty cycle**

![Diagram of PWM signals]

### 39.4.13 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one tim_occ output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 466 shows an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1
39.4.14 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The tim_ocref_clr_int source depends on the OCREF clear selection feature implementation, refer to Section 39.3: TIM2/TIM3/TIM4/TIM5 implementation.

If the OCREF clear selection feature is implemented, the tim_ocref_clr_int can be selected between the tim_ocref_clr input and the tim_etrf input (tim_etrf_in after the filter) by configuring the OCCS bit in the TIMx_SMCR register. The tim_ocref_clr input can be selected among several tim_ocref_clr[7:0] inputs, using the OCRSEL[2:0] bitfield in the TIMx_AF2 register, as shown in Figure 467 below.
If the OCREF clear selection feature is not implemented, the tim_ocref_clr_int input is directly connected to the tim_etrf input.

For example, the tim_ocref_clr_int signal can be connected to the output of a comparator to be used for current handling. In this case, tim_etrf_in must be configured as follows:

1. The external trigger prescaler must be kept off: bits ETPS[1:0] in the TIMx_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application's needs.

Figure 468 shows the behavior of the tim_ocxref signal when the tim_etrf input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.
Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), tim_ocxref is enabled again at the next counter overflow.

39.4.15 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- CNT<CCRx ≤ ARR (in particular, 0<CCRx),

### Figure 469. Example of One-pulse mode

For example one may want to generate a positive pulse on tim_oc1 with a length of t\textsubscript{PULSE} and after a delay of t\textsubscript{DELAY} as soon as a positive edge is detected on the tim_ti2 input pin.

Let’s use tim_ti2fp2 as trigger 1:

1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 on tim_ti2 by writing CC2S=01 in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS=00110 in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to '110 in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The \( t_{\text{DELAY}} \) is defined by the value written in the TIMx_CCR1 register.
- The \( t_{\text{PULSE}} \) is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0 to ‘1 when a compare match occurs and a transition from ‘1 to ‘0 when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to ‘0 in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register must be low.
Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CCR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CCR1 register is set to ‘0’, so the Repetitive Mode is selected.

**Particular case: tim_ocx fast enable:**

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay \( t_{\text{DELAY}} \) min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 39.4.16 Retriggerable one-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one-pulse mode described in Section 39.4.15:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode CCRx must be above or equal to ARR.

**Note:** In Retriggerable one-pulse mode, the CCxIF flag is not significant.

The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
39.4.17 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulse width generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on the Figure 471 below.

The Figure 472 below shows how the pulse is generated for edge-aligned and encoder operating modes.
This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bit fields in TIMx_CCMR2 register.

The pulse width is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

where \( t_{PWG} = (2^{PWPRSC[2:0]}) \times t_{tim\_ker\_ck} \).

This gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

**Note:** If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the 1st arriving trigger is extended (because of the re-trigger), while the pulse width of the last arriving trigger is correct (as shown on the Figure 473 below).
39.4.18 Encoder interface mode

**Quadrature encoder**

To select Encoder Interface mode write SMS='0001 in the TIMx_SMCR register if the counter is counting on tim_ti1 edges only, SMS='0010 if it is counting on tim_ti2 edges only and SMS='0011 if it is counting on both tim_ti1 and tim_ti2 edges.

Select the tim_ti1 and tim_ti2 polarity by programming the CC1P and CC2P bits in the TIMx_CCMR register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well.

The two inputs tim_ti1 and tim_ti2 are used to interface to an incremental encoder. Refer to Table 408. The counter is clocked by each valid transition on tim_ti1fp1 or tim_ti2fp2 (tim_ti1 and tim_ti2 after input filter and polarity selection, tim_ti1fp1=tim_ti1 if not filtered and not inverted, tim_ti2fp2=tim_ti2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to '1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_ti1 or tim_ti2), whatever the counter is counting on tim_ti1 only, tim_ti2 only or both tim_ti1 and tim_ti2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the-quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_ti1 and tim_ti2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

*Figure 474* gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= 01 (TIMx_CCMR1 register, tim tí1fp1 mapped on tim tí1)
- CC2S= 01 (TIMx_CCMR2 register, tim tí2fp2 mapped on tim tí2)
- CC1P and CC1NP = ‘0’ (TIMx_CCER register, tim tí1fp1 noninverted, tim tí1fp1=tim tí1)
- CC2P and CC2NP = ‘0’ (TIMx_CCER register, tim tí2fp2 noninverted, tim tí2fp2=tim tí2)
- SMS= 0011 (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN= 1 (TIMx_CR1 register, Counter is enabled)
Figure 474. Example of counter operation in encoder interface mode

![Diagram](MSv62349V1)

**Figure 475** gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P=1).

Figure 475. Example of encoder interface mode with tim_ti1fp1 polarity inverted

![Diagram](MSv62350V1)
The Figure 476 below shows the timer counter value during a speed reversal, for various counting modes.

**Figure 476. Quadrature encoder counting modes**

The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

**Clock plus direction encoder mode**

In addition to the quadrature encoder mode, the timer offers support other types of encoders.

In the “clock plus direction” mode shown on Figure 477, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.
This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1010: x2 mode, the counter is updated on both rising and falling edges of the clock
- 1011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity

The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

**Figure 477. Direction plus clock encoder mode**

**Directional Clock encoder mode**

In the “directional clock” mode on Figure 478, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1100: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to Figure 478 below) and CCxP = 1 corresponds to low-level idle state (refer to Figure 479 below).
- 1101: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to Figure 478 below), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to Figure 479 below).
The Table 409 here-below details how the directional clock mode operates, for any input transition.
The counter can be reset by an Index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the `tim_etr_in` input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMx_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.

Commercially available encoders are proposed with several options for index pulse conditioning, as per the Figure 480 below:

- gated with A and B: the pulse width is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulse width is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulse width is up to one channel period, without any alignment to the edges

</table>
The circuitry tolerates jitter on index signal, whatever the gating mode, as shown on Figure 481 below.

In ungated mode, the signal must be strictly below 2 encoder periods. If the pulse width is greater or equal to 2 encoder period, the counter is reset multiple times.

The timer supports the 3 gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (i.e. channel A and channel B state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The Index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:
- The counter is reset during up-counting (DIR bit = 0)
- The counter is set to TIMx_ARR when down counting

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. The Figure 482 below shows at which position is the index generated, for a simplistic example (an encoder providing 4 edges per mechanical rotation).
The Figure 482 below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is '11' (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the '11' state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

**Figure 482. Index generation for IPOS[1:0] = 11**

The Figure 483 below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is '11' (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the '11' state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

**Figure 483. Counter reading with index gated on channel A (IPOS[1:0] = 11)**

The Figure 484 below presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.
The Figure 484 below shows how the ‘gated on A & B’ mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.

The Figure 485 and Figure 487 detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.
Figure 486. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)
The Figure 488 below shows how the index is managed in x1 and x2 modes.
**Directional index sensitivity**

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

The Figure 489 below shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

![Diagram](MSv45774V1)

**Figure 489. Directional index sensitivity**
Special first index event management

The FIDX bit in the TIMx_ECR register allows the Index to be taken only once, as shown on the Figure 490 below. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be re-armed by writing the FIDX bit to 0 and setting it again to 1.

**Figure 490. Counter reset as function of FIDX bit setting**

Index blanking

The Index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the Figure 491 below.

This mode is enabled using the IBLK[1:0] bitfield in the TIMx_ECR register, as following:

- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input

**Figure 491. Index blanking**
Index management in non-quadrature mode

The Figure 492 and Figure 493 below detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:
- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

Encoder error management

For encoder configurations where 2 quadrature signals are available, it is possible to detect transition errors. The reading on the 2 inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on the Figure 494. below. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR status.
A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.

**Figure 494. State diagram for quadrature encoded signals**

For encoder having an Index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The Index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an Index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on Figure 495 below.

**Figure 495. Up-counting encoder error detection**

![Diagram showing the error detection process](image-url)
In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 496 below, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

**Figure 496. Down-counting encode error detection**

An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

**Functional encoder Interrupts**

The following interrupts are also available in encoder mode:

- **Direction change**: any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.

- **Index event**: the Index event sets the IDXF interrupt flag in the TIMx_SR status register. An Index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the Update interrupt rate, by switching from x4 to x2 to x1 mode, as show on the Figure 497 below.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMPS bit in the TIMx_SMCR register.

- SMPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting.
- SMPS = 1: the transfer is triggered by the Index event.

Figure 497. Encoder mode change with preload transferred on update (SMPS = 0)

Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register. It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

39.4.19 Direction bit output

It is possible to output a direction signal out of the timer, on the tim_oc3 and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bit field to 1011 in the TIMx_CCMR2 register.
This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

### 39.4.20 UIF bit remapping
The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register's bit 31 (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

### 39.4.21 Timer input XOR function
The TI1S bit in the TIM1xx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in Section 38.3.29: Interfacing with Hall sensors on page 1508.

### 39.4.22 Timers and external trigger synchronization
The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

**Slave mode: Reset mode**
The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the
trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Figure 498. Control circuit in reset mode**

![Control circuit in reset mode](MSv62361V1)

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.
**Note:** The configuration “CCxP=CCxNP=1” (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.
Slave mode selection preload for run-time encoder mode update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

Slave mode – combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode – external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_t1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on tim_etr_in and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_t1 as the input source by writing TS=00101 in TIMx_SMCR register.

A rising edge on tim_t1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.
39.4.23 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

*Figure 502* and *Figure 503* show examples of master/slave timer connections.

*Figure 502. Master/Slave timer example*
Note: The timers with one channel only (see Figure 503) do not feature a master mode. However, the tim_oc1 output signal can serve as trigger for slave timer (see TIMx internal trigger connection table in Section 39.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals). The tim_oc1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger. For instance, if the destination timer tim_ker_ck clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

Using one timer as prescaler for another timer

For example, TIM_mstr can be configured to act as a prescaler for TIM_slv. Refer to Figure 502. To do this:

1. Configure TIM_mstr in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS=010 is written in the TIM_mstr CR2 register, a rising edge is output on tim_trgo each time an update event is generated.
2. To connect the tim_trgo output of TIM_mstr to TIM_slv, TIM_slv must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM_slv_SMCR register (writing TS=00010).
3. Then the slave mode controller must be put in external clock mode 1 (write SMS=111 in the TIM_slv_SMCR register). This causes TIM_slv to be clocked by the rising edge of the periodic TIM_mstr trigger signal (which correspond to the TIM_mstr counter overflow).
4. Finally both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

Note: If tim_ocx is selected on TIM_mstr as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM_slv.

Using one timer to enable another timer

In this example, we control the enable of TIM_slv with the output compare 1 of TIM_mstr. Refer to Figure 502 for connections. TIM_slv counts on the divided internal clock only when tim_oc1ref of TIM_mstr is high. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck ($f_{\text{tim_cnt\_ck}} = \frac{f_{\text{tim_ker_ck}}}{3}$).
1. Configure TIM\_mstr master mode to send its Output Compare 1 Reference (tim\_oc1ref) signal as trigger output (MMS=100 in the TIM\_mstr\_CR2 register).
2. Configure the TIM\_mstr tim\_oc1ref waveform (TIM\_mstr\_CCMR1 register).
3. Configure TIM\_slv to get the input trigger from TIM\_mstr (TS=00010 in the TIM\_slv\_SMCR register).
4. Configure TIM\_slv in gated mode (SMS=101 in TIM\_slv\_SMCR register).
5. Enable TIM\_slv by writing ‘1 in the CEN bit (TIM\_slv\_CR1 register).
6. Start TIM\_mstr by writing ‘1 in the CEN bit (TIM\_mstr\_CR1 register).

**Note:** The slave timer counter clock is not synchronized with the master timer counter clock, this mode only affects the TIM\_slv counter enable signal.

![Figure 504. Gating TIM\_slv with tim\_oc1ref of TIM\_mstr](image)

In the example in *Figure 504*, the TIM\_slv counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM\_mstr. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIM\_EGR registers.

In the next example (refer to *Figure 505*), we synchronize TIM\_mstr and TIM\_slv. TIM\_mstr is the master and starts from 0. TIM\_slv is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM\_slv stops when TIM\_mstr is disabled by writing ‘0 to the CEN bit in the TIM\_mstr\_CR1 register:
1. Configure TIM_mstr master mode to send its Output Compare 1 Reference (tim_oc1ref) signal as trigger output (MMS=100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS=101 in TIM_slv_SMCR register).
5. Reset TIM_mstr by writing ‘1’ in UG bit (TIM_mstr_EGR register).
6. Reset TIM_slv by writing ‘1’ in UG bit (TIM_slv_EGR register).
7. Initialize TIM_slv to 0xE7 by writing ‘0xE7’ in the TIM_slv counter (TIM_slv_CNT).
8. Enable TIM_slv by writing ‘1’ in the CEN bit (TIM_slv_CR1 register).
9. Start TIM_mstr by writing ‘1’ in the CEN bit (TIM_mstr_CR1 register).
10. Stop TIM_mstr by writing ‘0’ in the CEN bit (TIM_mstr_CR1 register).

**Figure 505. Gating TIM_slv with Enable of TIM_mstr**

![Diagram](MSv62377V1)

**Using one timer to start another timer**

In this example, we set the enable of TIM_slv with the update event of TIM_mstr. Refer to Figure 502 for connections. TIM_slv starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by TIM_mstr. When TIM_slv receives the trigger signal its CEN bit is automatically set and the counter counts until we write ‘0’ to the CEN bit in the TIM_slv_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck (ftim_ker_ck = ftim_cnt_ck / 3).

1. Configure TIM_mstr master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr period (TIM_mstr_ARR registers).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in trigger mode (SMS=110 in TIM_slv_SMCR register).
5. Start TIM_mstr by writing ‘1’ in the CEN bit (TIM_mstr_CR1 register).
As in the previous example, both counters can be initialized before starting counting. 
*Figure 507* shows the behavior with the same configuration as in *Figure 506* but in trigger mode instead of gated mode (SMS=110 in the TIM_slv_SMCR register).

**Starting 2 timers synchronously in response to an external trigger**

In this example, we set the enable of TIM_mstr when its tim_ti1 input rises, and the enable of TIM_slv with the enable of TIM_mstr. Refer to *Figure 502* for connections. To ensure the counters are aligned, TIM_mstr must be configured in Master/Slave mode (slave with respect to tim_ti1, master with respect to TIM_slv):
1. Configure TIM_mstr master mode to send its Enable as trigger output (MMS=001 in the TIM_mstr_CR2 register).
2. Configure TIM_mstr slave mode to get the input trigger from tim_ti1 (TS=00100 in the TIM_mstr_SMCR register).
3. Configure TIM_mstr in trigger mode (SMS=110 in the TIM_mstr_SMCR register).
4. Configure the TIM_mstr in Master/Slave mode by writing MSM=1 (TIM_mstr_SMCR register).
5. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00000 in the TIM_slv_SMCR register).
6. Configure TIM_slv in trigger mode (SMS=110 in the TIM_slv_SMCR register).

When a rising edge occurs on tim_ti1 (TIM_mstr), both counters starts counting synchronously on the internal clock and both TIF flags are set.

Note: In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIMx_CNT). One can see that the master/slave mode insert a delay between CNT_EN and CK_PSC on TIM_mstr.

Figure 508. Triggering TIM_mstr and TIM_slv with TIM_mstr tim_ti1 input

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

39.4.24 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
39.4.25  DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:
00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see Section 39.5.29: TIMx DMA control register (TIMx_DCR)(x = 2 to 5) for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.

2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE and DBSS = 1.

3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).

4. Enable TIMx

5. Enable the DMA channel

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.
Note: A null value can be written to the reserved registers.

39.4.26 TIM2/TIM3/TIM4/TIM5 DMA requests

The TIM2/TIM3/TIM4/TIM5 can generate a DMA requests, as shown in Table 410.

<table>
<thead>
<tr>

Note: Some timer’s DMA requests may not be connected to the DMA controller. Refer to the DMA section(s) for more details.

39.4.27 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continues to work normally or stops.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

39.4.28 TIM2/TIM3/TIM4/TIM5 low-power modes

<table>

</table>

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 DITHEN: Dithering Enable
0: Dithering disabled
1: Dithering enabled

Note: The DITTHEN bit can only be modified when CEN bit is reset.

Bit 11 UIFREMAP: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 CKD[1:0]: Clock division
This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and sampling clock used by the digital filters (tim_etr_in, tim_tix),
00: \( tDTS = t\text{tim}_\text{ker}_{\text{ck}} \)
01: \( tDTS = 2 \times t\text{tim}_\text{ker}_{\text{ck}} \)
10: \( tDTS = 4 \times t\text{tim}_\text{ker}_{\text{ck}} \)
11: Reserved

Bit 7 ARPE: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:5 CMS[1:0]: Center-aligned mode selection
00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).
01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down.
10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up.
11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down.

Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)
Bit 4 **DIR**: Direction
0: Counter used as upcounter
1: Counter used as downcounter

*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value
(ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is
set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been
previously set by software. However trigger mode can set the CEN bit automatically by
hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.

RM0481 Rev 1 1649/3119
Bits 31:26  Reserved, must be kept at reset value.
Bits 24:8  Reserved, must be kept at reset value.

Bit 7  **TI1S**: tim_ti1 selection
0: The tim_ti1_in[15:0] multiplexer output is to tim_ti1 input
1: The tim_ti1_in[15:0], tim_ti2_in[15:0] and tim_ti3_in[15:0] multiplexers outputs are XORed
   and connected to the tim_ti1 input. See also Section 38.3.29: Interfacing with Hall sensors
   on page 1508.

Bits 25, 6, 5, 4  **MMS[3:0]**: Master mode selection
These bits are used to select the information to be sent in master mode to slave timers for
synchronization (tim_trgo). The combination is as follows:
0000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If
   the reset is generated by the trigger input (slave mode controller configured in reset
   mode) then the signal on tim_trgo is delayed compared to the actual reset.
0001: **Enable** - the Counter enable signal, CNT_EN, is used as trigger output (tim_trgo). It is
   useful to start several timers at the same time or to control a window in which a slave
   timer is enabled. The Counter Enable signal is generated by a logic AND between
   CEN control bit and the trigger input when configured in gated mode.
   When the Counter Enable signal is controlled by the trigger input, there is a delay on
   tim_trgo, except if the master/slave mode is selected (see the MSM bit description in
   TIMx_SMCR register).
0010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a
   master timer can then be used as a prescaler for a slave timer.
0011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to
   be set (even if it was already high), as soon as a capture or a compare match
   occurred (tim_trgo).
0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)
0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)
0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)
0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)
1000: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim_trgo).
   This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011,
   1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to
   unexpected behavior.
Others: Reserved

*Note*: The clock of the slave timer or ADC must be enabled prior to receive events from the
master timer, and must not be changed on-the-fly while triggers are received from the
master timer.

Bit 3  **CCDS**: Capture/compare DMA selection
0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bits 2:0  Reserved, must be kept at reset value.
39.5.3 TIMx slave mode control register (TIMx_SMCR)\((x = 2 \text{ to } 5)\)

Address offset: 0x008  
Reset value: 0x0000 0000

</tbody>
</table>

**Bits 31:26** Reserved, must be kept at reset value.

**Bit 25 SMSPS**: SMS preload source  
This bit selects whether the events that triggers the SMS[3:0] bitfield transfer from preload to active  
0: The transfer is triggered by the Timer’s Update event  
1: The transfer is triggered by the Index event

**Bit 24 SMSPES**: SMS preload enable  
This bit selects whether the SMS[3:0] bitfield is preloaded  
0: SMS[3:0] bitfield is not preloaded  
1: SMS[3:0] preload is enabled

**Bits 23:22** Reserved, must be kept at reset value.

**Bits 19:17** Reserved, must be kept at reset value.

**Bit 15 ETP**: External trigger polarity  
This bit selects whether tim_etr_in or tim_etr_in is used for trigger operations  
0: tim_etr_in is non-inverted, active at high level or rising edge  
1: tim_etr_in is inverted, active at low level or falling edge

**Bit 14 ECE**: External clock enable  
This bit enables External clock mode 2.  
0: External clock mode 2 disabled  
1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.  

**Note**: Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS=111 and TS=00111). It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).  
If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf.

**Bits 13:12** ETPS[1:0]: External trigger prescaler  
External trigger signal tim_etrp frequency must be at most 1/4 of tim_ker_ck frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etrp_in.  
00: Prescaler OFF  
01: tim_etrp frequency divided by 2  
10: tim_etrp frequency divided by 4  
11: tim_etrp frequency divided by 8
Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample `tim_etrp` signal and the length of the digital filter applied to `tim_etrp`. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

<table>

</tbody>
</table>

Bit 7 **MSM**: Master/Slave mode

- 0: No action
- 1: The effect of an event on the trigger input (`tim_trgi`) is delayed to allow a perfect synchronization between the current timer and its slaves (through `tim_trgo`). It is useful if we want to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]:** Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- **00000:** Internal trigger 0 (tim_itr0)
- **00001:** Internal trigger 1 (tim_itr1)
- **00010:** Internal trigger 2 (tim_itr2)
- **00011:** Internal trigger 3 (tim_itr3)
- **00100:** tim_ti1 edge detector (tim_ti1f_ed)
- **00101:** Filtered timer input 1 (tim_ti1fp1)
- **00110:** Filtered timer input 2 (tim_ti2fp2)
- **00111:** External trigger input (tim_etrf)
- **01000:** Internal trigger 4 (tim_itr4)
- **01001:** Internal trigger 5 (tim_itr5)
- **01010:** Internal trigger 6 (tim_itr6)
- **01011:** Internal trigger 7 (tim_itr7)
- **01100:** Internal trigger 8 (tim_itr8)
- **01101:** Internal trigger 9 (tim_itr9)
- **01110:** Internal trigger 10 (tim_itr10)
- **01111:** Internal trigger 11 (tim_itr11)
- **10000:** Internal trigger 12 (tim_itr12)
- **10001:** Internal trigger 13 (tim_itr13)
- **10010:** Internal trigger 14 (tim_itr14)
- **10011:** Internal trigger 15 (tim_itr15)
- **Others:** Reserved

See [Section 39.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals](#) for product specific implementation details.

**Note:** These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3  **OCCS:** OCREF clear selection

This bit is used to select the OCREF clear source

- **0:** tim_ocref_clr_int is connected to the tim_ocref_clr input
- **1:** tim_ocref_clr_int is connected to tim_etrf

**Note:** If the OCREF clear selection feature is not supported, this bit is reserved and forced by hardware to '0'. [Section 39.3: TIM2/TIM3/TIM4/TIM5 implementation](#)
General-purpose timers (TIM2/TIM3/TIM4/TIM5)

Bits 16, 2, 1, 0 \( \text{SMS}[3:0] \): Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to
the polarity selected on the external input (see Input Control register and Control Register
description.
0000: Slave mode disabled - if CEN = `1 then the prescaler is clocked directly by the internal
clock.
0001: Encoder mode 1 - Counter counts up/down on tim_ti1fp1 edge depending on
    tim_ti2fp2 level.
0010: Encoder mode 2 - Counter counts up/down on tim_ti2fp2 edge depending on
    tim_ti1fp1 level.
0011: Encoder mode 3 - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges
depending on the level of the other input.
0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the
    counter and generates an update of the registers.
0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high.
    The counter stops (but is not reset) as soon as the trigger becomes low. Both start and
    stop of the counter are controlled.
0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not
    reset). Only the start of the counter is controlled.
0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the
    counter.
1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi)
    reinitializes the counter, generates an update of the registers and starts the counter.
1001: Combined gated + reset mode - The counter clock is enabled when the trigger input
    (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and
    stop of the counter are controlled.
1010: Encoder mode: Clock plus direction, x2 mode.
1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by
    CC2P.
1100: Encoder mode: Directional Clock, x2 mode.
1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity
    is set by CC1P and CC2P.
1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge
    sensitivity is set by CC1P.
1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge
    sensitivity is set by CC2P.

Note: The gated mode must not be used if tim_ti1f_ed is selected as the trigger input
    (TS=00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on tim_ti1f,
    whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be
    enabled prior to receive events from the master timer, and the clock frequency
    (prescaler) must not be changed on-the-fly while triggers are received from the master
    timer.

Bits 31:24 Reserved, must be kept at reset value.

**Bit 23** **TERRF**: Transition error interrupt flag

This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to ‘0’.

0: No encoder transition error has been detected.

1: An encoder transition error has been detected

**Bit 22** **IERRF**: Index error interrupt flag

This flag is set by hardware when an index error is detected. It is cleared by software by writing it to ‘0’.

0: No index error has been detected.

1: An index error has been detected
Bit 21 **DIRF**: Direction change interrupt flag
This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to ‘0’.  
0: No direction change  
1: Direction change

Bit 20 **IDXF**: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to ‘0’.  
0: No index event occurred.  
1: An index event has occurred

Bits 19:13 Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag  
Refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag  
Refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag  
Refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag  
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.  
0: No overcapture has been detected.  
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag  
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.  
0: No trigger event occurred.  
1: Trigger interrupt pending.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag  
Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag  
Refer to CC1IF description

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 TG: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 CC4G: Capture/compare 4 generation
Refer to CC1G description

Bit 3 CC3G: Capture/compare 3 generation
Refer to CC1G description
Bit 2  **CC2G**: Capture/compare 2 generation
   Refer to CC1G description

Bit 1  **CC1G**: Capture/compare 1 generation
   This bit is set by software in order to generate an event, it is automatically cleared by hardware.
   0: No action
   1: A capture/compare event is generated on channel 1:
      **If channel CC1 is configured as output:**
      CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
      **If channel CC1 is configured as input:**
      The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0  **UG**: Update generation
   This bit can be set by software, it is automatically cleared by hardware.
   0: No action
   1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

### 39.5.7 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

**Input capture mode**

- Bits 31:16  Reserved, must be kept at reset value.
- Bits 15:12  **IC2F[3:0]**: Input capture 2 filter
- Bits 11:10  **IC2PSC[1:0]**: Input capture 2 prescaler
General-purpose timers (TIM2/TIM3/TIM4/TIM5)

Bits 9:8 \textbf{CC2S[1:0]}: Capture/compare 2 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC2 channel is configured as output.
- 01: CC2 channel is configured as input, \text{tim\_ic2} is mapped on \text{tim\_ti2}.
- 10: CC2 channel is configured as input, \text{tim\_ic2} is mapped on \text{tim\_ti1}.
- 11: CC2 channel is configured as input, \text{tim\_ic2} is mapped on \text{tim\_trc}. This mode is working only if an internal trigger input is selected through TS bit (\text{TIMx\_SMCR register}).

\textbf{Note}: \text{CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER)}.

Bits 7:4 \textbf{IC1F[3:0]}: Input capture 1 filter
This bit-field defines the frequency used to sample \text{tim\_ti1} input and the length of the digital filter applied to \text{tim\_ti1}. The digital filter is made of an event counter in which \text{N} consecutive events are needed to validate a transition on the output:
- 0000: No filter, sampling is done at \text{fDTS}
- 0001: \text{fSAMPLING}=\text{ftim\_ker\_ck}, \text{N}=2
- 0010: \text{fSAMPLING}=\text{ftim\_ker\_ck}, \text{N}=4
- 0011: \text{fSAMPLING}=\text{ftim\_ker\_ck}, \text{N}=8
- 0100: \text{fSAMPLING}=\text{fDTS}/2, \text{N}=6
- 0101: \text{fSAMPLING}=\text{fDTS}/2, \text{N}=8
- 0110: \text{fSAMPLING}=\text{fDTS}/4, \text{N}=6
- 0111: \text{fSAMPLING}=\text{fDTS}/4, \text{N}=8
- 1000: \text{fSAMPLING}=\text{fDTS}/8, \text{N}=6
- 1001: \text{fSAMPLING}=\text{fDTS}/8, \text{N}=8
- 1010: \text{fSAMPLING}=\text{fDTS}/16, \text{N}=5
- 1011: \text{fSAMPLING}=\text{fDTS}/16, \text{N}=6
- 1100: \text{fSAMPLING}=\text{fDTS}/16, \text{N}=8
- 1101: \text{fSAMPLING}=\text{fDTS}/32, \text{N}=5
- 1110: \text{fSAMPLING}=\text{fDTS}/32, \text{N}=6
- 1111: \text{fSAMPLING}=\text{fDTS}/32, \text{N}=8

Bits 3:2 \textbf{IC1PSC[1:0]}: Input capture 1 prescaler
This bit-field defines the ratio of the prescaler acting on \text{CC1} input (\text{tim\_ic1}). The prescaler is reset as soon as \text{CC1E}=0 (\text{TIMx\_CCER register}).
- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0 \textbf{CC1S[1:0]}: Capture/Compare 1 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, \text{tim\_ic1} is mapped on \text{tim\_ti1}
- 10: CC1 channel is configured as input, \text{tim\_ic1} is mapped on \text{tim\_ti2}
- 11: CC1 channel is configured as input, \text{tim\_ic1} is mapped on \text{tim\_trc}. This mode is working only if an internal trigger input is selected through TS bit (\text{TIMx\_SMCR register}).

\textbf{Note}: \text{CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER)}. 
39.5.8 TIMx capture/compare mode register 1 [alternate]
(TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Output compare mode

- Bits 31:25 Reserved, must be kept at reset value.
- Bits 23:17 Reserved, must be kept at reset value.
  - Bit 15 **OC2CE**: Output compare 2 clear enable
  - Bits 24, 14:12 **OC2M[3:0]**: Output compare 2 mode
    refer to OC1M description on bits 6:4
  - Bit 11 **OC2PE**: Output compare 2 preload enable
  - Bit 10 **OC2FE**: Output compare 2 fast enable
  - Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection
    This bit-field defines the direction of the channel (input/output) as well as the used input.
    00: CC2 channel is configured as output
    01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
    10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
    11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)
    Note: **CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER)**.
  - Bit 7 **OC1CE**: Output compare 1 clear enable
    0: tim_oc1ref is not affected by the tim_ocref_clr_int input
    1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input
Bits 16, 6:4 **OC1M[3:0]:** Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas tim_oc1 active level depends on CC1P bit.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (tim_oc1ref=0) as long as TIMx_CNT> TIMx_CCR1 else active (tim_oc1ref=1).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT> TIMx_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved.

1011: Reserved.

1100: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc is the logical OR between tim_oc1ref and tim_oc2ref.

1101: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc is the logical AND between tim_oc1ref and tim_oc2ref.

1110: Asymmetric PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

**Note:** In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.
39.5.9 TIMx capture/compare mode register 2 (TIMx_CCMR2)(x = 2 to 5)

Address offset: 0x01C
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

**Input capture mode**

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC4F[3:0]**: Input capture 4 filter

Bits 11:10 **IC4PSC[1:0]**: Input capture 4 prescaler
39.5.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 2 to 5)

Address offset: 0x01C
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

</table>
Bit 7  **CC2NP**: Capture/Compare 2 output Polarity.
       Refer to CC1NP description

Bit 6  Reserved, must be kept at reset value.

Bit 5  **CC2P**: Capture/Compare 2 output Polarity.
       refer to CC1P description

Bit 4  **CC2E**: Capture/Compare 2 output enable.
       Refer to CC1E description

Bit 3  **CC1NP**: Capture/Compare 1 output Polarity.
      
      **CC1 channel configured as output**: CC1NP must be kept cleared in this case.
      **CC1 channel configured as input**: This bit is used in conjunction with CC1P to define
      tim_ti1fp1/tim_ti2fp1 polarity. refer to CC1P description.

Bit 2  Reserved, must be kept at reset value.

Bit 1  **CC1P**: Capture/Compare 1 output Polarity.

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity
of Ti1FP1 and Ti2FP1 for trigger or capture operations.
CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to Ti1FP1 rising edge
(capture or trigger operations in reset, external clock or trigger mode).
Ti1FP1 is not inverted (trigger operation in gated mode or encoder mode).
CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to Ti1FP1 falling edge
(capture or trigger operations in reset, external clock or trigger mode).
Ti1FP1 is inverted (trigger operation in gated mode or encoder mode).
CC1NP=1, CC1P=0: non-inverted/both edges. The circuit is sensitive to both Ti1FP1 rising
and falling edges (capture or trigger operations in reset, external clock or trigger mode),
Ti1FP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.
CC1NP=1, CC1P=1: this configuration is reserved, it must not be used.

Bit 0  **CC1E**: Capture/Compare 1 output enable.

0: Capture mode disabled / OC1 is not active
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

<table>

</tbody>
</table>

- Bit 31: **UIFCPY_CNT[31]**: Value depends on UIFREMAP in TIMx_CR1.  
  - If UIFREMAP = 0  
    - **CNT[31]**: Most significant bit of counter value  
  - If UIFREMAP = 1  
    - **UIFCPY**: UIF Copy  
      This bit is a read-only copy of the UIF bit of the TIMx_ISR register

- Bits 30:0 **CNT[30:0]**: Least significant part of counter value
  - **Non-dithering mode (DITHEN = 0)**: The register holds the counter value.
  - **Dithering mode (DITHEN = 1)**: The register holds the non-dithered part in CNT[30:0]. The fractional part is not available.
### 39.5.16 TIMx auto-reload register (TIMx_ARR)(x = 2, 5)

Address offset: 0x02C  
Reset value: 0xFFFF FFFF

<table>
<thead>
<tr>
<th>Bit 31:0</th>
<th>ARR[31:0]: Auto-reload value</th>
</tr>
</thead>
</table>

ARR is the value to be loaded in the actual auto-reload register.  
Refer to the Section 39.4.3: Time-base unit on page 1576 for more details about ARR update and behavior.  
The counter is blocked while the auto-reload value is null.  
Non-dithering mode (DITHEN = 0)  
The register holds the auto-reload value.  
Dithering mode (DITHEN = 1)  
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

### 39.5.17 TIMx capture/compare register 1 (TIMx_CCR1)(x = 3, 4)

Address offset: 0x034  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:0</th>
<th>CCR1[31:16]: Capture/compare value</th>

</thead>
</table>

CCR1[19:16]: Capture/compare value

Refer to the Section 39.4.3: Time-base unit on page 1576 for more details about CCR1 update and behavior.
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  CCR1[19:0]: Capture/compare 1 value

If channel CC1 is configured as output:
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is
loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit
OC1PE). Else the preload value is copied in the active capture/compare 1 register when an
update event occurs.
The active capture/compare register contains the value to be compared to the counter
TIMx_CNT and signaled on tim_oc1 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the
dithered part.

If channel CC1 is configured as input:
CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The
TIMx_CCR1 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0)
The CCR1[15:0] bits hold the capture value. The CCR1[19:16] bits are reserved.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR1[19:0]. The CCR1[3:0] bits are reset.

39.5.18  TIMx capture/compare register 1 (TIMx_CCR1)(x = 2, 5)

Address offset: 0x034

 Bits 31:0  **CCR1[31:0]**: Capture/compare 1 value

**If channel CC1 is configured as output:**
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

**Non-dithering mode (DITHEN = 0)**
The register holds the compare value.

**Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR1[31:4]. The CCR1[3:0] bitfield contains the dithered part.

**If channel CC1 is configured as input:**
CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

**Non-dithering mode (DITHEN = 0)**
The register holds the capture value.

**Dithering mode (DITHEN = 1)**
The register holds the capture in CCR1[31:0]. The CCR1[3:0] bits are reset.

**CCR2[15:0]**: Capture value.
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR2[19:0]**: Capture/compare 1 value

If channel CC2 is configured as output:
- CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
- The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

  - **Non-dithering mode** (DITHEN = 0)
  - The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

  - **Dithering mode** (DITHEN = 1)
  - The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input:
- CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

  - **Non-dithering mode** (DITHEN = 0)
  - The CCR2[15:0] bits hold the capture value. The CCR2[19:16] bits are reserved.

  - **Dithering mode** (DITHEN = 1)
  - The register holds the capture in CCR2[19:0]. The CCR2[3:0] bits are reset.

### 39.5.20  TIMx capture/compare register 2 (TIMx_CCR2)(x = 2, 5)

Address offset: 0x038

Reset value: 0x0000 0000
Bits 31:0 $\text{CCR2}[31:0]$: Capture/compare 2 value

If channel CC2 is configured as output:

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

Non-dithering mode ($\text{DITHEN} = 0$)

The register holds the compare value.

Dithering mode ($\text{DITHEN} = 1$)

The register holds the integer part in CCR2[31:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input:

CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

Non-dithering mode ($\text{DITHEN} = 0$)

The register holds the capture value.

Dithering mode ($\text{DITHEN} = 1$)

The register holds the capture in CCR2[31:0]. The CCR2[3:0] bits are reset.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]:** DMA burst source selection  
This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).  
0000: Reserved  
0001: Update  
0010: CC1  
0011: CC2  
0100: CC3  
0101: CC4  
0110: COM  
0111: Trigger  
Others: reserved

Bits 15:13 Reserved, must be kept at reset value.
Bits 12:8 DBL[4:0]: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

00000: 1 transfer
00001: 2 transfers
00010: 3 transfers
...
11010: 26 transfers

Example: Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2_CR1.

–If DBL = 7 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation:

(TIMx_CR1 address) + DBA + (DMA index), where DMA index = DBL

In this example, 7 bytes are added to (TIMx_CR1 address) + DBA, which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx_CR1 address) + DBA

According to the configuration of the DMA Data Size, several cases may occur:

–If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.

–If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on.

So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 DBA[4:0]: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:

00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,
...

39.5.30 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5)

Address offset: 0x3E0

Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address

(TIMx_CR1 address) + (DBA + DMA index) × 4

where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).
### 39.5.31 TIMx register map

Refer to Section 2.3 on page 111 for the register boundary addresses.
40 Basic timers (TIM6/TIM7)

40.1 TIM6/TIM7 introduction

The basic timers TIM6/TIM7 consist in a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time-base generation.

The basic timer can also be used for triggering the digital-to-analog converter. This is done with the trigger output of the timer.

The timers are completely independent, and do not share any resources.

40.2 TIM6/TIM7 main features

Basic timer (TIM6/TIM7) features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow
40.3 TIM6/TIM7 functional description

40.3.1 TIM6/TIM7 block diagram

</tbody>
</table>
40.3.3 **TIM6/TIM7 clocks**

The timer bus interface is clocked by the *tim_pclk* APB clock.

The counter clock *tim_ker_ck* is connected to the *tim_pclk* input.

The CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock *tim_ker_ck*.

*Figure 510* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

![Figure 510. Control circuit in normal mode, internal clock divided by 1](MSv62317v2)

40.3.4 **Time-base unit**

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.
The counter is clocked by the prescaler output `tim_cnt_ck`, which is enabled only when the counter enable bit (CEN) in the TIMx_CR1 register is set.

Note that the actual counter enable signal `tim_cnt_en` is set 1 clock cycle after CEN bit set.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as the TIMx_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 511* and *Figure 512* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

**Figure 511. Counter timing diagram with prescaler division change from 1 to 2**
40.3.5 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generate at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.
**Figure 513. Counter timing diagram, internal clock divided by 1**

Figure 515. Counter timing diagram, internal clock divided by 4

Figure 516. Counter timing diagram, internal clock divided by N
Figure 517. Counter timing diagram, update event when ARPE = 0 (TIMx_ARR not preloaded)
Dithering mode

The time base effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This affects the way the TIMx_ARR is behaving, and is useful for adjusting the average counter period when the timer is used as a trigger (typically for a DAC).

The operating principle is to have the actual ARR value slightly changed (adding or not one timer clock period) over 16 consecutive counting periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average counting period.

The Figure 519 below presents the dithering principle applied to 4 consecutive counting periods.
When the dithering mode is enabled, the register coding is changed as following (see Figure 520 for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value

**Note:** The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The DITHEN bit must be reset
3. The CEN bit can be set (eventually with ARPE = 1).

**Figure 520. Data format and register coding in dithering mode**

The minimum frequency is given by the following formula:
The maximum TIMx_ARR value is limited to 0xFFFFE in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 521 below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

**Figure 521. F_Cnt resolution vs frequency**

The period changes are spread over 16 consecutive periods, as described in the Figure 522 below.

**Figure 522. PWM dithering pattern**

The auto-reload and compare values increments are spread following specific patterns described in the Table 416 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

### 40.3.6 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register’s bit 31 (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.
40.3.7  **ADC triggers**

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

*Note:* The clock of the slave peripherals (such as timer, ADC) receiving the TIM_TRGO signal must be enabled prior to receiving events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

40.3.8  **TIM6/TIM7 DMA requests**

The TIM6/TIM7 can generate a single DMA request, as shown in *Table 417.*

<table>
<thead>
<tr>
<th>DMA acronym</th>
<th>DMA request</th>
<th>Enable control bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>tim_upd_dma</td>
<td>Update</td>
<td>UDE</td>
</tr>
</tbody>
</table>

40.3.9  **Debug mode**

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or be stopped.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

40.3.10 **TIM6/TIM7 low-power modes**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The timer operation is stopped and the register content is kept. No interrupt can be generated.</td>
</tr>
<tr>
<td>Standby</td>
<td>The timer is powered-down and must be reinitialized after exiting the Standby mode.</td>
</tr>
</tbody>
</table>

40.3.11 **TIM6/TIM7 interrupts**

The TIM6/TIM7 can generate a single interrupt, as shown in *Table 419.*

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
<th>Exit from Sleep mode</th>
<th>Exit from Stop and Standby mode</th>
</tr>
</thead>
<tbody>

<td>Update</td>
<td>UIF</td>
<td>UIE</td>
<td>write 0 in UIF</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>
### 40.4 TIM6/TIM7 registers

Refer to *Section 1.2 on page 101* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

#### 40.4.1 TIMx control register 1 (TIMx_CR1)(x = 6 to 7)

Address offset: 0x00

Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit 15:13</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 12</td>
<td><strong>DITHEN</strong>: Dithering enable</td>
</tr>
<tr>
<td>0</td>
<td>Dithering disabled</td>
</tr>
<tr>
<td>1</td>
<td>Dithering enabled</td>
</tr>
<tr>
<td>Note: The DITHEN bit can only be modified when CEN bit is reset.</td>
<td></td>
</tr>
<tr>
<td>Bit 11</td>
<td><strong>UIFREMAP</strong>: UIF status bit remapping</td>
</tr>
<tr>
<td>0</td>
<td>No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.</td>
</tr>
<tr>
<td>1</td>
<td>Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.</td>
</tr>
<tr>
<td>Bits 10:8</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bit 7</td>
<td><strong>ARPE</strong>: Auto-reload preload enable</td>
</tr>
<tr>
<td>0</td>
<td>TIMx_ARR register is not buffered.</td>
</tr>
<tr>
<td>1</td>
<td>TIMx_ARR register is buffered.</td>
</tr>
<tr>
<td>Bits 6:4</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bit 3</td>
<td><strong>OPM</strong>: One-pulse mode</td>
</tr>
<tr>
<td>0</td>
<td>Counter is not stopped at update event</td>
</tr>
<tr>
<td>1</td>
<td>Counter stops counting at the next update event (clearing the CEN bit).</td>
</tr>
</tbody>
</table>
Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generates an update interrupt or DMA request if enabled.
These events can be:
  – Counter overflow/underflow
  – Setting the UG bit
  – Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  – Counter overflow/underflow
  – Setting the UG bit
  – Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled
**CEN** is cleared automatically in one-pulse mode, when an update event occurs.
### 40.4.2 TIMx control register 2 (TIMx_CR2)\((x = 6 \text{ to } 7)\)

Address offset: 0x04  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
<td></td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:7  Reserved, must be kept at reset value.

Bits 6:4  **MMS[2:0]: Master mode selection**  
These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

- 000: **Reset** - the UG bit from the TIMx_EGR register is used as a trigger output (tim_trgo).  
- 001: **Enable** - the Counter enable signal, tim_cnt_en, is used as a trigger output (tim_trgo).  
- 010: **Update** - The update event is selected as a trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

*Note:* The clock of the slave timer or the peripheral receiving the tim_trgo must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bits 3:0  Reserved, must be kept at reset value.

### 40.4.3 TIMx DMA/Interrupt enable register (TIMx_DIER)\((x = 6 \text{ to } 7)\)

Address offset: 0x0C  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:9  Reserved, must be kept at reset value.

Bit 8  **UDE**: Update DMA request enable  
0: Update DMA request disabled.  
1: Update DMA request enabled.

Bits 7:1  Reserved, must be kept at reset value.

Bit 0  **UIE**: Update interrupt enable  
0: Update interrupt disabled.  
1: Update interrupt enabled.
40.4.4 TIMx status register (TIMx_SR)(x = 6 to 7)

Address offset: 0x10
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
– On counter overflow if UDIS = 0 in the TIMx_CR1 register.
– When CNT is reinitialized by software using the UG bit in the TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

40.4.5 TIMx event generation register (TIMx_EGR)(x = 6 to 7)

Address offset: 0x14
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<td></td>
<td>w</td>
</tr>
</tbody>
</table>

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action.
1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

40.4.6 TIMx counter (TIMx_CNT)(x = 6 to 7)

Address offset: 0x24
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:0  **PSC[15:0]**: Prescaler value

The counter clock frequency $f_{tim\_cnt\_ck}$ is equal to $f_{tim\_psc\_ck} / (PSC[15:0] + 1)$. PSC contains the value to be loaded into the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx_EGR register.)

40.4.8  TIMx auto-reload register (TIMx_ARR)(x = 6 to 7)
Address offset: 0x2C
Reset value: 0x0000 FFFF

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded into the actual auto-reload register. Refer to Section 40.3.4: Time-base unit on page 1689 for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null. **Non-dithering mode (DITHEN = 0)**

The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reserved.

**Dithering mode (DITHEN = 1)**

The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

Bit 31  **UIFCPY**: UIF copy

This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in TIMx_CR1 is reset, bit 31 is reserved and read as 0.

Bits 30:16  Reserved, must be kept at reset value.

Bits 15:0  **CNT[15:0]**: Counter value

**Non-dithering mode (DITHEN = 0)**

The register holds the counter value.

**Dithering mode (DITHEN = 1)**

The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.
### TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

| Offset | Register name | S31 | S30 | S29 | S28 | S27 | S26 | S25 | S24 | S23 | S22 | S21 | S20 | S19 | S18 | S17 | S16 | S15 | S14 | S13 | S12 | S11 | S10 | S9 | S8 | S7 | S6 | S5 | S4 | S3 | S2 | S1 | S0 |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 0x00   | TIMx_CR1      |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        |               |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | Reset value   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 0x04   | TIMx_CR2      |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        |               |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | Reset value   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 0x08   | Reserved      |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 0x0C   | TIMx_DIER     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

41 General-purpose timers (TIM12/TIM13/TIM14)

41.1 TIM12/TIM13/TIM14 introduction

The TIM12/TIM13/TIM14 general-purpose timers consist in a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM12/TIM13/TIM14 timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 41.4.20: Timer synchronization (TIM12 only).

41.2 TIM12 main features

The features of the TIM12 general-purpose timer include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal trigger)
  - Trigger event (counter start, stop, initialization or count by internal trigger)
  - Input capture
  - Output compare
41.3 TIM13/TIM14 main features

The features of general-purpose timers TIM13/TIM14 include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed "on the fly")
- independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare

41.4.3 Time-base unit

The main block of the timer is a 16-bit up-counter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 525 and Figure 526 give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 525. Counter timing diagram with prescaler division change from 1 to 2

Figure 526. Counter timing diagram with prescaler division change from 1 to 4
41.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller on TIM12) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 531. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)
Figure 532. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)

41.4.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1 (for TIM12): external input pin (tim_ti1 or tim_ti2, if available)
- Internal trigger inputs (tim_itrx) (for TIM12): connecting the trigger output from another timer. For instance, another timer can be configured as a prescaler for TIM12. Refer to Section : Using one timer as prescaler for another timer for more details.

Internal clock source (tim_ker_ck)

The internal clock source is the default clock source for TIM13/TIM14.

For TIM12, the internal clock source is selected when the slave mode controller is disabled (SMS='000'). The CEN bit in the TIMx_CR1 register and the UG bit in the TIMx_EGR register are then used as control bits and can be changed only by software (except for UG which remains cleared). As soon as the CEN bit is programmed to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 533 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1

This mode is selected when SMS='111' in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:
1. Select the proper `tim_t[i]2_in[15:0]` source (internal or external) with the `TI2SEL[3:0]` bits in the `TIMx_TISEL` register.
2. Configure channel 2 to detect rising edges on the `tim_t[i]2` input by writing `CC2S = '01'` in the `TIMx_CCMR1` register.
3. Configure the input filter duration by writing the `IC2F[3:0]` bits in the `TIMx_CCMR1` register (if no filter is needed, keep `IC2F='0000'`).
4. Select the rising edge polarity by writing `CC2P='0'` and `CC2NP='0'` in the `TIMx_CCER` register.
5. Configure the timer in external clock mode 1 by writing `SMS='111'` in the `TIMx_SMCR` register.
6. Select `tim_t[i]2` as the trigger input source by writing `TS='110'` in the `TIMx_SMCR` register.
7. Enable the counter by writing `CEN='1'` in the `TIMx_CR1` register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on `tim_t[i]2`, the counter counts once and the `TIF` flag is set.

The delay between the rising edge on `tim_t[i]2` and the actual clock of the counter is due to the resynchronization circuit on `tim_t[i]2` input.

![Figure 535. Control circuit in external clock mode 1](image)

41.4.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

*Figure 536, Figure 537, Figure 538* and *Figure 539* give an overview of a capture/compare channel.

The input stage samples the corresponding `tim_t[i]x` input to generate a filtered signal `tim_t[i]xf`. Then, an edge detector with polarity selection generates a signal (`tim_t[i]xfpy`) which
can be used as trigger input by the slave mode controller or as the capture command. It is
prescaled before the capture register (ICxPS).

**Figure 536. Capture/compare channel 1 input stage (TIM13/TIM14)**

The output stage generates an intermediate waveform which is then used for reference:
tim_ocxref (active high). The polarity acts at the end of the chain.
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 41.4.7 Input capture mode

In input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding tim_icx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxF (TIMx_SR register) is set. CCxF can be
cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_t1 input rises. To do this, use the following procedure:

1. Select the proper tim_t1_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_t1 input, so write the CC1S bits to ‘01’ in the TIMx_CCMR1 register. As soon as CC1S becomes different from ‘00’, the channel is configured in input mode and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (by programming the ICxF bits in the TIMx_CCMRx register if the input is one of the tim_tix inputs). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_t1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to ‘0011’ in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_t1 channel by programming CC1P and CC1NP bits to ‘00’ in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

**Note:** IC interrupt requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

### 41.4.8 PWM input mode (TIM12 only)

This mode allows to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIM_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges)
This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two tim_icx signals are mapped on the same tim_tix input.
- These 2 tim_icx signals are active on edges with opposite polarity.
- One of the two tim_tixfpy signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on tim_ti1 using the following procedure (depending on tim_ker_ck frequency and prescaler value):

1. Select the proper tim_ti1_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to ‘01’ in the TIMx_CCMR1 register (tim_ti1 selected).
3. Select the active polarity for tim_ti1fp1 (used both for capture in TIMx_CCR1 and counter clear): program the CC1P and CC1NP bits to ‘00’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to ‘10’ in the TIMx_CCMR1 register (tim_ti1 selected).
5. Select the active polarity for tim_ti1fp2 (used for capture in TIMx_CCR2): program the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to ‘00101’ in the TIMx_SMCR register (tim_ti1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to ‘100’ in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

**41.4.9 Forced output mode**

In output mode (CCxS bits = ‘00’ in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.
To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write ‘0101’ in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP='0' (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to ‘0100’ in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the output compare mode section below.

### 41.4.10 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

1. Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM='0000'), be set active (OCxM='0001'), be set inactive (OCxM='0010') or can toggle (OCxM='0011') on match.
2. Sets a flag in the interrupt status register (CCxiF bit in the TIMx_SR register).
3. Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

**Procedure:**

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxiE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = ‘0011’ to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = ‘0’ to disable preload register
   - Write CCxP = ‘0’ to select active high polarity
   - Write CCxE = ‘1’ to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=’0’, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 541.
41.4.11 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

The tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. The tim_ocx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CNT ≤ TIMx_CCRx.

The timer is able to generate PWM in edge-aligned mode only since the counter is upcounting.

In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1’. If the compare value is 0 then tim_ocxref is held at ‘0’. Figure 542 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.
Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The Figure 543 below presents the dithering principle applied to 4 consecutive PWM cycles.
When the dithering mode is enabled, the register coding is changed as following (see Figure 544 for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- the MSBs are left-shifted to the bits 19:4 and are coding for the base value.

**Note:** The following sequence must be followed when resetting the DITHEN bit:

4. CEN and ARPE bits must be reset
5. The DITHEN bit must be reset
6. The CCIF flags must be cleared
7. The CEN bit can be set (eventually with ARPE = 1).

**Figure 544. Data format and register coding in dithering mode**

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \geq F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\text{MaxResolution}}
\]
Dithering mode disabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode enabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\frac{65535}{16} + \frac{15}{16}} \)

**Note:** The maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 545 below, the dithering mode allows to increase the PWM resolution whatever the PWM frequency.

**Figure 545. PWM resolution vs frequency**

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in the Figure 546 below.
Figure 546. PWM dithering pattern

![Figure showing PWM dithering pattern]

The auto-reload and compare values increments are spread following specific patterns described in the **Table 426** below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

41.4.12 Combined PWM mode (TIM12 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 547 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2
- Channel 2 is configured in PWM mode 1
41.4.13 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be as follows:

\[ \text{CNT} < \text{CCR}x \leq \text{ARR} \] (in particular, \( 0 < \text{CCR}x \))
For example one may want to generate a positive pulse on tim_oc1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the tim_ti2 input pin.

Use tim_ti2fp2 as trigger 1:
1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 to tim_ti2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS='00110' in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to '110' in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).
- The tDELAY is defined by the value written in the TIMx_CCR1 register.
- The tPULSE is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M='0111' in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to ‘0’ in this example.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over...
from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to '0', so the Repetitive Mode is selected.

**Particular case: tim_ocx fast enable**

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 41.4.14 Retriggerable one pulse mode (TIM12 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with non-retriggerable one pulse mode described in Section 41.4.13: One-pulse mode:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for retrigerrable OPM mode 1 or 2.

If the timer is configured in up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones. This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

**Figure 549. Retriggerable one pulse mode**
41.4.15 **UIF bit remapping**

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

41.4.16 **Timer input XOR function**

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins tim_ti1 and tim_ti2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in **Figure 550**.

![Figure 550. Measuring time interval between edges on 2 signals](image)

41.4.17 **TIM12 external trigger synchronization**

The TIM12 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset mode.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = '01' in the TIMx_CCMR1
configure the timer in reset mode by writing SMS='100' in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS='00101' in TIMx_SMCR register.
3. Start the counter by writing CEN='1' in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request can be sent if enabled (depending on the TIE bit in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Figure 551. Control circuit in reset mode**

---

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S='01' in TIMx_CCMR1 register. Program CC1P='1' and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in gated mode by writing SMS='101' in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS='00101' in TIMx_SMCR register.
3. Enable the counter by writing CEN='1' in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN='0', whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S='01' in TIMx_CCMR1 register. Program CC2P='1' and CC2NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS='110' in TIMx_SMCR register. Select tim_ti2 as the input source by writing TS='001110' in TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.
41.4.18 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

41.4.19 Slave mode – combined reset + gated mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
41.4.20 Timer synchronization (TIM12 only)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 39.4.23: Timer synchronization for details.

Note: The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

41.4.21 Using timer output as trigger for other timers (TIM13/TIM14 only)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any timer on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination's timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.
41.4.22 ADC triggers (TIM12 only)

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

41.4.23 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or stop.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to the debug section.

41.5 TIM12/TIM13/TIM14 low-power modes

|       1: TIMx_ARR register is buffered.       |

| Bits 6:4 Reserved, must be kept at reset value. |

| Bit 3  OPM: One-pulse mode                    |
|       0: Counter is not stopped on the update event |
|       1: Counter stops counting on the next update event (clearing the CEN bit). |
Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
- 0: Any of the following events generates an update interrupt if enabled. These events can be:
  - Counter overflow
  - Setting the UG bit
  - Update generation through the slave mode controller
- 1: Only counter overflow generates an update interrupt if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable update event (UEV) generation.
- 0: UEV enabled. An UEV is generated by one of the following events:
  - Counter overflow
  - Setting the UG bit
  Buffered registers are then loaded with their preload values.
- 1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0 **CEN**: Counter enable
- 0: Counter disabled
- 1: Counter enabled
  CEN is cleared automatically in one-pulse mode, when an update event occurs.

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

</tbody>
</table>

Bits 31:22 Reserved, must be kept at reset value.

Bits 19:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 MSM: Master/Slave mode
0: No action
1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful in order to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]: Trigger selection**

This TS[4:0] bitfield selects the trigger input to be used to synchronize the counter.

00000: Internal Trigger 0 (tim_itr0)
00001: Internal Trigger 1 (tim_itr1)
00010: Internal Trigger 2 (tim_itr2)
00011: Internal Trigger 3 (tim_itr3)
00100: tim_ti1 Edge Detector (tim_ti1f_ed)
00101: Filtered Timer Input 1 (tim_ti1fp1)
00110: Filtered Timer Input 2 (tim_ti2fp2)
01000: Internal Trigger 4 (tim_itr4)
01001: Internal Trigger 5 (tim_itr5)
01010: Internal Trigger 6 (tim_itr6)
01011: Internal Trigger 7 (tim_itr7)
01100: Internal Trigger 8 (tim_itr8)
01101: Internal Trigger 9 (tim_itr9)
01110: Internal Trigger 10 (tim_itr10)
01111: Internal Trigger 10 (tim_itr11)
10000: Internal Trigger 10 (tim_itr12)
10001: Internal Trigger 10 (tim_itr13)
10010: Internal Trigger 10 (tim_itr14)
10011: Internal Trigger 10 (tim_itr15)

Others: Reserved

See *Table 425: TIMx internal trigger connection* for more details on the meaning of tim_itrX for each timer.

*Note*: These bits must be changed only when they are not used (for example when SMS='000') to avoid wrong edge detections at the transition.

Bit 3  Reserved, must be kept at reset value.
Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.
0001: Reserved
0010: Reserved
0011: Reserved
0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.
0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.
0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.
1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.
1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
Other codes: reserved.

*Note:* The gated mode (including gated + reset mode) must not be used if tim_ti1f_ed is selected as the trigger input (TS='00100'). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on tim_ti1f, whereas the gated mode checks the level of the trigger signal.

*Note:* The clock of the slave peripherals (timer, ADC,...) receiving the tim_trgo signals must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

### 41.7.4 TIM12 Interrupt enable register (TIM12_DIER)

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag

Refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.

- 0: No overcapture has been detected.
- 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

- 0: No trigger event occurred.
- 1: Trigger interrupt pending.

Bits 5:3 Reserved, must be kept at reset value.
41.7.6 TIM12 event generation register (TIM12_EGR)

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action
1: The TIF flag is set in the TIMx_SR register. Related interrupt can occur if enabled

Bits 5:3 Reserved, must be kept at reset value.
41.7.7 TIM12 capture/compare mode register 1 (TIM12_CCMR1)

Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits in this register have different functions in input and output modes.

**Input capture mode:**

</table>

**Bits 31:16**  Reserved, must be kept at reset value.

**Bits 15:12**  IC2F[3:0]: Input capture 2 filter

**Bits 11:10**  IC2PSC[1:0]: Input capture 2 prescaler

**Bits 9:8**  CC2S[1:0]: Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TIM_t12
10: CC2 channel is configured as input, IC2 is mapped on TIM_t1f
11: CC2 channel is configured as input, IC2 is mapped on TIM_trc. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).*
Bits 7:4  **IC1F[3:0]**: Input capture 1 filter

This bitfield defines the frequency used to sample the tim_t1 input and the length of the
digital filter applied to tim_t1. The digital filter is made of an event counter in which N
consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at fDTS
- 0001: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), N=2
- 0010: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), N=4
- 0011: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), N=8
- 0100: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/2 \), N=6
- 0101: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/2 \), N=8
- 0110: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/4 \), N=6
- 0111: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/4 \), N=8
- 1000: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/8 \), N=6
- 1001: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/8 \), N=8
- 1010: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/16 \), N=5
- 1011: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/16 \), N=6
- 1100: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/16 \), N=8
- 1101: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/32 \), N=5
- 1110: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/32 \), N=6
- 1111: \( f_{\text{SAMPLING}} = f_{\text{DTS}}/32 \), N=8

Bits 3:2  **IC1PSC[1:0]**: Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on the CC1 input (tim_ic1).
The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).

- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0  **CC1S[1:0]**: Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_t1
- 10: CC1 channel is configured as input, tim_ic1 is mapped on tim_t2
- 11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working
  only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note*: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

### 41.7.8 TIM12 capture/compare mode register 1 [alternate]

**(TIM12_CCMR1)**

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture
mode (previous section). The direction of a channel is defined by configuring the
 corresponding CCxS bits. All the other bits in this register have different functions in input
and output modes.
### Output compare mode:

</tr>
</tbody>
</table>
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas the active level of tim_oc1 depends on the CC1P.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. The tim_oc1ref signal is forced high when the TIMx_CNT counter matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. The tim_oc1ref signal is forced low when the TIMx_CNT counter matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1

0100: Force inactive level - tim_oc1ref is forced low

0101: Force active level - tim_oc1ref is forced high

0110: PWM mode 1 - channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else it is inactive

0111: PWM mode 2 - channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else it is active

1000: Retriggable OPM mode 1 - The channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1001: Retriggable OPM mode 2 - The channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1ref is the logical OR between tim_oc1ref and tim_oc2ref.

1101: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1ref is the logical AND between tim_oc1ref and tim_oc2ref.

1110: Reserved,

1111: Reserved

Note: In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.
Bit 3 **OC1PE**: Output compare 1 preload enable
   0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken into account immediately
   1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded into the active register at each update event

Bit 2 **OC1FE**: Output compare 1 fast enable
   This bit is used to accelerate the effect of an event on the trigger in input on the CC output.
   0: CC1 behaves normally depending on the counter and CCR1 values even when the trigger is ON. The minimum delay to activate the CC1 output when an edge occurs on the trigger input is 5 clock cycles
   1: An active edge on the trigger input acts like a compare match on the CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
   This bitfield defines the direction of the channel (input/output) as well as the used input.
   00: CC1 channel is configured as output
   01: CC1 channel is configured as input, tim_ic1 is mapped on tim_tl1
   10: CC1 channel is configured as input, tim_ic1 is mapped on tim_tl2
   11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

   **Note**: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

### 41.7.9 TIM12 capture/compare enable register (TIM12_CCER)

**Address offset**: 0x020

**Reset value**: 0x0000

</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CC2NP**: Capture/Compare 2 output Polarity
   Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity
   Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable
   Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity
   CC1 channel configured as output: CC1NP must be kept cleared
   CC1 channel configured as input: CC1NP is used in conjunction with CC1P to define tim_tl1fp1/tim_tl2fp1 polarity (refer to CC1P description).
Bit 2 Reserved, must be kept at reset value.

Bit 1 CC1P: Capture/Compare 1 output Polarity.

0: tim_oc1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: tim_oc1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of tim_t1fp1 and tim_t2fp1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to tim_t1fp1 rising edge (capture or trigger operations in reset, external clock or trigger mode), tim_t1fp1 is not inverted (trigger operation in gated mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to tim_t1fp1 falling edge (capture or trigger operations in reset, external clock or trigger mode), tim_t1fp1 is inverted (trigger operation in gated mode).

CC1NP=1, CC1P=0: non-inverted/both edges. The circuit is sensitive to both tim_t1fp1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), tim_t1fp1 is not inverted (trigger operation in gated mode).

CC1NP=1, CC1P=1: This configuration is reserved, it must not be used.

Bit 0 CC1E: Capture/Compare 1 output enable.

0: Capture mode disabled / tim_oc1 is not active
1: Capture mode enabled / tim_oc1 signal is output on the corresponding output pin

<table>

CNT[15:0]

1752/3119 RM0481 Rev 1
Bit 31  **UIFCPY**: UIF Copy
This bit is a read-only copy of the UIF bit in the TIMx_ISR register.

Bits 30:16  Reserved, must be kept at reset value.

Bits 15:0  **CNT[15:0]**: Counter value

Non-dithering mode (DITHEN = 0)
The register holds the counter value.

Dithering mode (DITHEN = 1)
The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

### 41.7.11 TIM12 prescaler (TIM12_PSC)

Bits 15:0  **PSC[15:0]**: Prescaler value

The counter clock frequency \( f_{\text{tim_cnt_ck}} \) is equal to \( f_{\text{tim_psc_ck}} / (PSC[15:0] + 1) \).
PSC contains the value to be loaded into the active prescaler register at each update event.
(including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in "reset mode").

### 41.7.12 TIM12 auto-reload register (TIM12_ARR)

Address offset: 0x02C  
Reset value: 0x0000 FFFF

<table>

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.
Refer to the Section 41.4.3: Time-base unit on page 1712 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.

Non-dithering mode (DITHEN = 0)
The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.

Dithering mode (DITHEN = 1)
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.
41.7.13 TIM12 capture/compare register 1 (TIM12_CCR1)

Address offset: 0x034
Reset value: 0x0000 0000

CCR1[15:0]

Bits 31:20 Reserved, must be kept at reset value.
Bits 19:0 **CCR1[19:0]**: Capture/compare 1 value

**If channel CC1 is configured as output:**
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.
- **Non-dithering mode (DITHEN = 0)**
The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.
- **Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

**If channel CC1 is configured as input:**
CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.
- **Non-dithering mode (DITHEN = 0)**
The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.
- **Dithering mode (DITHEN = 1)**
The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

41.7.14 TIM12 capture/compare register 2 (TIM12_CCR2)

Address offset: 0x038
Reset value: 0x0000 0000

| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

1754/3119 RM0481 Rev 1
Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR2[19:0]**: Capture/compare 2 value

If channel CC2 is configured as output:

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on tim_oc2 output.

Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)
The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input:

CCR2 is the counter value transferred by the last input capture 1 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)
The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)
The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

### 41.7.15 TIM12 timer input selection register (TIM12_TISEL)

Address offset: 0x05C

Reset value: 0x0000

<p>| | | | | | | | | | | | | |</p>

</table>

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **TI2SEL[3:0]**: selects tim_ti2_in[15:0] input

0000: TIMx_CH2 input (tim_ti2_in0)
0001: tim_ti2_in1
...
0100: tim_ti2_in15
Refer to *Table 424: Interconnect to the tim_ti2 input multiplexer* for interconnects list.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **TI1SEL[3:0]**: selects tim_ti1_in[15:0] input

0000: TIMx_CH1 input (tim_ti1_in0)
0001: tim_ti1_in1
...
1111: tim_ti1_in15
Refer to *Table 423: Interconnect to the tim_ti1 input multiplexer* for interconnects list.
## 41.7.16 TIM12 register map

TIM12 registers are mapped as 16-bit addressable registers as described below:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Register name</th>
<th>Offset</th>
<th>Register name</th>

- **TIM12_EGR**: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
- **TIM12_CCMR1**: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
- **TIM12_CCER**: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
- **TIM12_CNT**: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
- **TIM12_PSC**: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
Refer to Section 2.3 on page 111 for the register boundary addresses.
41.8 TIM13/TIM14 registers

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

41.8.1 TIMx control register 1 (TIMx_CR1)(x = 13, 14)

Address offset: 0x000
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
0: Dithering disabled
1: Dithering enabled

*Note: The DITHEN bit can only be modified when CEN bit is reset.*

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and sampling clock used by the digital filters (tim_tix),
00: tDTS = tim_ker_ck
01: tDTS = 2 × tim_ker_ck
10: tDTS = 4 × tim_ker_ck
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped on the update event
1: Counter stops counting on the next update event (clearing the CEN bit).
Bit 2  **URS:** Update request source
This bit is set and cleared by software to select the update interrupt (UEV) sources.
0: Any of the following events generate an UEV if enabled:
   – Counter overflow
   – Setting the UG bit
1: Only counter overflow generates an UEV if enabled.

Bit 1  **UDIS:** Update disable
This bit is set and cleared by software to enable/disable update interrupt (UEV) event generation.
0: UEV enabled. An UEV is generated by one of the following events:
   – Counter overflow
   – Setting the UG bit.
   Buffered registers are then loaded with their preload values.
1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0  **CEN:** Counter enable
0: Counter disabled
1: Counter enabled

*Note:* External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

### 41.8.2 TIMx Interrupt enable register (TIMx_DIER)(x = 13, 14)
Address offset: 0x00C
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:2  Reserved, must be kept at reset value.

Bit 1  **CC1IE:** Capture/Compare 1 interrupt enable
0: CC1 interrupt disabled
1: CC1 interrupt enabled

Bit 0  **UIE:** Update interrupt enable
0: Update interrupt disabled
1: Update interrupt enabled

### 41.8.3 TIMx status register (TIMx_SR)(x = 13, 14)
Address offset: 0x010
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>

<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

|    | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 |

ST
Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred.

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on TIM_ic1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCRER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
– At overflow and if UDIS=’0’ in the TIMx_CR1 register.
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=’0’ and UDIS=’0’ in the TIMx_CR1 register.

### 41.8.4 TIMx event generation register (TIMx_EGR)(x = 13, 14)

**CC1G** **UG**

W W
Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
- **If channel CC1 is configured as output**: CC1IF flag is set, corresponding interrupt or is sent if enabled.
- **If channel CC1 is configured as input**: The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared.

### 41.8.5 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 13, 14)

Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

#### Input capture mode:

</table>

*Bits 31:17* Reserved, must be kept at reset value.

*Bits 15:7* Reserved, must be kept at reset value.

*Bits 16, 6, 4 OC1M[3:0]:* Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas tim_oc1 active level depends on CC1P bit.

0000: Frozen. The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT = TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx_CNT < TIMx_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT < TIMx_CCR1 else active.

Others: Reserved

*Note:* In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.
41.8.7 **TIMx capture/compare enable register**

**(TIMx_CCER)(x = 13, 14)**

Address offset: 0x020

Reset value: 0x0000

<table>

</tbody>
</table>

Bits 15:4 Reserved, must be kept at reset value.

**Bit 3 CC1NP**: Capture/Compare 1 complementary output Polarity.

CC1 channel configured as output: CC1NP must be kept cleared.
CC1 channel configured as input: CC1NP bit is used in conjunction with CC1P to define tim_ti1fp1 polarity (refer to CC1P description).
Bit 2  Reserved, must be kept at reset value.

Bit 1  **CC1P**: Capture/Compare 1 output Polarity.

0: tim_oc1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: tim_oc1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of tim_ti1fp1 for capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to tim_ti1fp1 rising edge (capture or trigger operations in reset, external clock or trigger mode), tim_ti1fp1 is not inverted (trigger operation in gated mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to tim_ti1fp1 falling edge (capture or trigger operations in reset, external clock or trigger mode), tim_ti1fp1 is inverted (trigger operation in gated mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both tim_ti1fp1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), tim_ti1fp1 not inverted (trigger operation in gated mode).

CC1NP=1, CC1P=0: This configuration is reserved, it must not be used.

Bit 0  **CC1E**: Capture/Compare 1 output enable.

0: Capture mode disabled / tim_oc1 is not active
1: Capture mode enabled / tim_oc1 signal is output on the corresponding output pin

<table>

</tbody>
</table>

Bits 15:0 PSC[15:0]: Prescaler value

- The counter clock frequency \( \text{tim}_\text{cnt}_\text{ck} \) is equal to \( \frac{f_{\text{tim}_\text{psc}_\text{ck}}}{(PSC[15:0] + 1)} \).
- PSC contains the value to be loaded in the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

41.8.10 TIMx auto-reload register (TIMx_ARR)\((x = 13, 14)\)

</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 ARR[19:0]: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the Section 41.4.3: Time-base unit on page 1712 for more details about ARR update and behavior.

- The counter is blocked while the auto-reload value is null.
- Non-dithering mode (DITHEN = 0)
- The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.
- Dithering mode (DITHEN = 1)
41.8.11 TIMx capture/compare register 1 (TIMx_CCR1)(x = 13, 14)

Address offset: 0x034
Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 CCR1[19:0]: Capture/compare 1 value

If channel CC1 is configured as output:
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register
(bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when
an update event occurs.
The active capture/compare register contains the value to be compared to the counter
TIMx_CNT and signaled on tim_oc1 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the
dithered part.

If channel CC1 is configured as input:
CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The
TIMx_CCR1 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0)
The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

41.8.12 TIMx timer input selection register (TIMx_TISEL)(x = 13, 14)

Address offset: 0x05C
Reset value: 0x0000
41.8.13 TIM13/TIM14 register map

TIMx registers are mapped as 16-bit addressable registers as described in the tables below:

### Table 432. TIM13/TIM14 register map and reset values

42 General purpose timers (TIM15/TIM16/TIM17)

42.1 TIM15/TIM16/TIM17 introduction

The TIM15/TIM16/TIM17 timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/TIM16/TIM17 timers are completely independent, and do not share any resources. TIM15 can be synchronized as described in Section 42.4.26: Timer synchronization (TIM15 only).

42.2 TIM15 main features

TIM15 includes the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time (for channel 1 only)
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)
42.3 TIM16/TIM17 main features

The TIM16/TIM17 timers include the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input

42.4.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output `tim_cnt_ck`, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 556* and *Figure 557* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

**Figure 556. Counter timing diagram with prescaler division change from 1 to 2**

![Counter timing diagram](image)
42.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

**Figure 558. Counter timing diagram, internal clock divided by 1**
Figure 559. Counter timing diagram, internal clock divided by 2

Figure 560. Counter timing diagram, internal clock divided by 4
Figure 561. Counter timing diagram, internal clock divided by N

Figure 562. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)
### 42.4.5 Repetition counter

**Section 42.4.3: Time-base unit** describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented at each counter overflow.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 564). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.

![Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)](image)
42.4.6 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2, if available)
- Internal trigger inputs (tim_itrx) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15. Refer to Using one timer to enable another timer for more details.

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000), then the CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed.
only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock \( \text{tim\_ker\_ck} \).

*Figure 565* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

*Figure 565. Control circuit in normal mode, internal clock divided by 1*

![Control circuit in normal mode, internal clock divided by 1](image)

**External clock source mode 1**

This mode is selected when \( \text{SMS}=111 \) in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

*Figure 566. \text{tim\_ti2} external clock connection example*

![tim\_ti2 external clock connection example](image)

For example, to configure the upcounter to count in response to a rising edge on the \text{tim\_ti2} input, use the following procedure:
1. Select the proper `tim_ti2_in[15:0]` source (internal or external) with the `TI2SEL[3:0]` bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the `tim_ti2` input by writing `CC2S = '01'` in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the `IC2F[3:0]` bits in the TIMx_CCMR1 register (if no filter is needed, keep `IC2F=0000`).
4. Select rising edge polarity by writing `CC2P=0` in the TIMx_CCRER register.
5. Configure the timer in external clock mode 1 by writing `SMS=111` in the TIMx_SMCR register.
6. Select `tim_ti2` as the trigger input source by writing `TS=00110` in the TIMx_SMCR register.
7. Enable the counter by writing `CEN=1` in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on `tim_ti2`, the counter counts once and the `TIF` flag is set.

The delay between the rising edge on `tim_ti2` and the actual clock of the counter is due to the resynchronization circuit on `tim_ti2` input.

**42.4.7 Capture/compare channels**

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

*Figure 568* to *Figure 571* give an overview of one Capture/Compare channel.

The input stage samples the corresponding `tim_tix` input to generate a filtered signal `tim_tixf`. Then, an edge detector with polarity selection generates a signal (`tim_tixfpy`) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (`ICxPS`).
The output stage generates an intermediate waveform which is then used for reference: `tim_ocxref` (active high). The polarity acts at the end of the chain.

**Figure 569. Capture/compare channel 1 main circuit**
42.4.8 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding TIMx_ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was
already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_ti1_in[15:1] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_ti1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_ti1 channel by writing CC1P bit to 0 in the TIMx_CCR1 register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

**Note:** IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
42.4.9 **PWM input mode (only for TIM15)**

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIMx_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two tim_icx signals are mapped on the same tim_tix input.
- These 2 tim_icx signals are active on edges with opposite polarity.
- One of the two tim_tixfpy signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on tim_ti1 using the following procedure (depending on tim_ker_ck frequency and prescaler value):

1. Select the proper tim_ti1_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_ti1 selected).
3. Select the active polarity for tim_ti1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_ti1 selected).
5. Select the active polarity for tim_ti1fp2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_ti1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.
42.4.10 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

42.4.11 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP...
bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 573.
42.4.12 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing '110' (PWM mode 1) or '111' (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The TIM15/TIM16/TIM17 are capable of upcounting only. Refer to Upcounting mode on page 1778.
In the following example, we consider PWM mode 1. The reference PWM signal \texttt{tim\_ocxref} is high as long as \texttt{TIMx\_CNT} < \texttt{TIMx\_CCRx} else it becomes low. If the compare value in \texttt{TIMx\_CCRx} is greater than the auto-reload value (in \texttt{TIMx\_ARR}) then \texttt{tim\_ocxref} is held at ‘1’. If the compare value is 0 then \texttt{tim\_ocxref} is held at ‘0’. \textit{Figure 574} shows some edge-aligned PWM waveforms in an example where \texttt{TIMx\_ARR}=8.

\textbf{Figure 574. Edge-aligned PWM waveforms (ARR=8)}

| \texttt{CCxIF} | CMS=01 | CMS=10 | CMS=11 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| \texttt{tim\_ocxref} |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

\textbf{Dithering mode}

The PWM mode effective resolution can be increased by enabling the dithering mode, using the \texttt{DITHEN} bit in the \texttt{TIMx\_CR1} register. This applies to both the \texttt{CCR} (for duty cycle resolution increase) and \texttt{ARR} (for PWM frequency resolution increase).

The operating principle is to have the actual \texttt{CCR} (or \texttt{ARR}) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The \textit{Figure 575} below presents the dithering principle applied to 4 consecutive PWM cycles.
When the dithering mode is enabled, the register coding is changed as following (see Figure 576 for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- the MSBs are left-shifted to the bits 19:4 and are coding for the base value.

**Note:** The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The ARR[3:0] bits must be reset
3. The CCIF flags must be cleared
4. The CEN bit can be set (eventually with ARPE = 1).

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\max_{\text{Resolution}}}
\]
Dithering mode disabled: \[ F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \]

Dithering mode enabled: \[ F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \]

**Note:** The maximum TIMx ARR and TIMxCCRx values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the **Figure 577** below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

**Figure 577. PWM resolution vs frequency**

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in the **Figure 578** below.
The auto-reload and compare values increments are spread following specific patterns described in the Table 440 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Table 440. CCR and ARR register change dithering pattern

42.4.13 Combined PWM mode (TIM15 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

*Figure 579* represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
42.4.14 Complementary outputs and dead-time insertion

The TIM15/TIM16/TIM17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output tim_ocx or complementary tim_ocxn) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals tim_ocx and tim_ocxn are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 447: Output control bits for complementary tim_oc1 and tim_oc1n channels with break feature (TIM16/TIM17) on page 1859 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).
Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform tim_ocxref, it generates 2 outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 580. Complementary output with symmetrical dead-time insertion.**

![Diagram showing complementary output with symmetrical dead-time insertion.](image)

The DTAE bit in the TIMx_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on Figure 581.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must be not modified while CEN = 1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMX_DTR2 register. The preload value is loaded in the active register on the next update event.

**Note:** If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 42.8.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on page 1863 for delay calculation.
**Re-directing tim_ocxref to tim_ocx or tim_ocxn**

In output mode (forced, output compare or PWM), tim_ocxref can be re-directed to the tim_ocx output or to tim_ocxn output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

*Note:* When only tim_ocxn is enabled (CCxE=0, CCxNE=1), it is *not* complemented and becomes active as soon as tim_ocxref is high. For example, if CCxNP=0 then tim_ocx=tim_ocxref. On the other hand, when both tim_ocx and tim_ocxn are enabled (CCxE=CCxNE=1) tim_ocx becomes active when tim_ocxref is high whereas tim_ocxn is complemented and becomes active when tim_ocxref is low.

**42.4.15 Using the break function**

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The break input is usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break channel gathers both system-level fault (clock failure, ECC / parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register is used to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shutdown level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 447: Output control bits for complementary tim_oc1 and tim_oc1n channels with break feature (TIM16/TIM17) on page 1859 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function is enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.
The break is generated by the `tim_brk` inputs which has:
- Programmable polarity (BKP bit in the TIMx_BDTR register)
- Programmable enable bit (BKE bit in the TIMx_BDTR register)
- Programmable filter (BKF[3:0] bits in the TIMx_BDTR register) to avoid spurious events.

The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx_AF1 register.

The sources for break (`tim_brk`) channel are:
- External sources connected to one of the TIM_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a `tim_brk_cmpx` input (refer to Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation)
  - coming from a system break request on the `tim_sys_brk` inputs (refer to Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation)

Break events can also be generated by software using BG bit in the TIMx_EGR register. All sources are ORed before entering the timer `tim_brk` inputs, as per Figure 584 below.

![Figure 584. Break circuitry overview](image)

**Caution:** An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example, using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.
When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.

- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO) else the enable output remains high.

- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 tim_ker_ck clock cycles).
  - If OSSI=0 then the timer releases the enable outputs (taken over by the GPIO which forces a Hi-Z state) else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.

- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written with 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

Note: The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the tim_brk input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR Register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable and polarity). The protection can be selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to Section 42.8.14: TIMx break and dead-time register (TIMx_BDTR) (x = 16 to 17). The LOCK bits can be written only once after an MCU reset.

The Figure 585 shows an example of behavior of the outputs in response to a break.

BREAK (MOE)
42.4.16 Bidirectional break input

The TIM15/TIM16/TIM17 are featuring bidirectional break I/Os, as represented on Figure 586.

They are used to have:
- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged

The tim_brk input is configured in bidirectional mode using the BKBID bit in the TIMxBDTR register. The BKBID programming bit can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode requires the I/O to be configured in open-drain mode with active low polarity (using BKinP and BKP bits). Any break request coming either from system (for example CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software event (triggered by setting the BG bit) also causes the break I/O to be forced to '0' to indicate to the external components that the timer has entered in break state. However, this is valid only if the break is enabled (BKE = 1). When a software break event is generated with BKE = 0, the outputs are put in safe state and the break flag is set, but there is no effect on the TIM_BKin I/O.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:
- The break input path is always active: a break event is active even if the BKDSRM bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 441)

Arming and re-arming break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).
The following procedure must be followed to re-arm the protection after a break event:

- The BKDSRM bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

**Figure 586. Output redirection**

---

### 42.4.17 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The tim_ocref_clr_int input can be selected among several inputs, as shown on Figure 587 below.
42.4.18 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 588 describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.
Figure 588. 6-step generation, COM example (OSSR=1)

Example 1

- **Counter (CNT)**
  - (CCRx)

  - **tim_ocxn**
42.4.19 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- $\text{CNT} < \text{CCR}_x \leq \text{ARR}$ (in particular, $0 < \text{CCR}_x$)

![Figure 589. Example of one pulse mode.](MSv62344V1)

For example one may want to generate a positive pulse on TIM_OC1 with a length of $t_{\text{PULSE}}$ and after a delay of $t_{\text{DELAY}}$ as soon as a positive edge is detected on the TIM_TI2 input pin.

Let's use TIM_TI2FP2 as trigger 1:

1. Select the proper TIM_TI2_IN[15:1] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TIM_TI2FP2 to TIM_TI2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. TIM_TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure TIM_TI2FP2 as trigger for the slave mode controller (TIM_TRGI) by writing TS='00110' in the TIMx_SMCR register.
5. TIM_TI2FP2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value ($\text{TIMx.ARR} - \text{TIMx.CCR1}$).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to ‘0’ in this example.

Since only 1 pulse is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

Particular case: tim_ocx fast enable

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY.min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 42.4.20 Retriggerable one pulse mode (TIM15 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 42.4.19:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retrigerrable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

*This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.*
42.4.21 UIF bit remapping

The UIFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

42.4.22 Timer input XOR function (TIM15 only)

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins tim_ti1 and tim_ti2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in Figure 591.

42.4.23 External trigger synchronization (TIM15 only)

The TIM timers are linked together internally for timer synchronization or chaining.
The TIM15 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P='0' and CC1NP='0' in the TIMx_CCRER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Figure 592. Control circuit in reset mode**
**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when `tim_ti1` input is low:

1. Configure the channel 1 to detect low levels on `tim_ti1`. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP = '0' in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select `tim_ti1` as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as `tim_ti1` is low and stops as soon as `tim_ti1` becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on `tim_ti1` and the actual stop of the counter is due to the resynchronization circuit on `tim_ti1` input.

**Figure 593. Control circuit in gated mode**

![Control circuit in gated mode](image-url)
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P='1' and CC2NP='0' in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in the TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in the TIMx_SMCR register. When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 594. Control circuit in trigger mode

Slave mode selection preload for run-time update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

42.4.24 Slave mode – combined reset + trigger mode (TIM15 only)

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

42.4.25 Slave mode – combined reset + gated mode (TIM15 only)

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).
42.4.26 Timer synchronization (TIM15 only)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 39.4.23: Timer synchronization for details.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

42.4.27 Using timer output as trigger for other timers (TIM16/TIM17 only)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any timer on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination’s timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

42.4.28 ADC triggers (TIM15 only)

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

42.4.29 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests on a single event. The main purpose is to be able to re-program several timer registers multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:

00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,
The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see Section 42.8.19: TIMx DMA control register (TIMx_DCR)(x = 16 to 17) for details).

For example, the timer DMA burst feature can be used to update the contents of the CCRx registers (x = 2, 3, 4) on an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into the CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   - DBL = 3 transfers, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register is to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

**Note:** A null value can be written to the reserved registers.

### 42.4.30 TIM15/TIM16/TIM17 DMA requests

The TIM15/TIM16/TIM17 can generate a DMA requests, as shown in Table 442.

<table>

</tr>
</tbody>
</table>

1. Available for TIM15 only.

### 42.4.31 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or stop.
The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.

For more details, refer to the debug section.

### 42.5 TIM15/TIM16/TIM17 low-power modes

<table>

</table>

Bits 15:13 Reserved, must be kept at reset value.

- **Bit 12 DITHEN**: Dithering enable  
  0: Dithering disabled  
  1: Dithering enabled  
  *Note: The DITHEN bit can only be modified when CEN bit is reset.*

- **Bit 11 UIFREMAP**: UIF status bit remapping  
  0: No remapping. UIF status bit is not copied to TIM15_CNT register bit 31.  
  1: Remapping enabled. UIF status bit is copied to TIM15_CNT register bit 31.

- **Bit 10 Reserved, must be kept at reset value.**

- **Bits 9:8 CKD[1:0]**: Clock division  
  This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters (tim_tix)  
  00: tDTS = tim_ker_ck  
  01: tDTS = 2*tim_ker_ck  
  10: tDTS = 4*tim_ker_ck  
  11: Reserved

- **Bit 7 ARPE**: Auto-reload preload enable  
  0: TIM15_ARR register is not buffered  
  1: TIM15_ARR register is buffered

- **Bits 6:4 Reserved, must be kept at reset value.**

- **Bit 3 OPM**: One-pulse mode  
  0: Counter is not stopped at update event  
  1: Counter stops counting at the next update event (clearing the bit CEN)
Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt if enabled. These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt if enabled

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled
1: Counter enabled

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 42.7.2 TIM15 control register 2 (TIM15_CR2)

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **OIS2**: Output idle state 2 (tim_oc2 output)

0: \( \text{tim\_oc2}=0 \) when MOE=0
1: \( \text{tim\_oc2}=1 \) when MOE=0

*Note: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in the TIM15_BKR register).*

Bit 9 **OIS1N**: Output idle state 1 (tim_oc1n output)

0: \( \text{tim\_oc1n}=0 \) after a dead-time when MOE=0
1: \( \text{tim\_oc1n}=1 \) after a dead-time when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BKR register).*

Bit 8 **OIS1**: Output idle state 1 (tim_oc1 output)

0: \( \text{tim\_oc1}=0 \) after a dead-time when MOE=0
1: \( \text{tim\_oc1}=1 \) after a dead-time when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BKR register).*
Bit 7  **TI1S**: tim_ti1 selection
0: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input
1: The tim_ti1_in[15:0] and tim_ti2_in[15:0] multiplexers output are connected to the tim_ti1 input (XOR combination)

Bits 6:4  **MMS[2:0]**: Master mode selection
These bits are used to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:
000:  **Reset** - the UG bit from the TIM15_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.
001:  **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIM15_SMCR register).
010:  **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.
011:  **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).
100:  **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo).
101:  **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo).

Bit 3  **CCDS**: Capture/compare DMA selection
0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bit 2  **CCUS**: Capture/compare control update selection
0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi.

*Note: This bit acts only on channels that have a complementary output.*

Bit 1  Reserved, must be kept at reset value.

Bit 0  **CCPC**: Capture/compare preloaded control
0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **SMSPE**: SMS preload enable

This bit selects whether the SMS[3:0] bitfield is preloaded.

0: SMS[3:0] bitfield is not preloaded  
1: SMS[3:0] preload is enabled

Bits 23:22 Reserved, must be kept at reset value.

Bits 19:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **MSM**: Master/slave mode

0: No action  
1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]: Trigger selection**

This bit field selects the trigger input to be used to synchronize the counter.

- 00000: Internal Trigger 0 (tim_itr0)
- 00001: Internal Trigger 1 (tim_itr1)
- 00010: Internal Trigger 2 (tim_itr2)
- 00011: Internal Trigger 3 (tim_itr3)
- 00100: tim_ti1 Edge Detector (tim_ti1f_ed)
- 00101: Filtered Timer Input 1 (tim_ti1fp1)
- 00110: Filtered Timer Input 2 (tim_ti2fp2)
- 00111: Reserved
- 01000: Internal Trigger 4 (tim_itr4)
- 01001: Internal Trigger 5 (tim_itr5)
- 01010: Internal Trigger 6 (tim_itr6)
- 01011: Internal Trigger 7 (tim_itr7)
- 01100: Internal Trigger 8 (tim_itr8)
- 01101: Internal Trigger 9 (tim_itr9)
- 01110: Internal Trigger 10 (tim_itr10)
- 10000: Internal trigger 12 (tim_itr12)
- 10001: Internal trigger 13 (tim_itr13)
- 10010: Internal trigger 14 (tim_itr14)
- 10011: Internal trigger 15 (tim_itr15)

Others: Reserved

See [Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals](#) for more details on **tim_itrx** meaning for each timer.

*Note:* These bits must be changed only when they are not used (for example when **SMS=000**) to avoid wrong edge detections at the transition.

Bit 3  **Reserved**, must be kept at reset value.
Bits 16, 2, 1, 0  **SMS[3:0]: Slave mode selection**

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.
0001: Reserved
0010: Reserved
0011: Reserved
0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.
0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.
0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.
1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.
1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
Others: Reserved.

**Note:** The gated mode must not be used if tim_t1f_ed is selected as the trigger input (TS='00100'). Indeed, tim_t1f_ed outputs 1 pulse for each transition on tim_t1f, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

</tbody>
</table>

Bits 15:11: Reserved, must be kept at reset value.
Bit 7 BIF: Break interrupt flag
   This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
   0: No break event occurred
   1: An active level has been detected on the break input

Bit 6 TIF: Trigger interrupt flag
   This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
   0: No trigger event occurred
   1: Trigger interrupt pending

Bit 5 COMIF: COM interrupt flag
   This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.
   0: No COM event occurred
   1: COM interrupt pending

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 CC2IF: Capture/Compare 2 interrupt flag
   refer to CC1IF description

Bit 1 CC1IF: Capture/Compare 1 interrupt flag
   This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
   0: No compare match / No input capture occurred
   1: A compare match or an input capture occurred

   If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

   If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 UIF: Update interrupt flag
   This bit is set by hardware on an update event. It is cleared by software.
   0: No update occurred.
   1: Update interrupt pending. This bit is set by hardware when the registers are updated:
      – At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIM15_CR1 register.
      – When CNT is reinitialized by software using the UG bit in TIM15_EGR register, if URS=0 and UDIS=0 in the TIM15_CR1 register.
      – When CNT is reinitialized by a trigger event (refer to Section 42.7.3: TIM15 slave mode control register (TIM15_SMCR)), if URS=0 and UDIS=0 in the TIM15_CR1 register.

42.7.7 TIM15 capture/compare mode register 1 (TIM15_CCMR1)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

### Input capture mode

| Bit 31:16 | Reserved, must be kept at reset value. |
| Bit 15:12 | IC2F[3:0]: Input capture 2 filter |
| Bit 11:10 | IC2PSC[1:0]: Input capture 2 prescaler |
| Bit 9:8   | CC2S[1:0]: Capture/Compare 2 selection |

This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC2 channel is configured as output
- 01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
- 10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
- 11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

**Note:** CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIM15_CCER).
42.7.8 TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).
Output compare mode:

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12  **OC2M[3:0]**: Output compare 2 mode

Bit 11  **OC2PE**: Output compare 2 preload enable

Bit 10  **OC2FE**: Output compare 2 fast enable

Bits 9:8  **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.

01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2.

10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1.

11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIM15_SMCR register).

**Note**: **CC2S** bits are writable only when the channel is OFF (**CC2E = '0'** in **TIM15_CCER**).

Bit 7  **OC1CE**: Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int input.

1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input.
Bits 16, 6:4 **OC1M[3:0]:** Output compare 1 mode

These bits define the behavior of the output reference signal `tim_oc1ref` from which `tim_oc1` and `tim_oc1n` are derived. `tim_oc1ref` is active high whereas `tim_oc1` and `tim_oc1n` active level depends on `CC1P` and `CC1NP` bits.

0000: Frozen - The comparison between the output compare register TIM15_CCR1 and the counter TIM15_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. `tim_oc1ref` signal is forced high when the counter TIM15_CNT matches the capture/compare register 1 (TIM15_CCR1).

0010: Set channel 1 to inactive level on match. `tim_oc1ref` signal is forced low when the counter TIM15_CNT matches the capture/compare register 1 (TIM15_CCR1).

0011: Toggle - `tim_oc1ref` toggles when TIM15_CNT=TIM15_CCR1.

0100: Force inactive level - `tim_oc1ref` is forced low.

0101: Force active level - `tim_oc1ref` is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIM15_CNT<TIM15_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIM15_CNT<TIM15_CCR1 else active.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on `tim_trgi` signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved

1011: Reserved

1100: Combined PWM mode 1 - `tim_oc1ref` has the same behavior as in PWM mode 1. `tim_oc1ref` is the logical OR between `tim_oc1ref` and `tim_oc2ref`.

1101: Combined PWM mode 2 - `tim_oc1ref` has the same behavior as in PWM mode 2. `tim_oc1ref` is the logical AND between `tim_oc1ref` and `tim_oc2ref`.

1110: Reserved

1111: Reserved,

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S='00' (the channel is configured in output). In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

On channels that have a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.
Bit 3 **OC1PE**: Output Compare 1 preload enable

- 0: Preload register on TIM15_CCR1 disabled. TIM15_CCR1 can be written at anytime, the new value is taken in account immediately.
- 1: Preload register on TIM15_CCR1 enabled. Read/Write operations access the preload register. TIM15_CCR1 preload value is loaded in the active register at each update event.

*Note*: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

- 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
- 1: An active edge on the trigger input acts like a compare match on CC1 output. Then, tim_ocx is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

- 00: CC1 channel is configured as output.
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1.
- 10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2.
- 11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

*Note*: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIM15_CER).

### 42.7.9 TIM15 capture/compare enable register (TIM15_CCER)

Address offset: 0x20

Reset value: 0x0000

</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.

- Bit 7 **CC2NP**: Capture/Compare 2 complementary output polarity
  - Refer to CC1NP description

- Bit 6 Reserved, must be kept at reset value.

- Bit 5 **CC2P**: Capture/Compare 2 output polarity
  - Refer to CC1P description

- Bit 4 **CC2E**: Capture/Compare 2 output enable
  - Refer to CC1E description
Bit 3 CC1NP: Capture/Compare 1 complementary output polarity
CC1 channel configured as output:
0: tim_oc1n active high
1: tim_oc1n active low
CC1 channel configured as input:
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1 and tim_ti2fp1. Refer to CC1P description.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S="00" (the channel is configured in output).
On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2 CC1NE: Capture/Compare 1 complementary output enable
0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 CC1P: Capture/Compare 1 output polarity
CC1 channel configured as output:
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.
CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode).
CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode).
CC1NP=1, CC1P=0: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode).
CC1NP=1, CC1P=1: this configuration is reserved, it must not be used.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).
On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 CC1E: Capture/Compare 1 output enable
0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 445 for details.
Table 445. Output control bits for complementary tim_ocx and tim_ocxn channels with break feature (TIM15)

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary tim_ocx and tim_ocxn channels depends on the tim_ocx and tim_ocxn channel state and GPIO control and alternate function selection registers.
42.7.10 TIM15 counter (TIM15_CNT)

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]: Auto-reload value**

ARR is the value to be loaded in the actual auto-reload register.
Refer to the [Section 42.4.3: Time-base unit on page 1776](#) for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
**Non-dithering mode (DITHEN = 0)**
The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.
**Dithering mode (DITHEN = 1)**
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

42.7.13 TIM15 repetition counter register (TIM15_RCR)

Address offset: 0x30
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>

<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **REP[7:0]: Repetition counter reload value**

This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable.
When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIM15_RCR register is not taken in account until the next repetition update event.
It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode:
- the number of PWM periods in edge-aligned mode
- the number of half PWM period in center-aligned mode
42.7.14 TIM15 capture/compare register 1 (TIM15_CCR1)

Address offset: 0x34
Reset value: 0x0000 0000

| 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16 |

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR1[19:0]**: Capture/compare 1 value

**If channel CC1 is configured as output:**
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIM15_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIM15_CNT and signaled on tim_oc1 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

**If channel CC1 is configured as input:**
CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0)
The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

CCR2[15:0]

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  CCR2[19:0]: Capture/compare 2 value

If channel CC2 is configured as output:
CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIM15_CCMR2 register
(bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when
an update event occurs.
The active capture/compare register contains the value to be compared to the counter
TIM15_CNT and signalled on tim_oc2 output.

Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)
The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the
dithered part.

If channel CC2 is configured as input:
CCR2 is the counter value transferred by the last input capture 1 event (tim_ic2). The
TIMx_CCR2 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)
The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)
The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

MOE  AOE  BKP  BKE  OSSR  OSSI  LOCK[1:0]  DTG[7:0]
| rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  |

Note:  As the BKBID, BKDSRM, BKF[3:0], AOE, BKP, BKE, OSSR, OSSI and DTG[7:0] bits may
be write-locked depending on the LOCK configuration, it may be necessary to configure all
of them during the first write access to the TIM15_BDTR register.

RM0481 Rev 1 1837/3119
Bits 31:29  Reserved, must be kept at reset value.

Bit 28  **BKBID**: Break bidirectional

0: Break input tim_brk in input mode
1: Break input tim_brk in bidirectional mode

In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

*Note*: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

*Note*: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27  Reserved, must be kept at reset value.

Bit 26  **BKDSRM**: Break disarm

0: Break input tim_brk is armed
1: Break input tim_brk is disarmed

This bit is cleared by hardware when no break source is active.

The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled until it is reset by hardware, indicating that the fault condition has disappeared.

*Note*: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bits 25:20  Reserved, must be kept at reset value.

Bits 19:16  **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample the tim_brk input signal and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

0000: No filter, tim_brk acts asynchronously
0001: \(f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}}, N = 2\)
0010: \(f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}}, N = 4\)
0011: \(f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}}, N = 8\)
0100: \(f_{\text{SAMPLING}} = f_{\text{DTS}/2}, N = 6\)
0101: \(f_{\text{SAMPLING}} = f_{\text{DTS}/2}, N = 8\)
0110: \(f_{\text{SAMPLING}} = f_{\text{DTS}/4}, N = 6\)
0111: \(f_{\text{SAMPLING}} = f_{\text{DTS}/4}, N = 8\)
1000: \(f_{\text{SAMPLING}} = f_{\text{DTS}/8}, N = 6\)
1001: \(f_{\text{SAMPLING}} = f_{\text{DTS}/8}, N = 8\)
1010: \(f_{\text{SAMPLING}} = f_{\text{DTS}/16}, N = 5\)
1011: \(f_{\text{SAMPLING}} = f_{\text{DTS}/16}, N = 6\)
1100: \(f_{\text{SAMPLING}} = f_{\text{DTS}/16}, N = 8\)
1101: \(f_{\text{SAMPLING}} = f_{\text{DTS}/32}, N = 5\)
1110: \(f_{\text{SAMPLING}} = f_{\text{DTS}/32}, N = 6\)
1111: \(f_{\text{SAMPLING}} = f_{\text{DTS}/32}, N = 8\)

*Note*: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).
Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as the tim_brk input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: tim_ocx and tim_ocxn outputs are disabled or forced to idle state depending on the OSSI bit.
1: tim_ocx and tim_ocxn outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIM15_CCER register)

See tim_ocx/tim_ocxn enable description for more details (Section 42.7.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1831).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software
1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 13 **BKP**: Break polarity

0: Break input tim_brk is active low
1: Break input tim_brk is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

0: Break inputs (tim_brk and tim_sys_brk clock failure event) disabled
1: Break inputs (tim_brk and tim_sys_brk clock failure event) enabled

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See tim_ocx/tim_ocxn enable description for more details (Section 42.7.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1831).

0: When inactive, tim_ocx/tim_ocxn outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)
1: When inactive, tim_ocx/tim_ocxn outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See tim_ocx/tim_ocxn enable description for more details (Section 42.7.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1831).

0: When inactive, tim_ocx/tim_ocxn outputs are disabled (tim_ocx/tim_ocxn enable output signal=0)
1: When inactive, tim_ocx/tim_ocxn outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. tim_ocx/tim_ocxn enable output signal=1)

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIM15_BDTR register).*
42.7.17 TIM15 timer deadtime register 2 (TIM15_DTR2)

Address offset: 0x054
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **DTPE**: Deadtime preload enable
0: Deadtime value is not preloaded
1: Deadtime value preload is enabled

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).*
Bit 16 **DTAE**: Deadtime asymmetric enable
- 0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register
- 1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.

*Note*: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **DTGF[7:0]**: Dead-time falling edge generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.

- \( DTGF[7:5]=0x0 \Rightarrow DTF=DTGF[7:0] \times t_{dtg} = t_{DTS} \)
- \( DTGF[7:5]=10x \Rightarrow DTF=(64+DTGF[5:0]) \times t_{dtg} = 2t_{DTS} \)
- \( DTGF[7:5]=110 \Rightarrow DTF=(32+DTGF[4:0]) \times t_{dtg} = 8t_{DTS} \)
- \( DTGF[7:5]=111 \Rightarrow DTF=(32+DTGF[4:0]) \times t_{dtg} = 16t_{DTS} \)

Example if \( T_{DTS}=125\text{ns} \)(8MHz), dead-time possible values are:
- 0 to 15875 ns by 125 ns steps,
- 16 us to 31750 ns by 250 ns steps,
- 32 us to 63us by 1 us steps,
- 64 us to 126 us by 2 us steps

*Note*: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 **TI2SEL[3:0]**: selects tim_ti2_in[15:0] input
- 0000: TIM15_CH2 input (tim_ti2_in0)
- 0001: tim_ti2_in1
- ...
- 1111: tim_ti2_in15

Refer to Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals for interconnects list.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **TI1SEL[3:0]**: selects tim_ti1_in[15:0] input
- 0000: TIM15_CH1 input (tim_ti1_in0)
- 0001: tim_ti1_in1
- ...
- 1111: tim_ti1_in15

Refer to Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals for interconnects list.
42.7.19 TIM15 alternate function register 1 (TIM15_AF1)

Address offset: 0x060
Reset value: 0x0000 0001

Refer to Section 42.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 BKCMP4P: tim_brk_cmp4 input polarity
This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp4 input is active high
1: tim_brk_cmp4 input is active low
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 12 BKCMP3P: tim_brk_cmp3 input polarity
This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp3 input is active high
1: tim_brk_cmp3 input is active low
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 11 BKCMP2P: tim_brk_cmp2 input polarity
This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp2 input is active high
1: tim_brk_cmp2 input is active low
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 10 BKCMP1P: tim_brk_cmp1 input polarity
This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp1 input is active high
1: tim_brk_cmp1 input is active low
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).
Bit 9 **BKINP**: TIMx_BKIN input polarity

This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: TIMx_BKIN input is active high
1: TIMx_BKIN input is active low

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable

This bit enables the tim_brk_cmp8 for the timer’s tim_brk input. mdf_brkx output is ‘ORed’ with the other tim_brk sources.

0: tim_brk_cmp8 input disabled
1: tim_brk_cmp8 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable

This bit enables the tim_brk_cmp7 for the timer’s tim_brk input. COMP7 output is ‘ORed’ with the other tim_brk sources.

0: tim_brk_cmp7 input disabled
1: tim_brk_cmp7 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable

This bit enables the tim_brk_cmp6 for the timer’s tim_brk input. tim_brk_cmp6 output is ‘ORed’ with the other tim_brk sources.

0: tim_brk_cmp6 input disabled
1: tim_brk_cmp6 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 5 **BKCMP5E**: tim_brk_cmp5 enable

This bit enables the tim_brk_cmp5 for the timer’s tim_brk input. tim_brk_cmp5 output is ‘ORed’ with the other tim_brk sources.

0: tim_brk_cmp5 input disabled
1: tim_brk_cmp5 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 4 **BKCMP4E**: tim_brk_cmp4 enable

This bit enables the tim_brk_cmp4 for the timer’s tim_brk input. tim_brk_cmp4 output is ‘ORed’ with the other tim_brk sources.

0: tim_brk_cmp4 input disabled
1: tim_brk_cmp4 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 3 **BKCMP3E**: tim_brk_cmp3 enable

This bit enables the tim_brk_cmp3 for the timer’s tim_brk input. tim_brk_cmp3 output is ‘ORed’ with the other tim_brk sources.

0: tim_brk_cmp3 input disabled
1: tim_brk_cmp3 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*
42.7.20 TIM15 alternate function register 2 (TIM15_AF2)

</tbody>
</table>

**DBS[3:0]: DMA burst source selection**

This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).

- 0000: Reserved
- 0001: Update
- 0010: CC1
- 0110: COM
- 0111: Trigger
- Other: reserved

**DBL[4:0]: DMA burst length**

This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIM15_DMAR address).

- 00000: 1 transfer,
- 00001: 2 transfers,
- 00010: 3 transfers,
- ...
- 10001: 18 transfers.

**DBA[4:0]: DMA base address**

This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIM15_DMAR address). DBA is defined as an offset starting from the address of the TIM15_CR1 register.

Example:

- 00000: TIM15_CR1,
- 00001: TIM15_CR2,
- 00010: TIM15_SMCR,
- ...
### 42.7.22 TIM15 DMA address for full transfer (TIM15_DMAR)

Address offset: 0x3E0  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Offset</th>
<th>Bits 31:0 DMAR[31:0]: DMA register for burst accesses</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A read or write operation to the DMAR register accesses the register located at the address TIM15_CR1 address + (DBA + DMA index) x 4 where TIM15_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIM15_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIM15_DCR).</td>
</tr>
</tbody>
</table>

### 42.7.23 TIM15 register map

TIM15 registers are mapped as 16-bit addressable registers as described in the table below:

<table>

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 DITHEN: Dithering enable

0: Dithering disabled
1: Dithering enabled

Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 UIFREMAP: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 CKD[1:0]: Clock division

This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters (tim_tix),

00: tDTS = tim_ker_ck
01: tDTS = 2×tim_ker_ck
10: tDTS = 4×tim_ker_ck
11: Reserved

Bit 7 ARPE: Auto-reload preload enable

0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 OPM: One pulse mode

0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 URS: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
1: nly counter overflow/underflow generates an update interrupt or DMA request if enabled.
Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.
- 0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.
- 1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
- 0: Counter disabled
- 1: Counter enabled

*Note:* External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

### 42.8.2 TIMx control register 2 (TIMx_CR2)(x = 16 to 17)

**Address offset:** 0x04

**Reset value:** 0x0000

**Bits 15:10** Reserved, must be kept at reset value.

**Bit 9 OIS1N**: Output Idle state 1 (tim_oc1n output)
- 0: tim_oc1n=0 after a dead-time when MOE=0
- 1: tim_oc1n=1 after a dead-time when MOE=0

*Note:* This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).

**Bit 8 OIS1**: Output Idle state 1 (tim_oc1 output)
- 0: tim_oc1=0 after a dead-time when MOE=0
- 1: tim_oc1=1 after a dead-time when MOE=0

*Note:* This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).

**Bits 7:4** Reserved, must be kept at reset value.

**Bit 3 CCDS**: Capture/compare DMA selection
- 0: CCx DMA request sent when CCx event occurs
- 1: CCx DMA requests sent when update event occurs

**Bit 2 CCUS**: Capture/compare control update selection
- 0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
- 1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when a rising edge occurs on tim_trgi (if available).

*Note:* This bit acts only on channels that have a complementary output.

**Bit 1** Reserved, must be kept at reset value.
Bit 0 **CCPC**: Capture/compare preloaded control
   0: CCxE, CCxNE and OCxM bits are not preloaded
   1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated
      only when COM bit is set.

   *Note: This bit acts only on channels that have a complementary output.*

### 42.8.3 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 16 to 17)

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 CC1OF: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.

0: No overcapture has been detected
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.

Bit 7 BIF: Break interrupt flag
This flag is set by hardware as soon as the tim_brk input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred
1: An active level has been detected on the break input

Bit 6 Reserved, must be kept at reset value.

Bit 5 COMIF: COM interrupt flag
This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.

0: No COM event occurred
1: COM interrupt pending

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 CC1IF: Capture/Compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).

0: No compare match / No input capture occurred
1: A compare match or an input capture occurred

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).
Bit 0  **UIF**: Update interrupt flag
   This bit is set by hardware on an update event. It is cleared by software.
   0: No update occurred.
   1: Update interrupt pending. This bit is set by hardware when the registers are updated:
      - At overflow regarding the repetition counter value (update if repetition counter = 0)
        and if the UDIS=0 in the TIMx_CR1 register.
      - When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if
        URS=0 and UDIS=0 in the TIMx_CR1 register.

### 42.8.5  TIMx event generation register (TIMx_EGR)(x = 16 to 17)

Address offset: 0x14
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

- **Bit 15:8** Reserved, must be kept at reset value.
- **Bit 7** **BG**: Break generation
   This bit is set by software in order to generate an event, it is automatically cleared by
   hardware.
   0: No action.
   1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or
   DMA transfer can occur if enabled.
- **Bit 6** Reserved, must be kept at reset value.
- **Bit 5** **COMG**: Capture/Compare control update generation
   This bit can be set by software, it is automatically cleared by hardware.
   0: No action
   1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits
   
   **Note**: This bit acts only on channels that have a complementary output.
- **Bits 4:2** Reserved, must be kept at reset value.
- **Bit 1** **CC1G**: Capture/Compare 1 generation
   This bit is set by software in order to generate an event, it is automatically cleared by
   hardware.
   0: No action.
   1: A capture/compare event is generated on channel 1:
   - **If channel CC1 is configured as output**:
     CC1IF flag is set. Corresponding interrupt or DMA request is sent if enabled.
   - **If channel CC1 is configured as input**:
     The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set,
     the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the
     CC1IF flag was already high.
- **Bit 0** **UG**: Update generation
   This bit can be set by software, it is automatically cleared by hardware.
   0: No action.
   1: Reinitialize the counter and generates an update of the registers. Note that the prescaler
   counter is cleared too (anyway the prescaler ratio is not affected).
42.8.6  **TIMx capture/compare mode register 1 (TIMx_CCMR1)**  
(x = 16 to 17)

Address offset: 0x18  
Reset value: 0x0000 0000  

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

### Input capture mode

</tbody>
</table>

| Bit 3:2  | **IC1PSC[1:0]**: Input capture 1 prescaler |
|          | This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register). |
|          | 00: no prescaler, capture is done each time an edge is detected on the capture input. |
|          | 01: capture is done once every 2 events |
|          | 10: capture is done once every 4 events |
|          | 11: capture is done once every 8 events |
Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
- Others: Reserved

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).*

**42.8.7 TIMx capture/compare mode register 1 [alternate]**
**(TIMx_CCMR1)(x = 16 to 17)**

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

**Output compare mode:**

- Bits 31:17 Reserved, must be kept at reset value.
- Bits 15:8 Reserved, must be kept at reset value.
- Bit 7 **OC1CE**: Output Compare 1 clear enable
  - 0: tim_oc1ref is not affected by the tim_ocref_clr input.
  - 1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr input.
Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal `tim_oc1ref` from which `tim_oc1` and `tim_oc1n` are derived. `tim_oc1ref` is active high whereas `tim_oc1` and `tim_oc1n` active level depends on `CC1P` and `CC1NP` bits.

- **0000**: Frozen - The comparison between the output compare register `TIMx_CCR1` and the counter `TIMx_CNT` has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.
- **0001**: Set channel 1 to active level on match. `tim_oc1ref` signal is forced high when the counter `TIMx_CNT` matches the capture/compare register 1 (`TIMx_CCR1`).
- **0010**: Set channel 1 to inactive level on match. `tim_oc1ref` signal is forced low when the counter `TIMx_CNT` matches the capture/compare register 1 (`TIMx_CCR1`).
- **0011**: Toggle - `tim_oc1ref` toggles when `TIMx_CNT=TIMx_CCR1`.
- **0100**: Force inactive level - `tim_oc1ref` is forced low.
- **0101**: Force active level - `tim_oc1ref` is forced high.
- **0110**: PWM mode 1 - Channel 1 is active as long as `TIMx_CNT<TIMx_CCR1` else inactive.
- **0111**: PWM mode 2 - Channel 1 is inactive as long as `TIMx_CNT<TIMx_CCR1` else active.
- Others: Reserved

**Note**: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in `TIMx_BDTR` register) and `CC1S='00'` (the channel is configured in output).

In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

Bit 3 **OC1PE**: Output Compare 1 preload enable

- **0**: Preload register on `TIMx_CCR1` disabled. `TIMx_CCR1` can be written at anytime, the new value is taken in account immediately.
- **1**: Preload register on `TIMx_CCR1` enabled. Read/Write operations access the preload register. `TIMx_CCR1` preload value is loaded in the active register at each update event.

**Note**: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in `TIMx_BDTR` register) and `CC1S='00'` (the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in `TIMx_CR1` register), to have the output pulse starting as soon as possible after the starting trigger.

- **0**: `CC1` behaves normally depending on counter and `CCR1` values even when the trigger is ON. The minimum delay to activate `CC1` output when an edge occurs on the trigger input is 5 clock cycles.
- **1**: An active edge on the trigger input acts like a compare match on `CC1` output. Then, `tim_ocx` is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate `CC1` output is reduced to 3 clock cycles.

**OC1FE** acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: `CC1` channel is configured as output
- **01**: `CC1` channel is configured as input, `tim_ic1` is mapped on `tim_t1`
- Others: Reserved

**Note**: `CC1S` bits are writable only when the channel is OFF (`CC1E = ‘0’` in `TIMx_CCER`).
42.8.8 TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17)

Address offset: 0x20
Reset value: 0x0000

</tbody>
</table>

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity
- CC1 channel configured as output:
  - 0: tim_oc1n active high
  - 1: tim_oc1n active low
- CC1 channel configured as input:
  This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1. Refer to the description of CC1P.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (the channel is configured in output).
On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a commutation event is generated.*
General purpose timers (TIM15/TIM16/TIM17)

Bit 2  **CC1NE**: Capture/Compare 1 complementary output enable
0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1  **CC1P**: Capture/Compare 1 output polarity
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

*When CC1 channel is configured as input*, both CC1NP/CC1P bits select the active polarity of T11FP1 and T12FP1 for trigger or capture operations.

- CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to T1xFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is not inverted (trigger operation in gated mode).
- CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to T1xFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is inverted (trigger operation in gated mode).
- CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both T1xFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is not inverted (trigger operation in gated mode).
- CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

*Note*: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0  **CC1E**: Capture/Compare 1 output enable
0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

*When CC1 channel is configured as output*, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to *Table 447* for details.

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OIS1, OIS1N, CC1P and CC1NP bits must be kept cleared.

**Note:** The state of the external I/O pins connected to the complementary tim_oc1 and tim_oc1n channels depends on the tim_oc1 and tim_oc1n channel state and GPIO control and alternate function selection registers.

Bit 31 **UIFCPY: UIF Copy**
This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in TIMx_CR1 is reset, bit 31 is reserved.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]: Counter value**

- **Non-dithering mode (DITHEN = 0)**
  - The register holds the counter value.
- **Dithering mode (DITHEN = 1)**
  - The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

42.8.10 TIMx prescaler (TIMx_PSC)(x = 16 to 17)

</tbody>
</table>

Bits 15:0 **PSC[15:0]: Prescaler value**

The counter clock frequency (tim_cnt_ck) is equal to f_{tim_psc_ck} / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).
42.8.11  TIMx auto-reload register (TIMx_ARR)(x = 16 to 17)

Address offset: 0x2C  
Reset value: 0x0000 FFFF

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-20</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>19-0</td>
<td>ARR[19:0]: Auto-reload value</td>
</tr>
</tbody>
</table>

ARR is the value to be loaded in the actual auto-reload register. Refer to the Section 42.4.3: Time-base unit on page 1776 for more details about ARR update and behavior. The counter is blocked while the auto-reload value is null.

Non-dithering mode (DITHEN = 0)  
The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.

Dithering mode (DITHEN = 1)  
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

42.8.12  TIMx repetition counter register (TIMx_RCR)(x = 16 to 17)

Address offset: 0x30  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-8</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>7-0</td>
<td>REP[7:0]: Repetition counter reload value</td>
</tr>
</tbody>
</table>

This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enabled. It also defines the update interrupt generation rate, if this interrupt is enabled. When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIMx_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode:

- the number of PWM periods in edge-aligned mode
- the number of half PWM period in center-aligned mode
### 42.8.13 TIMx capture/compare register 1 (TIMx_CCR1)(x = 16 to 17)

</tbody>
</table>

Bits 31:20  Reserved, must be kept at reset value.  
Bits 19:0  CCR1[19:0]: Capture/Compare 1 value

**If channel CC1 is configured as output:**
- CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
- It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
- The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

**Non-dithering mode (DITHEN = 0)**
- The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**
- The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

**If channel CC1 is configured as input:**
- CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1).

**Non-dithering mode (DITHEN = 0)**
- The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**
- The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.
42.8.14 TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17)

Address offset: 0x44
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |   |   |   |   |   |   |   |   |   |
| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |   |   |   |   |   |   |   |   |   |

Note: As the BKBID, BKDSRM, BKF[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **BKBID**: Break Bidirectional
0: Break input tim_brk in input mode
1: Break input tim_brk in bidirectional mode

In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **BKDSRM**: Break Disarm
0: Break input tim_brk is armed
1: Break input tim_brk is disarmed

This bit is cleared by hardware when no break source is active. The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bits 25:20  Reserved, must be kept at reset value.

Bits 19:16  **BKF[3:0]**: Break filter
This bit-field defines the frequency used to sample tim_brk input and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:
- 0000: No filter, tim_brk acts asynchronously
- 0001: $f_{SAMPLING} = f_{tim.ker_ck}$, N=2
- 0010: $f_{SAMPLING} = f_{tim.ker_ck}$, N=4
- 0011: $f_{SAMPLING} = f_{tim.ker_ck}$, N=8
- 0100: $f_{SAMPLING} = f_{DTS}/2$, N=6
- 0101: $f_{SAMPLING} = f_{DTS}/2$, N=8
- 0110: $f_{SAMPLING} = f_{DTS}/4$, N=6
- 0111: $f_{SAMPLING} = f_{DTS}/4$, N=8
- 1000: $f_{SAMPLING} = f_{DTS}/8$, N=6
- 1001: $f_{SAMPLING} = f_{DTS}/8$, N=8
- 1010: $f_{SAMPLING} = f_{DTS}/16$, N=5
- 1011: $f_{SAMPLING} = f_{DTS}/16$, N=6
- 1100: $f_{SAMPLING} = f_{DTS}/32$, N=5
- 1101: $f_{SAMPLING} = f_{DTS}/32$, N=6
- 1110: $f_{SAMPLING} = f_{DTS}/32$, N=8
- 1111: $f_{SAMPLING} = f_{DTS}/32$, N=8

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 15  **MOE**: Main output enable
This bit is cleared asynchronously by hardware as soon as the tim_brk input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.
- 0: tim_oc1 and tim_oc1n outputs are disabled or forced to idle state depending on the OSSI bit.
- 1: tim_oc1 and tim_oc1n outputs are enabled if their respective enable bits are set (CC1E, CC1NE in TIMx_CCER register)

See tim_oc1/tim_oc1n enable description for more details ([Section 42.8.8: TIMx capture/compare enable register (TIMx_CCER) (x = 16 to 17) on page 1857](#)).

Bit 14  **AOE**: Automatic output enable
- 0: MOE can be set only by software
- 1: MOE can be set by software or automatically at the next update event (if the tim_brk input is not active)

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13  **BKP**: Break polarity
- 0: Break input tim_brk is active low
- 1: Break input tim_brk is active high

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12  **BKE**: Break enable
- 0: Break inputs (tim_brk and tim_sys_brk event) disabled
- 1: Break inputs (tim_brk and tim_sys_brk event) enabled

**Note:** This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See tim_oc1/tim_oc1n enable description for more details (Section 42.8.8: TIMx capture/compare enable register (TIMx_CCER) (x = 16 to 17) on page 1857).

0: When inactive, tim_oc1/tim_oc1n outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)

1: When inactive, tim_oc1/tim_oc1n outputs are enabled with their inactive level as soon as CC1E=1 or CC1NE=1 (the output is still controlled by the timer).

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See tim_oc1/tim_oc1n enable description for more details (Section 42.8.8: TIMx capture/compare enable register (TIMx_CCER) (x = 16 to 17) on page 1857).

0: When inactive, tim_oc1/tim_oc1n outputs are disabled (tim_oc1/tim_oc1n enable output signal=0)

1: When inactive, tim_oc1/tim_oc1n outputs are forced first with their idle level as soon as CC1E=1 or CC1NE=1. tim_oc1/tim_oc1n enable output signal=1)

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected

01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKBID/BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.*

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

\[ DTG[7:5]=0xx \Rightarrow DT=DTG[7:0] \times t_{\text{dts}} \text{ with } t_{\text{dts}}=t_{\text{DTS}} \]

\[ DTG[7:5]=10x \Rightarrow DT=(64+DTG[5:0]) \times t_{\text{dts}} \text{ with } T_{\text{dts}}=2x_{\text{DTS}} \]

\[ DTG[7:5]=110 \Rightarrow DT=(32+DTG[4:0]) \times t_{\text{dts}} \text{ with } T_{\text{dts}}=8x_{\text{DTS}} \]

\[ DTG[7:5]=111 \Rightarrow DT=(32+DTG[4:0]) \times t_{\text{dts}} \text{ with } T_{\text{dts}}=16x_{\text{DTS}} \]

Example if T_{\text{DTS}}=125ns (8MHz), dead-time possible values are:

- 0 to 15875 ns by 125 ns steps,
- 16 µs to 31750 ns by 250 ns steps,
- 32 µs to 63 µs by 1 µs steps,
- 64 µs to 126 µs by 2 µs steps

*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*
### 42.8.15 TIMx timer deadtime register 2 (TIMx_DTR2)(x = 16 to 17)

Bits 31:18  Reserved, must be kept at reset value.

**Bit 17 DTPE**: Deadtime preload enable
- 0: Deadtime value is not preloaded
- 1: Deadtime value preload is enabled

*Note*: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

**Bit 16 DTAE**: Deadtime asymmetric enable
- 0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register
- 1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.

*Note*: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 15:8  Reserved, must be kept at reset value.

**Bits 7:0 DTGF[7:0]**: Dead-time falling edge generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.

- \( \text{DTGF}[7:5]=0xx \rightarrow \text{DTF} = \text{DTGF}[7:0] \times t_{\text{dtg}} = t_{\text{DTS}} \)
- \( \text{DTGF}[7:5]=10x \rightarrow \text{DTF} = (64+\text{DTGF}[5:0]) \times t_{\text{dtg}} = 2x t_{\text{DTS}} \)
- \( \text{DTGF}[7:5]=110 \rightarrow \text{DTF} = (32+\text{DTGF}[4:0]) \times t_{\text{dtg}} = 8x t_{\text{DTS}} \)
- \( \text{DTGF}[7:5]=111 \rightarrow \text{DTF} = (32+\text{DTGF}[4:0]) \times t_{\text{dtg}} = 16x t_{\text{DTS}} \)

Example if \( T_{\text{DTS}}=125\text{ns} \) (8MHz), dead-time possible values are:
- 0 to 15875 ns by 125 ns steps,
- 16 us to 31750 ns by 250 ns steps,
- 32 us to 63us by 1 us steps,
- 64 us to 126 us by 2 us steps

*Note*: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 31:14  Reserved, must be kept at reset value.

Bit 13  **BKCMP4P**: tim_brk_cmp4 input polarity

This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: tim_brk_cmp4 input is active high
- 1: tim_brk_cmp4 input is active low

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 12 **BKCMP3P**: tim_brk_cmp3 input polarity
This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the
BKP polarity bit.
0: tim_brk_cmp3 input is active high
1: tim_brk_cmp3 input is active low

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 11 **BKCMP2P**: tim_brk_cmp2 input polarity
This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the
BKP polarity bit.
0: tim_brk_cmp2 input is active high
1: tim_brk_cmp2 input is active low

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **BKCMP1P**: tim_brk_cmp1 input polarity
This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the
BKP polarity bit.
0: tim_brk_cmp1 input is active high
1: tim_brk_cmp1 input is active low

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9 **BKINP**: TIMx_BKIN input polarity
This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed
together with the BKP polarity bit.
0: TIMx_BKIN input is active high
1: TIMx_BKIN input is active low

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable
This bit enables the tim_brk_cmp8 for the timer’s tim_brk input. mdf_brkx output is 'ORed'
with the other tim_brk sources.
0: tim_brk_cmp8 input disabled
1: tim_brk_cmp8 input enabled

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable
This bit enables the tim_brk_cmp7 for the timer’s tim_brk input. tim_brk_cmp7 output is
'ORed' with the other tim_brk sources.
0: tim_brk_cmp7 input disabled
1: tim_brk_cmp7 input enabled

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable
This bit enables the tim_brk_cmp6 for the timer’s tim_brk input. tim_brk_cmp6 output is
'ORed' with the other tim_brk sources.
0: tim_brk_cmp6 input disabled
1: tim_brk_cmp6 input enabled

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 5 **BKCMP5E**: tim\_brk\_cmp5 enable

This bit enables the tim\_brk\_cmp5 for the timer’s tim\_brk input. tim\_brk\_cmp5 output is ‘OREd’ with the other tim\_brk sources.

- 0: tim\_brk\_cmp5 input disabled
- 1: tim\_brk\_cmp5 input enabled

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 4 **BKCMP4E**: tim\_brk\_cmp4 enable

This bit enables the tim\_brk\_cmp4 for the timer’s tim\_brk input. tim\_brk\_cmp4 output is ‘OREd’ with the other tim\_brk sources.

- 0: tim\_brk\_cmp4 input disabled
- 1: tim\_brk\_cmp4 input enabled

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 3 **BKCMP3E**: tim\_brk\_cmp3 enable

This bit enables the tim\_brk\_cmp3 for the timer’s tim\_brk input. tim\_brk\_cmp3 output is ‘OREd’ with the other tim\_brk sources.

- 0: tim\_brk\_cmp3 input disabled
- 1: tim\_brk\_cmp3 input enabled

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 2 **BKCMP2E**: tim\_brk\_cmp2 enable

This bit enables the tim\_brk\_cmp2 for the timer’s tim\_brk input. tim\_brk\_cmp2 output is ‘OREd’ with the other tim\_brk sources.

- 0: tim\_brk\_cmp2 input disabled
- 1: tim\_brk\_cmp2 input enabled

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 1 **BKCMP1E**: tim\_brk\_cmp1 enable

This bit enables the tim\_brk\_cmp1 for the timer’s tim\_brk input. tim\_brk\_cmp1 output is ‘OREd’ with the other tim\_brk sources.

- 0: tim\_brk\_cmp1 input disabled
- 1: tim\_brk\_cmp1 input enabled

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 0 **BKINE**: TIMx\_BKIN input enable

This bit enables the TIMx\_BKIN alternate function input for the timer’s tim\_brk input. TIMx\_BKIN input is ‘OREd’ with the other tim\_brk sources.

- 0: TIMx\_BKIN input disabled
- 1: TIMx\_BKIN input enabled

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).
### 42.8.18 TIMx alternate function register 2 (TIMx_AF2)(x = 16 to 17)

<th>Address Offset</th>
<th>Format</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x03DC</td>
<td></td>
<td>DBA[4:0]</td>
<td></td>
</tr>
</tbody>
</table>
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:16  **DBSS[3:0]: DMA burst source selection**
This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).
- 0000: Reserved
- 0001: Update
- 0010: CC1
- Other: reserved

Bits 15:13  Reserved, must be kept at reset value.

Bits 12:8  **DBL[4:0]: DMA burst length**
This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).
- 00000: 1 transfer,
- 00001: 2 transfers,
- 00010: 3 transfers,
- ... 10001: 18 transfers.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **DBA[4:0]: DMA base address**
This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

**Example:**
- 00000: TIMx_CR1,
- 00001: TIMx_CR2,
- 00010: TIMx_SMCR,
- ...

**Example:** Let us consider the following transfer: DBL = 7 transfers and DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.

### 42.8.20 TIM16/TIM17 DMA address for full transfer
(TIMx_DMAR) (x = 16 to 17)

Address offset: 0x3E0

Reset value: 0x0000 0000
Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address

\[(\text{TIM}x\_\text{CR1 address}) + (\text{DBA} + \text{DMA index}) \times 4\]

where TIM\_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIM\_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIM\_DCR).
### 42.8.21 TIM16/TIM17 register map

TIM16/TIM17 registers are mapped as 16-bit addressable registers as described in the table below:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Register name</th>

43 Low-power timer (LPTIM)

43.1 Introduction

The LPTIM is a 16-bit timer that benefits from the ultimate developments in power consumption reduction. Thanks to its diversity of clock sources, the LPTIM is able to keep running in all power modes except for Standby mode. Given its capability to run even with no internal clock source, the LPTIM can be used as a “Pulse Counter” which can be useful in some applications. Also, the LPTIM capability to wake up the system from low-power modes, makes it suitable to realize “Timeout functions” with extremely low power consumption.

The LPTIM introduces a flexible clock scheme that provides the needed functionalities and performance, while minimizing the power consumption.

43.2 LPTIM main features

- 16 bit upcounter
- 3-bit prescaler with 8 possible dividing factors (1,2,4,8,16,32,64,128)
- Selectable clock
  - Internal clock sources: configurable internal clock source (see RCC section)
  - External clock source over LPTIM input (working with no LP oscillator running, used by Pulse Counter application)
- 16 bit ARR autoreload register
- 16 bit capture/compare register
- Continuous/One-shot mode
- Selectable software/hardware input trigger
- Programmable Digital Glitch filter
- Configurable output: Pulse, PWM
- Configurable I/O polarity
- Encoder mode
- Repetition counter
- Up to 2 independent channels for:
  - Input capture
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on 10 events
- DMA request generation on the following events:
  - Update event
  - Input capture
43.3 LPTIM implementation

*Table 449* describes LPTIM implementation on STM32H563/H573 and STM32H562 devices. The full set of features is implemented in LPTIM1, 2, 3, 5 and 6. LPTIM4 supports a smaller set of features.

43.4.4 LPTIM reset and clocks

The LPTIM can be clocked using several clock sources. It can be clocked using an internal clock signal which can be any configurable internal clock source selectable through the RCC (see RCC section for more details). Also, the LPTIM can be clocked using an external clock signal injected on its external Input1. When clocked with an external clock source, the LPTIM may run in one of these two possible configurations:

- The first configuration is when the LPTIM is clocked by an external signal but in the same time an internal clock signal is provided to the LPTIM from configurable internal clock source (see RCC section).
- The second configuration is when the LPTIM is solely clocked by an external clock source through its external Input1. This configuration is the one used to realize Timeout function or Pulse counter function when all the embedded oscillators are turned off after entering a low-power mode.

Programming the CKSEL and COUNTMODE bits allows controlling whether the LPTIM uses an external clock source or an internal one.

When configured to use an external clock source, the CKPOL bits are used to select the external clock signal active edge. If both edges are configured to be active ones, an internal clock signal must also be provided (first configuration). In this case, the internal clock signal frequency must be at least four times higher than the external clock signal frequency.
43.4.5 **Glitch filter**

The LPTIM inputs, either external (mapped to GPIOs) or internal (mapped on the chip-level to other embedded peripherals), are protected with digital filters that prevent any glitches and noise perturbations to propagate inside the LPTIM. This is in order to prevent spurious counts or triggers.

Before activating the digital filters, an internal clock source must first be provided to the LPTIM. This is necessary to guarantee the proper operation of the filters.

The digital filters are divided into three groups:

- The first group of digital filters protects the LPTIM internal or external inputs. The digital filters sensitivity is controlled by the CKFLT bits.
- The second group of digital filters protects the LPTIM internal or external trigger inputs. The digital filters sensitivity is controlled by the TRGFLT bits.
- The third group of digital filters protects the LPTIM internal or external input captures. The digital filters sensitivity is controlled by the ICxF bits.

*Note:* The digital filters sensitivity is controlled by groups. It is not possible to configure each digital filter sensitivity separately inside the same group.

The filter sensitivity acts on the number of consecutive equal samples that is detected on one of the LPTIM inputs to consider a signal level change as a valid transition. **Figure 597** shows an example of glitch filter behavior in case of a 2 consecutive samples programmed.

![Glitch filter timing diagram](MS32490V1)

*Note:* In case no internal clock signal is provided, the digital filter must be deactivated by setting the CKFLT, ICxF and TRGFLT bits to ‘0’. In that case, an external analog filter may be used to protect the LPTIM external inputs against glitches.

43.4.6 **Prescaler**

The LPTIM 16-bit counter is preceded by a configurable power-of-2 prescaler. The prescaler division ratio is controlled by the PRESC[2:0] 3-bit field. The table below lists all the possible division ratios:

<table>
<thead>
<tr>
<th>programming</th>
<th>dividing factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>/1</td>
</tr>
<tr>
<td>001</td>
<td>/2</td>
</tr>
</tbody>
</table>

*Table 461. Prescaler division ratios*
43.4.7 Trigger multiplexer

The LPTIM counter may be started either by software or after the detection of an active edge on one of the 8 trigger inputs.

TRIGEN[1:0] is used to determine the LPTIM trigger source:

- When TRIGEN[1:0] equals ‘00’, The LPTIM counter is started as soon as one of the CNTSTRT or the SNGSTRT bits is set by software. The three remaining possible values for the TRIGEN[1:0] are used to configure the active edge used by the trigger inputs. The LPTIM counter starts as soon as an active edge is detected.
- When TRIGEN[1:0] is different than ‘00’, TRIGSEL[2:0] is used to select which of the 8 trigger inputs is used to start the counter.

The external triggers are considered asynchronous signals for the LPTIM. So after a trigger detection, a two-counter-clock period latency is needed before the timer starts running due to the synchronization.

If a new trigger event occurs when the timer is already started it is ignored (unless timeout function is enabled).

**Note:** The timer must be enabled before setting the SNGSTRT/CNTSTRT bits. Any write on these bits when the timer is disabled is discarded by hardware.

**Note:** When starting the counter by software (TRIGEN[1:0] = 00), there is a delay of 3 kernel clock cycles between the LPTIM_CR register update (set one of SNGSTRT or CNTSTRT bits) and the effective start of the counter.

43.4.8 Operating mode

The LPTIM features two operating modes:

- **The Continuous mode:** the timer is free running, the timer is started from a trigger event and never stops until the timer is disabled
- **One-shot mode:** the timer is started from a trigger event and stops when an LPTIM update event is generated.

**One-shot mode**

To enable the one-shot counting, the SNGSTRT bit must be set.

A new trigger event re-starts the timer. Any trigger event occurring after the counter starts and before the next LPTIM update event, is discarded.
In case an external trigger is selected, each external trigger event arriving after the SNGSTRT bit is set, and after the repetition counter has stopped (after the update event), and if the repetition register content is different from zero, the repetition counter gets reloaded with the value already contained by the repetition register and a new one-shot counting cycle is started as shown in Figure 598.

**Figure 598. LPTIM output waveform, single counting mode configuration when repetition register content is different than zero (with PRELOAD = 1)**

- Set-once mode activated:

Note that when the WAVE bitfield in the LPTIM_CFRG register is set, the Set-once mode is activated. In this case, the counter is only started once following the first trigger, and any subsequent trigger event is discarded as shown in Figure 599.

**Figure 599. LPTIM output waveform, Single counting mode configuration and Set-once mode activated (WAVE bit is set)**

In case of software start (TRIGEN[1:0] = ‘00’), the SNGSTRT setting starts the counter for one-shot counting.

**Continuous mode**

To enable the continuous counting, the CNTSTRT bit must be set.
In case an external trigger is selected, an external trigger event arriving after CNTSTRT is set, starts the counter for continuous counting. Any subsequent external trigger event is discarded as shown in Figure 600.

In case of software start (TRIGEN[1:0] = ‘00’), setting CNTSTRT starts the counter for continuous counting.

**Figure 600. LPTIM output waveform, Continuous counting mode configuration**

SNGSTRT and CNTSTRT bits can only be set when the timer is enabled (The ENABLE bit is set to ‘1’). It is possible to change “on the fly” from One-shot mode to Continuous mode.

If the Continuous mode was previously selected, setting SNGSTRT switches the LPTIM to the One-shot mode. The counter (if active) stops as soon as an LPTIM update event is generated.

If the One-shot mode was previously selected, setting CNTSTRT switches the LPTIM to the Continuous mode. The counter (if active) restarts as soon as it reaches ARR.

### 43.4.9 Timeout function

The detection of an active edge on one selected trigger input can be used to reset the LPTIM counter. This feature is controlled through the TIMOUT bit.

The first trigger event starts the timer, any successive trigger event resets the LPTIM counter and the repetition counter and the timer restarts.

A low-power timeout function can be realized. The timeout value corresponds to the compare value; if no trigger occurs within the expected time frame, the MCU is waked-up by the compare match event.

### 43.4.10 Waveform generation

Two 16-bit registers, the LPTIM_ARR (autoreload register) and LPTIM_CCRx (capture/compare register), are used to generate several different waveforms on LPTIM output.

The timer can generate the following waveforms:

- The PWM mode: the LPTIM output is set as soon as the counter value in LPTIM_CNT exceeds the compare value in LPTIM_CCRx. The LPTIM output is reset as soon as a
match occurs between the LPTIM_ARR and the LPTIM_CNT register. For more details see Section 43.4.19: PWM mode.

- The One-pulse mode: the output waveform is similar to the one of the PWM mode for the first pulse, then the output is permanently reset
- The Set-once mode: the output waveform is similar to the One-pulse mode except that the output is kept to the last signal level (depends on the output configured polarity).

The above described modes require that the LPTIM_ARR register value be strictly greater than the LPTIM_CCRx register value.

The LPTIM output waveform can be configured through the WAVE bit as follow:

- Resetting the WAVE bit to ‘0’ forces the LPTIM to generate either a PWM waveform or a One pulse waveform depending on which bit is set: CNTSTRT or SNGSTRT.
- Setting the WAVE bit to ‘1’ forces the LPTIM to generate a Set-once mode waveform.

The WAVPOL/CCxP bit controls the LPTIM output polarity. The change takes effect immediately, so the output default value changes immediately after the polarity is reconfigured, even before the timer is enabled.

Signals with frequencies up to the LPTIM clock frequency divided by 2 can be generated. Figure 601 below shows the three possible waveforms that can be generated on the LPTIM output. Also, it shows the effect of the polarity change using the WAVPOL/CCxP bit.

**Figure 601. Waveform generation**
43.4.11 Register update

The LPTIM_ARR register, the LPTIM_RCR register and the LPTIM_CCRx register are updated immediately after the APB bus write operation or in synchronization with the next LPTIM update event if the timer is already started.

The PRELOAD bit controls how the LPTIM_ARR, the LPTIM_RCR and the LPTIM_CCRx registers are updated:

- When the PRELOAD bit is reset to ‘0’, the LPTIM_ARR, the LPTIM_RCR and the LPTIM_CCRx registers are immediately updated after any write access.
- When the PRELOAD bit is set to ‘1’, the LPTIM_ARR, the LPTIM_RCR and the LPTIM_CCRx registers are updated at next LPTIM update event, if the timer has been already started.

The LPTIM APB interface and the LPTIM kernel logic use different clocks, so there is some latency between the APB write and the moment when these values are available to the counter comparator. Within this latency period, any additional write into these registers must be avoided.

The ARROK flag, the REPOK flag and the CMPxOK flag in the LPTIM_ISR register indicate when the write operation is completed to respectively the LPTIM_ARR register, the LPTIM_RCR register and the LPTIM_CCRx register.

After a write to the LPTIM_ARR, the LPTIM_RCR or the LPTIM_CCRx register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before respectively the ARROK flag, the REPOK flag or the CMPxOK flag be set, leads to unpredictable results.

43.4.12 Counter mode

The LPTIM counter can be used to count external events on the LPTIM Input1 or it can be used to count internal clock cycles. The CKSEL and COUNTMODE bits control which source is used for updating the counter.

In case the LPTIM is configured to count external events on Input1, the counter can be updated following a rising edge, falling edge or both edges depending on the value written to the CKPOL[1:0] bits.

The count modes below can be selected, depending on CKSEL and COUNTMODE values:

- CKSEL = 0: the LPTIM is clocked by an internal clock source
  - COUNTMODE = 0
    The LPTIM is configured to be clocked by an internal clock source and the LPTIM counter is configured to be updated following each internal clock pulse.
  - COUNTMODE = 1
    The LPTIM external Input1 is sampled with the internal clock provided to the LPTIM.
    Consequently, in order not to miss any event, the frequency of the changes on the external Input1 signal must never exceed the frequency of the internal clock.
provided to the LPTIM. Also, the internal clock provided to the LPTIM must not be prescaled (PRES[2:0] = 000).

- CKSEL = 1: the LPTIM is clocked by an external clock source
  COUNTMODE value is don’t care.
  In this configuration, the LPTIM has no need for an internal clock source (except if the glitch filters are enabled). The signal injected on the LPTIM external Input1 is used as system clock for the LPTIM. This configuration is suitable for operation modes where no embedded oscillator is enabled.
  For this configuration, the LPTIM counter can be updated either on rising edges or falling edges of the input1 clock signal but not on both rising and falling edges.
  Since the signal injected on the LPTIM external Input1 is also used to clock the LPTIM kernel logic, there is some initial latency (after the LPTIM is enabled) before the counter is incremented. More precisely, the first five active edges on the LPTIM external Input1 (after LPTIM is enable) are lost.

43.4.13 Timer enable

The ENABLE bit located in the LPTIM_CR register is used to enable/disable the LPTIM kernel logic. After setting the ENABLE bit, a delay of two counter clock is needed before the LPTIM is actually enabled.

The LPTIM_CFGR register must be modified only when the LPTIM is disabled.

43.4.14 Timer counter reset

In order to reset the content of LPTIM_CNT register to zero, two reset mechanisms are implemented:

- The synchronous reset mechanism: the synchronous reset is controlled by the COUNTRST bit in the LPTIM_CR register. After setting the COUNTRST bitfield to ‘1’, the reset signal is propagated in the LPTIM kernel clock domain. So it is important to note that a few clock pulses of the LPTIM kernel logic elapse before the reset is taken into account. This makes the LPTIM counter count few extra pluses between the time when the reset is trigger and it become effective. Since the COUNTRST bit is located in the APB clock domain and the LPTIM counter is located in the LPTIM kernel clock domain, a delay of 3 clock cycles of the kernel clock is needed to synchronize the reset signal issued by the APB clock domain when writing ‘1’ to the COUNTRST bit.

- The asynchronous reset mechanism: the asynchronous reset is controlled by the RSTARE bit located in the LPTIM_CR register. When this bit is set to ‘1’, any read access to the LPTIM_CNT register resets its content to zero. Asynchronous reset must be triggered within a timeframe in which no LPTIM core clock is provided. For example when LPTIM Input1 is used as external clock source, the asynchronous reset must be applied only when there is enough insurance that no toggle occurs on the LPTIM Input1.
  Note that to read reliably the content of the LPTIM_CNT register two successive read accesses must be performed and compared. A read access can be considered reliable when the value of the two read accesses is equal. Unfortunately when asynchronous reset is enabled there is no possibility to read twice the LPTIM_CNT register.

Warning: There is no mechanism inside the LPTIM that prevents the two reset mechanisms from being used simultaneously. So
43.4.15 Encoder mode

This mode allows handling signals from quadrature encoders used to detect angular position of rotary elements. Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value programmed into the LPTIM_ARR register (0 up to ARR or ARR down to 0 depending on the direction). Therefore LPTIM_ARR must be configured before starting the counter. From the two external input signals, Input1 and Input2, a clock signal is generated to clock the LPTIM counter. The phase between those two signals determines the counting direction.

The Encoder mode is only available when the LPTIM is clocked by an internal clock source. The signals frequency on both Input1 and Input2 inputs must not exceed the LPTIM internal clock frequency divided by 4. This is mandatory in order to guarantee a proper operation of the LPTIM.

Direction change is signalized by the two Down and Up flags in the LPTIM_ISR register. Also, an interrupt can be generated for both direction change events if enabled through the DOWNIE bit.

To activate the Encoder mode the ENC bit has to be set to ‘1’. The LPTIM must first be configured in Continuous mode.

When Encoder mode is active, the LPTIM counter is modified automatically following the speed and the direction of the incremental encoder. Therefore, its content always represents the encoder’s position. The count direction, signaled by the Up and Down flags, correspond to the rotation direction of the encoder rotor.

According to the edge sensitivity configured using the CKPOL[1:0] bits, different counting scenarios are possible. The following table summarizes the possible combinations, assuming that Input1 and Input2 do not switch at the same time.

<table>
<thead>
<tr>
<th>Active edge</th>
<th>Level on opposite signal (Input1 for Input2, Input2 for Input1)</th>
<th>Input1 signal</th>
<th>Input2 signal</th>
</tr>
</thead>
<tbody>
<tr>

<td>Down</td>
</tr>
</tbody>
</table>

The following figure shows a counting sequence for Encoder mode where both-edge sensitivity is configured.
Caution: In this mode the LPTIM must be clocked by an internal clock source, so the CKSEL bit must be maintained to its reset value which is equal to ‘0’. Also, the prescaler division ratio must be equal to its reset value which is 1 (PRESC[2:0] bits must be ‘000’).

Figure 602. Encoder mode counting sequence

43.4.16 Repetition Counter

The LPTIM features a repetition counter that decrements by 1 each time an LPTIM counter overflow event occurs. A repetition counter underflow event is generated when the repetition counter contains zero and the LPTIM counter overflows. Next to each repetition counter underflow event, the repetition counter gets loaded with the content of the REP[7:0] bitfield which belongs to the repetition register LPTIM_RCR.

A repetition underflow event is generated on each and every LPTIM counter overflow when the REP[7:0] register is set to 0.

When PRELOAD = 1, writing to the REP[7:0] bitfield has no effect on the content of the repetition counter until the next repetition underflow event occurs. The repetition counter continues to decrement each LPTIM counter overflow event and only when a repetition underflow event is generated, the new value written into REP[7:0] is loaded into the repetition counter. This behavior is depicted in Figure 603.
A repetition counter underflow event is systematically associated with LPTIM preloaded registers update (refer to section "Register update" for more information).

Repetition counter underflow event is signaled to the software through the update event (UE) flag mapped into the LPTIM_ISR register. When set, the UE flag can trigger an LPTIM interrupt if its respective update event interrupt enable (UEIE) control bit, mapped to the LPTIM_DIER register, is set.

The repetition register LPTIM_RCR is located in the APB bus interface clock domain where the repetition counter itself is located in the LPTIM kernel clock domain. Each time a new value is written to the LPTIM_RCR register, that new content is propagated from the APB bus interface clock domain to the LPTIM kernel clock domain so that the new written value is loaded to the repetition counter immediately after a repetition counter underflow event. The synchronization delay for the new written content is four APB clock cycles plus three LPTIM kernel clock cycles and it is signaled by the REPOK flag located in the LPTIM_ISR register when it is elapsed. When the LPTIM kernel clock cycle is relatively slow, for instance when the LPTIM kernel is being clocked by the LSI clock source, it can be lengthy to keep polling on the REPOK flag by software to detect that the synchronization of the LPTIM_RCR register content is finished. For that reason, the REPOK flag, when set, can generate an interrupt if its associated REPOKIE control bit in the LPTIM_DIER register is set.

**Note:** After a write to the LPTIM_RCR register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the REPOK flag is set, leads to unpredictable results.

**Caution:** When using repetition counter with PRELOAD = 0, LPTIM_RCR register must be changed at least five counter cycles before the autoreload match event, otherwise an unpredictable behavior may occur.
43.4.17 Capture/compare channels

Each capture/compare channel is built around a capture/compare register, an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control) for PWM.

**Input stage**

The input stage samples the corresponding LPTIx input to generate a filtered signal LPTIxF. Then, an edge detector with polarity selection generates ICx signal used as the capture command. It is prescaled to generate the capture command signal (ICxPS).

**Output stage**

The output stage generates an intermediate waveform which is then used for reference: OCxREF (active high). The polarity acts at the end of the chain.

43.4.18 Input capture mode

In Input capture mode, the capture/compare registers (LPTIM_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. Assuming input capture is enabled on a channel x (CCxE set) and when a capture occurs, the corresponding CCxIF flag (LPTIM_ISR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (LPTIM_ISR register) is set. CCxIF can be cleared by software by writing the CCxICF to 1 or by reading the captured data stored in the LPTIM_CCRx register. CCxOF is cleared by writing CCxOCF to 1.

*Note:* In DMA mode, the input capture channel have to be enabled (set CCxE bit) the last, after enabling the IC DMA request and after starting the counter. This is in order to prevent generating an input capture DMA request when the counter is not started yet.

**Input capture Glitch filter latency**

When a trigger event arrives on channel x input (LPTIx) and depending on the configured glitch filter (ICxF[1:0] field in CCMRx register) and on the kernel clock prescaler value...
(PRESCH[2:0] field in CFGR register), there is a variable latency that leads to a systematic offset (see Table 463) between the captured value stored in the CCRx register and the real value corresponding to the capture trigger.

This offset has no impact on pulse width measurement as it is systematic and compensated between two captures.

The real capture value corresponding to the input capture trigger can be calculated using the below formula:

Real capture value = captured(LPTIM_CCRx) - offset

The relevant offset must be used depending on the glitch filter and on the kernel clock prescaler value (PRESCH field in CFGR register)

**Example:** determining the real capture value when PRESCH[2:0] = 0x2 and ICxF = 0x3.

For this configuration (PRESCH[2:0] = 0x2 and ICxF = 0x3) and according to the Table 463, the offset is 5.

Assuming that the captured value in CCRx is 9 (LPTIM_CNT = 9), this means that the capture trigger occurred when the LPTIM_CNT was equal to 9 - 5 = 4.

43.4.19 PWM mode

The PWM mode enables to generate a signal with a frequency determined by the value of the LPTIM_ARR register and a duty cycle determined by the value of the LPTIM_CCRx register. The LPTIM is able to generate PWM in edge-aligned mode.

OCx polarity is software programmable using the CCxP bit in the LPTIM_CCMRx register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the LPTIM_CCMRx register. Refer to the LPTIM_CCMRx register description for more details.

*Figure 606* gives an example where the LPTIM channel 1 is configured in PWM mode with LPTIM_CCR1 = 6 then 1 and LPTIM_ARR=10.

**PWM mode with immediate update PRELOAD = 0**

The PWM mode with PRELOAD = 0 enables the early change of the output level within the current PWM cycle. Based on the immediate update (PRELOAD = 0) of the LPTIM.CCRx register and on the continuous comparison of LPTIM.CNT and LPTIM.CCRx registers, it permits to have a new duty cycle value applied as soon as possible within the current PWM cycle, without having to wait for the completion of the current PWM period.

When the (PRELOAD = 0), the OCxREF signal level can be changed on-the-fly by software (or DMA) by updating the compare value in the LPTIM.CCRx register.

Depending on the written compare value and on the current counter and compare values, the OCxREF level is re-assigned as illustrated below:

- If the new compare value does not exceed the current counter value and the current compare value exceeds the counter, OCxREF level is re-assigned high as soon as the new compare value is written.
- If the new compare value exceeds the counter value and the current compare value does not exceed the counter, OCxREF level is re-assigned low as soon as the new compare value is written.

The output reference signal OCxREF level is left unchanged when none of the new compare value and the current compare value exceed the counter. Figure 608 illustrates the behavior of the OCxREF signal level when PRELOAD = 0 and PRELOAD = 1.
Note: For both PWM modes, the compare match, auto-reload match and the update event flags are set one LPTIM counter cycle later after the corresponding event, the OCxREF level is also changed one LPTIM counter cycle later after the corresponding event. For instance when the LPTIM_CCRx is set to 3 the CCxIF is set when the LPTIM_CNT = 4. Figure 606 illustrates this behavior.

43.4.20 DMA requests

The LPTIM has the capability to generate two categories of DMA requests:
- DMA requests used to retrieve the input-capture counter values
- DMA update requests are used to re-program part of the LPTIMER, multiple times, at regular intervals, without software overhead.

Input capture DMA request

Each LPTIM channel has its dedicated input capture DMA request. A DMA request is generated (if CCxDE bit is set in LPTIM_DIER) and CCxIF is set each time a capture is ready in the CCRx register. The captured values in CCRx can then be transferred regularly by DMA to the desired memory destination. The CCxIF is automatically cleared by hardware when the captured value in CCRx register is read.

Note: The ICx DMA request signal lptim_icx_dma is reset in the following conditions:
- if the corresponding DMA request is disabled (clear CCxDE bit in the LPTIM_DIER register)
- or if the channel x is disabled (clear CCxE bit)
- or if the LPTIM is disabled (clear the ENABLE bit in the LPTIM_CR register)

Update event DMA request

A DMA request is generated (if UEDE is set in LPTIM_DIER) and the UE flag is set at each update event. DMA request can be used to regularly update the LPTIM_ARR, the LPTIM_RCR or the LPTIM_CCRx registers permitting to generate custom PWM waveforms.
The UE is automatically cleared by hardware upon any bus master (like CPU or DMA) write access to the LPTIM_ARR register.

Note: The UE DMA request signal lptim_ue_dma is reset in the following conditions:
- if the corresponding DMA request is disabled (clear UEDE bit in the LPTIM DIER register)
- or if the LPTIM is disabled (clear the ENABLE bit in the LPTIM_CR register)

43.4.21 Debug mode

When the microcontroller enters debug mode (core halted), the LPTIM counter either continues to work normally or stops, depending on the DBG_LPTIM_STOP configuration bit in the DBG module.

43.5 LPTIM low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. LPTIM interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>If the LPTIM is clocked by an oscillator available in Stop mode, LPTIM is functional and the interrupts cause the device to exit the Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The LPTIM peripheral is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

Note: All DMA requests must be disabled (reset UEDE and CCxDE bits) before entering Sleep, Stop and Standby modes.

43.6 LPTIM interrupts

The following events generate an interrupt/wake-up event, if they are enabled through the LPTIM_DIER register:
- Compare match
- Auto-reload match (whatever the direction if encoder mode)
- External trigger event
- Autoreload register write completed
- Compare register write completed
- Direction change (encoder mode), programmable (up / down / both).
- Update Event
- Repetition register update OK
- Input capture occurred
- Over-capture occurred
- Interrupt enable register update OK

Note: If any bit in the LPTIM_DIER register is set after that its corresponding flag in the LPTIM_ISR register (Status Register) is set, the interrupt is not asserted.

1. Each LPTIM event can wake up the device from Stop mode only if the LPTIM instance supports the wake-up from Stop mode feature. Refer to Section 43.3: LPTIM implementation.

2. If LPTIM does not implement any channel this event does not exist. Refer to Section 43.3: LPTIM implementation.

3. If LPTIM does not support encoder mode feature, this event does not exist. Refer to Section 43.3: LPTIM implementation.

### 43.7 LPTIM registers

Refer to Section 1.2: List of abbreviations for registers on page 101 for a list of abbreviations used in register descriptions.

The peripheral registers can only be accessed by words (32-bit).
### 43.7.1 LPTIM4 interrupt and status register (LPTIM4_ISR)

Address offset: 0x000  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:25</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 24   | **DIEROK**: Interrupt enable register update OK  
  DIEROK is set by hardware to inform application that the APB bus write operation to the LPTIM_DIER register has been successfully completed. DIEROK flag can be cleared by writing 1 to the DIEROKCF bit in the LPTIM_ICR register. |
| Bit 23:9 | Reserved, must be kept at reset value. |
| Bit 8    | **REPOK**: Repetition register update OK  
  REPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_RCR register has been successfully completed. REPOK flag can be cleared by writing 1 to the REPOKCF bit in the LPTIM_ICR register. |
| Bit 7    | **UE**: LPTIM update event occurred  
  UE is set by hardware to inform application that an update event was generated. UE flag can be cleared by writing 1 to the UECF bit in the LPTIM_ICR register. |
| Bit 6    | **DOWN**: Counter direction change up to down  
  In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.  
  **Note**: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3: LPTIM implementation. |
| Bit 5    | **UP**: Counter direction change down to up  
  In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.  
  **Note**: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3: LPTIM implementation. |
| Bit 4    | **ARROK**: Autoreload register update OK  
  ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register. |
| Bit 3    | **CMP1OK**: Compare register 1 update OK  
  CMP1OK is set by hardware to inform application that the APB bus write operation to the LPTIM_CCR1 register has been successfully completed. CMP1OK flag can be cleared by writing 1 to the CMP1OKCF bit in the LPTIM_ICR register.
Bit 2 **EXTTRIG**: External trigger edge event

EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

Bit 1 **ARRM**: Autoreload match

ARRM is set by hardware to inform application that LPTIM_CNT register’s value reached the LPTIM_ARR register’s value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

Bit 0 **CC1IF**: Compare 1 interrupt flag

The CC1IF flag is set by hardware to inform application that LPTIM_CNT register value matches the compare register’s value. The CC1IF flag can be cleared by writing 1 to the CC1CF bit in the LPTIM_ICR register.

0: No match
1: The content of the counter LPTIM_CNT register value has matched the LPTIM_CCR1 register’s value

### 43.7.2 LPTIMx interrupt and status register [alternate] (LPTIMx_ISR)  
(x = 1 to 3, 5, 6)

This description of the register can only be used for output compare mode. See next section for input capture mode.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROK**: Interrupt enable register update OK

DIEROK is set by hardware to inform application that the APB bus write operation to the LPTIM_DIER register has been successfully completed. DIEROK flag can be cleared by writing 1 to the DIEROKCF bit in the LPTIM_ICR register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 Reserved, must be kept at reset value.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CMP2OK**: Compare register 2 update OK

CMP2OK is set by hardware to inform application that the APB bus write operation to the LPTIM_CCR2 register has been successfully completed. CMP2OK flag can be cleared by writing 1 to the CMP2OKCF bit in the LPTIM_ICR register.

**Note:** If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bits 18:12 Reserved, must be kept at reset value.

Bits 9:0 Reserved, must be kept at reset value.
Bit 11  Reserved, must be kept at reset value.

Bit 10  Reserved, must be kept at reset value.

Bit 9  **CC2IF**: Compare 2 interrupt flag

  **If channel CC2 is configured as output:**
  
  The CC2IF flag is set by hardware to inform application that LPTIM_CNT register value matches the compare register's value. CC2IF flag can be cleared by writing 1 to the CC2CF bit in the LPTIM_ICR register.

  0: No match
  
  1: The content of the counter LPTIM_CNT register value has matched the LPTIM_CCR2 register's value

  *Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.*

Bit 8  **REPOK**: Repetition register update OK

  REPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_RCR register has been successfully completed. REPOK flag can be cleared by writing 1 to the REPOKCF bit in the LPTIM_ICR register.

Bit 7  **UE**: LPTIM update event occurred

  UE is set by hardware to inform application that an update event was generated. The corresponding interrupt or DMA request is generated if enabled. UE flag can be cleared by writing 1 to the UECF bit in the LPTIM_ICR register. The UE flag is automatically cleared by hardware once the LPTIM_ARR register is written by any bus master like CPU or DMA.

Bit 6  **DOWN**: Counter direction change up to down

  In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.

  *Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.*

Bit 5  **UP**: Counter direction change down to up

  In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.

  *Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.*

Bit 4  **ARROK**: Autoreload register update OK

  ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

Bit 3  **CMP1OK**: Compare register 1 update OK

  CMP1OK is set by hardware to inform application that the APB bus write operation to the LPTIM_CCR1 register has been successfully completed. CMP1OK flag can be cleared by writing 1 to the CMP1OKCF bit in the LPTIM_ICR register.
Bit 2 **EXTTRIG**: External trigger edge event

EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

Bit 1 **ARRM**: Autoreload match

ARRM is set by hardware to inform application that LPTIM_CNT register’s value reached the LPTIM_ARR register’s value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

Bit 0 **CC1IF**: Compare 1 interrupt flag

If channel CC1 is configured as output:

The CC1IF flag is set by hardware to inform application that LPTIM_CNT register value matches the compare register’s value. CC1IF flag can be cleared by writing 1 to the CC1CF bit in the LPTIM_ICR register.

0: No match
1: The content of the counter LPTIM_CNT register value has matched the LPTIM_CCR1 register’s value

### 43.7.3 LPTIMx interrupt and status register [alternate] (LPTIMx_ISR) 
(x = 1 to 3, 5, 6)

This description of the register can only be used for input capture mode. See previous section for output compare mode.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROK**: Interrupt enable register update OK

DIEROK is set by hardware to inform application that the APB bus write operation to the LPTIM_DIER register has been successfully completed. DIEROK flag can be cleared by writing 1 to the DIEROKCF bit in the LPTIM_ICR register.

Bits 23:16 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC2OF**: Capture 2 over-capture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing 1 to the CC2OCF bit in the LPTIM_ICR register.

0: No over-capture has been detected.
1: The counter value has been captured in LPTIM_CCR2 register while CC2IF flag was already set.

*Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.*
Bit 12 **CC1OF**: Capture 1 over-capture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing 1 to the CC1OCF bit in the LPTIM_ICR register.
0: No over-capture has been detected.
1: The counter value has been captured in LPTIM_CCR1 register while CC1IF flag was already set.
*Note*: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC2IF**: Capture 2 interrupt flag
If channel CC2 is configured as input:
CC2IF is set by hardware to inform application that the current value of the counter is captured in LPTIM_CCR2 register. The corresponding interrupt or DMA request is generated if enabled. The CC2OF flag is set if the CC2IF flag was already high.
0: No input capture occurred
1: The counter value has been captured in the LPTIM_CCR2 register. (An edge has been detected on IC2 which matches the selected polarity). The CC2IF flag is automatically cleared by hardware once the captured value is read (CPU or DMA). The CC2IF flag can be cleared by writing 1 to the CC2CF bit in the LPTIM_ICR register.
*Note*: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bit 8 **REPOK**: Repetition register update OK
REPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_RCR register has been successfully completed. REPOK flag can be cleared by writing 1 to the REPOKCF bit in the LPTIM_ICR register.

Bit 7 **UE**: LPTIM update event occurred
UE is set by hardware to inform application that an update event was generated. UE flag can be cleared by writing 1 to the UECF bit in the LPTIM_ICR register.

Bit 6 **DOWN**: Counter direction change up to down
In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.
*Note*: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 5 **UP**: Counter direction change down to up
In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.
*Note*: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 4 **ARROK**: Autoreload register update OK
ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

Bit 3 Reserved, must be kept at reset value.
Bit 2 **EXTTRIG**: External trigger edge event
EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

Bit 1 **ARRM**: Autoreload match
ARRM is set by hardware to inform application that LPTIM_CNT register’s value reached the LPTIM_ARR register’s value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

Bit 0 **CC1IF**: capture 1 interrupt flag
If channel CC1 is configured as input:
CC1IF is set by hardware to inform application that the current value of the counter is captured in LPTIM_CCR1 register. The corresponding interrupt or DMA request is generated if enabled. The CC1OF flag is set if the CC1IF flag was already high.
0: No input capture occurred
1: The counter value has been captured in the LPTIM_CCR1 register. (An edge has been detected on IC1 which matches the selected polarity). The CC1IF flag is automatically cleared by hardware once the captured value is read (CPU or DMA). CC1IF flag can be cleared by writing 1 to the CC1CF bit in the LPTIM_ICR register.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIEROKCF**: Interrupt enable register update OK clear flag
Writing 1 to this bit clears the DIEROK flag in the LPTIM_ISR register.

Bits 23:9 Reserved, must be kept at reset value.

Bit 8 **REPOKCF**: Repetition register update OK clear flag
Writing 1 to this bit clears the REPOK flag in the LPTIM_ISR register.

Bit 7 **UECF**: Update event clear flag
Writing 1 to this bit clear the UE flag in the LPTIM_ISR register.

Bit 6 **DOWNCF**: Direction change to down clear flag
Writing 1 to this bit clear the DOWN flag in the LPTIM_ISR register.

Note: *If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.*

Bit 5 **UPCF**: Direction change to UP clear flag
Writing 1 to this bit clear the UP flag in the LPTIM_ISR register.

Note: *If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.*
Bit 4 ARROKCF: Autoreload register update OK clear flag
  Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register.

Bit 3 CMP1OKCF: Compare register 1 update OK clear flag
  Writing 1 to this bit clears the CMP1OK flag in the LPTIM_ISR register.

Bit 2 EXTTRIGCF: External trigger valid edge clear flag
  Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register.

Bit 1 ARRMCFCF: Autoreload match clear flag
  Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register.

Bit 0 CC1CF: Capture/compare 1 clear flag
  Writing 1 to this bit clears the CC1IF flag in the LPTIM_ISR register.

43.7.5 LPTIMx interrupt clear register [alternate] (LPTIMx_ICR)
(x = 1 to 3, 5, 6)

This description of the register can only be used for output compare mode. See next section for input capture compare mode.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 DIEROKCF: Interrupt enable register update OK clear flag
  Writing 1 to this bit clears the DIEROK flag in the LPTIM_ISR register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 Reserved, must be kept at reset value.

Bit 20 Reserved, must be kept at reset value.

Bit 19 CMP2OKCF: Compare register 2 update OK clear flag
  Writing 1 to this bit clears the CMP2OK flag in the LPTIM_ISR register.
  Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

Bits 18:12 Reserved, must be kept at reset value.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 CC2CF: Capture/compare 2 clear flag
  Writing 1 to this bit clears the CC2IF flag in the LPTIM_ISR register.
  Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.
**Low-power timer (LPTIM)**

Bit 8 **REPOKCF**: Repetition register update OK clear flag
Writing 1 to this bit clears the REPOK flag in the LPTIM_ISR register.

Bit 7 **UECF**: Update event clear flag
Writing 1 to this bit clears the UE flag in the LPTIM_ISR register.

Bit 6 **DOWNCF**: Direction change to down clear flag
Writing 1 to this bit clears the DOWN flag in the LPTIM_ISR register.
*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.*

Bit 5 **UPCF**: Direction change to UP clear flag
Writing 1 to this bit clears the UP flag in the LPTIM_ISR register.
*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.*

Bit 4 **ARROKCF**: Autoreload register update OK clear flag
Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register.

Bit 3 **CMP1OKCF**: Compare register 1 update OK clear flag
Writing 1 to this bit clears the CMP1OK flag in the LPTIM_ISR register.

Bit 2 **EXTTRIGCF**: External trigger valid edge clear flag
Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register.

Bit 1 **ARRMCF**: Autoreload match clear flag
Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register.

Bit 0 **CC1CF**: Capture/compare 1 clear flag
Writing 1 to this bit clears the CC1IF flag in the LPTIM_ISR register.

### 43.7.6 LPTIMx interrupt clear register [alternate] (LPTIMx_ICR)

(x = 1 to 3, 5, 6)

This description of the register can only be used for input capture mode. See previous section for output compare mode.

**Bits 31:25**  Reserved, must be kept at reset value.

**Bit 24** **DIEROKCF**: Interrupt enable register update OK clear flag
Writing 1 to this bit clears the DIEROK flag in the LPTIM_ISR register.

**Bits 23:16**  Reserved, must be kept at reset value.

**Bit 15**  Reserved, must be kept at reset value.

**Bit 14**  Reserved, must be kept at reset value.
### LPTIM4 interrupt enable register (LPTIM4_DIER)

### Bit Definitions

**Bit 13**  **CC2OCF**: Capture/compare 2 over-capture clear flag
- Writing 1 to this bit clears the CC2OF flag in the LPTIM_ISR register.
  - Note: If the LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

**Bit 12**  **CC1OCF**: Capture/compare 1 over-capture clear flag
- Writing 1 to this bit clears the CC1OF flag in the LPTIM_ISR register.
  - Note: If the LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.

**Bit 11**  Reserved, must be kept at reset value.

**Bit 10**  Reserved, must be kept at reset value.

**Bit 9**  **CC2CF**: Capture/compare 2 clear flag
- Writing 1 to this bit clears the CC2IF flag in the LPTIM_ISR register.
  - Note: If the LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.

**Bit 8**  **REPOKCF**: Repetition register update OK clear flag
- Writing 1 to this bit clears the REPOK flag in the LPTIM_ISR register.

**Bit 7**  **UECF**: Update event clear flag
- Writing 1 to this bit clears the UE flag in the LPTIM_ISR register.

**Bit 6**  **DOWNCF**: Direction change to down clear flag
- Writing 1 to this bit clears the DOWN flag in the LPTIM_ISR register.
  - Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

**Bit 5**  **UPCF**: Direction change to UP clear flag
- Writing 1 to this bit clears the UP flag in the LPTIM_ISR register.
  - Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

**Bit 4**  **ARROKCF**: Autoreload register update OK clear flag
- Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register.

**Bit 3**  Reserved, must be kept at reset value.

**Bit 2**  **EXTTRIGCF**: External trigger valid edge clear flag
- Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register.

**Bit 1**  **ARRMCF**: Autoreload match clear flag
- Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register.

**Bit 0**  **CC1CF**: Capture/compare 1 clear flag
- Writing 1 to this bit clears the CC1IF flag in the LPTIM_ISR register.
  - Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.
Caution: The LPTIMx_DIER register must only be modified when the LPTIM is enabled (ENABLE bit set to 1). After a write to the LPTIMx_DIER register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the DIEROK flag is set, leads to unpredictable results.
### 43.7.8 LPTIMx interrupt enable register [alternate] (LPTIMx_DIER)  
(x = 1 to 3, 5, 6)

This description of the register can only be used for output compare mode. See next section for input capture compare mode.

Address offset: 0x008  
Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

- **Bit 23** UEDE: Update event DMA request enable  
  0: UE DMA request disabled. Writing ‘0’ to the UEDE bit resets the associated ue_dma_req signal.  
  1: UE DMA request enabled  
  *Note: If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.*

- **Bit 22** Reserved, must be kept at reset value.

- **Bit 21** Reserved, must be kept at reset value.

- **Bit 20** Reserved, must be kept at reset value.

- **Bit 19** CMP2OKIE: Compare register 2 update OK interrupt enable  
  0: CMPOK register 2 interrupt disabled  
  1: CMPOK register 2 interrupt enabled  
  *Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.*

Bits 18:12 Reserved, must be kept at reset value.

- **Bit 11** Reserved, must be kept at reset value.

- **Bit 10** Reserved, must be kept at reset value.

- **Bit 9** CC2IE: Capture/compare 2 interrupt enable  
  0: Capture/compare 2 interrupt disabled  
  1: Capture/compare 2 interrupt enabled  
  *Note: If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.*

- **Bit 8** REPOKIE: Repetition register update OK interrupt Enable  
  0: Repetition register update OK interrupt disabled  
  1: Repetition register update OK interrupt enabled

- **Bit 7** UEIE: Update event interrupt enable  
  0: Update event interrupt disabled  
  1: Update event interrupt enabled
Bit 6 **DOWNIE**: Direction change to down Interrupt Enable
   0: DOWN interrupt disabled
   1: DOWN interrupt enabled

   *Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.*

Bit 5 **UPIE**: Direction change to UP Interrupt Enable
   0: UP interrupt disabled
   1: UP interrupt enabled

   *Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.*

Bit 4 **ARROKIE**: Autoreload register update OK Interrupt Enable
   0: ARROK interrupt disabled
   1: ARROK interrupt enabled

Bit 3 **CMP1OKIE**: Compare register 1 update OK interrupt enable
   0: CMPOK register 1 interrupt disabled
   1: CMPOK register 1 interrupt enabled

Bit 2 **EXTRTRIGIE**: External trigger valid edge Interrupt Enable
   0: EXTRTRIG interrupt disabled
   1: EXTRTRIG interrupt enabled

Bit 1 **ARRMIE**: Autoreload match Interrupt Enable
   0: ARRM interrupt disabled
   1: ARRM interrupt enabled

Bit 0 **CC1IE**: Capture/compare 1 interrupt enable
   0: Capture/compare 1 interrupt disabled
   1: Capture/compare 1 interrupt enabled

**Caution:** The LPTIMx_DIER register must only be modified when the LPTIM is enabled (ENABLE bit set to 1). After a write to the LPTIMx_DIER register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the DIEROK flag is set, leads to unpredictable results.

### 43.7.9 LPTIMx interrupt enable register [alternate] (LPTIMx_DIER) (x = 1 to 3, 5, 6)

This description of the register can only be used for input capture mode. See previous section for output compare mode.

Bits 31:28  Reserved, must be kept at reset value.
Bit 27  Reserved, must be kept at reset value.
Bit 26  Reserved, must be kept at reset value.
Bit 25  **CC2DE**: Capture/compare 2 DMA request enable
- 0: CC2 DMA request disabled. Writing '0' to the CC2DE bit resets the associated ic2 dma_req signal.
- 1: CC2 DMA request enabled
  
  **Note:** *If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.*

Bit 24  Reserved, must be kept at reset value.
Bit 23  **UEDE**: Update event DMA request enable
- 0: UE DMA request disabled. Writing '0' to the UEDE bit resets the associated ue_dma_req signal.
- 1: UE DMA request enabled
  
  **Note:** *If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.*

Bits 22:17  Reserved, must be kept at reset value.
Bit 16  **CC1DE**: Capture/compare 1 DMA request enable
- 0: CC1 DMA request disabled. Writing '0' to the CC1DE bit resets the associated ic1_dma_req signal.
- 1: CC1 DMA request enabled
  
  **Note:** *If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.*

Bit 15  Reserved, must be kept at reset value.
Bit 14  Reserved, must be kept at reset value.
Bit 13  **CC2OIE**: Capture/compare 2 over-capture interrupt enable
- 0: CC2 over-capture interrupt disabled
- 1: CC2 over-capture interrupt enabled
  
  **Note:** *If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.*

Bit 12  **CC1OIE**: Capture/compare 1 over-capture interrupt enable
- 0: CC1 over-capture interrupt disabled
- 1: CC1 over-capture interrupt enabled
  
  **Note:** *If LPTIM does not implement at least 1 channel this bit is reserved. Refer to Section 43.3.*

Bit 11  Reserved, must be kept at reset value.
Bit 10  Reserved, must be kept at reset value.
Bit 9  **CC2IE**: Capture/compare 2 interrupt enable
- 0: Capture/compare 2 interrupt disabled
- 1: Capture/compare 2 interrupt enabled
  
  **Note:** *If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3.*

Bit 8  **REPOKIE**: Repetition register update OK interrupt Enable
- 0: Repetition register update OK interrupt disabled
- 1: Repetition register update OK interrupt enabled

Bit 7  **UEIE**: Update event interrupt enable
- 0: Update event interrupt disabled
- 1: Update event interrupt enabled
Bit 6 **DOWNIE**: Direction change to down Interrupt Enable
0: DOWN interrupt disabled
1: DOWN interrupt enabled

*Note*: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 5 **UPIE**: Direction change to UP Interrupt Enable
0: UP interrupt disabled
1: UP interrupt enabled

*Note*: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.

Bit 4 **ARROKIE**: Autoreload register update OK Interrupt Enable
0: ARROK interrupt disabled
1: ARROK interrupt enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **EXTTRIGIE**: External trigger valid edge Interrupt Enable
0: EXTTRIG interrupt disabled
1: EXTTRIG interrupt enabled

Bit 1 **ARRMIE**: Autoreload match Interrupt Enable
0: ARRM interrupt disabled
1: ARRM interrupt enabled

Bit 0 **CC1IE**: Capture/compare 1 interrupt enable
0: Capture/compare 1 interrupt disabled
1: Capture/compare 1 interrupt enabled

**Caution**: The LPTIMx_DIER register must only be modified when the LPTIM is enabled (ENABLE bit set to 1). After a write to the LPTIMx_DIER register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before the DIEROK flag is set, leads to unpredictable results.

</tbody>
</table>

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 Reserved, must be kept at reset value.

Bits 28:25 Reserved, must be kept at reset value.
Bit 24 **ENC**: Encoder mode enable
The ENC bit controls the Encoder mode
0: Encoder mode disabled
1: Encoder mode enabled

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3.*

Bit 23 **COUNTMODE**: counter mode enabled
The COUNTMODE bit selects which clock source is used by the LPTIM to clock the counter:
0: the counter is incremented following each internal clock pulse
1: the counter is incremented following each valid clock pulse on the LPTIM external Input1

Bit 22 **PRELOAD**: Registers update mode
The PRELOAD bit controls the LPTIM_ARR, LPTIM_RCR and the LPTIM_CCRx registers update modality
0: Registers are updated after each APB bus write access
1: Registers are updated at the end of the current LPTIM period

Bit 21 **WAVPOL**: Waveform shape polarity
The WAVPOL bit controls the output polarity
0: The LPTIM output reflects the compare results between LPTIM_CNT and LPTIM_CCRx registers
1: The LPTIM output reflects the inverse of the compare results between LPTIM_CNT and LPTIM_CCRx registers

*Note: If the LPTIM implements at least one capture/compare channel, this bit is reserved. Refer to Section 43.3.*

Bit 20 **WAVE**: Waveform shape
The WAVE bit controls the output shape
0: Deactivate Set-once mode
1: Activate the Set-once mode

Bit 19 **TIMOUT**: Timeout enable
The TIMOUT bit controls the Timeout feature
0: A trigger event arriving when the timer is already started is ignored
1: A trigger event arriving when the timer is already started resets and restarts the LPTIM counter and the repetition counter

Bits 18:17 **TRIGEN[1:0]**: Trigger enable and polarity
The TRIGEN bits controls whether the LPTIM counter is started by an external trigger or not. If the external trigger option is selected, three configurations are possible for the trigger active edge:
00: software trigger (counting start is initiated by software)
01: rising edge is the active edge
10: falling edge is the active edge
11: both edges are active edges

Bit 16 Reserved, must be kept at reset value.
Bits 15:13 **TRIGSEL[2:0]:** Trigger selector
The TRIGSEL bits select the trigger source that serves as a trigger event for the LPTIM among the below 8 available sources:
000: lptim_ext_trig0
001: lptim_ext_trig1
010: lptim_ext_trig2
011: lptim_ext_trig3
100: lptim_ext_trig4
101: lptim_ext_trig5
110: lptim_ext_trig6
111: lptim_ext_trig7
See [Section 43.4.3: LPTIM input and trigger mapping](#) for details.

Bit 12 Reserved, must be kept at reset value.

Bits 11:9 **PRESC[2:0]:** Clock prescaler
The PRESC bits configure the prescaler division factor. It can be one among the following division factors:
000: /1
001: /2
010: /4
011: /8
100: /16
101: /32
110: /64
111: /128

Bit 8 Reserved, must be kept at reset value.

Bits 7:6 **TRGFLT[1:0]:** Configurable digital filter for trigger
The TRGFLT value sets the number of consecutive equal samples that are detected when a level change occurs on an internal trigger before it is considered as a valid level transition. An internal clock source must be present to use this feature
00: any trigger active level change is considered as a valid trigger
01: trigger active level change must be stable for at least 2 clock periods before it is considered as valid trigger.
10: trigger active level change must be stable for at least 4 clock periods before it is considered as valid trigger.
11: trigger active level change must be stable for at least 8 clock periods before it is considered as valid trigger.

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **CKFLT[1:0]:** Configurable digital filter for external clock
The CKFLT value sets the number of consecutive equal samples that are detected when a level change occurs on an external clock signal before it is considered as a valid level transition. An internal clock source must be present to use this feature
00: any external clock signal level change is considered as a valid transition
01: external clock signal level change must be stable for at least 2 clock periods before it is considered as valid transition.
10: external clock signal level change must be stable for at least 4 clock periods before it is considered as valid transition.
11: external clock signal level change must be stable for at least 8 clock periods before it is considered as valid transition.
43.7.11 LPTIM control register (LPTIM_CR)

Address offset: 0x010
Reset value: 0x0000 0000

<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 RSTARE: Reset after read enable
This bit is set and cleared by software. When RSTARE is set to ‘1’, any read access to LPTIM_CNT register asynchronously resets LPTIM_CNT register content.
This bit can be set only when the LPTIM is enabled.

Bit 3 COUNTRST: Counter reset
This bit is set by software and cleared by hardware. When set to ‘1’ this bit triggers a synchronous reset of the LPTIM_CNT counter register. Due to the synchronous nature of this reset, it only takes place after a synchronization delay of 3 LPTimer core clock cycles (LPTimer core clock may be different from APB clock).
This bit can be set only when the LPTIM is enabled. It is automatically reset by hardware.

Caution: COUNTRST must never be set to ‘1’ by software before it is already cleared to ‘0’ by hardware. Software must consequently check that COUNTRST bit is already cleared to ‘0’ before attempting to set it to ‘1’.
Bit 2  CNTSTRT: Timer start in Continuous mode  
This bit is set by software and cleared by hardware.  
In case of software start (TRIGEN[1:0] = ‘00’), setting this bit starts the LPTIM in Continuous mode.  
If the software start is disabled (TRIGEN[1:0] different than ‘00’), setting this bit starts the timer in Continuous mode as soon as an external trigger is detected.  
If this bit is set when a single pulse mode counting is ongoing, then the timer does not stop at the next match between the LPTIM.ARR and LPTIM.CNT registers and the LPTIM counter keeps counting in Continuous mode.  
This bit can be set only when the LPTIM is enabled. It is automatically reset by hardware.

Bit 1  SNGSTRT: LPTIM start in Single mode  
This bit is set by software and cleared by hardware.  
In case of software start (TRIGEN[1:0] = ‘00’), setting this bit starts the LPTIM in single pulse mode.  
If the software start is disabled (TRIGEN[1:0] different than ‘00’), setting this bit starts the LPTIM in single pulse mode as soon as an external trigger is detected.  
If this bit is set when the LPTIM is in continuous counting mode, then the LPTIM stops at the following match between LPTIM.ARR and LPTIM.CNT registers.  
This bit can only be set when the LPTIM is enabled. It is automatically reset by hardware.

Bit 0  ENABLE: LPTIM enable  
The ENABLE bit is set and cleared by software.  
0: LPTIM is disabled. Writing ‘0’ to the ENABLE bit resets all the DMA request signals (input capture and update event DMA requests).  
1: LPTIM is enabled

43.7.12  LPTIM compare register 1 (LPTIM_CCR1)

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  CCR1[15:0]: Capture/compare 1 value  
If channel CC1 is configured as output:  
CCR1 is the value to be loaded in the capture/compare 1 register.  
Depending on the PRELOAD option, the CCR1 register is immediately updated if the PRELOAD bit is reset and updated at next LPTIM update event if PREOD bit is reset.  
The capture/compare register 1 contains the value to be compared to the counter LPTIM_CNT and signaled on OC1 output.  
If channel CC1 is configured as input:  
CCR1 becomes read-only, it contains the counter value transferred by the last input capture 1 event.  
The LPTIM_CCR1 register is read-only and cannot be programmed.  
If LPTIM does not implement any channel:  
The compare register 1 contains the value to be compared to the counter LPTIM_CNT and signaled on LPTIM output.
Caution: The LPTIM_CCR1 register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).

ARR[15:0]: Auto reload value

Bits 15:0

Bits 31:16 Reserved, must be kept at reset value.

Caution: The LPTIM_ARR register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).

43.7.14 LPTIM counter register (LPTIM.CNT)

Address offset: 0x01C
Reset value: 0x0000 0000

CNT[15:0]: Counter value

Bits 15:0

Bits 31:16 Reserved, must be kept at reset value.

Caution: When the LPTIM is running with an asynchronous clock, reading the LPTIM_CNT register may return unreliable values. So in this case it is necessary to perform two consecutive read accesses and verify that the two returned values are identical.
### 43.7.15 LPTIM configuration register 2 (LPTIM\_CFGR2)

Address offset: 0x024  
Reset value: 0x0000 0000

| Bit 31:22 | Address offset: 0x024  
Reset value: 0x0000 0000 |

</tr>
</tbody>
</table>

Bits 31:8 Reserved, must be kept at reset value.  
Bits 7:0 **REP[7:0]**: Repetition register value  
REP is the repetition value for the LPTIM.

**Caution:** The LPTIM_RCR register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’). When using repetition counter with PRELOAD = 0, LPTIM_RCR register must be changed at least five counter cycles before the auto reload match event, otherwise an unpredictable behavior may occur.

### 43.7.17 LPTIM capture/compare mode register 1 (LPTIM_CCMR1)

Address offset: 0x02C  
Reset value: 0x0000 0000

The channels can be used in input (capture mode) or in output (PWM mode). The direction of a channel is defined by configuring the corresponding CCxSEL bits.

</tbody>
</table>
Bits 31:30  Reserved, must be kept at reset value.

Bits 29:28  **IC2F[1:0]: Input capture 2 filter**
This bitfield defines the number of consecutive equal samples that are detected when a level change occurs on an external input capture signal before it is considered as a valid level transition. An internal clock source must be present to use this feature.

- 00: any external input capture signal level change is considered as a valid transition
- 01: external input capture signal level change must be stable for at least 2 clock periods before it is considered as valid transition.
- 10: external input capture signal level change must be stable for at least 4 clock periods before it is considered as valid transition.
- 11: external input capture signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 27:26  Reserved, must be kept at reset value.

Bits 25:24  **IC2PSC[1:0]: Input capture 2 prescaler**
This bitfield defines the ratio of the prescaler acting on the CC2 input (IC2).

- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 23:20  Reserved, must be kept at reset value.

Bits 19:18  **CC2P[1:0]: Capture/compare 2 output polarity.**
Condition: CC2 as output
Only bit2 is used to set polarity when output mode is enabled, bit3 is don't care.
- 0: OC2 active high
- 1: OC2 active low

Condition: CC2 as input
This field is used to select the IC2 polarity for capture operations.
- 00: rising edge, circuit is sensitive to IC2 rising edge
- 01: falling edge, circuit is sensitive to IC2 falling edge
- 10: reserved, do not use this configuration.
- 11: both edges, circuit is sensitive to both IC2 rising and falling edges.

Bit 17  **CC2E**: Capture/compare 2 output enable.
Condition: CC2 as output
- 0: Off - OC2 is not active. Writing '0' to the CC2E bit resets the uc_dma_req signal only if all the other LPTIM channels are disabled.
- 1: On - OC2 signal is output on the corresponding output pin

Condition: CC2 as input
This bit determines if a capture of the counter value can actually be done into the input capture/compare register 2 (LPTIM_CCR2) or not.
- 0: Capture disabled. Writing '0' to the CC2E bit resets the associated ic2_dma_req signal.
- 1: Capture enabled.

Bit 16  **CC2SEL**: Capture/compare 2 selection
This bitfield defines the direction of the channel, input (capture) or output mode.
- 0: CC2 channel is configured in output PWM mode
- 1: CC2 channel is configured in input capture mode

Bits 15:14  Reserved, must be kept at reset value.
Bits 13:12 IC1F[1:0]: Input capture 1 filter
This bitfield defines the number of consecutive equal samples that are detected when a level change occurs on an external input capture signal before it is considered as a valid level transition. An internal clock source must be present to use this feature.
00: any external input capture signal level change is considered as a valid transition
01: external input capture signal level change must be stable for at least 2 clock periods before it is considered as valid transition.
10: external input capture signal level change must be stable for at least 4 clock periods before it is considered as valid transition.
11: external input capture signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 IC1PSC[1:0]: Input capture 1 prescaler
This bitfield defines the ratio of the prescaler acting on the CC1 input (IC1).
00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:2 CC1P[1:0]: Capture/compare 1 output polarity.
Condition: CC1 as output
Only bit2 is used to set polarity when output mode is enabled, bit3 is don't care.
0: OC1 active high, the LPTIM output reflects the compare results between LPTIM.ARR and LPTIM.CCRx registers
1: OC1 active low, the LPTIM output reflects the inverse of the compare results between LPTIM.ARR and LPTIM.CCRx registers

Condition: CC1 as input
This field is used to select the IC1 polarity for capture operations.
00: rising edge, circuit is sensitive to IC1 rising edge
01: falling edge, circuit is sensitive to IC1 falling edge
10: reserved, do not use this configuration.
11: both edges, circuit is sensitive to both IC1 rising and falling edges.

Bit 1 CC1E: Capture/compare 1 output enable.
Condition: CC1 as output
0: Off - OC1 is not active. Writing '0' to the CC1E bit resets the ue_dma_req signal only if all the other LPTIM channels are disabled.
1: On - OC1 signal is output on the corresponding output pin

Condition: CC1 as input
This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (LPTIM.CCR1) or not.
0: Capture disabled. Writing '0' to the CC1E bit resets the associated ic1_dma_req signal.
1: Capture enabled.

Bit 0 CC1SEL: Capture/compare 1 selection
This bitfield defines the direction of the channel input (capture) or output mode.
0: CC1 channel is configured in output PWM mode
1: CC1 channel is configured in input capture mode

Caution: After a write to the LPTIM.CCMRx register, a new write operation to the same register can only be performed after a delay that must be equal or greater than the value of (PRESC × 3)
kernel clock cycles, PRESC[2:0] being the clock decimal division factor (1, 2, 4,..128). Any successive write violating this delay, leads to unpredictable results.

Caution: The CCxSEL, ICxF[1:0], CCxP[1:0] and ICxPSC[1:0] fields must only be modified when the channel x is disabled (CCxE bit reset to 0).

If LPTIM does not implement any channel this register is reserved. Refer to Section 43.3.

43.7.18 LPTIM compare register 2 (LPTIM_CCR2)

Address offset: 0x034
Reset value: 0x0000 0000

Caution: The LPTIM_CCR2 register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).

Note: If the LPTIM implements less than 2 channels this register is reserved. Refer to Section 43.3: LPTIM implementation.

43.7.19 LPTIM register map

The following table summarizes the LPTIM registers.

<table>
<thead>
<tr>
<th>Offset</th>

1. If LPTIM does not implement at least 2 channels this bit is reserved. Refer to Section 43.3: LPTIM implementation.
2. If LPTIM does not support encoder mode feature, this bit is reserved. Refer to Section 43.3: LPTIM implementation.
3. If the LPTIM implements at least one capture/compare channel, this bit is reserved. Refer to Section 43.3: LPTIM implementation.
4. If LPTIM does not implement any channel this register is reserved. Refer to Section 43.3: LPTIM implementation.
5. If the LPTIM implements less than 2 channels this register is reserved. Refer to Section 43.3: LPTIM implementation.

Refer to Section 2.3 on page 111 for the register boundary addresses.
44 Independent watchdog (IWDG)

44.1 Introduction

The independent watchdog (IWDG) peripheral offers a high safety level, thanks to its capability to detect malfunctions due to software or hardware failures.

The IWDG is clocked by an independent clock, and stays active even if the main clock fails.

In addition, the watchdog function is performed in the $V_{DD}$ voltage domain, allowing the IWDG to remain functional even in low-power modes. Refer to Section 44.3 to check the capability of the IWDG in this product.

The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, making it very reliable to detect any unexpected behavior.

44.2 IWDG main features

- 12-bit down-counter
- Dual voltage domain, thus enabling operation in low-power modes
- Independent clock
- Early wake-up interrupt generation
- Reset generation
  - In case of timeout
  - In case of refresh outside the expected window

1. ‘X’ = supported, ‘-’ = not supported.
2. Refer to the RCC section for additional information.
3. Controlled via DBG_IWDG_STOP in DBG section.
4. Controlled via the option byte IWDG_STOP in FLASH section.
5. Controlled via the option byte IWDG_STDBY in FLASH section.
6. Controlled via the option byte IWDG_SW in FLASH section.

## 44.4 IWDG functional description

### 44.4.1 IWDG block diagram

*Figure 609* shows the functional blocks of the independent watchdog module.

*Figure 609. Independent watchdog block diagram*

The register and IRQ interfaces are located into the V\textsubscript{CORE} voltage domain. The watchdog function itself is located into the V\textsubscript{DD} voltage domain to remain functional in low-power modes. See *Section 44.3* for IWDG capabilities.

The register and IRQ interfaces are mainly clocked by the APB clock (iwdg\_pclk), while the watchdog function is clocked by a dedicated kernel clock (iwdg\_ker\_ck). A synchronization mechanism makes the data exchange between the two domains possible. Note that most of the registers located in the register interface are shadowed into the V\textsubscript{DD} voltage domain.

The IWDG down-counter (IWDCNT) is clocked by the prescaled clock (presc\_ck). The prescaled clock is generated from the kernel clock iwdg\_ker\_ck divided by the prescaler, according to PR[3:0] bitfield.
### 44.4.2 IWDG internal signals

The list of IWDG internal signals is detailed in Table 468.

### 44.4.3 Software and hardware watchdog modes

The watchdog modes allow the application to select the way the IWDG is enabled, either by software commands (Software watchdog mode), or automatically (Hardware watchdog mode). All other functions work similarly for both Software and Hardware modes.

The Software watchdog mode is the default working mode. The independent watchdog is started by writing the value 0x0000 CCCC into the **IWDG key register (IWDG_KR)**, and the IWDCNT starts counting down from the reset value (0xFFF).

In the Hardware watchdog mode the independent watchdog is started automatically at power-on, or every time it is reset (via iwgd_in_rst). The IWDCNT down-counter starts counting down from the reset value 0xFFF. The hardware watchdog mode feature is enabled through the device option bits, see Section 44.3 for details.

When the IWDG is enabled the ONF flag is set to 1.

When the IWDCNT reaches 0x000, a reset signal is generated (iwgd_out_rst asserted).

Whenever the key value 0x0000 AAAA is written in the **IWDG key register (IWDG_KR)**, the IWGD_RLR value is reloaded into the IWDCNT, and the watchdog reset is prevented.

Due to re-synchronization delays, the IWDG must be refreshed before the IWDCNT down-counter reaches 1.

Once started, the IWDG can be stopped only when it is reset (iwgd_in_rst asserted).

As shown in Figure 610, when the refresh command is executed, one period of presc_ck later, the IWDCNT is reloaded with the content of RL[11:0].
1. If window option activated.

If the IWDG is not refreshed before the IWDCNT reaches 1, then the IWDG generates a reset (i.e. iwdg_out_rst asserted). In return, the RCC resets the IWDG (assertion of iwdg_in_rst) to clear the reset source.

44.4.4 Window option

The IWDG can also work as a window watchdog by setting the appropriate window in the IWDG window register (IWDG_WINR).

If the reload operation is performed while the counter is greater than WIN[11:0] + 1 a reset is generated. WIN[11:0] is located in the IWDG window register (IWDG_WINR). As shown in Figure 611, the reset is generated one period of presc_ck after the unexpected refresh command.

The default value of the IWDG window register (IWDG_WINR) is 0x0000 0xFFF, so, if not updated, the window option is disabled.

As soon as the window value changes, the down-counter (IWDCNT) is reloaded with the RL[11:0] value to ease the estimation for where the next refresh must take place.
Configuring the IWDG when the window option is enabled

1. Enable the IWDG by writing 0x0000 CCCC in the IWDG key register (IWDG_KR).
2. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
3. Write the IWDG prescaler by programming IWDG prescaler register (IWDG_PR).
4. Write the IWDG reload register (IWDG_RLR).
5. If needed, enable the early wake-up interrupt, and program the early wake-up comparator, by writing the proper values into the IWDG early wake-up interrupt register (IWDG_EWCR).
6. Write to the IWDG window register (IWDG_WINR). This automatically reloads the IWDCNT down-counter with the RL[11:0] value.
7. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
8. Write 0x0000 0000 into IWDG key register (IWDG_KR) to write-protect registers.

Note: Step 7 can be skipped if the application does not intend to disable the APB clock after the completion of this sequence.

Configuring the IWDG when the window option is disabled

When the window option it is not used, the IWDG can be configured as follows:
1. Enable the IWDG by writing 0x0000 CCCC in the IWDG key register (IWDG_KR).
2. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
3. Write the prescaler by programming the IWDG prescaler register (IWDG_PR).
4. Write the IWDG reload register (IWDG_RLR).
5. If needed, enable the early wake-up interrupt, and program the early wake-up comparator, by writing the proper values into the IWDG early wake-up interrupt register (IWDG_EWCR).
6. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
7. Refresh the counter with RL[11:0] value, and write-protect registers by writing 0x0000 AAAA into IWDG key register (IWDG_KR).

**Updating the window comparator**

It is possible to update the window comparator when the IWDG is already running. The IWDCNT is reloaded as well. The following sequence can be performed to update the window comparator:
1. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
2. Write to the IWDG window register (IWDG_WINR). This automatically reloads the IWDCNT down-counter with RL[11:0] value.
3. Wait for WVU = 0
4. Lock registers by writing IWDG_KR to 0x0000 0000

Step 3 can be skipped if the application does not intend to disable the APB clock after the completion of this sequence.

*Figure 612* shows this sequence. As soon as the IWDG_WINR register is written, the WVU flag goes high. The new window value and the reload of IWDCNT with RL[11:0] are effective on the next rising edge of presc_ck. The WVU flag goes back to 0, in the worst case, two kernel clock periods later. So WVU remains high at most one period of presc_ck, plus two periods of the kernel clock.

*Figure 612. Example of window comparator update*

---

(1) Write 0x0000 5555 into IWDG_KR to unlock registers
(2) Write new value into IWDG_WINR
(3) Write 0x0000 0000 into IWDG_KR to lock registers without refresh
44.4.5 Debug

When the processor enters into Debug mode (core halted), the IWDCNT down-counter either continues to work normally or stops, depending on debug capability of the product. Refer to Section 44.3 for details on the capabilities of this product.

44.4.6 Register access protection

Write accesses to IWDG prescaler register (IWDG_PR), IWDG reload register (IWDG_RLR), IWDG early wake-up interrupt register (IWDG_EWCR) and IWDG window register (IWDG_WINR) are protected. To modify them, first write 0x0000 5555 in the IWDG key register (IWDG_KR). A write access to this register with a different value breaks the sequence and register access is protected again. This is the case of the reload operation (writing 0x0000 AAAA).

A status register is available to indicate that an update of the prescaler or the down-counter reload value or the window value is ongoing.

44.5 IWDG low-power modes

Depending on option bytes configuration, the IWDG can continue counting or not during the low-power modes. Refer to Section 44.3 for details.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. IWDG interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The IWDG remains active or not, depending on option bytes configuration. Refer to Section 44.3 for details. IWDG interrupts cause the device exit the Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The IWDG remains active or not, depending on option bytes configuration. Refer to Section 44.3 for details. IWDG interrupts do not make the device to exit from Standby mode.</td>
</tr>
</tbody>
</table>

44.6 IWDG interrupts

The IWDG offers the possibility to generate an early interrupt depending on the value of the down-counter. The early interrupt is enabled by setting the EWIE bit of the IWDG early wake-up interrupt register (IWDG_EWCR) to 1.

A comparator value (EWIT[11:0]) allows the application to define at which position the early interrupt must be generated.

When the IWDCNT down-counter reaches the value of EWIT[11:0] - 1, the iwdg_wkup is activated, making it possible for the system to exit from low-power mode if needed.

When the APB clock is available, the iwdg_it is activated as well.

In addition the flag EWIF of the IWDG status register (IWDG_SR) is set to 1.

The EWI interrupt is acknowledged by writing ‘1’ to the EWIC bit in the IWDG early wake-up interrupt register (IWDG_EWCR).
Writing into the IWDG_EWCR register also triggers a refresh of the down-counter (IWDCNT) with the reload value RL[11:0].

**Figure 613. Independent watchdog interrupt timing diagram**

The early wake-up interrupt (EWI) can be used if specific safety operations or data logging must be performed before the watchdog reset is generated.

**Changing the early wake-up comparator value**

It is possible to change the early wake-up comparator value or to enable/disable the interrupt generation at any time, by performing the following sequence:

1. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
2. Enable or disable the early wake-up interrupt, and/or program the early wake-up comparator, by writing the proper values into the IWDG early wake-up interrupt register (IWDG_EWCR).
3. Wait for EWU = ’0’, EWU is located into the IWDG status register (IWDG_SR).
4. Write-protect registers by writing 0x0000 0000 to IWDG key register (IWDG_KR).

Step 3 can be skipped if the application does not intend to disable the APB clock after the completion of this sequence.

*Figure 613* shows this sequence. As soon as the IWDG_EWCR register is written, the EWU flag goes high. The new comparator value and the reload of IWDCNT with RL[11:0] are effective on the next rising edge of presc_ck. The EWU flag goes back to 0, in the worst case, two kernel clock periods later. So, EWU remains high at most one period of presc_ck, plus two periods of the kernel clock.
**44.7 IWDG registers**

Refer to *Section 1.2 on page 101* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

Most of the registers located into the register interface are shadowed into the VDD voltage domain. When the iwdg_in_rst is asserted, the watchdog logic and the shadow registers located into the VDD voltage domain are reset.

When the application reads back a watchdog register, the hardware transfers the value of the corresponding shadow register to the register interface.

When the application writes a watchdog register, the hardware updates the corresponding shadow register.

</table>

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **KEY[15:0]**: Key value (write only, read 0x0000)

These bits can be used for several functions, depending upon the value written by the application:
- 0xAAAA: reloads the RL[11:0] value into the IWDCNT down-counter (watchdog refresh), and write-protects registers. This value must be written by software at regular intervals, otherwise the watchdog generates a reset when the counter reaches 0.
- 0x5555: enables write-accesses to the registers.
- 0xCCCC: enables the watchdog (except if the hardware watchdog option is selected) and write-protects registers.
- Values different from 0x5555: write-protects registers.

Note that only IWDG_PR, IWDG_RLR, IWDG_EWCR and IWDG_WINR registers have a write-protection mechanism.

44.7.2 IWDG prescaler register (IWDG_PR)

Bits 31:4  Reserved, must be kept at reset value.
### Bits 3:0 PR[3:0]: Prescaler divider

These bits are write access protected, see Section 44.4.6. They are written by software to select the prescaler divider feeding the counter clock. PVU bit of the IWDG status register (IWDG_SR) must be reset to be able to change the prescaler divider.

*Note: Reading this register returns the prescaler value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the IWDG status register (IWDG_SR) is reset.*

#### 44.7.3 IWDG reload register (IWDG_RLR)

**Address offset:** 0x08  
**Reset value:** 0x0000 0FFF

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>

<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

**Bits 11:0 RL[11:0]: Watchdog counter reload value**

These bits are write access protected, see Section 44.4.6. They are written by software to define the value to be loaded in the watchdog counter each time the value 0xAAA is written in the IWDG key register (IWDG_KR). The watchdog counter counts down from this value. The timeout period is a function of this value and the prescaler.clock. It is not recommended to set RL[11:0] to a value lower than 2.

The RVU bit in the IWDG status register (IWDG_SR) must be reset to be able to change the reload value.

*Note: Reading this register returns the reload value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing, hence the value read from this register is valid only when the RVU bit in the IWDG status register (IWDG_SR) is reset.*

#### 44.7.4 IWDG status register (IWDG_SR)

**Address offset:** 0x0C  
**Reset value:** 0x0000 0000 (0xFFFF FEFF)

This register contains various status flags. Note that the mask value between parenthesis means that the reset value of ONF bit is not defined. When the IWDG is configured in
software mode, the reset value of ONF bit is 0, when the IWDG is configured in hardware
mode, the reset value of ONF bit is 1.

<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:15  Reserved, must be kept at reset value.

Bit 14  EWIF: Watchdog early interrupt flag
   This bit is set to ‘1’ by hardware in order to indicate that an early interrupt is pending. This bit
   must be cleared by the software by writing the bit EWIC of IWDG_EWCR register to ‘1’.

Bits 13:9  Reserved, must be kept at reset value.

Bit 8  ONF: Watchdog enable status bit
   Set to ‘1’ by hardware as soon as the IWDG is started. In software mode, it remains to ‘1’ until
   the IWDG is reset. In hardware mode, this bit is always set to ‘1’.
   0: The IWDG is not activated
   1: The IWDG is activated and needs to be refreshed regularly by the application

Bits 7:4  Reserved, must be kept at reset value.

Bit 3  EWU: Watchdog interrupt comparator value update
   This bit is set by hardware to indicate that an update of the interrupt comparator value
   (EWIT[11:0]) or an update of the EWIE is ongoing. It is reset by hardware when the update
   operation is completed in the VDD voltage domain (takes up to one period of presc_ck and
   two periods of the IWDG kernel clock iwdg_ker_ck).
   The EWIT[11:0] and EWIE fields can be updated only when EWU bit is reset.

Bit 2  WVU: Watchdog counter window value update
   This bit is set by hardware to indicate that an update of the window value is ongoing. It is
   reset by hardware when the reload value update operation is completed in the VDD voltage
   domain (takes up to one period of presc_ck and two periods of the IWDG kernel clock
   iwdg_ker_ck).
   The window value can be updated only when WVU bit is reset.
   This bit is generated only if generic “window” = 1.

Bit 1  RVU: Watchdog counter reload value update
   This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset
   by hardware when the reload value update operation is completed in the VDD voltage domain
   (takes up to six periods of the IWDG kernel clock iwdg_ker_ck).
   The reload value can be updated only when RVU bit is reset.

Bit 0  PVU: Watchdog prescaler value update
   This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is
   reset by hardware when the prescaler update operation is completed in the VDD voltage domain
   (takes up to six periods of the IWDG kernel clock iwdg_ker_ck).
   The prescaler value can be updated only when PVU bit is reset.

Note:  If several reload, prescaler, early interrupt position or window values are used by the
   application, it is mandatory to wait until RVU bit is reset before changing the reload value, to
   wait until PVU bit is reset before changing the prescaler value, to wait until WVU bit is reset.
before changing the window value, and to wait until EWU bit is reset before changing the early interrupt position value. After updating the prescaler and/or the reload/window/early interrupt value, it is not necessary to wait until RVU or PVU or WVU or EWU is reset before continuing code execution, except in case of low-power mode entry.

44.7.5 IWDG window register (IWDG_WINR)

Address offset: 0x10
Reset value: 0x0000 0FFF

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|   |   |   |   |   |   |   |   |   |   |   |   |
| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **WIN[11:0]:** Watchdog counter window value

These bits are write access protected, see Section 44.4.6. They contain the high limit of the window value to be compared with the downcounter.

To prevent a reset, the IWDCNT downcounter must be reloaded when its value is lower than WIN[11:0] + 1 and greater than 1.

The WVU bit in the **IWDG status register (IWDG_SR)** must be reset to be able to change the reload value.

**Note:** Reading this register returns the reload value from the VDD voltage domain. This value may not be valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the WVU bit in the IWDG status register (IWDG_SR) is reset.

44.7.6 IWDG early wake-up interrupt register (IWDG_EWCR)

Address offset: 0x14
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|   |   |   |   |   |   |   |   |   |   |   |   |
| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|   |   |   |   |   |   |   |   |   |   |   |   |

<table>
<thead>
<tr>
<th>EWIE</th>
<th>EWIC</th>
<th>Res</th>
<th>Res</th>
<th>EWIT[11:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>w</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.
Bit 15 **EWIE**: Watchdog early interrupt enable  
Set and reset by software.  
0: The early interrupt interface is disabled.  
1: The early interrupt interface is enabled.  
The EWU bit in the **IWDG status register (IWDG_SR)** must be reset to be able to change the value of this bit.

Bit 14 **EWIC**: Watchdog early interrupt acknowledge  
The software must write a 1 into this bit in order to acknowledge the early wake-up interrupt and to clear the EWIF flag. Writing 0 has no effect, reading this flag returns a 0.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:0 **EWIT[11:0]**: Watchdog counter window value  
These bits are write access protected (see **Section 44.4.6**). They are written by software to define at which position of the IWDCNT down-counter the early wake-up interrupt must be generated. The early interrupt is generated when the IWDCNT is lower or equal to EWIT[11:0] - 1.  
EWIT[11:0] must be bigger than 1.  
An interrupt is generated only if EWIE = 1.  
The EWU bit in the **IWDG status register (IWDG_SR)** must be reset to be able to change the reload value.  
**Note**: Reading this register returns the Early wake-up comparator value and the Interrupt enable bit from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing, hence the value read from this register is valid only when the EWU bit in the **IWDG status register (IWDG_SR)** is reset.
### 44.7.7  IWDG register map

#### Table 471. IWDG register map and reset values

| Offset | Register name | Register | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to Section 2.3 on page 111 for the register boundary addresses.
45 System window watchdog (WWDG)

45.1 Introduction

The system window watchdog (WWDG) is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence.

The watchdog circuit generates a reset on expiry of a programmed time period, unless the program refreshes the contents of the down-counter before the T6 bit is cleared. A reset is also generated if the 7-bit down-counter value (in the control register) is refreshed before the down-counter reaches the window register value. This implies that the counter must be refreshed in a limited window.

The WWDG clock is prescaled from the APB clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The WWDG is best suited for applications requiring the watchdog to react within an accurate timing window.

45.2 WWDG main features

- Programmable free-running down-counter
- Conditional reset
  - Reset (if watchdog activated) when the down-counter value becomes lower than 0x40
  - Reset (if watchdog activated) if the down-counter is reloaded outside the window (see Figure 616)
- Early wake-up interrupt (EWI): triggered (if enabled and the watchdog activated) when the down-counter is equal to 0x40

45.3 WWDG implementation

<td>X</td>
</tr>
</tbody>
</table>

1. "X" = supported, "-" = not supported.
2. Refer to the RCC section for additional information.
3. Controlled via DBG_WWDG_STOP in DBG block.
45.4 **WWDG functional description**

If the watchdog is activated (the WDGA bit is set in the WWDG_CR register), and when the 7-bit down-counter (T[6:0] bits) is decremented from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WWDG_CR register at regular intervals during normal operation to prevent a reset. This operation can take place only when the counter value is lower than or equal to the window register value, and higher than 0x3F. The value to be stored in the WWDG_CR register must be between 0xFF and 0xC0.

Refer to Figure 615 for the WWDG block diagram.

45.4.1 **WWDG block diagram**

![WWDG Block Diagram](image)

45.4.2 **WWDG internal signals**

*Table 473* gives the list of WWDG internal signals.

<table>
<thead>

<td>Digital output</td>
<td>WWDG reset signal output</td>
</tr>
<tr>
<td>wwdg_it</td>
<td>Digital output</td>
<td>WWDG early interrupt output</td>
</tr>
</tbody>
</table>
45.4.3 Enabling the watchdog

When the user option WWDG_SW selects “Software window watchdog”, the watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG_CR register, then it cannot be disabled again, except by a reset.

When the user option WWDG_SW selects “Hardware window watchdog”, the watchdog is always enabled after a reset, it cannot be disabled.

45.4.4 Controlling the down-counter

This down-counter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments that represent the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value, due to the unknown status of the prescaler when writing to the WWDG_CR register (see Figure 616). The WWDG configuration register (WWDG_CFR) contains the high limit of the window: to prevent a reset, the down-counter must be reloaded when its value is lower than or equal to the window register value, and greater than 0x3F. Figure 616 describes the window watchdog process.

Note: The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

45.4.5 How to program the watchdog timeout

Use the formula in Figure 616 to calculate the WWDG timeout.

---

Warning: When writing to the WWDG_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.
The formula to calculate the timeout value is given by:

\[ t_{\text{WWDG}} = t_{\text{PCLK}} \times 4096 \times 2^{\text{WDGTB}[2:0]} \times (T[5:0] + 1) \] (ms)

where:
- \( t_{\text{WWDG}} \): WWDG timeout
- \( t_{\text{PCLK}} \): APB clock period measured in ms
- 4096: value corresponding to internal divider

As an example, if APB frequency is 48 MHz, WDGTB[2:0] is set to 3 and T[5:0] is set to 63:

\[ t_{\text{WWDG}} = \frac{1}{48000} \times 4096 \times 2^3 \times (63 + 1) = 43.69\text{ms} \]

Refer to the datasheet for the minimum and maximum values of \( t_{\text{WWDG}} \).

**45.4.6 Debug mode**

When the device enters debug mode (processor halted), the WWDG counter either continues to work normally or stops, depending on the configuration bit in DBG module. For more details, refer to *Section 58: Debug support (DBG)*.
45.5 **WWDG interrupts**

The early wake-up interrupt (EWI) can be used if specific safety operations or data logging must be performed before the reset is generated. To enable the early wake-up interrupt, the application must:

- Write EWIF bit of WWDG_SR register to 0, to clear unwanted pending interrupt
- Write EWI bit of WWDG_CFR register to 1, to enable interrupt

When the down-counter reaches the value 0x40, a watchdog interrupt is generated, and the corresponding interrupt service routine (ISR) can be used to trigger specific actions (such as communications or data logging), before resetting the device.

In some applications, the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case the corresponding ISR must reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The watchdog interrupt is cleared by writing '0' to the EWIF bit in the WWDG_SR register.

*Note:* When the watchdog interrupt cannot be served (for example due to a system lock in a higher priority task), the WWDG reset is eventually generated.

<table>
<thead>
<tr>
<th>Table 474. WWDG interrupt requests</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Interrupt</strong></td>
</tr>
<tr>
<td>----------------</td>
</tr>
<tr>
<td>WWDG(2)</td>
</tr>
</tbody>
</table>

1. The WWDG interrupt can have additional capabilities, refer to *Section 45.3* for details.
2. WWDG vector corresponds to the assertion of the wwdg_it signal.

45.6 **WWDG registers**

Refer to *Section 1.2 on page 101* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by halfwords (16-bit) or words (32-bit).

45.6.1 **WWDG control register (WWDG_CR)**

Address offset: 0x000

Reset value: 0x0000 007F

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>WDGA</td>
</tr>
<tr>
<td>rs</td>
</tr>
</tbody>
</table>
Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **WDGA**: Activation bit

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled
1: Watchdog enabled

Bits 6:0 **T[6:0]**: 7-bit counter (MSB to LSB)

These bits contain the value of the watchdog counter, decremented every \((4096 \times 2^{WDGTB[2:0]})\) PCLK cycles. A reset is produced when it is decremented from 0x40 to 0x3F (T6 becomes cleared).

### 45.6.2 WWDG configuration register (WWDG_CFR)

</tr>
</tbody>
</table>

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:11 **WDGTB[2:0]**: Timer base

The timebase of the prescaler can be modified as follows:

000: CK counter clock (PCLK div 4096) div 1
001: CK counter clock (PCLK div 4096) div 2
010: CK counter clock (PCLK div 4096) div 4
011: CK counter clock (PCLK div 4096) div 8
100: CK counter clock (PCLK div 4096) div 16
101: CK counter clock (PCLK div 4096) div 32
110: CK counter clock (PCLK div 4096) div 64
111: CK counter clock (PCLK div 4096) div 128

Bit 10 Reserved, must be kept at reset value.

Bit 9 **EWI**: Early wake-up interrupt enable

Set by software and cleared by hardware after a reset. When set, an interrupt occurs whenever the counter reaches the value 0x40.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **W[6:0]**: 7-bit window value

These bits contain the window value to be compared with the down-counter.
45.6.3  WWDG status register (WWDG_SR)

Address offset: 0x008
Reset value: 0x0000 0000

<table>

Refer to Section 2.3 on page 111 for the register boundary addresses.
46  Real-time clock (RTC)

46.1  Introduction

The RTC provides an automatic wake-up to manage all low-power modes.

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupts.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).

The RTC is functional in V_{BAT} mode.

46.2  RTC main features

The RTC supports the following features (see Figure 617: RTC block diagram):

• Calendar with subseconds, seconds, minutes, hours (12 or 24 format), week day, date, month, year, in BCD (binary-coded decimal) format.
• Binary mode with 32-bit free-running counter.
• Automatic correction for 28, 29 (leap year), 30, and 31 days of the month.
• Two programmable alarms.
• On-the-fly correction from 1 to 32767 RTC clock pulses. This can be used to synchronize it with a master clock.
• Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
• Digital calibration circuit with 0.95 ppm resolution, to compensate for quartz crystal inaccuracy.
• Timestamp feature which can be used to save the calendar content. This function can be triggered by an event on the timestamp pin, or by a tamper event, or by a switch to V_{BAT} mode.
• 17-bit auto-reload wake-up timer (WUT) for periodic events with programmable resolution and period.
• TrustZone support:
  – RTC fully securable
  – Alarm A, alarm B, wake-up Timer and timestamp individual secure or nonsecure configuration
• Alarm A, alarm B, wake-up Timer and timestamp individual privilege protection

The RTC is supplied through a switch that takes power either from the V_{DD} supply when present or from the V_{BAT} pin.

The RTC is functional in V_{BAT} mode and in all low-power modes when it is clocked by the LSE.

All RTC events (Alarm, wake-up Timer, Timestamp) can generate an interrupt and wake-up the device from the low-power modes.

</tr>
</tbody>
</table>

RTC_OUT1 and RTC_OUT2 which select one of the following two outputs:
- CALIB: 512 Hz or 1 Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC_CR register.
- TAMPALRM: This output is the OR between rtc_tamp_evt and ALARM signals.

ALARM is enabled by configuring the OSEL[1:0] bits in the RTC_CR register which select the alarm A, alarm B or wake-up outputs. rtc_tamp_evt is enabled by setting the TAMPOE bit in the RTC_CR register which selects the tamper event outputs.

Table 477. RTC internal input/output signals

</tr>
</tbody>
</table>

The RTC kernel clock is usually the LSE at 32.768 kHz although it is possible to select other clock sources in the RCC (refer to RCC for more details). Some functions are not available in some low-power modes or VBAT when the selected clock is not LSE. Refer to Section 46.4: RTC low-power modes for more details.
The TZEN option bit is used to activate TrustZone in the device.
TZEN = 1: TrustZone activated.
TZEN = 0: TrustZone disabled.
When TrustZone is disabled, the APB access to the RTC registers are nonsecure.
The triggers outputs can be used as triggers for other peripherals.

### 46.3.3 GPIOs controlled by the RTC and TAMP

The GPIOs included in the Battery Backup Domain (Vs) are directly controlled by the peripherals providing functions on these I/Os, whatever the GPIO configuration.

RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 and TAMP_OUT3 are mapped on the same pin (PC13). The RTC and TAMP functions mapped on PC13 are available in all low-power modes and in VBAT mode.

The output mechanism follows the priority order shown in **Table 479**.

</table>

1. OD: open drain; PP: push-pull.
2. In this configuration the GPIO must be configured in input.
RTC_OUT2, TAMP_IN2 and TAMP_OUT3 are mapped on the same pin (PI8). PI8 configuration is controlled by the RTC, whatever the PI8 GPIO configuration. The RTC or TAMP functions mapped on PI8 are available in all low-power modes and in VBAT mode.

The output mechanism follows the priority order shown in Table 480.

</table>
In addition, it is possible to output RTC_OUT2 on PB2 or PI8 pin thanks to OUT2EN and OUT2_RMP bits. The different functions are mapped on RTC_OUT1 or on RTC_OUT2 depending on OSEL, COE and OUT2EN configuration, as shown in table Table 481.

#### 46.3.4 RTC secure protection modes

By default after a backup domain power-on reset, all RTC registers can be read or written in both secure and nonsecure modes, except for the RTC secure configuration register (RTC_SECCFGR) which can be written in secure mode only. The RTC protection configuration is not affected by a system reset.

When the SEC bit is set in the RTC_SECCFGR register:
- Writing the RTC registers is possible only in secure mode.
- Reading RTC_SECCFGR, RTC_PRIVCFGR, RTC_MISR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in secure and nonsecure modes. All the other RTC registers can be read only in secure mode.

When the SEC bit is cleared, it is still possible to protect some of the registers by setting dedicated INITSEC, CALSEC, TSSEC, WUTSEC, ALRASEC or ALRBSEC control bits. If all these bits are also set, all the RTC registers can be read in secure and nonsecure mode.

- When INITSEC is set:
  - RTC_TR, RTC_DR, RTC_PRER registers, plus INIT, BIN and BCDU in RTC_ICSR, FMT control bits in RTC_CR and INITPRIV in the RTC_PRIVCFGR can be written only in secure mode.
  - These registers and control bits can be read in secure and nonsecure mode.

- When CALSEC is set:
  - RTC_SHIFTR and RTC_CALR registers, plus ADD1H, SUB1H and REFCKON control bits in the RTC_CR and CALPRIV in the RTC_PRIVCFGR can be written only in secure mode.
  - These registers and control bits can be read in secure and nonsecure mode.

- When ALRASEC is set:
  - RTC_ALRMAR, RTC_ALRMASSR and RTC_ALRABINR registers, plus ALRAE, ALRAFCLR, ALRAIE and SSRUIE in the RTC_CR, CALRAF and CSSRUF in the
RTC_SCR, ALRAF and SSRUF in RTC_SR, and ALRAMF and SSRUMF in RTC_SMISR can be read and written only in secure mode.

- ALRAPRIV in the RTC_PRIVCFGR can be written only in secure mode.

- When ALRBSEC is set:
  - RTC_ALRMBR, RTC_ALRMBSSR and RTC_ALRBBINR registers, plus ALRBE ALRBFCLR, ALRBIE in the RTC_CR, CALRBF in the RTC_SCR, ALRBF in RTC_SR, and ALRBMF in RTC_SMISR can be read and written only in secure mode.
  - ALRBPRIV in the RTC_PRIVCFGR can be written only in secure mode.

- When WUTSEC is set:
  - RTC_WUTR register, plus WUTE, WUTIE and WUCKSEL control bits in the RTC_CR, CWUTF in the RTC_SCR, WUTF in RTC_SR, and WUTMF in RTC_SMISR can be read and written only in secure mode.
  - WUTPRIV in the RTC_PRIVCFGR can be written only in secure mode.

- When TSSEC is set:
  - RTC_TSTR, RTC_TSDR and RTC_TSSSR registers, plus TAMPTS, ITSE, TSE, TSIE, TSEDGE control bits in the RTC_CR, CITSF, CTSOVF and CTSF bits in the RTC_SCR, TSF, TSOVF and ITSF in RTC_SR, and TSMF, TSOVMF and ITSMF in RTC_SMISR can be read and written only in secure mode.
  - TSPRIV in the RTC_PRIVCFGR can be written only in secure mode.

A nonsecure access to a secure-protected register is denied:

- There is no bus error generated.
- In case the register has a global protection: a notification is generated through a flag/interrupt in the TZIC (TrustZone illegal access controller). In case only a few bits of the register are protected (for registers with mixed features such as RTC_CR...), no notification is generated.
- When write protected, the bits are not written.
- When read protected they are read as 0.

As soon as at least one function is configured to be secured, the RTC reset and clock control is also secured in the RCC.

### 46.3.5 RTC privilege protection modes

By default after a backup domain power-on reset, all RTC registers can be read or written in both privileged and non-privileged modes, except for the RTC privilege mode control register (RTC_PRIVCFGR) which can be written in privilege mode only. The RTC protection configuration is not affected by a system reset.

When the PRIV bit is set in the RTC_PRIVCFGR register:

- Writing the RTC registers is possible only in privileged mode.
- Reading the RTC_SECCFG, RTC_PRIVCFGR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in privilege and non-privileged modes. All the other RTC registers can be read only in privilege mode.

When the PRIV bit is cleared, it is still possible to protect some of the registers by setting dedicated INITPRIV, CALPRIV, TSPRIV, WUTPRIV, ALRAPRIV or ALRBPRIV control bits. If
all these bits are also cleared, all the RTC registers can be read or written in privilege and non-privileged modes.

- When INITPRIV is set:
  - RTC_TR, RTC_DR, RTC_PRER registers, plus INIT, BIN and BCDU in RTC_ICSR and FMT control bits in RTC_CR, plus INITSEC in the RTC_SECCFGR can be written only in privilege mode.
  - These registers and control bits can be read in privilege and non-privileged mode.

- When CALPRIV is set:
  - RTC_SHIFTR and RTC_CALR registers, plus ADD1H, SUB1H and REFCKON control bits in the RTC_CR, plus CALDSEC in the RTC_SECCFGR can be written only in privilege mode.
  - These registers and control bits can be read in privilege and non-privileged mode.

- When ALRAPRIV is set:
  - RTC_ALRMAR, RTC_ALRMASSR and RTC_ALRABINR registers, plus ALRAE ALRAFCLR, ALRAIE and SSRUIE in the RTC_CR, and CALRAF and CSSRUF in the RTC_SCR, ALRAF and SSRUF in RTC_SR, and ALRAMF and SSRUMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - ALRAFSEC in the RTC_SECCFGR can be written only in privilege mode.

- When ALRBPRIV is set:
  - RTC_ALRMBR, RTC_ALRMBSSR and RTC_ALRBBINR registers, plus ALRBE ALRBFCLR, ALRBIE in the RTC_CR, and CALRBF in the RTC_SCR, ALRBF in RTC_SR, and ALRBMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - ALRBSEC in the RTC_SECCFGR can be written only in privilege mode.

- When WUTPRIV is set:
  - RTC_WUTR register, plus WUTE, WUTIE and WUCKSEL control bits in the RTC_CR, and CWUTF in the RTC_SCR, WUTF in RTC_SR, and WUTMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - WUTSEC in the RTC_SECCFGR can be written only in privilege mode.

- When TSPRIV is set:
  - RTC_TSTR, RTC_TSDR and RTC_TSSSR registers, plus TAMPTS, ITSE, TSE, TSIE, TSEDGE control bits in the RTC_CR, CITSF, CTSOVF and CTSF bits in the RTC_SCR, TSF, TSOVF and ITSF in RTC_SR, and TSMF, TSOVMF and ITSMF in RTC_MISR and RTC_SMISR can be read and written only in privilege mode.
  - TSSEC in the RTC_SECCFGR can be written only in privilege mode.

A non-privileged access to a privileged-protected register is denied:

- There is no bus error generated.
- When write protected, the bits are not written.
- When read protected they are read as 0.

46.3.6 Clock and prescalers

For more information on the RTC clock (RTCCLK) source configuration, refer to “Reset and clock control (RCC)”.
BCD mode (BIN=00)

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see Figure 617: RTC block diagram):

- A 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV_S bits of the RTC_PRER register.

**Note:** When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is $2^{22}$.

This corresponds to a maximum input frequency of around 4 MHz.

The $f_{ck\_apre}$ is given by the following formula:
