$$f_{CK\_APRE} = \frac{f_{RTCCLK}}{PREDIV\_A + 1}$$

The $ck\_apre$ clock is used to clock the binary RTC_SSR subsecond downcounter. When it reaches 0, RTC_SSR is reloaded with the content of PREDIV_S.

The $f_{ck\_spre}$ is given by the following formula:

$$f_{CK\_SPRE} = \frac{f_{RTCCLK}}{(PREDIV\_S + 1) \times (PREDIV\_A + 1)}$$

**Binary mode (BIN=01)**

The SSR binary down-counter is extended to 32-bit length and is free running. The time and date calendar BCD registers are not functional.

This down-counter is clocked by $ck\_apre$: the output of the 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.

PREDIV_S value is don't care.

**Mixed mode (BIN=10 or 11)**

The SSR binary down-counter is extended to 32-bit length and is free running. The time and date calendar BCD registers are also available.

This down-counter is clocked by $ck\_apre$: the output of the 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register. The bits BCDU[2:0] are
used to define when the calendar is incremented by 1 second, using the SSR least significant bits.

46.3.7 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC_SSR for the subseconds
- RTC_TR for the time
- RTC_DR for the date

Every RTCCLK periods, the current calendar value is copied into the shadow registers, and the RSF bit of RTC_ICSR register is set (see Section 46.6.12: RTC shift control register (RTC_SHIFTR)). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 4 RTCCLK periods.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the BYPSHAD control bit in the RTC_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC_SSR, RTC_TR or RTC_DR registers in BYPSHAD = 0 mode, the frequency of the APB clock (fAPB) must be at least 7 times the frequency of the RTC clock (fRTCCLK).

The shadow registers are reset by system reset.

46.3.8 Calendar ultra-low power mode

It is possible to reduce drastically the RTC power consumption by setting the LPCAL bit in the RTC_CALR register. In this configuration, the whole RTC is clocked by ck_apre only instead of both RTCCLK and ck_apre. Consequently, some flags delays are longer, and the calibration window is longer (refer to Section : RTC ultra-low-power mode).

The LPCAL bit is ignored (assumed to be 0) when asynchronous prescaler division factor (PREDIV_A+1) is not a power of 2.

Switching from LPCAL=0 to LPCAL=1 or from LPCAL=1 to LPCAL=0 is not immediate and requires a few ck_apre periods to complete.

46.3.9 Programmable alarms

The RTC unit provides programmable alarm: alarm A and alarm B. The description below is given for alarm A, but can be translated in the same way for alarm B.

The programmable alarm function is enabled through the ALRAE bit in the RTC_CR register.

The ALRAF is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC_ALRMASSR and RTC_ALRMAR. Each calendar field can be independently selected through the MSKx bits of the RTC_ALRMAR register, and through the MASKSSx bits of the RTC_ALRMASSR register.
When the binary mode is used, the subsecond field can be programmed in the alarm binary register RTC_ALRABINR.

The alarm interrupt is enabled through the ALRAIE bit in the RTC_CR register.

In case the Alarm is used to generate a trigger event for another peripheral, the ALRAF can be automatically cleared by hardware by configuring the ALRAFCLR bit at 1 in the RTC_CR register. In this configuration there is no need for software intervention if the only purpose is clearing the ALRAF flag.

**Caution:**

If the seconds field is selected (MSK1 bit reset in RTC_ALRMAR), the synchronous prescaler division factor set in the RTC_PRER register must be at least 3 to ensure correct behavior.

Alarm A and alarm B (if enabled by bits OSEL[1:0] in RTC_CR register) can be routed to the TAMPALRM output. TAMPALRM output polarity can be configured through bit POL the RTC_CR register.

### 46.3.10 Periodic auto-wake-up

The periodic wake-up flag is generated by a 16-bit programmable auto-reload down-counter. The wake-up timer range can be extended to 17 bits.

The wake-up function is enabled through the WUTE bit in the RTC_CR register.

The wake-up timer clock input ck_wut can be:

- **RTC clock (RTCCLK) divided by 2, 4, 8, or 16.**
  - When RTCCLK is LSE (32.768 kHz), this permits the wake-up interrupt period to be configured from 122 µs to 32 s, with a resolution down to 61 µs.
- **ck_spre (usually 1 Hz internal clock) in BCD mode, or the clock used to update the calendar as defined by BCDU in binary or mixed (BCD-binary) modes.**
  - When ck_spre frequency is 1 Hz, a wake-up time from 1 s to around 36 hours can be achieved with one-second resolution. This large programmable time range is divided in 2 parts:
    - from 1 s to 18 hours when WUCKSEL [2:1] = 10
    - and from around 18 h to 36 h when WUCKSEL[2:1] = 11. In this last case $2^{16}$ is added to the 16-bit counter current value. When the initialization sequence is complete (see *Programming the wake-up timer on page 1963*), the timer starts counting down. When the wake-up function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC_SR register, and the wake-up counter is automatically reloaded with its reload value (RTC_WUTR register value).

Depending on WUTOCLR in the RTC_WUTR register, the WUTF flag must either be cleared by software (WUTOCLR = 0x0000), or the WUTF is automatically cleared by hardware when the auto-reload down counter reaches WUTOCLR value (0x0000 < WUTOCLR ≤ WUT).

The wake-up flag is output on an internal signal rtc_wut that can be used by other peripherals (refer to section *Section 46.3.1: RTC block diagram*).

When the periodic wake-up interrupt is enabled by setting the WUTIE bit in the RTC_CR register, it can exit the device from low-power modes.
The periodic wake-up flag can be routed to the TAMPALRM output provided it has been enabled through bits OSEL[1:0] of RTC_CR register. TAMPALRM output polarity can be configured through the POL bit in the RTC_CR register.

System reset, as well as low-power modes (Sleep, Stop, and Standby) have no influence on the wake-up timer.

### 46.3.11 RTC initialization and configuration

**RTC Binary, BCD or Mixed mode**

By default the RTC is in BCD mode (BIN = 00 in the RTC_ICSR register): the RTC_SSR register contains the subsecond field SS[15:0], clocked by ck_apre, allowing to generate a 1 Hz clock to update the calendar registers in BCD format (RTC_TR and RTC_DR).

When the RTC is configured in binary mode (BIN = 01 in the RTC_ICSR register): the RTC_SSR register contains the binary counter SS[31:0], clocked by ck_apre. The calendar registers in BCD format (RTC_TR and RTC_DR) are not used.

When the RTC is configured in mixed mode (BIN = 10 or 11 in the RTC_ICSR register): the RTC_SSR register contains the binary counter SS[31:0], clocked by ck_apre. The calendar is updated (1 second increment) each time the SSR[BCDU+7:0] reaches 0.

**RTC register write protection**

After system reset, the RTC registers are protected against parasitic write access by the DBP bit in the power control peripheral (refer to the PWR power control section). DBP bit must be set in order to enable RTC registers write access.

After Backup domain reset, some of the RTC registers are write-protected: RTC_TR, RTC_DR, RTC_PRER, RTC_CALR, RTC_SHIFTR, the bits INIT, BIN and BCDU in RTC_ICSR and the bits FMT, SUB1H, ADD1H, REFCKON in RTC_CR.

The following steps are required to unlock the write protection on the protected RTC registers.

1. Write 0xCA into the RTC_WPR register.
2. Write 0x53 into the RTC_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

The registers protected by INITPRIV are write-protected by the INIT KEY.

The registers protected by CALDPRIV are write-protected by the CAL KEY.

In case PRIV or INITPRIV is set in the RTC_PRIVCFGR, and/or SEC or INITSEC is set in the RTC_SECCFGR: the INIT KEY is unlocked and locked only if the write accesses into the RTC_WPR register are done in the privilege and security mode defined by PRIV, INITPRIV, SEC, INITSEC configuration.

In case PRIV or CALPRIV is set in the RTC_PRIVCFGR, and/or SEC or CALSEC is set in the RTC_SECCFGR: the CAL KEY is unlocked and locked only if the write accesses into the RTC_WPR register are done in the privilege and security mode defined by PRIV, CALPRIV, SEC, CALSEC configuration.
Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC_ICSR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.

2. Poll INITF bit of in the RTC_ICSR register. The initialization phase mode is entered when INITF is set to 1.
   - If LPCAL=0: INITF is set around 2 RTCCLK cycles after INIT bit is set.
   - If LPCAL=1: INITF is set up to 2 ck_apre cycle after INIT bit is set.

3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC_PRER register, plus BIN and BCDU in the RTC_ICSR register.

4. Load the initial time and date values in the shadow registers (RTC_TR and RTC_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC_CR register.

5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded.
   - If LPCAL=0: the counting restarts after 4 RTCCLK clock cycles.
   - If LPCAL=1: the counting restarts after up to 2 RTCCLK + 1 ck_apre.

When the initialization sequence is complete, the calendar starts counting. The RTC_SSR content is initialized with:
- PREDIV_S in BCD mode (BIN=00)
- 0xFFFF FFFF in binary or mixed (BCD-binary) modes (BIN=01, 10 or 11).

In BCD mode, RTC_SSR contains the value of the synchronous prescaler counter. This enables one to calculate the exact time being maintained by the RTC down to a resolution of \(1 / (PREDIV_S + 1)\) seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value \(PREDIV_S[14:0]\). The maximum resolution allowed (30.52 \(\mu\)s with a 32768 Hz clock) is obtained with \(PREDIV_S\) set to 0x7FFF.

However, increasing \(PREDIV_S\) means that \(PREDIV_A\) must be decreased in order to maintain the synchronous prescaler output at 1 Hz. In this way, the frequency of the asynchronous prescaler output increases, which may increase the RTC dynamic consumption. The RTC dynamic consumption is optimized for \(PREDIV_A+1\) being a power of 2.

Note: After a system reset, the application can read the INITS flag in the RTC_ICSR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its Backup domain reset default value (0x00).

Note: To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC_ICSR register.

Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.
Programming the alarm

A similar procedure must be followed to program or update the programmable alarms. The procedure below is given for alarm A but can be translated in the same way for alarm B.

1. Clear ALRAE in RTC_CR to disable alarm A.
2. Program the alarm A registers (RTC_ALRMASSR/RTC_ALRMAR or RTC_ALRABINR).
3. Set ALRAE in the RTC_CR register to enable alarm A again.

Note: Each change of the RTC_CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.

Programming the wake-up timer

The following sequence is required to configure or change the wake-up timer auto-reload value (WUT[15:0] in RTC_WUTR):

1. Clear WUTE in RTC_CR to disable the wake-up timer.
2. Poll WUTWF until it is set in RTC_ICSR to make sure the access to wake-up auto-reload counter and to WUCKSEL[2:0] bits is allowed. This step must be skipped in calendar initialization mode.
   - If WUCKSEL[2] = 0: WUTWF is set around 1ck_wut + 1 RTCCLK cycles after WUTE bit is cleared.
   - If WUCKSEL[2] = 1: WUTWF is set up to 1ck_apre + 1 RTCCLK cycles after WUTE bit is cleared.
3. Program the wake-up auto-reload value WUT[15:0], WUTOCLR[15:0] and the wake-up clock selection (WUCKSEL[2:0] bits in RTC_CR). Set WUTE in RTC_CR to enable the timer again. The wake-up timer restarts down-counting.
   - If WUCKSEL[2] = 0: WUTWF is cleared around 1ck_wut + 1 RTCCLK cycles after WUTE bit is set.
   - If WUCKSEL[2] = 1: WUTWF is cleared up to 1ck_apre + 1 RTCCLK cycles after WUTE bit is set.

46.3.12 Reading the calendar

When BYPSHAD control bit is cleared in the RTC_CR register

To read the RTC calendar registers (RTC_SSR, RTC_TR and RTC_DR) properly, the APB clock frequency (fPCLK) must be equal to or greater than seven times the RTC clock frequency (fRTCCLK). This ensures a secure behavior of the synchronization mechanism.

If the APB clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC_ICSR register each time the calendar registers are copied into the RTC_SSR, RTC_TR and RTC_DR shadow registers. The copy is performed every RTCCLK cycle. To ensure consistency between the 3 values, reading either RTC_SSR or RTC_TR locks the values in the higher-order calendar shadow registers until RTC_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 1 RTCCLK periods: RSF must be cleared by software after the first calendar read, and
then the software must wait until RSF is set before reading again the RTC_SSR, RTC_TR and RTC_DR registers.

After waking up from low-power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC_SSR, RTC_TR and RTC_DR registers.

The RSF bit must be cleared after wake-up and not before entering low-power mode.

After a system reset, the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers. Indeed, a system reset resets the shadow registers to their default values.

After an initialization (refer to Calendar initialization and configuration on page 1962): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

After synchronization (refer to Section 46.3.14: RTC synchronization): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

When the BYPSHAD control bit is set in the RTC_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting from low-power modes (Stop or Standby), since the shadow registers are not updated during these modes.

When the BYPSHAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCLOCK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCLOCK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.

Note: While BYPSHAD = 1, instructions which read the calendar registers require one extra APB cycle to complete.

46.3.13 Resetting the RTC

The calendar shadow registers (RTC_SSR, RTC_TR and RTC_DR) and some bits of the RTC status register (RTC_ICSR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a Backup domain reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC_CR), the prescaler register (RTC_PRER), the RTC calibration register (RTC_CALR), the RTC shift register (RTC_SHIFTR), the RTC timestamp registers (RTC_TSSSR, RTC_TSTR and RTC_TSDR), the wake-up timer register (RTC_WUTR), the alarm A and alarm B registers (RTC_ALRMASSR/RTC_ALRMAR/RTC_ALRABINR and RTC_ALRMBSSR/RTC_ALRMBR/RTC_ALRBBINR).

In addition, when clocked by LSE, the RTC keeps on running under system reset if the reset source is different from the Backup domain reset one (refer to RCC for details about RTC clock sources not affected by system reset). When a Backup domain reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.
46.3.14 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the subsecond field (RTC_SSR or RTC_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by "shifting" its clock by a fraction of a second using RTC_SHIFTR.

The RTC can be finely adjusted using the RTC shift control register (RTC_SHIFTR). Writing to RTC_SHIFTR can shift (either delay or advance) the clock with a resolution of 1 ck_apre period.

The shift operation consists in adding the SUBFS[14:0] value to the synchronous prescaler counter SS[15:0]: this delays the clock.

If at the same time the ADD1S bit is set in BCD or mixed mode, this results in adding one second and at the same time subtracting a fraction of second, so this advances the clock. ADD1S has no effect in binary mode.

As soon as a shift operation is initiated by a write to the RTC_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.

Caution: In mixed mode (BIN=10 or 11), the SUBFS[14:BCDU+8] must be written with 0.

Caution: Before initiating a shift operation in BCD mode, the user must check that SS[15] = 0 in order to ensure that no overflow occurs. In mixed mode, the user must check that the bit SS[BCDU+8] = 0.

Caution: This synchronization feature is not compatible with the reference clock detection feature; firmware must not write to RTC_SHIFTR when REFCKON = 1.

46.3.15 RTC reference clock detection

This feature is available only in BCD mode (BIN=00).

The update of the RTC calendar can be synchronized to a reference clock, RTC_REFIN, which is usually the mains frequency (50 or 60 Hz). The precision of the RTC_REFIN reference clock should be higher than the 32.768 kHz LSE clock. When the RTC_REFIN detection is enabled (REFCKON bit of RTC_CR set to 1), the calendar is still clocked by the LSE, and RTC_REFIN is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest RTC_REFIN clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

The RTC detects if the reference clock source is present by using the 256 Hz clock (ck_apre) generated from the 32.768 kHz quartz. The detection is performed during a time window around each of the calendar updates (every 1 s). The window equals 7 ck_apre periods when detecting the first reference clock edge. A smaller window of 3 ck_apre periods is used for subsequent calendar updates.

Each time the reference clock is detected in the window, the asynchronous prescaler which outputs the ck_spre clock is forced to reload. This has no effect when the reference clock and the 1 Hz clock are aligned because the prescaler is being reloaded at the same
moment. When the clocks are not aligned, the reload shifts future 1 Hz clock edges a little for them to be aligned with the reference clock.

If the reference clock halts (no reference clock edge occurred during the 3 ck_apre window), the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a large 7 ck_apre period detection window centered on the ck_spre edge.

When the RTC_REFIN detection is enabled, PREDIV_A and PREDIV_S must be set to their default values:

- PREDIV_A = 0x007F
- PREDIV_S = 0x00FF

**Note:** RTC_REFIN clock detection is not available in Standby mode.

### 46.3.16 RTC smooth digital calibration

The RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using series of small adjustments (adding and/or subtracting individual ck_cal pulses).

If LPCAL=0: ck_cal = RTCCLK

If LPCAL=1: ck_cal = ck_apre

These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

**RTC ultra-low-power mode**

The RTC consumption can be reduced by setting the LPCAL bit in the RTC calibration register (RTC_CALR). In this case, the calibration mechanism is applied on ck_apre instead of RTCCLK. The resulting accuracy is the same, but the calibration is performed during a calibration cycle of about $2^{20} \times$ PREDIV_A x RTCCLK pulses instead of $2^{20}$ RTCCLK pulses when LPCAL=0.

**Smooth calibration mechanism**

The smooth calibration register (RTC_CALR) specifies the number of ck_cal clock cycles to be masked during the calibration cycle:

- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the calibration cycle.
- Setting CALM[1] to 1 causes two additional cycles to be masked.
- Setting CALM[2] to 1 causes four additional cycles to be masked.
- and so on up to CALM[8] set to 1 which causes 256 clocks to be masked.

**Note:** CALM[8:0] (RTC_CALR) specifies the number of ck_cal pulses to be masked during the calibration cycle. Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the calibration cycle at the moment when cal_cnt[19:0] is 0x80000; CALM[1] = 1 causes two other cycles to be masked (when cal_cnt is 0x40000 and 0xC0000); CALM[2] = 1 causes four other cycles to be masked (cal_cnt = 0x20000/0x60000/0xA0000/0xE0000); and so on up to CALM[8] = 1 which causes 256 clocks to be masked (cal_cnt = 0xXX800).

While CALM permits the RTC frequency to be reduced by up to 487.1 ppm with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm. Setting CALP
to 1 effectively inserts an extra \textit{ck\textsubscript{cal}} pulse every $2^{11}$ \textit{ck\textsubscript{cal}} cycles, which means that 512 clocks are added during every calibration cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 \textit{ck\textsubscript{cal}} cycles can be added during the calibration cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency (\textit{FCAL}) given the input frequency (\textit{FRTCCLK}) is as follows:

$$\textit{FCAL} = \textit{FRTCCLK} \times \left[1 + (\text{CALP} \times 512 - \text{CALM}) / (2^{20} + \text{CALM} - \text{CALP} \times 512)\right]$$

\textbf{Caution:} \textit{PREDIV\_A} must be greater or equal to 3.

\textbf{Calibration when \textit{PREDIV\_A} < 3}

The CALP bit can not be set to 1 when the asynchronous prescaler value (\textit{PREDIV\_A} bits in \texttt{RTC\_PRER} register) is less than 3. If CALP was already set to 1 and \textit{PREDIV\_A} bits are set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

It is however possible to perform a calibration with \textit{PREDIV\_A} less than 3 in BCD mode, the synchronous prescaler value (\textit{PREDIV\_S}) should be reduced so that each second is accelerated by 8 \textit{ck\textsubscript{cal}} clock cycles, which is equivalent to adding 256 clock cycles every calibration cycle. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each calibration cycle using only the CALM bits.

With a nominal RTCCLK frequency of 32768 Hz, when \textit{PREDIV\_A} equals 1 (division factor of 2), \textit{PREDIV\_S} should be set to 16379 rather than 16383 (4 less). The only other interesting case is when \textit{PREDIV\_A} equals 0, \textit{PREDIV\_S} should be set to 32759 rather than 32767 (8 less).

If \textit{PREDIV\_S} is reduced in this way, the formula given the effective frequency of the calibrated input clock is as follows:

$$\textit{FCAL} = \textit{FRTCCLK} \times \left[1 + (256 - \text{CALM}) / (2^{20} + \text{CALM} - 256)\right]$$

In this case, \texttt{CALM}[7:0] equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCLK is exactly 32768.00 Hz.

\textbf{Verifying the RTC calibration}

It is recommended to verify the RTC calibration with LPCAL = 0, in order to have a 32-second calibration cycle.

RTC precision is ensured by measuring the precise frequency of RTCCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 RTCCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.
However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.
  Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 RTCCLOCK cycles over 32 seconds, due to the limitation of the calibration resolution).
- CALW16 bit of the RTC_CALR register can be set to 1 to force a 16-second calibration cycle period.
  In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 RTCCLOCK cycles over 16 seconds). However, since the calibration resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when CALW16 is set to 1.
- CALW8 bit of the RTC_CALR register can be set to 1 to force a 8-second calibration cycle period.
  In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 RTCCLOCK cycles over 8 s). The long term RTC precision is also reduced to 1.907 ppm: CALM[1:0] bits are stuck at 00 when CALW8 is set to 1.

**Re-calibration on-the-fly**

The calibration register (RTC_CALR) can be updated on-the-fly while RTC_ICSR/INITF = 0, by using the follow process:

1. Poll the RTC_ICSR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC_CALR, if necessary. RECALPF is then automatically set to 1
3. Within three ck_apre cycles after the write operation to RTC_CALR, the new calibration settings take effect.

**46.3.17 Timestamp function**

Timestamp is enabled by setting the TSE or ITSE bits of RTC_CR register to 1.

When TSE is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when a timestamp event is detected on the RTC_TS pin.

When TAMPTS is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when an internal or external tamper event is detected. Refer to RTC control register (RTC_CR) and refer to Section : Timestamp on tamper event.

When ITSE is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when an internal timestamp event is detected. The internal timestamp event is generated by the switch to the VBAT supply.

When a timestamp event occurs, due to internal or external event, the timestamp flag bit (TSF) in RTC_SR register is set. In case the event is internal, the ITSF flag is also set in RTC_SR register.
By setting the TSIE bit in the RTC_CR register, an interrupt is generated when a timestamp event occurs.

If a new timestamp event is detected while the timestamp flag (TSF) is already set, the timestamp overflow flag (TSOVF) flag is set and the timestamp registers (RTC_TSTR and RTC_TSDR) maintain the results of the previous event.

**Note:** TSF is set up to 2 ck_apre cycles after the timestamp event from RTC_TS pin or from rtc_its internal signal occurs due to synchronization process. TSF is set up to 3 ck_apre cycles after tamper flags.

TSOVF is set up to only 1 ck_apre cycle after the event occurs. This means that if two timestamp events are close together, TSOVF can be seen as ‘1’ while TSF is still ‘0’. As a consequence, it is recommended to poll TSOVF only after TSF has been set.

**Caution:** If a timestamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a timestamp event occurring at the same moment, the application must not write 0 into TSF bit unless it has already read it to 1.

### 46.3.18 Calibration clock output

When the COE bit is set to 1 in the RTC_CR register, a reference clock is provided on the CALIB device output.

If the COSEL bit in the RTC_CR register is reset and PREDIV_A = 0x7F, the CALIB frequency is fRTCCLK/64. This corresponds to a calibration output at 512 Hz for an RTCCLK frequency at 32.768 kHz. The CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

When COSEL is set and “PREDIV_S+1” is a non-zero multiple of 256 (i.e: PREDIV_S[7:0] = 0xFF), the CALIB frequency is fRTCCLK/(256 * (PREDIV_A+1)). This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV_A = 0x7F, PREDIV_S = 0xFF), with an RTCCLK frequency at 32.768 kHz.

**Note:** When COSEL is cleared, the CALIB output is the output of the 6th stage of the asynchronous prescaler. If LPCAL is changed from 0 to 1, the output can be irregular (glitch…) during the LPCAL switch. If LPCAL = 1 this output is always available. If LPCAL = 0, no output is present if PREDIV_A is < 0x20.

When COSEL is set, the CALIB output is the output of the 8th stage of the synchronous prescaler.

### 46.3.19 Tamper and alarm output

The OSEL[1:0] control bits in the RTC_CR register are used to activate the alarm output TAMPALRM, and to select the function which is output. These functions reflect the contents of the corresponding flags in the RTC_SR register.

When the TAMPOE control bit is set in the RTC_CR, all external and internal tamper flags are ORed and routed to the TAMPALRM output. If OSEL = 00 the TAMPALRM output reflects only the tampers flags. If OSEL ≠ 00, the signal on TAMPALRM provides both tamper flags and alarm A, B, or wake-up flag.

The polarity of the TAMPALRM output is determined by the POL control bit in RTC_CR so that the opposite of the selected flags bit is output when POL is set to 1.
TAMPALRM output

The TAMPALRM pin can be configured in output open drain or output push-pull using the control bit TAMPALRM_TYPE in the RTC_CR register. It is possible to apply the internal pull-up in output mode thanks to TAMPALRM_PU in the RTC_CR.

Note: Once the TAMPALRM output is enabled, it has priority over CALIB on RTC_OUT1. In case the TAMPALRM is configured open-drain in the RTC, the RTC_OUT1 GPIO must be configured as input.

46.4 RTC low-power modes

Table 482. Effect of low-power modes on RTC

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect&lt;br&gt;RTC interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The RTC remains active when the RTC clock source is LSE or LSI. RTC interrupts&lt;br&gt;cause the device to exit the Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The RTC remains active when the RTC clock source is LSE or LSI. RTC interrupts&lt;br&gt;cause the device to exit the Standby mode.</td>
</tr>
</tbody>
</table>

The table below summarizes the RTC pins and functions capability in all modes.

Table 483. RTC pins functionality over modes

<table>
<thead>
<tr>
<th>Functions</th>
<th>Functional in all low-power modes except Standby mode</th>
<th>Functional in Standby mode</th>

</tbody>
</table>

1. The event flags are in the RTC_SR register.
2. The interrupt masked flags (resulting from event flags AND enable control bits) are in the RTC_SMISR register.
3. When the RTC is clocked by an oscillator functional in the low-power mode.
46.6 RTC registers

Refer to Section 1.2 of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

46.6.1 RTC time register (RTC_TR)

The RTC_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to Calendar initialization and configuration on page 1962 and Reading the calendar on page 1963.

This register is write protected. The write access procedure is described in RTC register write protection on page 1961.

This register can be write-protected against nonsecure access. Refer to Section 46.3.4: RTC secure protection modes.

This register can be write-protected against non-privileged access. Refer to Section 46.3.5: RTC privilege protection modes.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ST[2:0]**: Second tens in BCD format

Bits 3:0 **SU[3:0]**: Second units in BCD format
46.6.2 RTC date register (RTC_DR)

The RTC_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to Calendar initialization and configuration on page 1962 and Reading the calendar on page 1963.

This register is write protected. The write access procedure is described in RTC register write protection on page 1961.

This register can be write-protected against nonsecure access. Refer to Section 46.3.4: RTC secure protection modes.

This register can be write-protected against non-privileged access. Refer to Section 46.3.5: RTC privilege protection modes.

Bits 31:0 **SS[31:0]**: Synchronous binary counter
- **SS[31:16]**: Synchronous binary counter MSB values
  - When Binary or Mixed mode is selected (BIN = 01 or 10 or 11):
    - SS[31:16] are the 16 MSB of the SS[31:0] free-running down-counter.
  - When BCD mode is selected (BIN=00):
    - SS[31:16] are forced by hardware to 0x0000.
- **SS[15:0]**: Subsecond value/synchronous binary counter LSB values
  - When Binary mode is selected (BIN = 01 or 10 or 11):
    - SS[15:0] are the 16 LSB of the SS[31:0] free-running down-counter.
  - When BCD mode is selected (BIN=00):
    - SS[15:0] is the value in the synchronous prescaler counter. The fraction of a second is given by the formula below:
      - Second fraction = (PREDIV_S - SS) / (PREDIV_S + 1)
      - SS can be larger than PREDIV_S only after a shift operation. In that case, the correct time/date is one second less than as indicated by RTC_TR/RTC_DR.
### 46.6.4 RTC initialization control and status register (RTC_ICSR)

This register is write protected. The write access procedure is described in RTC register write protection on page 1961.

This register can be globally protected, or each bit of this register can be individually protected against nonsecure access. Refer to Section 46.3.4: RTC secure protection modes.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to Section 46.3.5: RTC privilege protection modes.

Address offset: 0x0C

Backup domain reset value: 0x0000 0007

System reset: not affected except INIT, INITF, and RSF bits which are cleared to 0

| Bit 31:17 | Reserved, must be kept at reset value. |
| Bit 16   | RECALPF: Recalibration pending Flag |
|          | The RECALPF status flag is automatically set to 1 when software writes to the RTC_CALR register, indicating that the RTC_CALR register is blocked. When the new calibration settings are taken into account, this bit returns to 0. Refer to Re-calibration on-the-fly. |
| Bit 15:13| Reserved, must be kept at reset value. |
| Bits 12:10 | BCDU[2:0]: BCD update (BIN = 10 or 11) |
|          | In mixed mode when both BCD calendar and binary extended counter are used (BIN = 10 or 11), the calendar second is incremented using the SSR Least Significant Bits. |
|          | 0x0: 1s calendar increment is generated each time SS[7:0] = 0 |
|          | 0x1: 1s calendar increment is generated each time SS[8:0] = 0 |
|          | 0x2: 1s calendar increment is generated each time SS[9:0] = 0 |
|          | 0x3: 1s calendar increment is generated each time SS[10:0] = 0 |
|          | 0x4: 1s calendar increment is generated each time SS[11:0] = 0 |
|          | 0x5: 1s calendar increment is generated each time SS[12:0] = 0 |
|          | 0x6: 1s calendar increment is generated each time SS[13:0] = 0 |
|          | 0x7: 1s calendar increment is generated each time SS[14:0] = 0 |
| Bits 9:8 | BIN[1:0]: Binary mode |
|          | 00: Free running BCD calendar mode (Binary mode disabled). |
|          | 01: Free running Binary mode (BCD mode disabled) |
|          | 10: Free running BCD calendar and Binary modes |
|          | 11: Free running BCD calendar and Binary modes |
Bit 7  **INIT**: Initialization mode
0: Free running mode
1: Initialization mode used to program time and date register (RTC_TR and RTC_DR), and prescaler register (RTC_PRER), plus BIN and BCDU fields. Counters are stopped and start counting from the new value when INIT is reset.

Bit 6  **INITF**: Initialization flag
When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler registers can be updated.
0: Calendar registers update is not allowed
1: Calendar registers update is allowed

Bit 5  **RSF**: Registers synchronization flag
This bit is set by hardware each time the calendar registers are copied into the shadow registers (RTC_SSR, RTC_TR and RTC_DR). This bit is cleared by hardware in initialization mode, while a shift operation is pending (SHPF = 1), or when in bypass shadow register mode (BYPShAD = 1). This bit can also be cleared by software. It is cleared either by software or by hardware in initialization mode.
0: Calendar shadow registers not yet synchronized
1: Calendar shadow registers synchronized

Bit 4  **INITS**: Initialization status flag
This bit is set by hardware when the calendar year field is different from 0 (Backup domain reset state).
0: Calendar has not been initialized
1: Calendar has been initialized

Bit 3  **SHPF**: Shift operation pending
This flag is set by hardware as soon as a shift operation is initiated by a write to the RTC_SHIFTR register. It is cleared by hardware when the corresponding shift operation has been executed. Writing to the SHPF bit has no effect.
0: No shift operation is pending
1: A shift operation is pending

Bit 2  **WUTWF**: Wake-up timer write flag
This bit is set by hardware when WUT value can be changed, after the WUTE bit has been set to 0 in RTC_CR.
It is cleared by hardware in initialization mode.
0: Wake-up timer configuration update not allowed except in initialization mode
1: Wake-up timer configuration update allowed

Bits 1:0  Reserved, must be kept at reset value.
46.6.5 RTC prescaler register (RTC_PRER)

This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to Calendar initialization and configuration on page 1962.

This register is write protected. The write access procedure is described in RTC register write protection on page 1961.

This register can be write-protected against nonsecure access. Refer to Section 46.3.4: RTC secure protection modes.

This register can be write-protected against non-privileged access. Refer to Section 46.3.5: RTC privilege protection modes.

Address offset: 0x10

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 PREDIV_A[6:0]: Asynchronous prescaler factor
This is the asynchronous division factor:
ck_apre frequency = RTCCLK frequency/(PREDIV_A+1)

Bit 15 Reserved, must be kept at reset value.

Bits 14:0 PREDIV_S[14:0]: Synchronous prescaler factor
This is the synchronous division factor:
ck_spre frequency = ck_apre frequency/(PREDIV_S+1)
46.6.6 **RTC wake-up timer register (RTC_WUTR)**

This register can be written only when WUTWF is set to 1 in RTC_ICSR.

This register can be protected against nonsecure access. Refer to *Section 46.3.4: RTC secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 46.3.5: RTC privilege protection modes*.

**WUTOCLR[15:0]**: Wake-up auto-reload output clear value

When WUTOCLR[15:0] is different from 0x0000, WUTF is set by hardware when the auto-reload down-counter reaches 0 and is cleared by hardware when the auto-reload downcounter reaches WUTOCLR[15:0]. When WUTOCLR[15:0] = 0x0000, WUTF is set by hardware when the WUT down-counter reaches 0 and is cleared by software.

**Bits 15:0** **WUT[15:0]**: Wake-up auto-reload value bits

When the wake-up timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck_wut cycles. The ck_wut period is selected through WUCKSEL[2:0] bits of the RTC_CR register.

When WUCKSEL[2] = 1, the wake-up timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.

The first assertion of WUTF occurs between WUT and (WUT + 2) ck_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] = 011 (RTCCLK/2) is forbidden.

46.6.7 **RTC control register (RTC_CR)**

*This register is write protected. The write access procedure is described in RTC register write protection on page 1961.*
This register can be globally protected, or each bit of this register can be individually protected against nonsecure access. Refer to Section 46.3.4: RTC secure protection modes.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to Section 46.3.5: RTC privilege protection modes.

Address offset: 0x18

Bit 31 **OUT2EN**: RTC_OUT2 output enable

With this bit set, the RTC outputs can be remapped on RTC_OUT2 as follows:

**OUT2EN = 0**: RTC output 2 disable

If OSEL ≠ 00 or TAMPOE = 1: TAMPALRM is output on RTC_OUT1

If OSEL = 00 and TAMPOE = 0 and COE = 1: CALIB is output on RTC_OUT1

**OUT2EN = 1**: RTC output 2 enable

If (OSEL ≠ 00 or TAMPOE = 1) and COE = 0: TAMPALRM is output on RTC_OUT2

If OSEL = 00 and TAMPOE = 0 and COE = 1: CALIB is output on RTC_OUT2

If (OSEL ≠ 00 or TAMPOE = 1) and COE = 1: CALIB is output on RTC_OUT2 and TAMPALRM is output on RTC_OUT1.

Bit 30 **TAMPALRM_TYPE**: TAMPALRM output type

0: TAMPALRM is push-pull output

1: TAMPALRM is open-drain output

Bit 29 **TAMPALRM PU**: TAMPALRM pull-up enable

0: No pull-up is applied on TAMPALRM output

1: A pull-up is applied on TAMPALRM output

Bit 28 **ALRBFCLR**: Alarm B flag automatic clear

0: Alarm B event generates a trigger event and ALRBF must be cleared by software to allow next alarm event.

1: Alarm B event generates a trigger event. ALRBF is automatically cleared by hardware after 1 ck_apre cycle.

Bit 27 **ALRAFCLR**: Alarm A flag automatic clear

0: Alarm A event generates a trigger event and ALRAF must be cleared by software to allow next alarm event.

1: Alarm A event generates a trigger event. ALRAF is automatically cleared by hardware after 1 ck_apre cycle.
Bit 26 TAMPOE: Tamper detection output enable on TAMPALRM
0: The tamper flag is not routed on TAMPALRM
1: The tamper flag is routed on TAMPALRM, combined with the signal provided by OSEL and with the polarity provided by POL.

Bit 25 TAMPTS: Activate timestamp on tamper detection event
0: Tamper detection event does not cause a RTC timestamp to be saved
1: Save RTC timestamp on tamper detection event
TAMPTS is valid even if TSE = 0 in the RTC_CR register. Timestamp flag is set up to 3 ck_apre cycles after the tamper flags.

Note: TAMPTS must be cleared before entering RTC initialization mode.

Bit 24 ITSE: timestamp on internal event enable
0: internal event timestamp disabled
1: internal event timestamp enabled

Bit 23 COE: Calibration output enable
This bit enables the CALIB output
0: Calibration output disabled
1: Calibration output enabled

Bits 22:21 OSEL[1:0]: Output selection
These bits are used to select the flag to be routed to TAMPALRM output.
00: Output disabled
01: Alarm A output enabled
10: Alarm B output enabled
11: Wake-up output enabled

Bit 20 POL: Output polarity
This bit is used to configure the polarity of TAMPALRM output.
0: The pin is high when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]), or when a TAMPxF/ITAMPxF is asserted (if TAMPOE = 1).
1: The pin is low when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]), or when a TAMPxF/ITAMPxF is asserted (if TAMPOE = 1).

Bit 19 COSEL: Calibration output selection
When COE = 1, this bit selects which signal is output on CALIB.
0: Calibration output is 512 Hz
1: Calibration output is 1 Hz
These frequencies are valid for RTCCLK at 32.768 kHz and prescalers at their default values (PREDIV_A = 127 and PREDIV_S = 255). Refer to Section 46.3.18: Calibration clock output.

Bit 18 BKP: Backup
This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.

Bit 17 SUB1H: Subtract 1 hour (winter time change)
When this bit is set outside initialization mode, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.
Setting this bit has no effect when current hour is 0.
0: No effect
1: Subtracts 1 hour to the current time. This can be used for winter time change.
Bit 16  **ADD1H**: Add 1 hour (summer time change)
    When this bit is set outside initialization mode, 1 hour is added to the calendar time. This bit is always read as 0.
    0: No effect
    1: Adds 1 hour to the current time. This can be used for summer time change

Bit 15  **TSIE**: Timestamp interrupt enable
    0: Timestamp interrupt disable
    1: Timestamp interrupt enable

Bit 14  **WUTIE**: Wake-up timer interrupt enable
    0: Wake-up timer interrupt disabled
    1: Wake-up timer interrupt enabled

Bit 13  **ALRBIE**: Alarm B interrupt enable
    0: Alarm B interrupt disable
    1: Alarm B interrupt enable

Bit 12  **ALRAIE**: Alarm A interrupt enable
    0: Alarm A interrupt disabled
    1: Alarm A interrupt enabled

Bit 11  **TSE**: timestamp enable
    0: timestamp disable
    1: timestamp enable

Bit 10  **WUTE**: Wake-up timer enable
    0: Wake-up timer disabled
    1: Wake-up timer enabled

    *Note*: When the wake-up timer is disabled, wait for WUTWF = 1 before enabling it again.

Bit 9  **ALRB**: Alarm B enable
    0: Alarm B disabled
    1: Alarm B enabled

Bit 8  **ALRA**: Alarm A enable
    0: Alarm A disabled
    1: Alarm A enabled

Bit 7  **SSRUIE**: SSR underflow interrupt enable
    0: SSR underflow interrupt disabled
    1: SSR underflow interrupt enabled

Bit 6  **FMT**: Hour format
    0: 24 hour/day format
    1: AM/PM hour format

Bit 5  **BYP SHAD**: Bypass the shadow registers
    0: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken from the shadow registers, which are updated once every two RTCCLOCK cycles.
    1: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken directly from the calendar counters.

    *Note*: If the frequency of the APB clock is less than seven times the frequency of RTCCLOCK, BYPSHAD must be set to 1.
Bit 4 **REFCKON**: RTC_REFIN reference clock detection enable (50 or 60 Hz)
0: RTC_REFIN detection disabled
1: RTC_REFIN detection enabled

*Note*: BIN must be 0x00 and PREDIV_S must be 0x00FF.

Bit 3 **TSEdge**: Timestamp event active edge
0: RTC_TS input rising edge generates a timestamp event
1: RTC_TS input falling edge generates a timestamp event

TSE must be reset when TSEdge is changed to avoid unwanted TSF setting.

Bits 2:0 **WUCKSEL[2:0]**: CK_wut wake-up clock selection
000: RTC/16 clock is selected
001: RTC/8 clock is selected
010: RTC/4 clock is selected
011: RTC/2 clock is selected
10x: ck_spre (usually 1 Hz) clock is selected in BCD mode. In binary or mixed mode, this is the clock selected by BCDU.
11x: ck_spre (usually 1 Hz) clock is selected in BCD mode. In binary or mixed mode, this is the clock selected by BCDU. Furthermore, $2^{16}$ is added to the WUT counter value.

*Note*: Bits 6 and 4 of this register can be written in initialization mode only (**RTC_ICSR/INITF** = 1).

**WUT** = wake-up unit counter value. WUT = (0x0000 to 0xFFFF) + 0x10000 added when WUCKSEL[2:1] = 11.

Bits 2 to 0 of this register can be written only when RTC_CR WUTE bit = 0 and RTC_ICSR WUTWF bit = 1.

*It is recommended not to change the hour during the calendar hour increment as it may mask the incrementation of the calendar hour.*

**ADD1H and SUB1H changes are effective in the next second.**

### 46.6.8 RTC privilege mode control register (**RTC_PRIVCFGR**)  
This register can be written only when the APB access is privileged. This register can be write-protected, or each bit of this register can be individually write-protected against nonsecure access depending on the RTC_SECCFGR configuration (refer to **Section 46.3.5: RTC privilege protection modes**).

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 PRIV: RTC privilege protection
0: All RTC registers can be written when the APB access is privileged or non-privileged, except the registers protected by other privilege protection bits.
1: All RTC registers can be written only when the APB access is privileged.

Bit 14 INITPRIV: Initialization privilege protection
0: RTC Initialization mode, calendar and prescalers registers can be written when the APB access is privileged or non-privileged.
1: RTC Initialization mode, calendar and prescalers registers can be written only when the APB access is privileged.

Bit 13 CALPRIV: Shift register, Delight saving, calibration and reference clock privilege protection
0: Shift register, Delight saving, calibration and reference clock can be written when the APB access is privileged or non-privileged.
1: Shift register, Delight saving, calibration and reference clock can be written only when the APB access is privileged.

Bits 12:4 Reserved, must be kept at reset value.

Bit 3 TSPRIV: Timestamp privilege protection
0: RTC Timestamp configuration and interrupt clear can be written when the APB access is privileged or non-privileged.
1: RTC Timestamp configuration and interrupt clear can be written only when the APB access is privileged.

Bit 2 WUTPRIV: Wake-up timer privilege protection
0: RTC wake-up timer configuration and interrupt clear can be written when the APB access is privileged or non-privileged.
1: RTC wake-up timer configuration and interrupt clear can be written only when the APB access is privileged.

Bit 1 ALRBPRIV: Alarm B privilege protection
0: RTC Alarm B configuration and interrupt clear can be written when the APB access is privileged or non-privileged.
1: RTC Alarm B configuration and interrupt clear can be written only when the APB access is privileged.

Bit 0 ALRAPRIV: Alarm A and SSR underflow privilege protection
0: RTC Alarm A and SSR underflow configuration and interrupt clear can be written when the APB access is privileged or non-privileged.
1: RTC Alarm A and SSR underflow configuration and interrupt clear can be written only when the APB access is privileged.

Note: Refer to Section 46.3.5: RTC privilege protection modes for details on the read protection.
46.6.9 RTC secure configuration register (RTC_SECCFGR)

This register can be written only when the APB access is secure.

This register can be globally write-protected, or each bit of this register can be individually write-protected against non-privileged access depending on the RTC_PRIVCFGR configuration (refer to Section 46.3.5: RTC privilege protection modes).

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 SEC: RTC global protection
0: All RTC registers can be written when the APB access is secure or non-secure, except the registers protected by other secure protection bits.
1: All RTC registers can be written only when the APB access is secure.

Bit 14 INITSEC: Initialization protection
0: RTC Initialization mode, calendar and prescalers registers can be written when the APB access is secure or nonsecure.
1: RTC Initialization mode, calendar and prescalers registers can be written only when the APB access is secure.

Bit 13 CALSEC: Shift register, daylight saving, calibration and reference clock protection
0: Shift register, daylight saving, calibration and reference clock can be written when the APB access is secure or nonsecure.
1: Shift register, daylight saving, calibration and reference clock can be written only when the APB access is secure.

Bits 12:4 Reserved, must be kept at reset value.

Bit 3 TSSEC: Timestamp protection
0: RTC timestamp configuration and interrupt clear can be written when the APB access is secure or nonsecure.
1: RTC timestamp configuration and interrupt clear can be written only when the APB access is secure.
Bit 2 **WUTSEC**: Wake-up timer protection
0: RTC wake-up timer configuration and interrupt clear can be written when the APB access is secure or nonsecure.
1: RTC wake-up timer configuration and interrupt clear can be written only when the APB access is secure.

Bit 1 **ALRBSEC**: Alarm B protection
0: RTC alarm B configuration and interrupt clear can be written when the APB access is secure or nonsecure.
1: RTC alarm B configuration and interrupt clear can be written only when the APB access is secure.

Bit 0 **ALRASEC**: Alarm A and SSR underflow protection
0: RTC alarm A and SSR underflow configuration and interrupt clear can be written when the APB access is secure or nonsecure.
1: RTC alarm A and SSR underflow configuration and interrupt clear can be written only when the APB access is secure.

**Note:** Refer to Section 46.3.4: RTC secure protection modes for details on the read protection.

Bits 31:8 Reserved, must be kept at reset value.
Bits 7:0 **KEY[7:0]**: Write protection key
This byte is written by software.
Reading this byte always returns 0x00.
Refer to RTC register write protection for a description of how to unlock RTC register write protection.
46.6.11 RTC calibration register (RTC_CALR)

This register is write protected. The write access procedure is described in RTC register write protection on page 1961.

This register can be write-protected against nonsecure access. Refer to Section 46.3.4: RTC secure protection modes.

This register can be write-protected against non-privileged access. Refer to Section 46.3.5: RTC privilege protection modes.

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **CALP**: Increase frequency of RTC by 488.5 ppm
0: No RTCCCLK pulses are added.
1: One RTCCCLK pulse is effectively inserted every $2^{41}$ pulses (frequency increased by 488.5 ppm).

This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. If the input frequency is 32768 Hz, the number of RTCCCLK pulses added during a 32-second window is calculated as follows:

$$(512 \times \text{CALP}) - \text{CALM}.$$ 

Refer to Section 46.3.16: RTC smooth digital calibration.

Bit 14 **CALW8**: Use an 8-second calibration cycle period
When CALW8 is set to 1, the 8-second calibration cycle period is selected.

*Note*: **CALM[1:0]** are stuck at 00 when CALW8 = 1. Refer to Section 46.3.16: RTC smooth digital calibration.

Bit 13 **CALW16**: Use a 16-second calibration cycle period
When CALW16 is set to 1, the 16-second calibration cycle period is selected. This bit must not be set to 1 if CALW8 = 1.

*Note*: **CALM[0]** is stuck at 0 when CALW16 = 1. Refer to Section 46.3.16: RTC smooth digital calibration.
Bit 12  **LPCAL**: RTC low-power mode  
  0: Calibration window is 2<sup>20</sup> RTCCLK, which is a high-consumption mode. This mode must be set only when less than 32s calibration window is required.  
  1: Calibration window is 2<sup>20</sup> ck_apre, which is the required configuration for ultra-low consumption mode.  

Bits 11:9  Reserved, must be kept at reset value.  

Bits 8:0  **CALM[8:0]**: Calibration minus  
The frequency of the calendar is reduced by masking CALM out of 2<sup>20</sup> RTCCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.  
To increase the frequency of the calendar, this feature should be used in conjunction with CALP. See [Section 46.3.16: RTC smooth digital calibration on page 1966](#).  

### 46.6.12 RTC shift control register (RTC_SHIFTR)

This register is write protected. The write access procedure is described in [RTC register write protection on page 1961](#).  

This register can be protected against nonsecure access. Refer to [Section 46.3.4: RTC secure protection modes](#).  

This register can be protected against non-privileged access. Refer to [Section 46.3.5: RTC privilege protection modes](#).

Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **SSRUMF**: SSR underflow nonsecure masked flag
This flag is set by hardware when the SSR underflow nonsecure interrupt occurs.

Bit 5  **ITSMF**: Internal timestamp nonsecure masked flag
This flag is set by hardware when a timestamp on the internal event occurs and timestamp nonsecure interrupt is raised.

Bit 4  **TSOVMF**: Timestamp overflow nonsecure masked flag
This flag is set by hardware when a timestamp interrupt occurs while TSMF is already set. It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit is cleared.

Bit 3  **TSMF**: Timestamp nonsecure masked flag
This flag is set by hardware when a timestamp nonsecure interrupt occurs. If ITSF flag is set, TSF must be cleared together with ITSF.

Bit 2  **WUTMF**: Wake-up timer nonsecure masked flag
This flag is set by hardware when the wake-up timer nonsecure interrupt occurs. This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.

Bit 1  **ALRBMF**: Alarm B nonsecure masked flag
This flag is set by hardware when the alarm B nonsecure interrupt occurs.

Bit 0  **ALRAMF**: Alarm A masked flag
This flag is set by hardware when the alarm A nonsecure interrupt occurs.

### 46.6.22 RTC secure masked interrupt status register (RTC_SMISR)

This register can be globally protected, or each bit of this register can be individually protected against nonsecure access. Refer to **Section 46.3.4: RTC secure protection modes**.

This register can be globally protected, or each bit of this register can be individually protected against non-privileged access. Refer to **Section 46.3.5: RTC privilege protection modes**.

**SS[31:16]**: Synchronous counter alarm value in Binary mode

This value is compared with the contents of the synchronous counter to determine if Alarm A is to be activated. Only bits 0 up MASKSS-1 are compared.

SS[14:0] is the mirror of SS[14:0] in the RTC_ALRMASSRR, and so can also be read or written through RTC_ALRMASSR.

### 46.6.26 RTC alarm B binary mode register (RTC_ALRBBINR)

This register can be written only when ALRBE is reset in RTC_CR register, or in initialization mode.

This register can be protected against nonsecure access. Refer to Section 46.3.4: RTC secure protection modes.

This register can be protected against non-privileged access. Refer to Section 46.3.5: RTC privilege protection modes.

47 Tamper and backup registers (TAMP)

47.1 Introduction

The anti-tamper detection circuit is used to protect sensitive data from external attacks. 32 32-bit backup registers are retained in all low-power modes and also in $V_{BAT}$ mode. The backup registers, as well as other secrets in the device, are protected by this anti-tamper detection circuit with 11 tamper pins and 13 internal tampers. The external tamper pins can be configured for edge detection, or level detection with or without filtering, or active tamper which increases the security level by auto checking that the tamper pins are not externally opened or shorted.
47.2 **TAMP main features**

- A tamper detection can optionally erase the backup registers, backup SRAM, SRAM2, caches and cryptographic peripherals. The device resources protected by tamper are named “device secrets”.
- 32 32-bit backup registers:
  - The backup registers (TAMP\_BKP\_xR) are implemented in the backup domain that remains powered-on by \( V_{BAT} \) when the \( V_{DD} \) power is switched off.
- Up to 11 tamper pins for 8 external tamper detection events:
  - Active tamper mode: continuous comparison between tamper output and input to protect from physical open-short attacks.
  - Flexible active tamper I/O management: from 5 meshes (each input associated to its own exclusive output) to 8 meshes (single output shared for up to 8 tamper inputs)
  - Passive tampers: ultra-low power edge or level detection with internal pull-up hardware management.
  - Configurable digital filter.
- 13 internal tamper events to protect against transient or environmental perturbation attacks
- Each tamper can be configured in two modes:
  - Confirmed mode: immediate erase of secrets on tamper detection, including backup registers erase
  - Potential mode: most of the secrets erase following a tamper detection are launched by software
- Any tamper detection can generate a RTC timestamp event.
- TrustZone support:
  - Tamper secure or nonsecure configuration.
  - Backup registers configuration in 3 configurable-size areas:
    - 1 read/write secure area.
    - 1 write secure/read nonsecure area.
    - 1 read/write nonsecure area.
  - Boot hardware key for secure AES, stored in backup registers, protected against read and write access.
- Tamper configuration and backup registers privilege protection
- Monotonic counter.

1. This monitoring must be enabled by setting MONEN in `PWR backup domain control register (PWR_BDCR)`.  
2. This monitoring must be enabled by setting LSEON in `PWR backup domain control register (PWR_BDCR)`.  
3. This signal is generated in the TAMP peripheral.

The TZEN option bit is used to activate TrustZone in the device.
TZEN = 1: TrustZone activated.
TZEN = 0: TrustZone disabled.

When TrustZone is disabled, the APB access to the TAMP registers are nonsecure.

### 47.3.3 GPIOs controlled by the RTC and TAMP

Refer to Section 46.3.3: GPIOs controlled by the RTC and TAMP.

### 47.3.4 TAMP register write protection

After system reset, the TAMP registers (including backup registers) are protected against parasitic write access by the DBP bit in the power control peripheral (refer to the PWR power control section). DBP bit must be set in order to enable TAMP registers write access.

### 47.3.5 TAMP secure protection modes

By default after a backup domain power-on reset, all TAMP registers can be read or written in both secure and nonsecure modes, except for the TAMP secure configuration register (TAMP_SECCFGR) which can be written in secure mode only. The TAMP protection configuration is not affected by a system reset.

- When the TAMPSEC bit is set in the TAMP_SECCFGR register:
  - Writing the TAMP registers is possible only in secure mode, except for the backup registers which have their own protection setting.
  - Reading TAMP_SECCFGR, TAMP_PRIVCFGR and TAMP_MISR is always possible in secure and nonsecure modes. All the other TAMP registers can be read only in secure mode, except for the backup registers and monotonic counters which have their own protection setting.

- When the CNT1SEC bit is set in the TAMP_SECCFGR register: the TAMP_COUNT1R can be read and written only in secure mode.

A nonsecure access to a secure-protected register is denied:

- There is no bus error generated.
- A notification is generated through a flag/interrupt in the TZIC (TrustZone illegal access controller).
- When write protected, the bits are not written.
- When read protected they are read as 0.

As soon as at least one function is configured to be secured, the TAMP reset and clock control is also secured in the RCC.
47.3.6 Backup registers protection zones

The backup registers protection is configured thanks to BKPRWSEC[7:0] and BKPWSEC[7:0] (refer to the figure below):

![Figure 619. Backup registers protection zones](image)

1. \( l \) = last backup register index

In case TZEN =1, the bits BKPWPRIV and BKPRWPRIV in the TAMP_PRIVCFGR can be written only in secure mode.

47.3.7 TAMP privilege protection modes

By default after a backup domain power-on reset, all TAMP registers can be read or written in both privileged and non-privileged modes, except for the TAMP privilege configuration register (TAMP_PRIVCFGR) which can be written in privilege mode only. The TAMP protection configuration is not affected by a system reset.

When the TAMPPRIV bit is set in the TAMP_PRIVCFGR register:
- Writing the TAMP registers is possible only in privilege mode, except for the backup registers and the monotonic counters which have their own protection setting.
- When the CNT1PRIV bit is set in the TAMP_PRIVCFGR register: the TAMP_COUNT1R can be read and written only in privilege mode.
- Reading TAMP_SECCFGR, TAMP_PRIVCFGR is always possible in privilege and non-privileged modes. All the other TAMP registers can be read only in privileged mode, except for the backup registers and the monotonic counters which have their own protection setting.

The backup registers protection is configured thanks to BKPRWSEC[7:0] and BKPRWPRIV for the protection zone 1, and thanks to BKPRWSEC[7:0], BKPWSEC[7:0] and BKPRWPRIV for the protection zone 2 (refer to Figure 619). The BHKLOCK bit can be written only in privileged mode when the BKPRWPRIV bit is set.

A non-privileged access to a privileged-protected register is denied:
- There is no bus error generated.
- When write protected, the bits are not written.
- When read protected they are read as 0.
47.3.8 Boot hardware key (BHK)

The eight first backup registers from TAMP_BKP0R to TAMP_BKP7R can be used to store a boot hardware key for the secure AES.

For this purpose, these registers must belong to the Protection Zone 1: BKPRWSEC must be greater or equal to 8.

Once the backup registers are written with the boot hardware key, the BHKLOCK bit must be set in the TAMP_SECCFGR register. Once BHKLOCK is set, the 8 backup registers cannot be accessed anymore by software: they are read as 0 and write to these registers is ignored. BHKLOCK cannot be cleared by software, and is cleared by hardware following a tamper event or when the readout protection (RDP) is disabled. It is also cleared with BKERASE command (in all cases the backup registers are also erased).

Refer to section secure AES co-processor (SAES) for details on procedure to download the boot hardware key in the SAES.

47.3.9 Tamper detection

The tamper detection main purpose is to protect the device secrets from device external attacks. The detection is made on events on TAMP_INx (x = pin index) I/Os, or on internal monitors detecting out-of-range device conditions.

The tamper detection can be configured for the following purposes:
- erase the backup registers and other device secrets stored in SRAMs or peripherals listed in Table 489: TAMP interconnection. The device secrets list is configurable thanks to TAMP resources protection configuration register (TAMP_RPCFGR).
- block the read/write access to the backup registers and other device secrets stored in SRAMs or peripherals listed in Table 489: TAMP interconnection. The device secrets list is configurable thanks to TAMP_RPCFGR.
- generate an interrupt, capable to wake-up from low-power modes
- generate a hardware trigger for the low-power timers, or a RTC timestamp event

The external I/Os tamper detection supports 2 main configurations:
- Passive mode: TAMP_INx I/Os are monitored and a tamper is detected either on edge or on level.
- Active mode: TAMP_INx (x = pin index) is continuously compared with TAMP_OUTy (y = pin index) allowing open-short detection.

A digital filter can be applied on external tamper detection to avoid false detection. In addition, it is possible to configure each tamper source in potential mode, so that the secrets erase is not launched by hardware on tamper detection. The secrets erase can then be launched by software after software checks.

47.3.10 TAMP backup registers and other device secrets erase

The backup registers (TAMP_BKPxR) are not reset by system reset or when the device wakes up from Standby mode.

The backup registers and the other device secrets are not reset when the corresponding mask is set (TAMPxMSK=1 in the TAMP_CR2 register).

Note: The backup registers are also erased when the readout protection of the flash is changed from level 1 to level 0.
Tamper and backup registers (TAMP)

Tamper detection – confirmed mode

The confirmed mode is selected for TAMPx (external tamper x) when TAMPxPOM = 0 in the TAMP_CR2 register. The confirmed mode is selected for ITAMPx (internal tamper x) when ITAMPxPOM = 0 in the TAMP_CR3 register. The effects of a tamper detection in confirmed mode are described with tamp_confirmed and tamp_confirmed_rpcfgx signals in the Table 489: TAMP interconnection.

This mode is selected to erase automatically the device secrets when the tamper is detected.

Tamper detection – potential mode

The potential mode is selected for TAMPx (external tamper x) when TAMPxPOM = 1 in the TAMP_CR2 register. The potential tamper mode is selected for ITAMPx (internal tamper x) when ITAMPxPOM = 1 in the TAMP_CR3 register. The effects of a tamper detection in potential mode are described with tamp_potential and tamp_potential_rpcfgx signals in the Table 489: TAMP interconnection.

This mode is selected to avoid irreversible erasure of some device secrets when the tamper is detected. In this mode, some device secrets are not erased when the corresponding tamper event is detected. In addition, the read and write accesses to these device secrets are blocked as soon as the tamper detection flag is set in potential mode, until this flag is cleared by setting the corresponding clear flag in the TAMP_SCR register. Therefore the software can perform some checks to discriminate false from true tampers, and decide to launch secrets erase only in case of the potential tamper is confirmed to be a true tamper. The device secrets are erased by software by setting the BKERASE bit in the TAMP_CR2 register.

Potential tamper to confirmed tamper timeout

Some internal tampers generate a tamper event if the independent watchdog reset occurs when another tamper flag is set (refer to Table 489: TAMP interconnection). The IWDG tamper must be configured with ITAMPxPOM = 0. This permits the erasure of device secrets to be forced by hardware after a timeout, in case the previous tamper event was in potential mode. This is equivalent to change the “potential tamper” into “confirmed tamper” if a watchdog reset occurs before any software decision following the potential tamper event.

Device resources protection configuration

Some device resources can be configured in order to be included to the list of the device secrets protected by tamper detection.

When RPCFGz = 0 in the TAMP_RPCFGR, the device resource associated to RPCFGz is not protected by the TAMP peripheral:
- It is not affected by tamper detection (whatever confirmed or potential mode)
- It is not affected by BKERASE software command
- It is not affected by BKBLOCK software command

When RPCFGz = 1 in the TAMP_RPCFGR, the device resource associated to RPCFGz is protected by the TAMP peripheral:
- It is affected by confirmed tamper detection and BKERASE software command, as described with tamp_confirmed_rpcfgz signal in Table 489: TAMP interconnection
- It is affected by potential tamper detection and BKBLOCK software command, as described with tamp_potential_rpcfgz signal in Table 489: TAMP interconnection
Device secrets access blocked by software

By default, the device secrets can be accessed by the application, except if a tamper event flag is detected: the device secrets access is not possible as long as a tamper flag is set.

It is possible to block the access to the device secrets by software, by setting the BKBLOCK bit of the TAMP_CR2 register. The device secrets access is possible only when BKBLOCK = 0 and no tamper flag is set.

### 47.3.11 Tamper detection configuration and initialization

Each input can be enabled by setting the corresponding TAMPxE bits to 1 in the TAMP_CR register.

Each TAMP_INx tamper detection input is associated with a flag TAMPxF in the TAMP_SR register.

By setting the TAMPxIE bit in the TAMP_IER register, an interrupt is generated when a tamper detection event occurs (when TAMPxF is set). Setting TAMPxIE is not allowed when the corresponding TAMPxMSK is set.

**Trigger output generation on tamper event**

The tamper event detection can be used as trigger input by the low-power timers.

When TAMPxMSK bit is cleared in TAMP_CR register, the TAMPxF flag must be cleared by software in order to allow a new tamper detection on the same pin.

When TAMPxMSK bit is set, the TAMPxF flag is masked, and kept cleared in TAMP_SR register. This configuration permits the low-power timers to be triggered automatically in Stop mode, without requiring the system wake-up to perform the TAMPxF clearing. In this case, the backup registers are not cleared.

This feature is available only when the tamper is configured in the Level detection with filtering on tamper inputs (passive mode) mode (TAMPFLT ≠ 00 and active mode is not selected).

**Timestamp on tamper event**

With TAMPPTS set to 1 in the RTC_CR, any internal or external tamper event causes a timestamp to occur. In case a timestamp occurs due to tamper event, either the TSF bit or the TSOVF bit is set in RTC_SR, in the same manner as if a normal timestamp event occurs.

**Note:** TSF is set up to 3 ck_apre cycles after TAMPxF flags. TSF is not set if RTCCCLK is stopped (it is set when RTCCCLK restarts).
Note: If TAMPxF is cleared before the expected rise of TSF, TSF is not set. Consequently, in case TAMPTS = 1, the software should either wait for timestamp flag before clearing the tamper flag, or should read the RTC counters values in the TAMP interrupt routine.

Edge detection on tamper inputs (passive mode)

If the TAMPFILT bits are 00, the TAMPI_nX pins generate tamper detection events when either a rising edge or a falling edge is observed depending on the corresponding TAMPxTRG bit. The internal pull-up resistors on the TAMPI_nX inputs are deactivated when edge detection is selected.

Caution: When TAMPFILT = 00 and TAMPxTRG = 0 (rising edge detection), a tamper event may be detected by hardware if the tamper input is already at high level before enabling the tamper detection.

After a tamper event has been detected and cleared, the TAMPI_nX should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (TAMP_BKPnX). This prevents the application from writing to the backup registers while the TAMPI_nX input value still indicates a tamper detection. This is equivalent to a level detection on the TAMPI_nX input.

Note: Tamper detection is still active when V_DD power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the TAMPx is mapped should be externally tied to the correct level.

Level detection with filtering on tamper inputs (passive mode)

Level detection with filtering is performed by setting TAMPFILT to a non-zero value. A tamper detection event is generated when either 2, 4, or 8 (depending on TAMPFILT) consecutive samples are observed at the level designated by the TAMPI_nX bits.

The TAMPI_nX inputs are precharged through the I/O internal pull-up resistance before its state is sampled, unless disabled by setting TAMPPUDIS to 1. The duration of the precharge is determined by the TAMPPRCH bits, allowing for larger capacitances on the TAMPI_nX inputs.

The trade-off between tamper detection latency and power consumption through the pull-up can be optimized by using TAMPFREQ to determine the frequency of the sampling for level detection.

Note: Refer to the microcontroller datasheet for the electrical characteristics of the pull-up resistors.

Active tamper detection

When the TAMPxAM bit is set in the TAMP_ATCR, the tamper events are configured in active mode, which is based on a comparison between a TAMP_OUTy pin and a TAMPI_nX pin. By default (ATOSHARE = 0) the comparison is made between TAMPI_nX and TAMP_OUTx (y = x). When ATOSHARE bit is set, the same output can be used for several tamper inputs. The TAMP_OUTy function is enabled on the I/O as soon as it is selected for comparison with an active tamper input TAMPI_nX (TAMPxEN = TAMPxAM = 1), thanks to ATOSHARE and ATOSELx bits. Refer to ATOSHARE and ATOSELx bits descriptions in the TAMP_ATCRx (x = 1, 2) registers.

Every two CK_ATPER cycles (CK_ATPER = 2ATPER × CK_ATPRE), TAMP_OUTy output pin provides a value provided by a pseudo random number generator (PRNG). After outputting this value, the TAMP_OUTy pin outputs its opposite value one CK_ATPER cycle after.
PRNG is consumed by the selected tamper outputs at a different frequency depending on the number of selected tamper outputs. The number of selected outputs depends on TAMPxAM, TAMPxE, ATOSEL and ATOSHARE.

- When only 1 output is selected: PRNG is consumed every 16 CK_ATPER periods.
- When 2 outputs are selected: PRNG is consumed every 8 CK_ATPER periods.
- When 3 or 4 outputs are selected: PRNG is consumed every 4 CK_ATPER periods.

</tbody>
</table>

1. Assuming f_RTCCLK = 32768 Hz.
2. This setting requires that (PREDIV_A+1) = 128 and (PREDIV_S+1) is a multiple of 16.
When 5 or more outputs are selected: PRNG is consumed every 2 CK_ATPER periods.
The PRNG needs minimum 9 CK_ATPRE cycles to output a new value. Consequently the minimum ATPER values for correct functionality are provided in the table below:

Table 492. Minimum ATPER value

<table>
<thead>
<tr>
<th>Number of selected outputs</th>

</tr>
</tbody>
</table>

The TAMP_INx pin is externally connected to TAMP_OUTy pin. The comparison is made between TAMP_OUTy output value and TAMP_INx received value, every CK_ATPRE cycle. In case a comparison mismatch occurs, the TAMPxF bit is set in the TAMP_SR register.

As an example, TAMP_OUT1 can be used for comparison with TAMP_IN1 and TAMP_IN2 by configuring and enabling both TAMP1 and TAMP2 in active mode, with ATOSHARE = 1, ATOSEL1 = 000 and ATOSEL2 = 000.

The active tamper can be combined with input filtering when FLTEN = 1. In this case, the tamper is detected only when 2 comparisons are false, in 4 consecutive comparison samples.

As illustrated in Figure 620, if FLTEN = 0, any mismatch between the TAMP_OUTy output and the associated TAMP_INx input when the latter is sampled generates a tamper. This is the case in all three examples (a), (b) and (c).

If FLTEN = 1, example (a) does not generate a tamper, since only one mismatch is detected in four consecutive comparisons. In example (b), a tamper is generated since two successive mismatches are detected. Example (c) also generates a tamper, since two mismatches occur in four consecutive comparisons, even though the mismatches do not occur on successive samples.
Setting FLTEN = 1 avoids unwanted detection of tampers due to glitches, bounce or transitory states on the TAMP_INx inputs, by ignoring single pulses which are shorter than one period of CK_ATPRE, programmed in the ATCKSEL field of the TAMP_ATCR1 register. The minimum filtered pulse width is listed in Table 493 for each possible setting of ATCKSEL, assuming f_RTCCLK = 32.768 kHz.

### Table 493. Active tamper filtered pulse duration

</tr>
</tbody>
</table>

1. This setting requires that \((\text{PREDIV}_A+1) = 128\) and \((\text{PREDIV}_S+1)\) is a multiple of 16.

**Note:** Multiple pulses which are shorter than one CK_ATPRE period may nevertheless cause a tamper if they result in two mismatches in four consecutive comparisons.

**Caution:**

Refer to section **Section : Calendar initialization and configuration**.

Refer also to **RTC alarm A subsecond register (RTC_ALRMASSR)**, **RTC alarm B subsecond register (RTC_ALRMBSSR)**, **RTC alarm A binary mode register (RTC_ALRABINR)** and **RTC alarm B binary mode register (RTC_ALRBBINR)** in case RTC binary mode is used in conjunction with ATCKSEL[3] = 1.

**Caution:**
Caution: The active tamper detection is no more functional in case of calendar overflow when ATCKSEL[3] = 1. It is mandatory to enable the internal tamper 5 on calendar overflow to ensure tamper protection.

The pseudo-random generator must be initialized with a seed. This is done by writing consecutively four 32-bit random values in the TAMP_ATSEEDR register. Programming the seed automatically sends it to the PRNG. As long as the new seed is transferred and elaborated by the PRNG, the SEEDF bit is set in the TAMP_ATOR and it is not allowed to switch off the TAMP APB clock. The duration of the elaboration is up to 184 APB clock cycles after the forth seed is written. Consequently, after writing a new seed, the user must wait until SEEDF is cleared before entering low-power modes.

The active tamper outputs are activated only after the first seed is written and the elaboration is completed. Then new seeds can be written and elaborated during active tamper activity.

**Active tamper initialization**

Here is the software procedure to initialize the active tampers after system reset:
Read INITS in TAMP_ATOR register.

- If INITS = 0x0 (initialization was not done):
  a) Write TAMP_ATCR to configure Active tamper clock, filter and output sharing if any, and active mode.
  b) Write TAMP_CR1 to enable tampers (all the needed tampers must be enabled in the same write access).
  c) Write SEED by writing four times in the TAMP_ATSEEDR.
  d) Wait until SEEDF = 0 in TAMP_ATOR. Backup registers are then protected by active tamper.

- If INITS = 0x1 (initialization already done):
  No initialization. To increase randomness a new SEED should be provided regularly. When a new SEED is provided, wait until SEEDF = 0 before entering a low-power mode which switches off the TAMP APB clock.

- In case the tampers are disabled by software, and re-enabled afterwards, the SEED must be written after enabling tampers:
  a) Write TAMP_CR1 to enable tampers (all the needed tampers must be enabled in the same write access).
  b) Write SEED by writing four times in the TAMP_ATSEEDR.
  c) Wait until SEEDF = 0 in TAMP_ATOR. Backup registers are then protected by active tamper.

### 47.4 TAMP low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. TAMP interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>No effect on all features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>No effect on all features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Standby mode.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Pin name</th>
<th>Functional in all low-power modes</th>
<th>Functional in VBAT mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>TAMP_IN[8:1]</td>
<td>Yes(^{(1)})</td>
<td>Yes(^{(1)})</td>
</tr>
<tr>
<td>TAMP_OUT[8:1]</td>
<td>Yes(^{(2)})</td>
<td>Yes(^{(3)})</td>
</tr>
</tbody>
</table>

1. Only PC13, PI8, PA0, PA1 and PA2 are functional in Standby and VBAT modes.
2. Only PC13, PA1 and PI8 are functional in Standby mode.
3. Only PC13, PA1 and PI8 are functional in VBAT mode.
47.5 TAMP interrupts

The interrupt channel is set in the masked interrupt status register or in the secure masked interrupt status register depending on its security mode configuration (TAMPSEC).

Table 496. Interrupt requests

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag(1)</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
<th>Exit from low-power modes</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td></td>
<td>Internal tamper</td>
<td>ITAMPy</td>
<td>ITAMPyl</td>
<td>Write 1 in CITAAPPy</td>
<td>Yes(3)</td>
</tr>
</tbody>
</table>

1. The event flags are in the TAMP_SR register.
2. The number of tampers and internal tampers events depend on products.
3. Refer to Table 494: Effect of low-power modes on TAMP for more details about available features in the low-power modes.

47.6 TAMP registers

Refer to Section 1.2 of the reference manual for a list of abbreviations used in register descriptions. The peripheral registers can be accessed by words (32-bit).

47.6.1 TAMP control register 1 (TAMP_CR1)

This register can be protected against nonsecure access. Refer to Section 47.3.5: TAMP secure protection modes.

This register can be protected against non-privileged access. Refer to Section 47.3.7: TAMP privilege protection modes.

RM0481 Rev 1 2023/3119
Bit 31  **TAMP8TRG**: Active level for tamper 8 input (active mode disabled)
- 0: If TAMPFLT ≠ 00 tamper 8 input staying low triggers a tamper detection event.
- 1: If TAMPFLT = 00 tamper 8 input rising edge triggers a tamper detection event.

Bit 30  **TAMP7TRG**: Active level for tamper 7 input (active mode disabled)
- 0: If TAMPFLT ≠ 00 tamper 7 input staying low triggers a tamper detection event.
- 1: If TAMPFLT = 00 tamper 7 input rising edge triggers a tamper detection event.

Bit 29  **TAMP6TRG**: Active level for tamper 6 input (active mode disabled)
- 0: If TAMPFLT ≠ 00 tamper 6 input staying low triggers a tamper detection event.
- 1: If TAMPFLT = 00 tamper 6 input rising edge triggers a tamper detection event.

Bit 28  **TAMP5TRG**: Active level for tamper 5 input (active mode disabled)
- 0: If TAMPFLT ≠ 00 tamper 5 input staying low triggers a tamper detection event.
- 1: If TAMPFLT = 00 tamper 5 input rising edge triggers a tamper detection event.

Bit 27  **TAMP4TRG**: Active level for tamper 4 input (active mode disabled)
- 0: If TAMPFLT ≠ 00 tamper 4 input staying low triggers a tamper detection event.
- 1: If TAMPFLT = 00 tamper 4 input rising edge triggers a tamper detection event.

Bit 26  **TAMP3TRG**: Active level for tamper 3 input
- 0: If TAMPFLT ≠ 00 tamper 3 input staying low triggers a tamper detection event.
- 1: If TAMPFLT = 00 tamper 3 input rising edge triggers a tamper detection event.

Bit 25  **TAMP2TRG**: Active level for tamper 2 input
- 0: If TAMPFLT ≠ 00 tamper 2 input staying low triggers a tamper detection event.
- 1: If TAMPFLT = 00 tamper 2 input rising edge triggers a tamper detection event.

Bit 24  **TAMP1TRG**: Active level for tamper 1 input
- 0: If TAMPFLT ≠ 00 tamper 1 input staying low triggers a tamper detection event.
- 1: If TAMPFLT = 00 tamper 1 input rising edge triggers a tamper detection event.

Bit 23  **BKERASE**: Backup registers and device secrets\(^{(1)}\) erase
- Writing “1” to this bit reset the backup registers and device secrets\(^{(1)}\). Writing 0 has no effect.
- This bit is always read as 0.

Bit 22  **BKBLOCK**: Backup registers and device secrets\(^{(1)}\) access blocked
- 0: backup registers and device secrets\(^{(1)}\) can be accessed if no tamper flag is set
- 1: backup registers and device secrets\(^{(1)}\) cannot be accessed

Bits 21:19  Reserved, must be kept at reset value.
Bit 18 **TAMP3MSK**: Tamper 3 mask
0: Tamper 3 event generates a trigger event and TAMP3F must be cleared by software to allow next tamper event detection.
1: Tamper 3 event generates a trigger event. TAMP3F is masked and internally cleared by hardware. The backup registers and device secrets\(^1\) are not erased.
*The tamper 3 interrupt must not be enabled when TAMP3MSK is set.*

Bit 17 **TAMP2MSK**: Tamper 2 mask
0: Tamper 2 event generates a trigger event and TAMP2F must be cleared by software to allow next tamper event detection.
1: Tamper 2 event generates a trigger event. TAMP2F is masked and internally cleared by hardware. The backup registers and device secrets\(^1\) are not erased.
*The tamper 2 interrupt must not be enabled when TAMP2MSK is set.*

Bit 16 **TAMP1MSK**: Tamper 1 mask
0: Tamper 1 event generates a trigger event and TAMP1F must be cleared by software to allow next tamper event detection.
1: Tamper 1 event generates a trigger event. TAMP1F is masked and internally cleared by hardware. The backup registers and device secrets\(^1\) are not erased.
*The tamper 1 interrupt must not be enabled when TAMP1MSK is set.*

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TAMP8POM**: Tamper 8 potential mode
0: Tamper 8 event detection is in confirmed mode\(^1\).
1: Tamper 8 event detection is in potential mode\(^2\).

Bit 6 **TAMP7POM**: Tamper 7 potential mode
0: Tamper 7 event detection is in confirmed mode\(^1\).
1: Tamper 7 event detection is in potential mode\(^2\).

Bit 5 **TAMP6POM**: Tamper 6 potential mode
0: Tamper 6 event detection is in confirmed mode\(^1\).
1: Tamper 6 event detection is in potential mode\(^2\).

Bit 4 **TAMP5POM**: Tamper 5 potential mode
0: Tamper 5 event detection is in confirmed mode\(^1\).
1: Tamper 5 event detection is in potential mode\(^2\).

Bit 3 **TAMP4POM**: Tamper 4 potential mode
0: Tamper 4 event detection is in confirmed mode\(^1\).
1: Tamper 4 event detection is in potential mode\(^2\).

Bit 2 **TAMP3POM**: Tamper 3 potential mode
0: Tamper 3 event detection is in confirmed mode\(^1\).
1: Tamper 3 event detection is in potential mode\(^2\).

Bit 1 **TAMP2POM**: Tamper 2 potential mode
0: Tamper 2 event detection is in confirmed mode\(^1\).
1: Tamper 2 event detection is in potential mode\(^2\).

Bit 0 **TAMP1POM**: Tamper 1 potential mode
0: Tamper 1 event detection is in confirmed mode\(^1\).
1: Tamper 1 event detection is in potential mode\(^2\).

1. The effects of tamper detection in confirmed mode is described with tamp_confirmed and tamp_confirmed_rpcfgx signals in Table 489: TAMP interconnection.
2. The effects of tamper detection in potential mode is described with tamp_potential and tamp_potential_rpcfgx signals in Table 489: TAMP interconnection.
### 47.6.3 TAMP control register 3 (TAMP_CR3)

This register can be protected against nonsecure access. Refer to Section 47.3.5: TAMP secure protection modes.

This register can be protected against non-privileged access. Refer to Section 47.3.7: TAMP privilege protection modes.

Address offset: 0x08

Backup domain reset value: 0x0000 0000

System reset: not affected

Bit 5 **ITAMP6POM**: Internal tamper 6 potential mode
0: Internal tamper 6 event detection is in confirmed mode(1).
1: Internal tamper 6 event detection is in potential mode(2).

Bit 4 **ITAMP5POM**: Internal tamper 5 potential mode
0: Internal tamper 5 event detection is in confirmed mode(1).
1: Internal tamper 5 event detection is in potential mode(2).

Bit 3 **ITAMP4POM**: Internal tamper 4 potential mode
0: Internal tamper 4 event detection is in confirmed mode(1).
1: Internal tamper 4 event detection is in potential mode(2).

Bit 2 **ITAMP3POM**: Internal tamper 3 potential mode
0: Internal tamper 3 event detection is in confirmed mode(1).
1: Internal tamper 3 event detection is in potential mode(2).

Bit 1 **ITAMP2POM**: Internal tamper 2 potential mode
0: Internal tamper 2 event detection is in confirmed mode(1).
1: Internal tamper 2 event detection is in potential mode(2).

Bit 0 **ITAMP1POM**: Internal tamper 1 potential mode
0: Internal tamper 1 event detection is in confirmed mode(1).
1: Internal tamper 1 event detection is in potential mode(2).

1. The effects of internal tamper detection in confirmed mode is described with tamp_confirmed and tamp_confirmed_rpcfgx signals in Table 489: TAMP interconnection.
2. The effects of internal tamper detection in potential mode is described with tamp_potential and tamp_potential_rpcfgx signals in Table 489: TAMP interconnection.

### 47.6.4 TAMP filter control register (TAMP_FLTCR)

This register can be protected against nonsecure access. Refer to Section 47.3.5: TAMP secure protection modes.

This register can be protected against non-privileged access. Refer to Section 47.3.7: TAMP privilege protection modes.

Address offset: 0x0C

Backup domain reset value: 0x0000 0000

System reset: not affected
Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **TAMPUDIS**: TAMP\_INx pull-up disable
This bit determines if each of the TAMPx pins are precharged before each sample.
0: Precharge TAMP\_INx pins before sampling (enable internal pull-up)
1: Disable precharge of TAMP\_INx pins.

Bits 6:5 **TAMPPRCH[1:0]**: TAMP\_INx precharge duration
These bits determine the duration of time during which the pull-up/is activated before each sample. TAMPPRCH is valid for each of the TAMP\_INx inputs.
0x0: 1 RTCCLK cycle
0x1: 2 RTCCLK cycles
0x2: 4 RTCCLK cycles
0x3: 8 RTCCLK cycles

Bits 4:3 **TAMPFLT[1:0]**: TAMP\_INx filter count
These bits determine the number of consecutive samples at the specified level (TAMP*TRG) needed to activate a tamper event. TAMPFLT is valid for each of the TAMP\_INx inputs.
0x0: Tamper event is activated on edge of TAMP\_INx input transitions to the active level (no internal pull-up on TAMP\_INx input).
0x1: Tamper event is activated after 2 consecutive samples at the active level.
0x2: Tamper event is activated after 4 consecutive samples at the active level.
0x3: Tamper event is activated after 8 consecutive samples at the active level.

Bits 2:0 **TAMPFREQ[2:0]**: Tamper sampling frequency
Determines the frequency at which each of the TAMP\_INx inputs are sampled.
0x0: RTCCLK / 32768 (1 Hz when RTCCLK = 32768 Hz)
0x1: RTCCLK / 16384 (2 Hz when RTCCLK = 32768 Hz)
0x2: RTCCLK / 8192 (4 Hz when RTCCLK = 32768 Hz)
0x3: RTCCLK / 4096 (8 Hz when RTCCLK = 32768 Hz)
0x4: RTCCLK / 2048 (16 Hz when RTCCLK = 32768 Hz)
0x5: RTCCLK / 1024 (32 Hz when RTCCLK = 32768 Hz)
0x6: RTCCLK / 512 (64 Hz when RTCCLK = 32768 Hz)
0x7: RTCCLK / 256 (128 Hz when RTCCLK = 32768 Hz)

**Note:** This register concerns only the tamper inputs in passive mode.

47.6.5 **TAMP active tamper control register 1 (TAMP\_ATCR1)**

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes.*

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes.*
Address offset: 0x10
Backup domain reset value: 0x0007 0000
System reset: not affected

Bit 31 **FLTEN**: Active tamper filter enable
0: Active tamper filtering disable
1: Active tamper filtering enable: a tamper event is detected when 2 comparison mismatches occur out of 4 consecutive samples.

Bit 30 **ATOSHARE**: Active tamper output sharing
0: Each active tamper input TAMP_INi is compared with its dedicated output TAMP_OUTi
1: Each active tamper input TAMP_INi is compared with TAMPOUTSELi defined by ATOSELi bits.

Bits 29:27 Reserved, must be kept at reset value.

Bits 26:24 **ATPER[2:0]**: Active tamper output change period
The tamper output is changed every CK_ATPER = (2^ATPER x CK_ATPRE) cycles. Refer to Table 492: Minimum ATPER value.

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **ATCKSEL[3:0]**: Active tamper RTC asynchronous prescaler clock selection
These bits selects the RTC asynchronous prescaler stage output. The selected clock is CK_ATPRE.
0000: RTCCLK is selected
0001: RTCCLK/2 is selected
0010: RTCCLK/4 is selected
0011: RTCCLK/8 is selected
0100: RTCCLK/16 is selected
0101: RTCCLK/32 is selected
0110: RTCCLK/64 is selected
0111: RTCCLK/128 is selected
1011: RTCCLK/2048 is selected when (PREDIV_A+1) = 128 and (PREDIV_S+1) is a multiple of 16.
Others: Reserved

Note: These bits can be written only when all active tampers are disabled. The write protection remains for up to 1.5 CK_ATPRE cycles after all the active tampers are disable.
Bits 15:14 **ATOSEL4[1:0]**: Active tamper shared output 4 selection
- 00: TAMPOUTSEL4 = TAMP_OUT1
- 01: TAMPOUTSEL4 = TAMP_OUT2
- 10: TAMPOUTSEL4 = TAMP_OUT3
- 11: TAMPOUTSEL4 = TAMP_OUT4

If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 13:12 **ATOSEL3[1:0]**: Active tamper shared output 3 selection
- 00: TAMPOUTSEL3 = TAMP_OUT1
- 01: TAMPOUTSEL3 = TAMP_OUT2
- 10: TAMPOUTSEL3 = TAMP_OUT3
- 11: TAMPOUTSEL3 = TAMP_OUT4

If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 11:10 **ATOSEL2[1:0]**: Active tamper shared output 2 selection
- 00: TAMPOUTSEL2 = TAMP_OUT1
- 01: TAMPOUTSEL2 = TAMP_OUT2
- 10: TAMPOUTSEL2 = TAMP_OUT3
- 11: TAMPOUTSEL2 = TAMP_OUT4

If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bits 9:8 **ATOSEL1[1:0]**: Active tamper shared output 1 selection
- 00: TAMPOUTSEL1 = TAMP_OUT1
- 01: TAMPOUTSEL1 = TAMP_OUT2
- 10: TAMPOUTSEL1 = TAMP_OUT3
- 11: TAMPOUTSEL1 = TAMP_OUT4

If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.

Bit 7 **TAMP8AM**: Tamper 8 active mode
- 0: Tamper 8 detection mode is passive.
- 1: Tamper 8 detection mode is active.

Bit 6 **TAMP7AM**: Tamper 7 active mode
- 0: Tamper 7 detection mode is passive.
- 1: Tamper 7 detection mode is active.

Bit 5 **TAMP6AM**: Tamper 6 active mode
- 0: Tamper 6 detection mode is passive.
- 1: Tamper 6 detection mode is active.

Bit 4 **TAMP5AM**: Tamper 5 active mode
- 0: Tamper 5 detection mode is passive.
- 1: Tamper 5 detection mode is active.

Bit 3 **TAMP4AM**: Tamper 4 active mode
- 0: Tamper 4 detection mode is passive.
- 1: Tamper 4 detection mode is active.
Bit 2 **TAMP3AM**: Tamper 3 active mode
0: Tamper 3 detection mode is passive.
1: Tamper 3 detection mode is active.

Bit 1 **TAMP2AM**: Tamper 2 active mode
0: Tamper 2 detection mode is passive.
1: Tamper 2 detection mode is active.

Bit 0 **TAMP1AM**: Tamper 1 active mode
0: Tamper 1 detection mode is passive.
1: Tamper 1 detection mode is active.

**Note:** Changing the active tampers configuration in this register is not allowed when a TAMPxAM bit is set, unless the corresponding TAMPxE bits are all cleared in the TAMP_CR1 register.

All tampers configured in active mode must be enabled at the same time (by setting all related TAMPxE in the same TAMP_CR1 write).

All tampers configured in active mode must be disabled at the same time (by clearing all related TAMPxE in the same TAMP_CR1 write).

A minimum duration of 1 CK_ATPRE period must be waited for after disabling the active tampers and before re-enabling them.

### 47.6.6 **TAMP active tamper seed register (TAMP_ATSEEDR)**

This register can be protected against nonsecure access. Refer to *Section 47.3.5: TAMP secure protection modes*.

This register can be protected against non-privileged access. Refer to *Section 47.3.7: TAMP privilege protection modes*.

Address offset: 0x14

Backup domain reset value: 0x0000 0000

System reset: not affected

Bits 31:0 **SEED[31:0]**: Pseudo-random generator seed value
This register must be written four times with 32-bit values to provide the 128-bit seed to the PRNG. Writing to this register automatically sends the seed value to the PRNG.
47.6.7  TAMP active tamper output register (TAMP_ATOR)

This register can be protected against nonsecure access. Refer to Section 47.3.5: TAMP secure protection modes.

This register can be protected against non-privileged access. Refer to Section 47.3.7: TAMP privilege protection modes.

Address offset: 0x18
Backup domain reset value: 0x0000 0000
System reset: not affected, except for SEEDF which is reset to 0.

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  INITS. Active tamper initialization status
This flag is set by hardware when the PRNG has absorbed the first 128-bit seed, meaning that the enabled active tampers are functional. This flag is cleared when the active tampers are disabled.

Bit 14  SEEDF: Seed running flag
This flag is set by hardware when a new seed is written in the TAMP_ATSEEDR. It is cleared by hardware when the PRNG has absorbed this new seed, and by system reset. The TAMP APB clock must not be switched off as long as SEEDF is set.

Bits 13:8  Reserved, must be kept at reset value.

Bits 7:0  PRNG[7:0]: Pseudo-random generator value
This field provides the values of the PRNG output. Because of potential inconsistencies due to synchronization delays, PRNG must be read at least twice. The read value is correct if it is equal to previous read value.
This field can only be read when the APB is in secure mode.

47.6.8  TAMP active tamper control register 2 (TAMP_ATCR2)

This register can be protected against nonsecure access. Refer to Section 47.3.5: TAMP secure protection modes.

This register can be protected against non-privileged access. Refer to Section 47.3.7: TAMP privilege protection modes.

If the TAMP_OUTx output is not available in the package pinout, the output selection value is reserved and must not be used.
Bits 22:20 **ATOSEL5[2:0]**: Active tamper shared output 5 selection
- 000: TAMPOUTSEL5 = TAMP_OUT1
- 001: TAMPOUTSEL5 = TAMP_OUT2
- 010: TAMPOUTSEL5 = TAMP_OUT3
- 011: TAMPOUTSEL5 = TAMP_OUT4
- 100: TAMPOUTSEL5 = TAMP_OUT5
- 101: TAMPOUTSEL5 = TAMP_OUT6
- 110: TAMPOUTSEL5 = TAMP_OUT7
- 111: TAMPOUTSEL5 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bits 19:17 **ATOSEL4[2:0]**: Active tamper shared output 4 selection
- 000: TAMPOUTSEL4 = TAMP_OUT1
- 001: TAMPOUTSEL4 = TAMP_OUT2
- 010: TAMPOUTSEL4 = TAMP_OUT3
- 011: TAMPOUTSEL4 = TAMP_OUT4
- 100: TAMPOUTSEL4 = TAMP_OUT5
- 101: TAMPOUTSEL4 = TAMP_OUT6
- 110: TAMPOUTSEL4 = TAMP_OUT7
- 111: TAMPOUTSEL4 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bits 18:17 are the mirror of ATOSEL2[1:0] in the TAMP_ATCR1, and so can also be read or written through TAMP_ATCR1.

Bits 16:14 **ATOSEL3[2:0]**: Active tamper shared output 3 selection
- 000: TAMPOUTSEL3 = TAMP_OUT1
- 001: TAMPOUTSEL3 = TAMP_OUT2
- 010: TAMPOUTSEL3 = TAMP_OUT3
- 011: TAMPOUTSEL3 = TAMP_OUT4
- 100: TAMPOUTSEL3 = TAMP_OUT5
- 101: TAMPOUTSEL3 = TAMP_OUT6
- 110: TAMPOUTSEL3 = TAMP_OUT7
- 111: TAMPOUTSEL3 = TAMP_OUT8
If the TAMP_OUTx output is not available in the package pinout, the ouput selection value is reserved and must not be used.

Bits 15:14 are the mirror of ATOSEL3[1:0] in the TAMP_ATCR1, and so can also be read or written through TAMP_ATCR1.
Note: Changing the active tampers configuration in this register is not allowed when a TAMPxAM bit is set, unless the corresponding TAMPxE bits are all cleared in the TAMP_CR1 register. All tampers configured in active mode must be enabled at the same time (by setting all related TAMPxE in the same TAMP_CR1 write). All tampers configured in active mode must be disabled at the same time (by clearing all related TAMPxE in the same TAMP_CR1 write). A minimum duration of 1 CK_ATPRE period must be waited for after disabling the active tampers and before re-enabling them.

### 47.6.9 TAMP secure configuration register (TAMP_SECCFRG)

If TZEN = 1, this register can be written only when the APB access is secure. If TZEN = 0, BKPRWSEC[7:0], BKPWSEC[7:0] and BHKLOCK can be written with nonsecure APB access, and TAMPSEC, CNT1SEC cannot be written.

This register can be globally write-protected, or each bit of this register can be individually write-protected against non-privileged access depending on the TAMP_PRIVCFGR configuration (refer to Section 47.3.7: TAMP privilege protection modes).
Address offset: 0x20
Backup domain reset value: 0x0000 0000
System reset: not affected

<table>
<thead>
<tr>
<th>Address</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-20</td>
<td>TAMPSEC: Tamper protection (excluding monotonic counters and backup registers)</td>
</tr>
<tr>
<td>30-29</td>
<td>BHKLOCK: Boot hardware key lock</td>
</tr>
<tr>
<td>28-24</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>23-16</td>
<td>BKPWSEC[7:0]: Backup registers write protection offset</td>
</tr>
<tr>
<td>15-8</td>
<td>Protection zone 2 is defined for backup registers from TAMP_BKPyR (y = BKPWSEC - 1, with BKPWSEC &gt; BKPRWSEC):</td>
</tr>
<tr>
<td>7-0</td>
<td>Protection zone 3 is defined for backup registers from TAMP_BKPIR (t = BKPWSEC if BKPWSEC ≥ BKPRWSEC, else t = BKPRWSEC):</td>
</tr>
</tbody>
</table>

Note: If TZEN=0: the protection zone 2 can be read and written with nonsecure access. Note: If BKPWPRIV is set, BKPRWSEC[7:0] can be written only in privileged mode.
Bit 15 **CNT1SEC**: Monotonic counter 1 secure protection
0: Monotonic counter 1 (TAMP_COUNT1R) can be read and written when the APB access is secure or nonsecure.
1: Monotonic counter 1 (TAMP_COUNT1R) can be read and written only when the APB access is secure.

Bits 14:8 Reserved, must be kept at reset value.

Bits 7:0 **BKPRWSEC[7:0]**: Backup registers read/write protection offset

**BKPRWSEC** value must be from 0 to 32.

**Protection zone 1** is defined for backup registers from TAMP_BKP0R to TAMP_BKPxR (x = BKPRWSEC-1, with BKPRWSEC ≥ 1).
- if TZEN=1, these backup registers can be read and written only with secure access.
  If BKPRWSEC = 0: there is no protection zone 1.

Refer to Figure 619: Backup registers protection zones.

Note: If TZEN=0: the protection zone 1 can be read and written with nonsecure access.
Note: If BKPRWPRIV is set, BKPRWSEC[7:0] can be written only in privileged mode.

### 47.6.10 TAMP privilege configuration register (TAMP_PRIVCFGFR)

This register can be written only when the APB access is privileged.

When TZEN = 1, this register can be write-protected, or each bit of this register can be individually write-protected against nonsecure access depending on the TAMP_SECCFGFR configuration (refer to Section 47.3.5: TAMP secure protection modes).

Address offset: 0x24

Backup domain reset value: 0x0000 0000

System reset: not affected
### 47.6.11 TAMP interrupt enable register (TAMP_IER)

This register can be protected against nonsecure access. Refer to Section 47.3.5: TAMP secure protection modes.

This register can be protected against non-privileged access. Refer to Section 47.3.7: TAMP privilege protection modes.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ITAMP15F**: Internal tamper 15 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 15.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **ITAMP13F**: Internal tamper 13 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 13.

Bit 27 **ITAMP12F**: Internal tamper 12 flag
This flag is set by hardware when a tamper detection event is detected on the internal tamper 12.
Bit 26  **ITAMP11F**: Internal tamper 11 flag
       This flag is set by hardware when a tamper detection event is detected on the internal tamper 11.

Bit 25  Reserved, must be kept at reset value.

Bit 24  **ITAMP9F**: Internal tamper 9 flag
       This flag is set by hardware when a tamper detection event is detected on the internal tamper 9.

Bit 23  **ITAMP8F**: Internal tamper 8 flag
       This flag is set by hardware when a tamper detection event is detected on the internal tamper 8.

Bit 22  **ITAMP7F**: Internal tamper 7 flag
       This flag is set by hardware when a tamper detection event is detected on the internal tamper 7.

Bit 21  **ITAMP6F**: Internal tamper 6 flag
       This flag is set by hardware when a tamper detection event is detected on the internal tamper 6.

Bit 20  **ITAMP5F**: Internal tamper 5 flag
       This flag is set by hardware when a tamper detection event is detected on the internal tamper 5.

Bit 19  **ITAMP4F**: Internal tamper 4 flag
       This flag is set by hardware when a tamper detection event is detected on the internal tamper 4.

Bit 18  **ITAMP3F**: Internal tamper 3 flag
       This flag is set by hardware when a tamper detection event is detected on the internal tamper 3.

Bit 17  **ITAMP2F**: Internal tamper 2 flag
       This flag is set by hardware when a tamper detection event is detected on the internal tamper 2.

Bit 16  **ITAMP1F**: Internal tamper 1 flag
       This flag is set by hardware when a tamper detection event is detected on the internal tamper 1.

Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **TAMP8F**: TAMP8 detection flag
       This flag is set by hardware when a tamper detection event is detected on the TAMP8 input.

Bit 6  **TAMP7F**: TAMP7 detection flag
       This flag is set by hardware when a tamper detection event is detected on the TAMP7 input.

Bit 5  **TAMP6F**: TAMP6 detection flag
       This flag is set by hardware when a tamper detection event is detected on the TAMP6 input.

Bit 4  **TAMP5F**: TAMP5 detection flag
       This flag is set by hardware when a tamper detection event is detected on the TAMP5 input.

Bit 3  **TAMP4F**: TAMP4 detection flag
       This flag is set by hardware when a tamper detection event is detected on the TAMP4 input.
47.6.13 TAMP nonsecure masked interrupt status register (TAMP_MISR)

This register can be protected against non-privileged access. Refer to Section 47.3.7: TAMP privilege protection modes.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CITAMP15F**: Clear ITAMP15 detection flag  
Writing 1 in this bit clears the ITAMP15F bit in the TAMP_SR register.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **CITAMP13F**: Clear ITAMP13 detection flag  
Writing 1 in this bit clears the ITAMP13F bit in the TAMP_SR register.

Bit 27 **CITAMP12F**: Clear ITAMP12 detection flag  
Writing 1 in this bit clears the ITAMP12F bit in the TAMP_SR register.
Bit 26  **CITAMP11F**: Clear ITAMP11 detection flag  
Writing 1 in this bit clears the ITAMP11F bit in the TAMP_SR register.

Bit 25  Reserved, must be kept at reset value.

Bit 24  **CITAMP9F**: Clear ITAMP9 detection flag  
Writing 1 in this bit clears the ITAMP9F bit in the TAMP_SR register.

Bit 23  **CITAMP8F**: Clear ITAMP8 detection flag  
Writing 1 in this bit clears the ITAMP8F bit in the TAMP_SR register.

Bit 22  **CITAMP7F**: Clear ITAMP7 detection flag  
Writing 1 in this bit clears the ITAMP7F bit in the TAMP_SR register.

Bit 21  **CITAMP6F**: Clear ITAMP6 detection flag  
Writing 1 in this bit clears the ITAMP6F bit in the TAMP_SR register.

Bit 20  **CITAMP5F**: Clear ITAMP5 detection flag  
Writing 1 in this bit clears the ITAMP5F bit in the TAMP_SR register.

Bit 19  **CITAMP4F**: Clear ITAMP4 detection flag  
Writing 1 in this bit clears the ITAMP4F bit in the TAMP_SR register.

Bit 18  **CITAMP3F**: Clear ITAMP3 detection flag  
Writing 1 in this bit clears the ITAMP3F bit in the TAMP_SR register.

Bit 17  **CITAMP2F**: Clear ITAMP2 detection flag  
Writing 1 in this bit clears the ITAMP2F bit in the TAMP_SR register.

Bit 16  **CITAMP1F**: Clear ITAMP1 detection flag  
Writing 1 in this bit clears the ITAMP1F bit in the TAMP_SR register.

Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **CTAMP8F**: Clear TAMP8 detection flag  
Writing 1 in this bit clears the TAMP8F bit in the TAMP_SR register.

Bit 6  **CTAMP7F**: Clear TAMP7 detection flag  
Writing 1 in this bit clears the TAMP7F bit in the TAMP_SR register.

Bit 5  **CTAMP6F**: Clear TAMP6 detection flag  
Writing 1 in this bit clears the TAMP6F bit in the TAMP_SR register.

Bit 4  **CTAMP5F**: Clear TAMP5 detection flag  
Writing 1 in this bit clears the TAMP5F bit in the TAMP_SR register.

Bit 3  **CTAMP4F**: Clear TAMP4 detection flag  
Writing 1 in this bit clears the TAMP4F bit in the TAMP_SR register.

Bit 2  **CTAMP3F**: Clear TAMP3 detection flag  
Writing 1 in this bit clears the TAMP3F bit in the TAMP_SR register.

Bit 1  **CTAMP2F**: Clear TAMP2 detection flag  
Writing 1 in this bit clears the TAMP2F bit in the TAMP_SR register.

Bit 0  **CTAMP1F**: Clear TAMP1 detection flag  
Writing 1 in this bit clears the TAMP1F bit in the TAMP_SR register.
47.6.16 TAMP monotonic counter 1 register (TAMP\_COUNT1R)

This register can be protected against nonsecure access. Refer to Section 47.3.5: TAMP secure protection modes.

This register can be protected against non-privileged access. Refer to Section 47.3.7: TAMP privilege protection modes.

Refer to Section 2.3 for the register boundary addresses.
48 Inter-integrated circuit (I2C) interface

48.1 Introduction

The I²C (inter-integrated circuit) bus interface handles communications between the microcontroller and the serial I²C bus. It provides multimaster capability, and controls all I²C bus-specific sequencing, protocol, arbitration and timing. It supports Standard-mode (Sm), Fast-mode (Fm) and Fast-mode Plus (Fm+).

The I²C bus interface is also SMBus (system management bus) and PMBus® (power management bus) compatible.

DMA can be used to reduce CPU overload.

48.2 I²C main features

- I²C bus specification rev.03 compatibility:
  - Slave and master modes
  - Multimaster capability
  - Standard-mode (up to 100 kHz)
  - Fast-mode (up to 400 kHz)
  - Fast-mode Plus (up to 1 MHz)
  - 7-bit and 10-bit addressing mode
  - Multiple 7-bit slave addresses (2 addresses, 1 with configurable mask)
  - All 7-bit addresses acknowledge mode
  - General call
  - Programmable setup and hold times
  - Easy to use event management
  - Optional clock stretching
  - Software reset

- 1-byte buffer with DMA capability

- Programmable analog and digital noise filters

The following features are also available, depending upon product implementation (see Section 48.3):

- SMBus specification rev.3.0 compatibility:
  - Hardware PEC (packet error checking) generation and verification with ACK control
  - Command and data acknowledge control
  - Address resolution protocol (ARP) support
  - Host and device support
  - SMBus alert
  - Timeouts and idle condition detection

- PMBus rev 1.3 standard compatibility

- Independent clock: a choice of independent clock sources allowing the I²C communication speed to be independent from the i2c_pclk reprogramming
• Wake-up from Stop mode on address match

48.3 I2C implementation

1. X = supported.

48.4 I2C functional description

In addition to receiving and transmitting data, this interface converts them from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The interface is connected to the I^2^C bus by a data pin (SDA) and by a clock pin (SCL). It can be connected with a standard (up to 100 kHz), Fast-mode (up to 400 kHz) or Fast-mode Plus (up to 1 MHz) I^2^C bus.

This interface can also be connected to an SMBus with data (SDA) and clock (SCL) pins.

If the SMBus feature is supported, the optional SMBus Alert pin (SMBA) is also available.
48.4.1 I2C block diagram

The block diagram of the I2C interface is shown in Figure 621.

**Figure 621. I2C block diagram**

The I2C is clocked by an independent clock source, which allows the I2C to operate independently from the i2c_pclk frequency.
48.4.2 I2C pins and internal signals

Table 499. I2C input/output pins

</tr>
<tr>
<td>i2c_tx_dma</td>
<td>Output</td>
<td>I2C transmit data DMA request (I2C_TX)</td>
</tr>
</tbody>
</table>

48.4.3 I2C clock requirements

The I2C kernel is clocked by i2c_ker_ck.

The i2c_ker_ck period tI2CCLK must respect the following conditions:
- \( t_{I2CCLK} < \left( t_{LOW} - t_{filters} \right) / 4 \)
- \( t_{I2CCLK} < t_{HIGH} \)

with:
- \( t_{LOW} \): SCL low time and \( t_{HIGH} \): SCL high time
- \( t_{filters} \): when enabled, sum of the delays brought by the analog and by the digital filters.

The digital filter delay is DNF x tI2CCLK.

The i2c_pclk clock period tPCLK must respect the condition:
- \( t_{PCLK} < 4 / 3 t_{SCL} \) (tSCL: SCL period)

Caution: When the I2C kernel is clocked by i2c_pclk, this clock must respect the conditions for tI2CCLK.

48.4.4 Mode selection

The interface can operate in one of the four following modes:
- Slave transmitter
- Slave receiver
- Master transmitter
- Master receiver
By default, it operates in slave mode. The interface automatically switches from slave to master when it generates a START condition, and from master to slave if an arbitration loss or a STOP generation occurs, allowing multimaster capability.

**Communication flow**

In master mode, the I2C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a START condition, and ends with a STOP condition. Both START and STOP conditions are generated in master mode by software.

In slave mode, the interface is capable of recognizing its own addresses (7- or 10-bit), and the general call address. The general call address detection can be enabled or disabled by software. The reserved SMBus addresses can also be enabled by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first byte(s) following the START condition contains the address (one in 7-bit mode, two in 10-bit mode). The address is always transmitted in master mode.

A ninth clock pulse follows the eight clock cycles of a byte transfer, during which the receiver must send an acknowledge bit to the transmitter (see Figure 622).

![Figure 622. I2C bus protocol](https://example.com/fig622)

Acknowledge can be enabled or disabled by software. The I2C interface addresses can be selected by software.

### 48.4.5 I2C initialization

**Enabling and disabling the peripheral**

The I2C peripheral clock must be configured and enabled in the clock controller, then the I2C can be enabled by setting the PE bit in the I2C_CR1 register.

When the I2C is disabled (PE = 0), the \( \text{I}^2 \text{C} \) performs a software reset. Refer to Section 48.4.6 for more details.

**Noise filters**

Before enabling the I2C peripheral by setting the PE bit in I2C_CR1 register, the user must configure the noise filters, if needed. By default, an analog noise filter is present on the SDA and SCL inputs. This filter is compliant with the \( \text{I}^2 \text{C} \) specification, which requires the suppression of spikes with pulse width up to 50 ns in Fast-mode and Fast-mode Plus.
user can disable this analog filter by setting the ANFOFF bit, and/or select a digital filter by configuring the DNF[3:0] bit in the I2C_CR1 register.

When the digital filter is enabled, the level of the SCL or the SDA line is internally changed only if it remains stable for more than $\text{DNF} \times \text{i2c_ker_ck}$ periods. This allows spikes with a programmable length of 1 to 15 i2c_ker_ck periods to be suppressed.

<td>Wake-up from Stop mode on address match is not available when digital filter is enabled</td>
</tr>
</tbody>
</table>

**Caution:** The filter configuration cannot be changed when the I2C is enabled.

**I2C timings**

The timings must be configured to guarantee correct data hold and setup times, in master and slave modes. This is done by programming the PRESC[3:0], SCLDEL[3:0] and SDADEL[3:0] bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C configuration window.
When the SCL falling edge is internally detected, a delay ($t_{SDADEL}$, impacting the hold time $t_{HD;DAT}$) is inserted before sending SDA output: $t_{SDADEL} = SDADEL \times t_{PRESC} + t_{I2CCLK}$, where $t_{PRESC} = (PRESC + 1) \times t_{I2CCLK}$.

The total SDA output delay is:

$$t_{SYNCl} + \frac{[SDADEL \times (PRESC + 1) + 1] \times t_{I2CCLK}}{(PRESC + 1) \times t_{I2CCLK}}$$

The delay $t_{SYNCl}$ duration depends upon:

- SCL falling slope
- When enabled, input delay brought by the analog filter: $t_{AF(min)} < t_{AF} < t_{AF(max)}$
- When enabled, input delay brought by the digital filter: $t_{DNF} = DNF \times t_{I2CCLK}$
- Delay due to SCL synchronization to $i2c\_ker\_ck$ clock (two to three $i2c\_ker\_ck$ periods)

To bridge the undefined region of the SCL falling edge, the user must program $SDADEL$ in such a way that:

$$\frac{[t_{(max)} + t_{HD;DAT(min)} - t_{AF(min)} - [(DNF + 3) \times t_{I2CCLK}]]}{(PRESC + 1) \times t_{I2CCLK}} \leq SDADEL$$
SDADEL ≤ \{t_{HD;DAT}(\text{max}) - t_{AF(\text{max})} - [(DNF + 4) \times t_{I2CCLK}] / \{(PRESC + 1) \times t_{I2CCLK}\}

**Note:**
\(t_{AF(\text{min})} / t_{AF(\text{max})}\) are part of the equation only when the analog filter is enabled. Refer to the device datasheet for \(t_{AF}\) values.

The maximum \(t_{HD;DAT}\) can be 3.45 µs for Standard-mode, 0.9 µs for Fast-mode, 0.45 µs for Fast-mode Plus. It must be lower than the maximum of \(t_{VD;DAT}\) by a transition time. This maximum must only be met if the device does not stretch the LOW period (\(t_{LOW}\)) of the SCL signal. If the clock stretches the SCL, the data must be valid by the set-up time before it releases the clock.

The SDA rising edge is usually the worst case. In this case the previous equation becomes:

SDADEL ≤ \{t_{VD;DAT}(\text{max}) - tr(\text{max}) - t_{AF(\text{max})} - [(DNF + 4) \times t_{I2CCLK}] / \{(PRESC + 1) \times t_{I2CCLK}\}.

**Note:** This condition can be violated when NOSTRETCH = 0, because the device stretches SCL low to guarantee the set-up time, according to the SCLDEL value.

Refer to Table 502 for \(tr\), \(t_{HD;DAT}\), and \(t_{VD;DAT}\) standard values.

- After \(t_{SDADEL}\), or after sending SDA output when the slave had to stretch the clock because the data was not yet written in I2C_TXDR register, SCL line is kept at low level during the setup time. This setup time is \(t_{SCLDEL} = (SCLDEL + 1) \times t_{PRESC}\), where \(t_{PRESC} = (PRESC + 1) \times t_{I2CCLK}\). \(t_{SCLDEL}\) impacts the setup time \(t_{SU;DAT}\).

To bridge the undefined region of the SDA transition (rising edge usually worst case), the user must program SCLDEL in such a way that:

\{(tr(\text{max}) + t_{SU;DAT}(\text{min})) / [(PRESC + 1)] \times t_{I2CCLK}] - 1 ≤ SCLDEL

Refer to Table 502 for \(tr\) and \(t_{SU;DAT}\) standard values.

The SDA and SCL transition time values to use are the ones in the application. Using the maximum values from the standard increases the constraints for the SDADEL and SCLDEL calculation, but ensures the feature, whatever the application.

**Note:** At every clock pulse, after SCL falling edge detection, the I2C master or slave stretches SCL low during at least \([(SDADEL + SCLDEL + 1)] \times (PRESC + 1) + 1\) x \(t_{I2CCLK}\), in both transmission and reception modes. In transmission mode, if the data is not yet written in I2C_TXDR when SDADEL counter is finished, the I2C keeps on stretching SCL low until the next data is written. Then new data MSB is sent on SDA output, and SCLDEL counter starts, continuing stretching SCL low to guarantee the data setup time.

If NOSTRETCH = 1 in slave mode, the SCL is not stretched. Consequently, the SDADEL must be programmed so that it guarantees a sufficient setup time.

| Unit |
Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0] and SCLL[7:0] bit fields in the I2C_TIMINGR register.

- When the SCL falling edge is internally detected, a delay is inserted before releasing the SCL output. This delay is \( t_{SCLL} = (SCLL + 1) \times t_{PRESC} \) where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \). \( t_{SCLL} \) impacts the SCL low time \( t_{LOW} \).
- When the SCL rising edge is internally detected, a delay is inserted before forcing the SCL output to low level. This delay is \( t_{SCLH} = (SCLH + 1) \times t_{PRESC} \), where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \). \( t_{SCLH} \) impacts the SCL high time \( t_{HIGH} \).

Refer to \textit{I2C master initialization} for more details.

**Caution:** Changing the timing configuration is not allowed when the I2C is enabled.

The I2C slave NOSTRETCH mode must also be configured before enabling the peripheral. Refer to \textit{I2C slave initialization} for more details.

**Caution:** Changing the NOSTRETCH configuration is not allowed when the I2C is enabled.

48.4.6 Software reset

A software reset can be performed by clearing the PE bit in the I2C_CR1 register. In that case I2C lines SCL and SDA are released. Internal states machines are reset and communication control bits, as well as status bits, come back to their reset value. The configuration registers are not impacted.

Impacted register bits:
1. I2C_CR2 register: START, STOP, NACK
2. I2C_ISR register: BUSY, TXE, TXIS, RXNE, ADDR, NACKF, TCR, TC, STOPF, BERR, ARLO, OVR

In addition when the SMBus feature is supported:
1. I2C_CR2 register: PECBYTE
2. I2C_ISR register: PECERR, TIMEOUT, ALERT

PE must be kept low during at least three APB clock cycles to perform the software reset. This is ensured by the following software sequence:
1. Write PE = 0
2. Check PE = 0
3. Write PE = 1
48.4.7 Data transfer

The data transfer is managed through transmit and receive data registers and a shift register.

Reception

The SDA input fills the shift register. After the eighth SCL pulse (when the complete data byte is received), the shift register is copied into I2C_RXDR register if it is empty (RXNE = 0). If RXNE = 1, meaning that the previous received data byte has not yet been read, the SCL line is stretched low until I2C_RXDR is read. The stretch is inserted between the eighth and ninth SCL pulse (before the acknowledge pulse).

Figure 625. Data reception
Transmission

If the I2C_TXDR register is not empty (TXE = 0), its content is copied into the shift register after the ninth SCL pulse (the acknowledge pulse). Then the shift register content is shifted out on SDA line. If TXE = 1, meaning that no data is written yet in I2C_TXDR, SCL line is stretched low until I2C_TXDR is written. The stretch is done after the ninth SCL pulse.

![Figure 626. Data transmission](image)

**Hardware transfer management**

The I2C features an embedded byte counter to manage byte transfer and to close the communication in various modes, such as:

- NACK, STOP and ReSTART generation in master mode
- ACK control in slave receiver mode
- PEC generation/checking when SMBus feature is supported

The byte counter is always used in master mode. By default, it is disabled in slave mode. It can be enabled by software by setting the SBC (slave byte control) bit in the I2C_CR1 register.

The number of bytes to be transferred is programmed in the NBYTES[7:0] bit field in the I2C_CR2 register. If the number of bytes to be transferred (NBYTES) is greater than 255, or if a receiver wants to control the acknowledge value of a received data byte, the reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this mode, the TCR flag is set when the number of bytes programmed in NBYTES is transferred, and an interrupt is generated if TCIE is set. SCL is stretched as long as TCR flag is set. TCR is cleared by software when NBYTES is written to a non-zero value.

When the NBYTES counter is reloaded with the last number of bytes, RELOAD bit must be cleared.
When RELOAD = 0 in master mode, the counter can be used in two modes:

- **Automatic end mode** (AUTOEND = 1 in the I2C_CR2 register). In this mode, the master automatically sends a STOP condition once the number of bytes programmed in the NBYTES[7:0] bit field is transferred.

- **Software end mode** (AUTOEND = 0 in the I2C_CR2 register). In this mode, software action is expected once the number of bytes programmed in the NBYTES[7:0] bit field is transferred; the TC flag is set and an interrupt is generated if the TCIE bit is set. The SCL signal is stretched as long as the TC flag is set. The TC flag is cleared by software when the START or STOP bit is set in the I2C_CR2 register. This mode must be used when the master wants to send a RESTART condition.

**Caution:** The AUTOEND bit has no effect when the RELOAD bit is set.

### 48.4.8 I2C slave mode

#### I2C slave initialization

To work in slave mode, the user must enable at least one slave address. Registers I2C_OAR1 and I2C_OAR2 are available to program the slave own addresses OA1 and OA2.

- OA1 can be configured either in 7-bit mode (by default), or in 10-bit addressing mode by setting the OA1MODE bit in the I2C_OAR1 register. OA1 is enabled by setting the OA1EN bit in the I2C_OAR1 register.

- If additional slave addresses are required, the second slave address OA2 can be configured. Up to seven OA2 LSB can be masked by configuring the OA2MSK[2:0] bits in the I2C_OAR2 register. Therefore for OA2MSK configured from 1 to 6, only OA2[7:2], OA2[7:3], OA2[7:4], OA2[7:5], OA2[7:6] or OA2[7] are compared with the received address. As soon as OA2MSK is not equal to 0, the address comparator for OA2 excludes the I2C reserved addresses (0000 XXX and 1111 XXX), which are not acknowledged. If OA2MSK = 7, all received 7-bit addresses are acknowledged (except reserved addresses). OA2 is always a 7-bit address. These reserved addresses can be acknowledged if they are enabled by the specific enable bit, if they are programmed in the I2C_OAR1 or I2C_OAR2 register with OA2MSK = 0.

OA2 is enabled by setting the OA2EN bit in the I2C_OAR2 register.

- The general call address is enabled by setting the GCEN bit in the I2C_CR1 register.

When the I2C is selected by one of its enabled addresses, the ADDR interrupt status flag is set, and an interrupt is generated if the ADDRIE bit is set.

By default, the slave uses its clock stretching capability, which means that it stretches the SCL signal at low level when needed, to perform software actions. If the master does not
support clock stretching, the I2C must be configured with NOSTRETCH = 1 in the I2C_CR1 register.

After receiving an ADDR interrupt, if several addresses are enabled, the user must read the ADDCODE[6:0] bits in the I2C_ISR register to check which address matched. DIR flag must also be checked to know the transfer direction.

**Slave clock stretching (NOSTRETCH = 0)**

In default mode, the I2C slave stretches the SCL clock in the following situations:

- When the ADDR flag is set: the received address matches with one of the enabled slave addresses. This stretch is released when the ADDR flag is cleared by software setting the ADDRCF bit.
- In transmission, if the previous data transmission is completed and no new data is written in I2C_TXDR register, or if the first data byte is not written when the ADDR flag is cleared (TXE = 1). This stretch is released when the data is written to the I2C_TXDR register.
- In reception when the I2C_RXDR register is not read yet and a new data reception is completed. This stretch is released when I2C_RXDR is read.
- When TCR = 1 in Slave Byte Control mode, reload mode (SBC = 1 and RELOAD = 1), meaning that the last data byte has been transferred. This stretch is released when then TCR is cleared by writing a non-zero value in the NBYTES[7:0] field.
- After SCL falling edge detection, the I2C stretches SCL low during 
  \[ (SDADEL + SCLDEL + 1) \times (PRESC+ 1) + 1 \] x t_{I2CCLK}.

**Slave without clock stretching (NOSTRETCH = 1)**

When NOSTRETCH = 1 in the I2C_CR1 register, the I2C slave does not stretch the SCL signal.

- The SCL clock is not stretched while the ADDR flag is set.
- In transmission, the data must be written in the I2C_TXDR register before the first SCL pulse corresponding to its transfer occurs. If not, an underrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. The OVR flag is also set when the first data transmission starts and the STOPF bit is still set (has not been cleared). Therefore, if the user clears the STOPF flag of the previous transfer only after writing the first data to be transmitted in the next transfer, it ensures that the OVR status is provided, even for the first data to be transmitted.
- In reception, the data must be read from the I2C_RXDR register before the ninth SCL pulse (ACK pulse) of the next data byte occurs. If not, an overrun occurs, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.
Slave byte control mode

To allow byte ACK control in slave reception mode, the Slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. This is required to be compliant with SMBus standards.

The Reload mode must be selected to allow byte ACK control in slave reception mode (RELOAD = 1). To get control of each byte, NBYTES must be initialized to 0x1 in the ADDR interrupt subroutine, and reloaded to 0x1 after each received byte. When the byte is received, the TCR bit is set, stretching the SCL signal low between the eighth and ninth SCL pulses. The user can read the data from the I2C_RXDR register, and then decide to acknowledge it or not by configuring the ACK bit in the I2C_CR2 register. The SCL stretch is released by programming NBYTES to a non-zero value: the acknowledge or not-acknowledge is sent, and the next byte can be received.

NBYTES can be loaded with a value greater than 0x1, and in this case, the reception flow is continuous during NBYTES data reception.

Note: The SBC bit must be configured when the I2C is disabled, or when the slave is not addressed, or when ADDR = 1.

The RELOAD bit value can be changed when ADDR = 1, or when TCR = 1.

Caution: The Slave byte control mode is not compatible with NOSTRETCH mode. Setting SBC when NOSTRETCH = 1 is not allowed.

Figure 627. Slave initialization flow

*SBC must be set to support SMBus features
Slave transmitter

A transmit interrupt status (TXIS) is generated when the I2C_TXDR register becomes empty. An interrupt is generated if the TXIE bit is set in the I2C_CR1 register.

The TXIS bit is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

When a NACK is received, the NACKF bit is set in the I2C_ISR register and an interrupt is generated if the NACKIE bit is set in the I2C_CR1 register. The slave automatically releases the SCL and SDA lines in order to let the master perform a STOP or a RESTART condition. The TXIS bit is not set when a NACK is received.

When a STOP is received and the STOPIE bit is set in the I2C_CR1 register, the STOPF flag is set in the I2C_ISR register and an interrupt is generated. In most applications, the SBC bit is usually programmed to 0. In this case, if TXE = 0 when the slave address is received (ADDR = 1), the user can choose either to send the content of the I2C_TXDR register as the first data byte, or to flush the I2C_TXDR register by setting the TXE bit in order to program a new data byte.

In Slave byte control mode (SBC = 1), the number of bytes to be transmitted must be programmed in NBYTES in the address match interrupt subroutine (ADDR = 1). In this case, the number of TXIS events during the transfer corresponds to the value programmed in NBYTES.

Caution: When NOSTRETCH = 1, the SCL clock is not stretched while the ADDR flag is set, so the user cannot flush the I2C_TXDR register content in the ADDR subroutine, in order to program the first data byte. The first data byte to be sent must be previously programmed in the I2C_TXDR register:

- This data can be the data written in the last TXIS event of the previous transmission message.
- If this data byte is not the one to be sent, the I2C_TXDR register can be flushed by setting the TXE bit in order to program a new data byte. The STOPF bit must be cleared only after these actions, in order to guarantee that they are executed before the first data transmission starts, following the address acknowledge.

If STOPF is still set when the first data transmission starts, an underrun error is generated (the OVR flag is set).

If a TXIS event is needed, (transmit interrupt or transmit DMA request), the user must set the TXIS bit in addition to the TXE bit, in order to generate a TXIS event.

48.4.9 I2C master mode

I2C master initialization

Before enabling the peripheral, the I2C master clock must be configured by setting the SCLH and SCLL bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.

A clock synchronization mechanism is implemented in order to support multi-master environment and slave clock stretching.

In order to allow clock synchronization:
- The low level of the clock is counted using the SCLL counter, starting from the SCL low level internal detection.
- The high level of the clock is counted using the SCLH counter, starting from the SCL high level internal detection.

The I2C detects its own SCL low level after a tSYNC1 delay depending on the SCL falling edge, SCL input noise filters (analog + digital) and SCL synchronization to the I2CxCLK clock. The I2C releases SCL to high level once the SCLL counter reaches the value programmed in the SCLL[7:0] bits in the I2C_TIMINGR register.

The I2C detects its own SCL high level after a tSYNC2 delay depending on the SCL rising edge, SCL input noise filters (analog + digital) and SCL synchronization to I2CxCLK clock. The I2C ties SCL to low level once the SCLH counter reaches the value programmed in the SCLH[7:0] bits in the I2C_TIMINGR register.

Consequently the master clock period is:
\[
\text{t}_{\text{SCL}} = \text{t}_{\text{SYNC1}} + \text{t}_{\text{SYNC2}} + \left\{[(\text{SCLH} + 1) + (\text{SCLL} + 1)] \times (\text{PRESC} + 1) \times \text{t}_{\text{I2CCLK}}\right\}
\]

The duration of tSYNC1 depends upon:
- SCL falling slope
- When enabled, input delay induced by the analog filter
- When enabled, input delay induced by the digital filter: DNF x tI2CCLK
- Delay due to SCL synchronization with i2c_ker_ck clock (two to three i2c_ker_ck periods)

The duration of tSYNC2 depends upon:
- SCL rising slope
- When enabled, input delay induced by the analog filter
- When enabled, input delay induced by the digital filter: DNF x tI2CCLK
- Delay due to SCL synchronization with i2c_ker_ck clock (two to three i2c_ker_ck periods)
Figure 634. Master clock generation

Refer to Section 48.4.10 for examples of I2C_TIMINGR settings vs. i2c_ker_ck frequency.

Master communication initialization (address phase)

In order to initiate the communication, the user must program the following parameters for the addressed slave in the I2C_CR2 register:

- Addressing mode (7-bit or 10-bit): ADD10
- Slave address to be sent: SADD[9:0]
- Transfer direction: RD_WRN
- In case of 10-bit address read: HEAD10R bit. HEAD10R must be configure to indicate if the complete address sequence must be sent, or only the header in case of a direction change.
- The number of bytes to be transferred: NBYTES[7:0]. If the number of bytes is equal to or greater than 255 bytes, NBYTES[7:0] must initially be filled with 0xFF.

The user must then set the START bit in I2C_CR2 register. Changing all the above bits is not allowed when START bit is set.

Then the master automatically sends the START condition followed by the slave address as soon as it detects that the bus is free (BUSY = 0) and after a delay of tBUF.

In case of an arbitration loss, the master automatically switches back to slave mode and can acknowledge its own address if it is addressed as a slave.
**Note:** The START bit is reset by hardware when the slave address is sent on the bus, whatever the received acknowledge value. The START bit is also reset by hardware if an arbitration loss occurs.

In 10-bit addressing mode, when the slave address first seven bits are NACKed by the slave, the master relaunches automatically the slave address transmission until ACK is received. In this case ADDRCF must be set if a NACK is received from the slave, to stop sending the slave address.

If the I2C is addressed as a slave (ADDR = 1) while the START bit is set, the I2C switches to slave mode and the START bit is cleared.

**Note:** The same procedure is applied for a repeated start condition. In this case BUSY = 1.

**Initialization of a master receiver addressing a 10-bit address slave**

- If the slave address is in 10-bit format, the user can choose to send the complete read sequence by clearing the HEAD10R bit in the I2C_CR2 register. In this case the master automatically sends the following complete sequence after the START bit is set:
  (Re)Start + Slave address 10-bit header Write + Slave address second byte + REStart + Slave address 10-bit header Read

**Figure 636. 10-bit address read access with HEAD10R = 0**

---

**Figure 635. Master initialization flow**

 Initialization of a master receiver addressing a 10-bit address slave

- If the slave address is in 10-bit format, the user can choose to send the complete read sequence by clearing the HEAD10R bit in the I2C_CR2 register. In this case the master automatically sends the following complete sequence after the START bit is set:
  (Re)Start + Slave address 10-bit header Write + Slave address second byte + REStart + Slave address 10-bit header Read

**Figure 636. 10-bit address read access with HEAD10R = 0**

---

**Figure 635. Master initialization flow**

 Initialization of a master receiver addressing a 10-bit address slave

- If the slave address is in 10-bit format, the user can choose to send the complete read sequence by clearing the HEAD10R bit in the I2C_CR2 register. In this case the master automatically sends the following complete sequence after the START bit is set:
  (Re)Start + Slave address 10-bit header Write + Slave address second byte + REStart + Slave address 10-bit header Read

**Figure 636. 10-bit address read access with HEAD10R = 0**

---
If the master addresses a 10-bit address slave, transmits data to this slave and then reads data from the same slave, a master transmission flow must be done first. Then a repeated start is set with the 10-bit slave address configured with HEAD10R = 1. In this case the master sends this sequence: ReStart + Slave address 10-bit header Read.

**Figure 637. 10-bit address read access with HEAD10R = 1**

### Master transmitter

In the case of a write transfer, the TXIS flag is set after each byte transmission, after the ninth SCL pulse when an ACK is received.

A TXIS event generates an interrupt if the TXIE bit is set in the I2C_CR1 register. The flag is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

The number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0]. If the total number of data bytes to be sent is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

The TXIS flag is not set when a NACK is received.

- When RELOAD = 0 and NBYTES data have been transferred:
  - In automatic end mode (AUTOEND = 1), a STOP is automatically sent.
  - In software end mode (AUTOEND = 0), the TC flag is set and the SCL line is stretched low in order to perform software actions:
    - A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition is sent on the bus.
    - A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

- If a NACK is received: the TXIS flag is not set, and a STOP condition is automatically sent after the NACK reception. the NACKF flag is set in the I2C_ISR register, and an interrupt is generated if the NACKIE bit is set.

ELSE
NBYTES = 0xFF; N = N-255
RELOAD = 1

End

No
Figure 640. Transfer bus diagrams for I2C master transmitter
(mandatory events only)

Example I2C master transmitter 2 bytes, automatic end mode (STOP)

INIT: program Slave address, program NBYTES = 2, AUTOEND=1, set START
EV1: TXIS ISR: wr data1
EV2: TXIS ISR: wr data2

Example I2C master transmitter 2 bytes, software end mode (RESTART)

INIT: program Slave address, program NBYTES = 2, AUTOEND=0, set START
EV1: TXIS ISR: wr data1
EV2: TXIS ISR: wr data2
EV3: TC ISR: program Slave address, program NBYTES = N, set START
Master receiver

In the case of a read transfer, the RXNE flag is set after each byte reception, after the eighth SCL pulse. An RXNE event generates an interrupt if the RXIE bit is set in the I2C_CR1 register. The flag is cleared when I2C_RXDR is read.

If the total number of data bytes to be received is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES[7:0] data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

• When RELOAD = 0 and NBYTES[7:0] data have been transferred:
  – In automatic end mode (AUTOEND = 1), a NACK and a STOP are automatically sent after the last received byte.
  – In software end mode (AUTOEND = 0), a NACK is automatically sent after the last received byte, the TC flag is set and the SCL line is stretched low in order to allow software actions:

    A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition, followed by slave address, are sent on the bus.

    A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

Introduction

The system management bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on I²C principles of operation. The SMBus provides a control bus for system and power management related tasks.

This peripheral is compatible with the SMBus specification (http://smbus.org).

The system management bus specification refers to three types of devices

- A slave is a device that receives or responds to a command.
- A master is a device that issues commands, generates the clocks, and terminates the transfer.
- A host is a specialized master that provides the main interface to the system’s CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

This peripheral can be configured as master or slave device, and also as a host.

Bus protocols

There are eleven possible command protocols for any given device. A device can use any or all of them to communicate. The protocols are Quick Command, Send Byte, Receive Byte, Write Byte, Write Word, Read Byte, Read Word, Process Call, Block Read, Block Write, and Block Write-Block Read Process Call. These protocols must be implemented by the user software.

For more details on these protocols, refer to SMBus specification (http://smbus.org).

Address resolution protocol (ARP)

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. To provide a mechanism to isolate each device for the purpose of address assignment, each device must implement a unique device identifier (UDID). This 128-bit number is implemented by software.

This peripheral supports the Address Resolution Protocol (ARP). The SMBus Device Default Address (0b1100 001) is enabled by setting SMBDEN bit in I2C_CR1 register. The ARP commands must be implemented by the user software.

Arbitration is also performed in slave mode for ARP support.

For more details of the SMBus address resolution protocol, refer to SMBus specification (http://smbus.org).

Received command and data acknowledge control

A SMBus receiver must be able to NACK each received command or data. In order to allow the ACK control in slave mode, the Slave Byte Control mode must be enabled by setting SBC bit in I2C_CR1 register. Refer to Slave byte control mode for more details.

Host notify protocol

This peripheral supports the host notify protocol by setting the SMBHEN bit in the I2C_CR1 register. In this case the host acknowledges the SMBus host address (0b0001 000).

When this protocol is used, the device acts as a master and the host as a slave.
SMBus alert

The SMBus ALERT optional signal is supported. A slave-only device can signal the host through the SMBALERT# pin that it wants to talk. The host processes the interrupt and simultaneously accesses all SMBALERT# devices through the alert response address (0b0001 100). Only the device(s) which pulled SMBALERT# low acknowledges the alert response address.

When configured as a slave device (SMBHEN = 0), the SMBA pin is pulled low by setting the ALERTEN bit in the I2C_CR1 register. The Alert Response Address is enabled at the same time.

When configured as a host (SMBHEN = 1), the ALERT flag is set in the I2C_ISR register when a falling edge is detected on the SMBA pin and ALERTEN = 1. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. When ALERTEN = 0, the ALERT line is considered high even if the external SMBALERT pin is low.

*If the SMBus ALERT pin is not needed, the SMBA pin can be used as a standard GPIO if ALERTEN = 0.*

Packet error checking

A packet error checking mechanism has been introduced in the SMBus specification to improve reliability and communication robustness. The packet error checking is implemented by appending a packet error code (PEC) at the end of each message transfer. The PEC is calculated by using the $C(x) = x^8 + x^2 + x + 1$ CRC-8 polynomial on all the message bytes (including addresses and read/write bits).

The peripheral embeds a hardware PEC calculator and allows a not acknowledge to be sent automatically when the received byte does not match with the hardware calculated PEC.

Timeouts

This peripheral embeds hardware timers in order to be compliant with the three timeouts defined in SMBus specification.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Parameter</th>
<th>Limits</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>$t_{TIMEOUT}$</td>
<td>Detect clock low timeout</td>
<td>25</td>
<td>35</td>
</tr>
<tr>
<td>$t_{LOW:SEXT}^{(1)}$</td>
<td>Cumulative clock low extend time (slave device)</td>
<td>-</td>
<td>25</td>
</tr>
<tr>
<td>$t_{LOW:MEXT}^{(2)}$</td>
<td>Cumulative clock low extend time (master device)</td>
<td>-</td>
<td>10</td>
</tr>
</tbody>
</table>

1. $t_{LOW:SEXT}$ is the cumulative time a given slave device is allowed to extend the clock cycles in one message from the initial START to the STOP. It is possible that another slave device or the master also extends the clock causing the combined clock low extend time to be greater than $t_{LOW:SEXT}$. Therefore, this parameter is measured with the slave device as the sole target of a full-speed master.

2. $t_{LOW:MEXT}$ is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master also extends the clock, causing the combined clock low time to be greater than $t_{LOW:MEXT}$ on a given byte. Therefore, this parameter is measured with a full speed slave device as the sole target of the master.
Bus idle detection

A master can assume that the bus is free if it detects that the clock and data signals have been high for \( t_{\text{IDLE}} > t_{\text{HIGH,MAX}} \) (refer to I2C timings).

This timing parameter covers the condition where a master has been dynamically added to the bus, and may not have detected a state transition on the SMBCLK or SMBDAT lines. In this case, the master must wait long enough to ensure that a transfer is not currently in progress. The peripheral supports a hardware bus idle detection.

48.4.12 SMBus initialization

This section is relevant only when SMBus feature is supported (see Section 48.3).

In addition to I2C initialization, some other specific initialization must be done to perform SMBus communication.

Received command and data acknowledge control (slave mode)

A SMBus receiver must be able to NACK each received command or data. To allow ACK control in slave mode, the Slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. Refer to Slave byte control mode for more details.

Specific address (slave mode)

The specific SMBus addresses must be enabled if needed. Refer to Bus idle detection for more details.

- The SMBus device default address (0b1100 001) is enabled by setting the SMBDEN bit in the I2C_CR1 register.
- The SMBus host address (0b0001 000) is enabled by setting the SMBHEN bit in the I2C_CR1 register.
- The alert response address (0b0001100) is enabled by setting the ALERTEN bit in the I2C_CR1 register.
Packet error checking

PEC calculation is enabled by setting the PECEN bit in the I2C_CR1 register. Then the PEC transfer is managed with the help of the hardware byte counter NBYTES[7:0] in the I2C_CR2 register. The PECEN bit must be configured before enabling the I2C.

The PEC transfer is managed with the hardware byte counter, so the SBC bit must be set when interfacing the SMBus in slave mode. The PEC is transferred after NBYTES - 1 data have been transferred when the PECBYTE bit is set and the RELOAD bit is cleared. If RELOAD is set, PECBYTE has no effect.

Caution: Changing the PECEN configuration is not allowed when the I2C is enabled.

<table>

</tr>
<tr>
<td>Slave Tx/Rx with PEC</td>
</tr>
</tbody>
</table>

Timeout detection

The timeout detection is enabled by setting the TIMOUTEN and TEXTEN bits in the I2C_TIMEOUTR register. The timers must be programmed in such a way that they detect a timeout before the maximum time given in the SMBus specification.

- **t_TIMEOUT check**
  
  To enable the t_TIMEOUT check, the 12-bit TIMEOUTA[11:0] bits must be programmed with the timer reload value, to check the t_TIMEOUT parameter. The TIDLE bit must be configured to 0 to detect the SCL low level timeout.

  Then the timer is enabled by setting the TIMOUTEN in the I2C_TIMEOUTR register.

  If SCL is tied low for a time greater than (TIMEOUTA + 1) x 2048 x tI2CCLK, the TIMEOUT flag is set in the I2C_ISR register.

  Refer to Table 509.

Caution: Changing the TIMEOUTA[11:0] bits and TIDLE bit configuration is not allowed when the TIMOUTEN bit is set.

- **t_LOW:SEXT and t_LOW:MEXT check**

  Depending on if the peripheral is configured as a master or as a slave, the 12-bit TIMEOUTB timer must be configured to check t_LOW:SEXT for a slave, and t_LOW:MEXT for a master. As the standard specifies only a maximum, the user can choose the same value for both. The timer is then enabled by setting the TEXTEN bit in the I2C_TIMEOUTR register.

  If the SMBus peripheral performs a cumulative SCL stretch for a time greater than (TIMEOUTB + 1) x 2048 x tI2CCLK, and in the timeout interval described in *Bus idle detection* section, the TIMEOUT flag is set in the I2C_ISR register.

  Refer to Table 510

Caution: Changing the TIMEOUTB configuration is not allowed when the TEXTEN bit is set.
Bus idle detection

To enable the \( t_{\text{idle}} \) check, the 12-bit \( \text{TIMEOUTA}[11:0] \) field must be programmed with the timer reload value, to obtain the \( t_{\text{idle}} \) parameter. The TIDLE bit must be configured to ‘1’ to detect both SCL and SDA high level timeout. The timer is then enabled by setting the TIMOUTEN bit in the I2C\_TIMEOUTR register.

If both the SCL and SDA lines remain high for a time greater than \( (\text{TIMEOUTA} + 1) \times 4 \times \text{I2CCLK} \), the TIMEOUT flag is set in the I2C\_ISR register.

Refer to Table 511.

Caution: Changing \( \text{TIMEOUTA} \) and TIDLE configuration is not allowed when \( \text{TIMEOUTEN} \) is set.

48.4.13 SMBus: I2C\_TIMEOUTR register configuration examples

This section is relevant only when SMBus feature is supported. Refer to Section 48.3.

- Configuring the maximum duration of \( t_{\text{TIMEOUT}} \) to 25 ms:

  Table 509. Examples of \( \text{TIMEOUTA} \) settings (max \( t_{\text{TIMEOUT}} = 25 \text{ ms} \))

48.4.14 SMBus slave mode

This section is relevant only when the SMBus feature is supported (refer to Section 48.3).

In addition to I2C slave transfer management (refer to Section 48.4.8), additional software flows are provided to support the SMBus.

SMBus slave transmitter

When the IP is used in SMBus, SBC must be programmed to 1 to enable the PEC transmission at the end of the programmed number of data bytes. When the PECBYTE bit
is set, the number of bytes programmed in NBYTES[7:0] includes the PEC transmission. In that case the total number of TXIS interrupts is NBYTES - 1, and the content of the I2C_PECR register is automatically transmitted if the master requests an extra byte after the NBYTES - 1 data transfer.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 645. Transfer sequence flow for SMBus slave transmitter N bytes + PEC
When the I2C is used in SMBus mode, SBC must be programmed to 1 to allow the PEC checking at the end of the programmed number of data bytes. In order to allow the ACK control of each byte, the reload mode must be selected (RELOAD = 1). Refer to Slave byte control mode for more details.

To check the PEC byte, the RELOAD bit must be cleared and the PECBYTE bit must be set. In this case, after NBYTES - 1 data have been received, the next received byte is compared with the internal I2C_PECR register content. A NACK is automatically generated if the comparison does not match, and an ACK is automatically generated if the comparison matches, whatever the ACK bit value. Once the PEC byte is received, it is copied into the I2C_RXDR register like any other data, and the RXNE flag is set.

In the case of a PEC mismatch, the PECERR flag is set and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

If no ACK software control is needed, the user can program PECBYTE = 1 and, in the same write operation, program NBYTES with the number of bytes to be received in a continuous flow. After NBYTES - 1 are received, the next received byte is checked as being the PEC.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.
Figure 647. Transfer sequence flow for SMBus slave receiver N bytes + PEC

Yes

Read I2C_RXDR.RXDATA

End
This section is relevant only when the SMBus feature is supported (refer to Section 48.3). In addition to I2C master transfer management (refer to Section 48.4.9), additional software flows are provided to support the SMBus.

**SMBus master transmitter**

When the SMBus master wants to transmit the PEC, the PECBYTE bit must be set and the number of bytes must be programmed in the NBYTES[7:0] field, before setting the START bit. In this case the total number of TXIS interrupts is NBYTES - 1. So if the PECBYTE bit is set when NBYTES = 0x1, the content of the I2C_PECR register is automatically transmitted.

If the SMBus master wants to send a STOP condition after the PEC, automatic end mode must be selected (AUTOEND = 1). In this case, the STOP condition automatically follows the PEC transmission.

When the SMBus master wants to send a RESTART condition after the PEC, software mode must be selected (AUTOEND = 0). In this case, once NBYTES - 1 have been
transmitted, the I2C_PECR register content is transmitted and the TC flag is set after the PEC transmission, stretching the SCL line low. The RESTART condition must be programmed in the TC interrupt subroutine.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 649. Bus transfer diagrams for SMBus master transmitter

Example SMBus master transmitter 2 bytes + PEC, automatic end mode (STOP)

Example SMBus master transmitter 2 bytes + PEC, software end mode (RESTART)
**SMBus master receiver**

When the SMBus master wants to receive the PEC followed by a STOP at the end of the transfer, automatic end mode can be selected (AUTOEND = 1). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. A NACK response is given to the PEC byte, followed by a STOP condition.

When the SMBus master receiver wants to receive the PEC byte followed by a RESTART condition at the end of the transfer, software mode must be selected (AUTOEND = 0). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. The TC flag is set after the PEC byte reception, stretching the SCL line low. The RESTART condition can be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.
Figure 650. Bus transfer diagrams for SMBus master receiver

Example SMBus master receiver 2 bytes + PEC, automatic end mode (STOP)

INIT: program Slave address, program NBYTES = 3, AUTOEND=1, set PECBYTE, set START
EV1: RXNE ISR: rd data1
EV2: RXNE ISR: rd data2
EV3: RXNE ISR: rd PEC

Example SMBus master receiver 2 bytes + PEC, software end mode (RESTART)

INIT: program Slave address, program NBYTES = 3, AUTOEND=0, set PECBYTE, set START
EV1: RXNE ISR: rd data1
EV2: RXNE ISR: rd data2
EV3: RXNE ISR: read PEC
EV4: TC ISR: program Slave address, program NBYTES = N, set START
48.4.15 Wake-up from Stop mode on address match

This section is relevant only when wake-up from Stop mode feature is supported (refer to Section 48.3).

The I2C is able to wake-up the MCU from Stop mode (APB clock is off), when it is addressed. All addressing modes are supported.

Wake-up from Stop mode is enabled by setting the WUPEN bit in the I2C_CR1 register. The HSI and CSI only oscillator must be selected as the clock source for I2CCLK in order to allow wake-up from Stop mode.

During Stop mode, the HSI and CSI only is switched off. When a START is detected, the I2C interface switches the HSI and CSI only on, and stretches SCL low until HSI and CSI only is woken up.

HSI and CSI only is then used for the address reception.

In case of an address match, the I2C stretches SCL low during MCU wake-up time. The stretch is released when ADDR flag is cleared by software, and the transfer goes on normally.

If the address does not match, the HSI and CSI only is switched off again and the MCU is not woken up.

Note: If the I2C clock is the system clock, or if WUPEN = 0, the HSI and CSI only is not switched on after a START is received.

Only an ADDR interrupt can wake-up the MCU. Therefore do not enter Stop mode when the I2C is performing a transfer as a master, or as an addressed slave after the ADDR flag is set. This can be managed by clearing SLEEPDEEP bit in the ADDR interrupt routine and setting it again only after the STOPF flag is set.

Caution: The digital filter is not compatible with the wake-up from Stop mode feature. If the DNF bit is not equal to 0, setting the WUPEN bit has no effect.

Caution: This feature is available only when the I2C clock source is the HSI and CSI only oscillator.

Caution: Clock stretching must be enabled (NOSTRETCH = 0) to ensure proper operation of the wake-up from Stop mode feature.

Caution: If wake-up from Stop mode is disabled (WUPEN = 0), the I2C peripheral must be disabled before entering Stop mode (PE = 0).

48.4.16 Error conditions

The following errors are the conditions that can cause a communication fail.

Bus error (BERR)

A bus error is detected when a START or a STOP condition is detected and is not located after a multiple of nine SCL clock pulses. A START or a STOP condition is detected when an SDA edge occurs while SCL is high.

The bus error flag is set only if the I2C is involved in the transfer as master or addressed slave (i.e not during the address phase in slave mode).

In case of a misplaced START or RESTART detection in slave mode, the I2C enters address recognition state like for a correct START condition.
When a bus error is detected, the BERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

**Arbitration lost (ARLO)**

An arbitration loss is detected when a high level is sent on the SDA line, but a low level is sampled on the SCL rising edge.

- In master mode, arbitration loss is detected during the address phase, data phase and data acknowledge phase. In this case, the SDA and SCL lines are released, the START control bit is cleared by hardware and the master switches automatically to slave mode.
- In slave mode, arbitration loss is detected during data phase and data acknowledge phase. In this case, the transfer is stopped, and the SCL and SDA lines are released.

When an arbitration loss is detected, the ARLO flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

**Overrun/underrun error (OVR)**

An overrun or underrun error is detected in slave mode when NOSTRETCH = 1 and:

- In reception when a new byte is received and the RXDR register has not been read yet. The new received byte is lost, and a NACK is automatically sent as a response to the new byte.
- In transmission:
  - When STOPF = 1 and the first data byte must be sent. The content of the I2C_TXDR register is sent if TXE = 0, 0xFF if not.
  - When a new byte must be sent and the I2C_TXDR register has not been written yet, 0xFF is sent.

When an overrun or underrun error is detected, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

**Packet error checking error (PECERR)**

This section is relevant only when the SMBus feature is supported (refer to Section 48.3).

A PEC error is detected when the received PEC byte does not match with the I2C_PECR register content. A NACK is automatically sent after the wrong PEC reception.

When a PEC error is detected, the PECERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.
Timeout error (TIMEOUT)

This section is relevant only when the SMBus feature is supported (refer to Section 48.3).

A timeout error occurs for any of these conditions:

- $\text{TIDLE} = 0$ and $\text{SCL}$ remained low for the time defined in the TIMEOUTA[11:0] bits: this is used to detect an SMBus timeout.
- $\text{TIDLE} = 1$ and both $\text{SDA}$ and $\text{SCL}$ remained high for the time defined in the TIMEOUTA[11:0] bits: this is used to detect a bus idle condition.
- Master cumulative clock low extend time reached the time defined in the TIMEOUTB[11:0] bits (SMBus $t_{\text{LOW:MEXT}}$ parameter).
- Slave cumulative clock low extend time reached the time defined in TIMEOUTB[11:0] bits (SMBus $t_{\text{LOW:SEXT}}$ parameter).

When a timeout violation is detected in master mode, a STOP condition is automatically sent.

When a timeout violation is detected in slave mode, SDA and SCL lines are automatically released.

When a timeout error is detected, the TIMEOUT flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Alert (ALERT)

This section is relevant only when the SMBus feature is supported (refer to Section 48.3).

The ALERT flag is set when the I2C interface is configured as a Host ($\text{SMBHEN} = 1$), the alert pin detection is enabled ($\text{ALERTEN} = 1$) and a falling edge is detected on the $\text{SMBA}$ pin. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

48.4.17 DMA requests

Transmission using DMA

DMA (direct memory access) can be enabled for transmission by setting the TXDMAEN bit in the I2C_CR1 register. Data is loaded from an SRAM area configured using the DMA peripheral (see Section 11: Direct memory access controller (DMA) on page 359) to the I2C_TXDR register whenever the TXIS bit is set.

Only the data are transferred with DMA.

- In master mode: the initialization, the slave address, direction, number of bytes and START bit are programmed by software (the transmitted slave address cannot be transferred with DMA). When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter. Refer to Master transmitter.
- In slave mode:
  - With $\text{NOSTRETCH} = 0$, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in ADDR interrupt subroutine, before clearing ADDR.
  - With $\text{NOSTRETCH} = 1$, the DMA must be initialized before the address match event.
- For instances supporting SMBus: the PEC transfer is managed with NBYTES counter. Refer to SMBus slave transmitter and SMBus master transmitter.
**Note:** If DMA is used for transmission, the TXIE bit does not need to be enabled.

**Reception using DMA**

DMA (direct memory access) can be enabled for reception by setting the RXDMAEN bit in the I2C_CR1 register. Data is loaded from the I2C_RXDR register to an SRAM area configured using the DMA peripheral (refer to Section 11: Direct memory access controller (DMA) on page 359) whenever the RXNE bit is set. Only the data (including PEC) are transferred with DMA.

- In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software. When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.
- In slave mode with NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in the ADDR interrupt subroutine, before clearing the ADDR flag.
- If SMBus is supported (see Section 48.3) the PEC transfer is managed with the NBYTES counter. Refer to SMBus slave receiver and SMBus master receiver.

**Note:** If DMA is used for reception, the RXIE bit does not need to be enabled.

### 48.4.18 Debug mode

When the microcontroller enters debug mode (core halted), the SMBus timeout either continues to work normally or stops, depending on the DBG_I2Cx_ configuration bits in the DBG module.

### 48.5 I2C low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>

1. The ADDR match event can wake up the device from Stop mode only if the I2C instance supports the Wake-up from Stop mode feature. Refer to Section 48.3.
48.7 I2C registers

Refer to Section 1.2 on page 101 for a list of abbreviations used in register descriptions.

The peripheral registers are accessed by words (32-bit).

48.7.1 I2C control register 1 (I2C_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

```

Bit 31 STOPFACL: STOP detection flag (STOPF) automatic clear
0: STOPF flag is set by hardware, cleared by software by setting STOPCF bit.
1: STOPF flag remains cleared by hardware. This mode can be used in NOSTRETCH slave mode, to avoid the overrun error if the STOPF flag is not cleared before next data transmission. This allows a slave data management by DMA only, without any interrupt from peripheral.

Bit 30 ADDRACL: Address match flag (ADDR) automatic clear
0: ADDR flag is set by hardware, cleared by software by setting ADDRCF bit.
1: ADDR flag remains cleared by hardware. This mode can be used in slave mode, to avoid the ADDR clock stretching if the I2C enables only one slave address. This allows a slave data management by DMA only, without any interrupt from peripheral.

Bits 29:25 Reserved, must be kept at reset value.

Bit 24 FMP: Fast-mode Plus 20 mA drive enable
0: 20 mA I/O drive disabled
1: 20 mA I/O drive enabled

Bit 23 PECEN: PEC enable
0: PEC calculation disabled
1: PEC calculation enabled

Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.
### Bit 22  **ALERTEN**: SMBus alert enable

- **0**: The SMBus alert pin (SMBA) is not supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is released and the Alert Response Address header is disabled (0001100x followed by NACK).
- **1**: The SMBus alert pin is supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is driven low and the Alert Response Address header is enabled (0001100x followed by ACK).

**Note**: When **ALERTEN** = 0, the SMBA pin can be used as a standard GPIO.

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.*

### Bit 21  **SMBDEN**: SMBus device default address enable

- **0**: Device default address disabled. Address 0b1100001x is NACKed.
- **1**: Device default address enabled. Address 0b1100001x is ACKed.

**Note**: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

### Bit 20  **SMBHEN**: SMBus host address enable

- **0**: Host address disabled. Address 0b0001000x is NACKed.
- **1**: Host address enabled. Address 0b0001000x is ACKed.

**Note**: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

### Bit 19  **GCEN**: General call enable

- **0**: General call disabled. Address 0b00000000 is NACKed.
- **1**: General call enabled. Address 0b00000000 is ACKed.

### Bit 18  **WUPEN**: Wake-up from Stop mode enable

- **0**: Wake-up from Stop mode disable.
- **1**: Wake-up from Stop mode enable.

**Note**: If the wake-up from Stop mode feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

**Note**: **WUPEN** can be set only when DNF = ‘0000’

### Bit 17  **NOSTRETCH**: Clock stretching disable

This bit is used to disable clock stretching in slave mode. It must be kept cleared in master mode.

- **0**: Clock stretching enabled
- **1**: Clock stretching disabled

**Note**: This bit can be programmed only when the I2C is disabled (PE = 0).

### Bit 16  **SBC**: Slave byte control

- **0**: Slave byte control disabled
- **1**: Slave byte control enabled

### Bit 15  **RXDMAEN**: DMA reception requests enable

- **0**: DMA mode disabled for reception
- **1**: DMA mode enabled for reception

### Bit 14  **TXDMAEN**: DMA transmission requests enable

- **0**: DMA mode disabled for transmission
- **1**: DMA mode enabled for transmission

### Bit 13  Reserved, must be kept at reset value.
Bit 12 ANFOFF: Analog noise filter OFF
0: Analog noise filter enabled
1: Analog noise filter disabled

Note: This bit can be programmed only when the I2C is disabled (PE = 0).

Bits 11:8 DNF[3:0]: Digital noise filter
These bits are used to configure the digital noise filter on SDA and SCL input. The digital filter, filters spikes with a length of up to DNF[3:0] * tI2CCLK
0000: Digital filter disabled
0001: Digital filter enabled and filtering capability up to 1 tI2CCLK
...
1111: digital filter enabled and filtering capability up to 15 tI2CCLK

Note: If the analog filter is enabled, the digital filter is added to it.
This filter can be programmed only when the I2C is disabled (PE = 0).

Bit 7 ERRIE: Error interrupts enable
0: Error detection interrupts disabled
1: Error detection interrupts enabled

Note: Any of these errors generate an interrupt:
Arbitration loss (ARLO)
Bus error detection (BERR)
Overrun/Underrun (OVR)
Timeout detection (TIMEOUT)
PEC error detection (PECERR)
Alert pin event detection (ALERT)

Bit 6 TCIE: Transfer complete interrupt enable
0: Transfer complete interrupt disabled
1: Transfer complete interrupt enabled

Note: Any of these events generate an interrupt:
Transfer complete (TC)
Transfer complete reload (TCR)

Bit 5 STOPIE: Stop detection interrupt enable
0: Stop detection (STOPF) interrupt disabled
1: Stop detection (STOPF) interrupt enabled

Bit 4 NACKIE: Not acknowledge received interrupt enable
0: Not acknowledge (NACKF) received interrupts disabled
1: Not acknowledge (NACKF) received interrupts enabled

Bit 3 ADDRIE: Address match interrupt enable (slave only)
0: Address match (ADDR) interrupts disabled
1: Address match (ADDR) interrupts enabled

Bit 2 RXIE: RX interrupt enable
0: Receive (RXNE) interrupts disabled
1: Receive (RXNE) interrupts enabled

Bit 1 TXIE: TX interrupt enable
0: Transmit (TXIS) interrupt disabled
1: Transmit (TXIS) interrupt enabled
Bit 0 **PE**: Peripheral enable
- 0: Peripheral disable
- 1: Peripheral enable

*Note:* When PE = 0, the I2C SCL and SDA lines are released. Internal state machines and status bits are put back to their reset value. When cleared, PE must be kept low for at least three APB clock cycles.

### 48.7.2 I2C control register 2 (I2C_CR2)

Address offset: 0x04

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

</tr>
</tbody>
</table>

**Bits 31:27** Reserved, must be kept at reset value.

**Bit 26** **PECBYTE**: Packet error checking byte

- This bit is set by software, and cleared by hardware when the PEC is transferred, or when a STOP condition or an Address matched is received, also when PE = 0.
- 0: No PEC transfer.
- 1: PEC transmission/reception is requested

*Note:* Writing 0 to this bit has no effect.

*This bit has no effect when RELOAD is set.*
*This bit has no effect is slave mode when SBC = 0.*
*If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0.*
*Refer to Section 48.3.*

**Bit 25** **AUTOEND**: Automatic end mode (master mode)

- This bit is set and cleared by software.
- 0: software end mode: TC flag is set when NBYTES data are transferred, stretching SCL low.
- 1: Automatic end mode: a STOP condition is automatically sent when NBYTES data are transferred.

*Note:* This bit has no effect in slave mode or when the RELOAD bit is set.

**Bit 24** **RELOAD**: NBYTES reload mode

- This bit is set and cleared by software.
- 0: The transfer is completed after the NBYTES data transfer (STOP or RESTART follows).
- 1: The transfer is not completed after the NBYTES data transfer (NBYTES is reloaded). TCR flag is set when NBYTES data are transferred, stretching SCL low.
Bits 23:16 **NBYES[7:0]**: Number of bytes
The number of bytes to be transmitted/received is programmed there. This field is don’t care in slave mode with SBC = 0.

*Note: Changing these bits when the START bit is set is not allowed.*

Bit 15 **NACK**: NACK generation (slave mode)
The bit is set by software, cleared by hardware when the NACK is sent, or when a STOP condition or an Address matched is received, or when PE = 0.
0: an ACK is sent after current received byte.
1: a NACK is sent after current received byte.

*Note: Writing 0 to this bit has no effect.*

This bit is used in slave mode only: in master receiver mode, NACK is automatically generated after last byte preceding STOP or RESTART condition, whatever the NACK bit value.
When an overrun occurs in slave receiver NOSTRETCH mode, a NACK is automatically generated, whatever the NACK bit value.
When hardware PEC checking is enabled (PECBYTE = 1), the PEC acknowledge value does not depend on the NACK value.

Bit 14 **STOP**: Stop generation (master mode)
The bit is set by software, cleared by hardware when a STOP condition is detected, or when PE = 0.

*In master mode:*
0: No Stop generation.
1: Stop generation after current byte transfer.

*Note: Writing 0 to this bit has no effect.*

Bit 13 **START**: Start generation
This bit is set by software, and cleared by hardware after the Start followed by the address sequence is sent, by an arbitration loss, by an address matched in slave mode, by a timeout error detection, or when PE = 0.
0: No Start generation.
1: Restart/Start generation:
If the I2C is already in master mode with AUTOEND = 0, setting this bit generates a Repeated start condition when RELOAD = 0, after the end of the NBYES transfer.
Otherwise setting this bit generates a START condition once the bus is free.

*Note: Writing 0 to this bit has no effect.*

The START bit can be set even if the bus is BUSY or I2C is in slave mode.
The bit has no effect when RELOAD is set.

Bit 12 **HEAD10R**: 10-bit address header only read direction (master receiver mode)
0: The master sends the complete 10-bit slave address read sequence: Start + 2 bytes 10-bit address in write direction + Restart + first seven bits of the 10-bit address in read direction.
1: The master only sends the first seven bits of the 10-bit address, followed by Read direction.

*Note: Changing this bit when the START bit is set is not allowed.*

Bit 11 **ADD10**: 10-bit addressing mode (master mode)
0: The master operates in 7-bit addressing mode,
1: The master operates in 10-bit addressing mode

*Note: Changing this bit when the START bit is set is not allowed.*
48.7.3 I2C own address 1 register (I2C_OAR1)

Address offset: 0x08
Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

| Bit 31:16 | Reserved, must be kept at reset value. |
| Bit 15 | OA1EN: Own address 1 enable |
| 0: Own address 1 disabled. The received slave address OA1 is NACKed. |
| 1: Own address 1 enabled. The received slave address OA1 is ACKed. |
| Bit 14:11 | Reserved, must be kept at reset value. |
| Bit 10 | OA1MODE: Own address 1 10-bit mode |
| 0: Own address 1 is a 7-bit address. |
| 1: Own address 1 is a 10-bit address. |
| Note: This bit can be written only when OA1EN = 0. |
| Bits 9:0 | OA1[9:0]: Interface own slave address |
| 7-bit addressing mode: OA1[7:1] contains the 7-bit own slave address. The bits OA1[9], OA1[8] and OA1[0] are don’t care. |
| 10-bit addressing mode: OA1[9:0] contains the 10-bit own slave address. |
| Note: These bits can be written only when OA1EN = 0. |
48.7.4 I2C own address 2 register (I2C_OAR2)

Address offset: 0x0C
Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to 2x i2c_pclk + 6 x i2c_ker_ck.

Bits 31:16  Reserved, must be kept at reset value.

Bit 15 **OA2EN**: Own address 2 enable
0: Own address 2 disabled. The received slave address OA2 is NACKed.
1: Own address 2 enabled. The received slave address OA2 is ACKed.

Bits 14:11  Reserved, must be kept at reset value.

Bits 10:8  **OA2MSK[2:0]**: Own address 2 masks
000: No mask
001: OA2[1] is masked and don’t care. Only OA2[7:2] are compared.
010: OA2[2:1] are masked and don’t care. Only OA2[7:3] are compared.
100: OA2[4:1] are masked and don’t care. Only OA2[7:5] are compared.
111: OA2[7:1] are masked and don’t care. No comparison is done, and all (except reserved) 7-bit received addresses are acknowledged.

*Note:* These bits can be written only when OA2EN = 0.
As soon as OA2MSK is not equal to 0, the reserved I2C addresses (0b0000xxx and 0b1111xxx) are not acknowledged even if the comparison matches.

Bits 7:1  **OA2[7:1]**: Interface address

7-bit addressing mode: 7-bit address

*Note:* These bits can be written only when OA2EN = 0.

Bit 0  Reserved, must be kept at reset value.
48.7.5 I2C timing register (I2C_TIMINGR)

Address offset: 0x10
Reset value: 0x0000 0000
Access: no wait states

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>

</tr>
<tr>
<td>Bits 31:28 PRESC[3:0]: Timing prescaler</td>
</tr>
</tbody>
</table>
| This field is used to prescale i2c_ker_ck in order to generate the clock period t<sub>PRESC</sub> used for data setup and hold counters (refer to I2C timings) and for SCL high and low level counters (refer to I2C master initialization).
| t<sub>PRESC</sub> = (PRESC + 1) x t<sub>I2CCLK</sub> |
| Bits 27:24 Reserved, must be kept at reset value. |
| Bits 23:20 SCLDEL[3:0]: Data setup time |
| This field is used to generate a delay t<sub>SCLDEL</sub> between SDA edge and SCL rising edge. In master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during t<sub>SCLDEL</sub>.
| t<sub>SCLDEL</sub> = (SCLDEL + 1) x t<sub>PRESC</sub> |
| Note: t<sub>SCLDEL</sub> is used to generate t<sub>SU:DAT</sub> timing. |
| Bits 19:16 SDADEL[3:0]: Data hold time |
| This field is used to generate the delay t<sub>SDADEL</sub> between SCL falling edge and SDA edge. In master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during t<sub>SDADEL</sub>.
| t<sub>SDADEL</sub> = SDADEL x t<sub>PRESC</sub> |
| Note: SDADEL is used to generate t<sub>HD:DAT</sub> timing. |
| Bits 15:8 SCLH[7:0]: SCL high period (master mode) |
| This field is used to generate the SCL high period in master mode.
| t<sub>SCLH</sub> = (SCLH + 1) x t<sub>PRESC</sub> |
| Note: SCLH is also used to generate t<sub>SU:STO</sub> and t<sub>HD:STA</sub> timing. |
| Bits 7:0 SCLL[7:0]: SCL low period (master mode) |
| This field is used to generate the SCL low period in master mode.
| t<sub>SCLL</sub> = (SCLL + 1) x t<sub>PRESC</sub> |
| Note: SCLL is also used to generate t<sub>BUF</sub> and t<sub>SU:STA</sub> timings. |

Note: This register must be configured when the I2C is disabled (PE = 0).

Note: The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.
I2C timeout register (I2C_TIMEOUTR)

Address offset: 0x14
Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

<table>

<tr>
<td>19</td>
<td>18</td>
<td>17</td>
<td>16</td>
</tr>
</tbody>
</table>

Bit 31 **TEXTEN**: Extended clock timeout enable
0: Extended clock timeout detection is disabled
1: Extended clock timeout detection is enabled. When a cumulative SCL stretch for more than \( t_{LOW:EXT} \) is done by the I2C interface, a timeout error is detected (TIMEOUT = 1).

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **TIMEOUTB[11:0]**: Bus timeout B
This field is used to configure the cumulative clock extension timeout:
- In master mode, the master cumulative clock low extend time \( t_{LOW:MEXT} \) is detected
- In slave mode, the slave cumulative clock low extend time \( t_{LOW:SEXT} \) is detected
\[ t_{LOW:EXT} = (\text{TIMEOUTB} + \text{TIDLE = 0}) \times 2048 \times \text{i2c_clk} \]
Note: These bits can be written only when TEXTEN = 0.

Bit 15 **TIMOUTEN**: Clock timeout enable
0: SCL timeout detection is disabled
1: SCL timeout detection is enabled: when SCL is low for more than \( t_{TIMEOUT} \) (TIDLE = 0) or high for more than \( t_{IDLE} \) (TIDLE = 1), a timeout error is detected (TIMEOUT = 1).

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **TIDLE**: Idle clock timeout detection
0: TIMEOUTA is used to detect SCL low timeout
1: TIMEOUTA is used to detect both SCL and SDA high timeout (bus idle condition)
Note: This bit can be written only when TIMOUTEN = 0.

Bits 11:0 **TIMEOUTA[11:0]**: Bus Timeout A
This field is used to configure:
The SCL low timeout condition \( t_{TIMEOUT} \) when TIDLE = 0
\[ t_{TIMEOUT} = (\text{TIMEOUTA} + 1) \times 2048 \times \text{i2c_clk} \]
The bus idle condition (both SCL and SDA high) when TIDLE = 1
\[ t_{IDLE} = (\text{TIMEOUTA} + 1) \times 4 \times \text{i2c_clk} \]
Note: These bits can be written only when TIMOUTEN = 0.

Note: If the SMBus feature is not supported, this register is reserved and forced by hardware to “0x00000000”. Refer to Section 48.3.
48.7.7 I2C interrupt and status register (I2C_ISR)

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:17 ADDCODE[6:0]: Address match code (slave mode)
These bits are updated with the received address when an address match event occurs (ADDR = 1).
In the case of a 10-bit address, ADDCODE provides the 10-bit header followed by the two MSBs of the address.

Bit 16 **DIR**: Transfer direction (slave mode)
This flag is updated when an address match event occurs (ADDR = 1).
0: Write transfer, slave enters receiver mode.
1: Read transfer, slave enters transmitter mode.

Bit 15 **BUSY**: Bus busy
This flag indicates that a communication is in progress on the bus. It is set by hardware when a START condition is detected. It is cleared by hardware when a STOP condition is detected, or when PE = 0.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **ALERT**: SMBus alert
This flag is set by hardware when SMBHEN = 1 (SMBus host configuration), ALERTEN = 1 and an SMBALERT event (falling edge) is detected on SMBA pin. It is cleared by software by setting the ALERTCF bit.

*Note:* This bit is cleared by hardware when PE = 0.
If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.

Bit 12 **TIMEOUT**: Timeout or t\text{LOW} detection flag
This flag is set by hardware when a timeout or extended clock timeout occurred. It is cleared by software by setting the TIMEOUTCF bit.

*Note:* This bit is cleared by hardware when PE = 0.
If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.
Bit 11 **PECERR**: PEC Error in reception
This flag is set by hardware when the received PEC does not match with the PEC register content. A NACK is automatically sent after the wrong PEC reception. It is cleared by software by setting the PECCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.*

Bit 10 **OVR**: Overrun/Underrun (slave mode)
This flag is set by hardware in slave mode with NOSTRETCH = 1, when an overrun/underrun error occurs. It is cleared by software by setting the OVRCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 9 **ARLO**: Arbitration lost
This flag is set by hardware in case of arbitration loss. It is cleared by software by setting the ARLOCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 8 **BERR**: Bus error
This flag is set by hardware when a misplaced Start or STOP condition is detected whereas the peripheral is involved in the transfer. The flag is not set during the address phase in slave mode. It is cleared by software by setting **BERRCF bit**.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 7 **TCR**: Transfer Complete Reload
This flag is set by hardware when RELOAD = 1 and NBYTES data have been transferred. It is cleared by software when NBYTES is written to a non-zero value.

*Note: This bit is cleared by hardware when PE = 0.*

**This flag is only for master mode, or for slave mode when the SBC bit is set.**

Bit 6 **TC**: Transfer Complete (master mode)
This flag is set by hardware when RELOAD = 0, AUTOEND = 0 and NBYTES data have been transferred. It is cleared by software when START bit or STOP bit is set.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 5 **STOPF**: Stop detection flag
This flag is set by hardware when a STOP condition is detected on the bus and the peripheral is involved in this transfer:
- either as a master, provided that the STOP condition is generated by the peripheral.
- or as a slave, provided that the peripheral has been addressed previously during this transfer.

It is cleared by software by setting the STOPCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 4 **NACKF**: Not Acknowledge received flag
This flag is set by hardware when a NACK is received after a byte transmission. It is cleared by software by setting the NACKCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 3 **ADDR**: Address matched (slave mode)
This bit is set by hardware as soon as the received slave address matched with one of the enabled slave addresses. It is cleared by software by setting **ADDRCF bit**.

*Note: This bit is cleared by hardware when PE = 0.*
Bit 2 **RXNE**: Receive data register not empty (receivers)
This bit is set by hardware when the received data is copied into the I2C_RXDR register, and is ready to be read. It is cleared when I2C_RXDR is read.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 1 **TXIS**: Transmit interrupt status (transmitters)
This bit is set by hardware when the I2C_TXDR register is empty and the data to be transmitted must be written in the I2C_TXDR register. It is cleared when the next data to be sent is written in the I2C_TXDR register.
This bit can be written to 1 by software only when NOSTRETCH = 1, to generate a TXIS event (interrupt if TXIE = 1 or DMA request if TXDMAEN = 1).

*Note: This bit is cleared by hardware when PE = 0.*

Bit 0 **TXE**: Transmit data register empty (transmitters)
This bit is set by hardware when the I2C_TXDR register is empty. It is cleared when the next data to be sent is written in the I2C_TXDR register.
This bit can be written to 1 by software in order to flush the transmit data register I2C_TXDR.

*Note: This bit is set by hardware when PE = 0.*

### 48.7.8 I2C interrupt clear register (I2C_ICR)

Address offset: 0x1C
Reset value: 0x0000 0000
Access: no wait states

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **ALERTCF**: Alert flag clear
Writing 1 to this bit clears the ALERT flag in the I2C_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.*

Bit 12 **TIMOUTCF**: Timeout detection flag clear
Writing 1 to this bit clears the TIMEOUT flag in the I2C_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.*

Bit 11 **PECCF**: PEC Error flag clear
Writing 1 to this bit clears the PECERR flag in the I2C_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 48.3.*

Bit 10 **OVRCF**: Overrun/Underrun flag clear
Writing 1 to this bit clears the OVR flag in the I2C_ISR register.
Bit 9 **ARLOCF**: Arbitration lost flag clear
Writing 1 to this bit clears the ARLO flag in the I2C_ISR register.

Bit 8 **BERRCF**: Bus error flag clear
Writing 1 to this bit clears the BERRF flag in the I2C_ISR register.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **STOPCF**: STOP detection flag clear
Writing 1 to this bit clears the STOPF flag in the I2C_ISR register.

Bit 4 **NACKCF**: Not Acknowledge flag clear
Writing 1 to this bit clears the NACKF flag in I2C_ISR register.

Bit 3 **ADDRCF**: Address matched flag clear
Writing 1 to this bit clears the ADDR flag in the I2C_ISR register. Writing 1 to this bit also clears the START bit in the I2C_CR2 register.

Bits 2:0 Reserved, must be kept at reset value.

### 48.7.9 I2C PEC register (I2C_PECR)

Address offset: 0x20
Reset value: 0x0000 0000
Access: no wait states

<table>

49  Improved inter-integrated circuit (I3C)

49.1 Introduction

The I3C interface handles communication between this device and others, such as sensors and host processor, connected on an I3C bus.

An I3C bus is a two-wire, serial single-ended, multidrop bus, intended to improve a legacy I2C bus.

The I3C SDR-only peripheral implements all the features required by the MIPI® I3C specification v1.1. It can control all I3C bus-specific sequencing, protocol, arbitration, and timing, and can act as controller (formerly known as master), or as target (formerly known as slave).

When acting as controller, the I3C peripheral improves the features of the I2C interface preserving some backward compatibility: it allows an I2C target to operate on an I3C bus in legacy I2C fast-mode (Fm) or legacy I2C fast-mode plus (Fm+), provided that the latter does not perform clock stretching.

The I3C peripheral can be used with DMA, to off-load the CPU.

49.2 I3C main features

The I3C peripheral supports:

- MIPI® I3C specification v1.1 (see details in Table 518), as:
  - I3C SDR-only primary controller
  - I3C SDR-only secondary controller
  - I3C SDR-only target
- I3C SCL bus clock frequency up to 12.5 MHz
- Registers configuration from the host application via the APB slave port
- Queued data transfers:
  - Transmit FIFO (TX-FIFO) for data bytes/words to be transmitted on the I3C bus
  - Receive FIFO (RX-FIFO) for received data bytes/words on the I3C bus
  - For each FIFO, optional DMA mode with a dedicated DMA channel
- Queued control/status transfers, when controller:
  - Control FIFO (C-FIFO) for control words to be sent on the I3C bus
  - Optional status FIFO (S-FIFO) for status words as received on the I3C bus
  - For each FIFO, optional DMA mode with a dedicated DMA channel
- Messages:
  - Legacy I2C read/write messages to legacy I2C targets in Fm/Fm+
  - I3C SDR read/write private messages
  - I3C SDR broadcast CCC messages (see details in Table 524)
  - I3C SDR read/write direct CCC messages (see details in Table 524)
• Frame-level management, when controller:
  – Optional C-FIFO and TX-FIFO preload
  – Multiple messages encapsulation
  – Optional arbitrable header generation on the I3C bus
  – HDR exit pattern generation on the I3C bus for error recovery
• Programmable bus timing, when controller:
  – SCL high and low period
  – SDA hold time
  – Bus free (minimum) time
  – Bus available/idle condition time
  – Clock stall time
• Target-initiated requests management:
  – Simultaneous support up to four targets, when controller
  – In-band interrupts, with programmable IBI payload (up to 4 bytes), with pending read notification support
  – Bus control request, with recovery flow support and hand-off delay
  – Hot-join mechanism
• HDR exit pattern detection, when target
• Bus error management:
  – CEx with x = 0, 1, 2, 3 when controller
  – TEx with x = 0, 1, ..., 6 when target
  – Bus control switch error and recovery
  – Target reset
• Individual programmable event-based management:
  – Per-event identification with flag reporting and clear control
  – Host application notification via flag polling, and/or via interrupt with a per-event programmable enable
  – Error type identification
• Wake-up from Stop mode(s), as controller (see Section 49.3.2):
  – On an in-band interrupt without payload
  – On a hot-join request
  – On a controller-role request
• Wakeup from Stop mode(s), as target (see Section 49.3.2):
  – On a reset pattern
  – On a missed start
• Multiclock domain management:
  – Separate APB clock and kernel clock, driven from independently programmed clock sources via the RCC, in addition to SCL clock
  – Minimum operating frequency for the kernel clock and the APB clock vs. the application-driven SCL clock (see clocks constraints in Section 49.6.2)
49.3  I3C implementation

49.3.1  I3C instantiation

There is a single I3C instance in the device.

49.3.2  I3C wake-up from low-power mode(s)

The peripheral can wake up the device from a low-power mode, as detailed in Table 515. For more details about the wake-up capabilities, refer to Section 49.13.

<table>
<thead>
<tr>
<th>Table 515. I3C wake-up</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Wake-up</strong></td>
</tr>
<tr>
<td>From Stop mode with SVOS3</td>
</tr>
</tbody>
</table>

49.3.3  I3C FIFOs

The FIFOs are implemented as defined in Table 516.

<table>
<thead>
<tr>

</tbody>
</table>

49.3.4  I3C triggers

This feature is not available in this product: no hardware trigger signal is connected as an input to the I3C peripheral.

49.3.5  I3C interrupt(s)

The interrupt mapping is implemented as detailed in Table 517.

<table>
<thead>

49.6 I3C reset and clocks

49.6.1 I3C reset

On a system reset, the I3C peripheral is reset.

Alternatively, the software can reset specifically the peripheral by writing the corresponding reset control bit (I3CxRST) of the reset and clock controller (RCC). Refer to the RCC section of this document for more details.

Additionally, when acting as target, the enabled peripheral (EN = 1 in the I3C_CFGR register) can receive an in-band reset pattern on the I3C bus from the controller. The software is then notified (when RSTF = 1 in the I3C_EVR register and/or the corresponding interrupt is enabled) to perform the requested action, as registered in RSTACT[1:0] of the I3C_DEVR0 register, on the former reception of the broadcast or direct RSTACT CCC. Refer to Table 524 and Section 49.16.16 for more details.

This reset interrupt notification can be used to wake up from a low power mode, where the I3C peripheral (typically in the VCore domain) is active.

For more details about the corresponding low-power mode(s), refer to the power management in the PWR section.

49.6.2 I3C clocks and requirements

As indicated in the Figure 651, the I3C peripheral is implemented with several clock domains:

- SCL bus clock: for the I3C bus interface
  - When controller: the user must set and can adjust SCL/SDA timings by programming I3C timing register 0 (I3C_TIMINGR0), I3C timing register 1 (I3C_TIMINGR1) and I3C timing register 2 (I3C_TIMINGR2), as summarized in Controller initialization and Updating the configuration for a transfer, as controller.
  - When target: the user must set and comply with the bus available condition (tAVAL for an in-band interrupt or controller-role request), and the bus idle condition (tIDLE for a hot-join request), by programming I3C timing register 1 (I3C_TIMINGR1), as summarized in Target initialization.
- I3CCLK kernel clock: for the I3C protocol management, data and control serialization/deserialization, controller and target finite state machines, bus clock and timings management
- APB clock: for the APB interface, DMA interface, events, and interrupt generation

APB clock and kernel clocks are driven from independently programmed clock sources via the RCC (refer to Section 11: Reset and clock control (RCC)).

I3C kernel clock requirement, as controller

According to the intended value of the SCL clock on the bus, the application must guarantee that the frequency of the I3CCLK kernel clock be at least 2x the frequency of the SCL clock

*Note:* Sustaining $F_{SCL_{max}} = 12.9$ MHz means a frequency of the I3CCLK kernel clock > 25.8 MHz.

I3C kernel clock requirements, as target

According to the intended value of the SCL clock on the bus, the application must guarantee a minimum operating frequency for the I3CCLK kernel clock, meeting the following constraints:

1. Period of the I3CCLK kernel clock < $t_{HIGH}$ (SCL clock high period)
   - $t_{HIGH \ min} = 24$ ns. A frequency higher than 41.7 MHz guarantees this constraint, which can be relaxed, depending on the I3C bus/controller
2. Period of the I3CCLK kernel clock < $t_{CASr}$ (clock after repeated start condition)
   - $t_{CASr \ min} = t_{CAS \ min} / 2 = 19.2$ ns. A frequency higher than 52 MHz guarantees this constraint, which can be relaxed, depending on the I3C bus/controller
3. Two periods of the I3CCLK kernel clock < $t_{LOW\_OD}$ (SCL clock low period in open drain)
   - $t_{LOW\_OD \ min} = 200$ ns. A frequency higher than 10 MHz guarantees this constraint, which can be relaxed, depending on the I3C bus/controller
4. Frequency of the I3CCLK kernel clock > 2.5x frequency of the SCL clock
   - $F_{SCL_{max}} = 12.9$ MHz. A frequency higher than 32.3 MHz guarantees this constraint, which can be relaxed, depending on the I3C controller

APB clock requirement

According to the intended value of the SCL clock on the bus, the application must guarantee a minimum operating frequency for the APB clock:

- APB clock period < 3x (SCL clock period) - I3CCLK kernel clock period

This means that $F_{APB} > [F_{SCL} \times F_{I3CCLK} / (3 \times F_{I3CCLK} - F_{SCL})]

*Note:* This equation can be simplified to a minimum value of 5 MHz for the APB frequency.
49.7 I3C peripheral state and programming

49.7.1 I3C peripheral state

The I3C peripheral plays the role of I3C bus controller, or the role of an I3C target. In any case (see Figure 652 and Figure 653) the peripheral is in one of the following states:

- **Disabled state:**
  - After an I3C reset (system reset or I3C reset from RCC), the peripheral is in disabled state.
  - When the software sets to 1 bit EN in the I3C_CFGR register, the peripheral takes into account the value of the different configuration registers, and switches to the (enabled and) idle state.

- **Idle state:**
  - After being enabled (EN = 1), the peripheral activates its I3CCLK and SCL clock domains, and is able to communicate on the I3C bus.
  - The software can partly update the I3C peripheral configuration, see Updating the configuration for a transfer, as controller and Updating the configuration of the I3C peripheral, as target for more details.
  - The peripheral switches to the (enabled and) active state, either:
    a) Once the software initiates a transfer (as controller: when the software initiates a frame transfer; as target: when the software initiates an IBI/CR/HJ request)
    b) Or once the hardware receives a request from another I3C device on the bus (as controller: after a start request from a target and a maximum TCAS time; as target: when receiving a broadcast/direct CCC or a private read/write).

- **Active state:**
  - The peripheral executes the transfer(s) on the bus
  - When the requested transfer(s) is(are) completed, the software is notified by an event from the I3C event register (I3C_EVR), and the corresponding interrupt is enabled by I3C interrupt enable register (I3C_IER). The peripheral switches to idle state, is still able to communicate on the bus, and can be (partly) reconfigured.
    a) As controller: the raised event/flag can be frame completed (FCF), IBI/controller-role/hot-join request completed (IBIF/CRF/HJF), or transfer error (ERRF)
    b) As target: the raised event/flag can be dynamic address assignment completed (DAUPDF), IBI completed (IBIENDF), controller-role gaining completed (CRUPDF), broadcast/direct CCC completed (xxUPDF/RSTF/GETF/STAF), private read/write completed (FCF), or transfer error (ERRF)

**Note:** The software can disable the peripheral (write EN = 0), partially resetting it (subparts within the SCL clock domain and the I3CCLK kernel clock domain). Event, interrupt, and clock request generation are also impacted. The previously written configuration of the APB registers is kept and not modified.

49.7.2 I3C controller state and programming sequence

*Figure 652* illustrates the overall programming sequence of the I3C peripheral acting as (primary) controller, including state transitions, main subtasks, and conditions, as explained in this section.
1. This feature is implementation-dependent and can be unavailable. Refer to Section 49.3.4: I3C triggers.
Controller initialization

When the controller is in disabled state (EN = 0 in the I3C_CFGR register), the software must initialize as follows:

- Configure **I3C configuration register (I3C_CFGR)** with the following fields:
  - CRINIT = 1: as I3C bus controller
  - HKSDAEN: high keeper on SDA enable/disable
- Configure I3C bus timings:
  a) **I3C timing register 0 (I3C_TIMINGR0)**:
     - SCL clock high time period (tDIG_H, tDIG_H_MIXED) in legacy I²C and I3C open-drain/push-pull
     - SCL clock low time period (tDIG_L, tDIG_OD_L) in legacy I²C and I3C open-drain/push-pull
  b) **I3C timing register 1 (I3C_TIMINGR1)**:
     - SDA hold time in push-pull (tHD_PP)
     - bus free condition time (I3C tCAS, legacy I²C tBUF)
     - I3C repeated start timing (tCASr, tCBSr)
     - I3C stop timing (tCBP)
     - SCL clock low maximum stalling on the ENTDAA CCC (tSTALDDAA), or on the ACK/NACK of a legacy I²C transfer, or the parity bit of a write data transfer, or on the ACK/NACK data phase of a legacy I²C write, or on the transition bit of an I3C read transfer, or on the ACK/NACK phase of a legacy I²C write (tSTALL), to adjust SCL clock low stalling, if needed by the peripheral itself, when used as controller
     - tNEWCRLock for controller-role hand-off procedure (after GETACCCR CCC)
  c) **I3C timing register 2 (I3C_TIMINGR2)**:
     - SCL clock low stalling time, with separated enable/disable for each phase, to adjust SCL clock low stalling, if needed on the SDA hand-off with the addressed I3C target or legacy I²C target
- Configure its own dynamic address: DA [6:0] field of the **I3C own device characteristics register (I3C_DEVR0)**
- Configure the management of any device target x: **I3C device x characteristics register (I3C_DEVRx)**, for x = 1 to x ≤ 4
- Configure the execution mode of a frame transfer or a target-requested transfer: **I3C configuration register (I3C_CFGR)**, with the following fields:
  - TXDMAEN, CDMAEN, RXDMAEN, SDMAEN: DMA mode enable/disable for respectively, TX-FIFO, C-FIFO, RX-FIFO, S-FIFO
  - TXTHRES, RXTHRES: respectively TX-FIFO and RX-FIFO byte/world threshold
  - TMODE: transmit mode (enable/disable for both TX-FIFO and C-FIFO preload)
  - SMODE: S-FIFO enable/disable
  - EXITPTRN, RSTPTRN: exit, reset pattern enable/disable
  - HJACK: hot-join acknowledge enable/disable
  - NOARBH: arbitrable header disable/enable
- Configure interrupt generation or polling mode from any event: **I3C interrupt enable register (I3C_IER)**
Then, the software can enable the I3C peripheral (set EN = 1)

Note: The software can write once all the fields of the I3C_CFGR while enabling it.

**Start a controller-initiated frame transfer**

When the controller is in enabled state (EN = 1 in the I3C_CFGR register), the software can initiate a frame transfer by any of the following configuration methods:

1. Software-triggering: on a write and set TSFSET = 1 in the I3C_CFGR register
   - This causes the hardware to raise the flag CFNFF = 1 in the I3C_EVR register, to request a first control word I3C_CR to be written.
2. No triggering: on a write of the first control word I3C_CR by software.

Then, regardless of the frame starting method, the I3C peripheral switches to active state. While the control word is not the last message of the I3C frame (while MEND = 0 in the I3C_CR register), and while there is no transfer error (while ERRF = 1 in the I3C_EVR register), the hardware keeps requesting a next control word, and continuing the frame transfer:

a) If the C-FIFO is not configured in DMA mode (CDMAEN = 0 in the I3C_CFGR register), the software writes a next control word following the flag CFNFF = 1 in the I3C_EVR register, or the corresponding interrupt if enabled (if CFNFIE = 1 in I3C_IER register)

b) If the C-FIFO is configured in DMA mode (CDMAEN = 1), a next control word is automatically pushed and written by the allocated DMA channel consequently to the asserted I3C DMA request (i3c_tc_dma).

**Start and receiving a target-initiated transfer**

When the controller is in enabled state (EN = 1 in the I3C_CFGR register), concurrently to a possible controller-initiated transfer, a target can initiate a transfer by issuing a start request (drive SDA low), provided the controller has allowed a hot-join request, an IBI request, or a controller-role request via the I3C_DEVR0 register.

In this case, even though the controller software has no intent to start a frame transfer, the hardware switches to active state (activates the SCL clock before a maximum tCAS time defined as 1 µs, 100 µs, 2 ms or 50 ms, depending on, respectively, the bus activity state 0, 1, 2 or 3) to receive the hot-join/in-band interrupt/controller-role request from the target.

For more information about the execution of target-initiated I3C bus transfer and its related programming as a controller, refer to the relevant figures in Section 49.9:

- Figure 664: IBI transfer, as controller/target
- Figure 665: Hot-join request transfer, as controller/target
- Figure 666: Controller-role request transfer, as controller/target

**Executing a (controller-initiated) frame transfer**

The controller executes on the bus the frame transfer until the completion of the last message (FCF = 1 in the I3C_EVR register), or a transfer error (ERRF = 1 in the I3C_EVR register), and the corresponding interrupt, if enabled. This is based on I3C_CR and I3C_TD(W)R registers, written explicitly by software or pushed by the allocated DMA channel, and based on the I3C_RD(W)R, read explicitly by the software or by the allocated DMA channel. Then the I3C controller switches back to idle state.
For more information about the execution of controller-initiated I3C bus transfer and its related programming as a controller, refer to figures in Section 49.9:

- Figure 654: I3C CCC messages, as controller
- Figure 655: I3C broadcast ENTDAA CCC, as controller
- Figure 656: I3C broadcast, direct read and direct write RSTACT CCC, as controller
- Figure 661: I3C private read/write messages, as controller
- Figure 663: Legacy I2C read/write messages, as controller

Figure 652 does not include the management of the FIFOs (TX-FIFO, RX-FIFO, C-FIFO, and S-FIFO). This is detailed in Section 49.10.

For each completed message without transfer error, the hardware reports the exchanged transfer on the I3C bus by updating I3C status register (I3C_SR), which can be read or not by the software when the S-FIFO is disabled (SMODE = 0 in the I3C_CFGR register).

- In the case of a direct CCC read or a private read transfer, in addition to the completion of the last message (FCF = 1 in the I3C_EVR register) or a transfer error (ERRF = 1 in the I3C_EVR register) and the corresponding interrupt if enabled, and provided that the S-FIFO is disabled for the status register I3C_SR (SMODE = 0 in the I3C_CFGR register), the software is notified if the read transfer is ended prematurely by the target by RXTGTENDF = 1 in the I3C_EVR register, and the corresponding interrupt, if enabled. The software can then read I3C_SR, to get more information about the executed transfer.

Alternatively, if the S-FIFO is enabled (SMODE = 1 in the I3C_CFGR register), the status register I3C_SR must be read for each executed message, either directly by the software (notified by SFNEF = 1 in the I3C_EVR register and the corresponding interrupt, if enabled), or via the DMA (if SDMAEN = 1 in the I3C_CFGR register), no matter if a read is prematurely ended by the target or not. Frame completion (FCF = 1 in the I3C_EVR register) occurs only after reading the status of the last message (S-FIFO is empty). For more information, refer to Section 49.10.4.

**Updating the configuration for a transfer, as controller**

Back in idle state, the software can update the configuration of the I3C peripheral before the next transfer:

- Modify SCL clock stalling via **I3C timing register 2 (I3C_TIMINGR2)**
- Modify the interrupt/polling mode policy via **I3C interrupt enable register (I3C_IER)**
- Modify the following fields of the **I3C configuration register (I3C_CFGR):**
  - TXTHRES, RXTHRES
  - TMODE, SMODE
  - TXDMAEN, CDMAEN, RXDMAEN, SDMAEN
  - EXITPTRN, RSTPTRN
  - NOARBH
- Modify/prepare the control words, status words, read/write data of the next frame transfer to be executed, by software and/or DMA
  - \textit{I3C message control register (I3C\_CR), I3C message control register [alternate] (I3C\_CR)}
  - \textit{I3C status register (I3C\_SR)}
  - \textit{I3C transmit data byte register (I3C\_TDR), I3C transmit data word register (I3C\_TDWR)}
  - \textit{I3C receive data byte register (I3C\_RDR), I3C receive data word register (I3C\_RDWR)}

- Typically after having issued and completed a broadcast/direct DISEC/ENEC CCC:
  - Modify the hot-join acknowledge policy via bit HJACK in the I3C\_CFGR register
  - Modify IBI/CR acknowledge policy to any target x, via \textit{I3C device x characteristics register (I3C\_DEVRx)}

The registers usage vs. the I3C peripheral role as controller is summarized in Section 49.8.1.

The static/dynamic registers fields usage when acting as controller is summarized in Table 522.

### 49.7.3 I3C target state and programming sequence

\textit{Figure 653} illustrates the overall programming sequence of the peripheral acting as target, including state transitions, main subtasks, and conditions as explained in this section.
Figure 653. I3C target state and programming sequence diagram
Target initialization

When the target is in disabled state (EN = 0 in the I3C_CFGR register), the software must initialize as follows:

- Set I3C peripheral as target: write and clear CRINIT = 0 in the I3C_CFGR register
- Set I3C bus timings via I3C timing register 1 (I3C_TIMINGR1): write AVAL[7:0] for:
  - Bus available condition time (tAVAL) for IBI or controller-role request
  - Bus idle condition time (tIDLE) for hot-join request
  - tNEWCRLock for controller-role hand-off procedure (after GETACCCR CCC)
- Configure target-initiated requests: write I3C own device characteristics register (I3C_DEVR0) with
  - IBIEN: in-band interrupt (also known as IBI) request enable/disable
  - CREN: controller-role request enable/disable
  - HJEN: hot-join request enable/disable
- Initialize target characteristics and capabilities: write
  - I3C bus characteristics register (I3C_BCR)
  - I3C device characteristics register (I3C_DCR)
  - I3C maximum read length register (I3C_MAXRLR)
  - I3C maximum write length register (I3C_MAXWLR)
  - I3C get capability register (I3C_GETCAPR)
  - I3C controller-role capability register (I3C_CRCAPR)
  - I3C get max data speed register (I3C_GETMXDSR)
  - I3C extended provisioned ID register (I3C_EPIDR)
- Configure the execution mode of a transfer: I3C configuration register (I3C_CFGR), with the following fields:
  - TXDMAEN, RXDMAEN: DMA mode enable/disable for, respectively, TX-FIFO and RX-FIFO
  - TXTHRES, RXTHRES: respectively TX-FIFO and RX-FIFO byte/world threshold
  - Disable S-FIFO: SMODE = 0 (default/reset value)
- Configure interrupt generation or polling mode from any event: I3C interrupt enable register (I3C_IER)

Then, the software can enable the I3C peripheral (write and set EN = 1).

Note: The software can write once all the fields of the I3C_CFGR register while enabling it.

Receiving a (broadcast CCC, direct read/write CCC or private read/write) message from the controller

When the target is in idle state (EN = 1 in the I3C_CFGR register), the target is ready to receive a communication message on the I3C bus from the controller, and is ready to switch to the active state.

Typically, first, the active target is receiving a broadcast ENTDAA CCC, possibly after optional received broadcast ENEC/DISEC CCC(s), and is then assigned a dynamic address. The event DAUPF in the I3C_EVR register is raised to 1, the related interrupt is generated if enabled, and the target goes back to idle state.
After that, the idle target is ready to receive any other broadcast CCC message, or direct read/write CCC, or private read/write message from the controller.

For more information about the execution of controller-initiated I3C bus transfers and its related programming as a target, including the updated I3C registers and fields, refer to figures in Section 49.9:

- Figure 657: I3C CCC messages, as target
- Figure 658: I3C broadcast ENTDAA CCC, as target
- Figure 659: I3C broadcast DEFTGTS CCC, as target
- Figure 660: I3C broadcast DEFR GPA CCC, as target
- Figure 662: I3C private read/write messages, as target

Figure 653 does not include the FIFOs management (TX-FIFO, RX-FIFO). This is detailed in Section 49.10.

Read the message status register

For each received and completed message without transfer error, the hardware reports the exchanged transfer on the I3C bus by updating the I3C status register (I3C_SR), which can be read by the software after being notified by the corresponding flag in the I3C event register (I3C_EVR), or by the corresponding interrupt if enabled in the I3C interrupt enable register (I3C_IER).

I3C status register (I3C_SR) must be read by the software after the following messages:

- A private read: to get the number of exchanged data bytes, as the controller can have ended the transfer earlier than expected by the target (if XDCNT[15:0] in the I3C_SR register is lower than TGTTDCNT[15:0] in the I3C_TGTTDR register). If so, software must flush the TX-FIFO (write TXFLUSH = 1 in the I3C_CFGR register).
- A DEFTGTS CCC or a DEFR GPA CCC: to get the number of received data bytes in the RX-FIFO

Start a (target-initiated) transfer

When the target goes first from disabled to idle state (software writes EN = 1 in the I3C_CFGR register), concurrently to be able to receive a broadcast CCC from the controller, the software can initiate a hot-join request (the software writes MTYPE[3:0] = 1000 in the I3C_CR register) to be eligible to participate to a next ENTDAA CCC, provided it is allowed to do so (HJEN = 1 in the I3C_DEVR0 register).

Once a dynamic address is assigned (DAUPF = 1 in the I3C_EVR register), more generally and possibly concurrently to a frame transfer emitted by the controller, the software can initiate an IBI (in-band interrupt request) to the controller, or a controller-role request by writing the related control word into the I3C_CR register.

For more information about the execution of target-initiated I3C bus transfer, and its related programming as a target, refer to figures in Section 49.9:

- Figure 664: IBI transfer, as controller/target
- Figure 665: Hot-join request transfer, as controller/target
- Figure 666: Controller-role request transfer, as controller/target
Updating the configuration of the I3C peripheral, as target

Back in idle state, the software can update the configuration of the I3C target before a next transfer:

- Modify the interrupt/polling mode policy via I3C interrupt enable register (I3C_IER)
- Modify following fields of the I3C configuration register (I3C_CFGFR):
  - TXTHRES, RXTHRES
  - TXDMAEN, RXDMAEN
- Modify/prepare the I3C IBI payload data register (I3C_IBIDR), if any payload (if BCR2 = 1 in the I3C_BCR register), before initiating an IBI transfer (write I3C message control register [alternate] (I3C_CR) with MTYPE[3:0] = 1010)
- Modify/prepare I3C target transmit configuration register (I3C_TGTTDR), to disable or enable the TX-FIFO to be preloaded with a defined number of data bytes to be transmitted, before receiving a private read or a direct CCC read (out of the GETSTATUS CCC) from the controller

The registers usage vs. the I3C peripheral role as target is summarized in Section 49.8.1.

The static/dynamic registers fields usage, when acting as target, is summarized in Table 523.

49.8 I3C registers and programming

49.8.1 I3C register set, as controller/target

Table 521 lists the registers and their usage versus the I3C peripheral role.

</table>

1. Bit EN in the I3C_CFRG register is written and set in disabled state (when the same bit is 0). This field can be also written and de-asserted in idle state.

2. These fields are typically written and initialized in disabled state during bus configuration. They are not write-protected when EN = 0, and can be also written and updated in other state(s).
### 49.8.3 I3C registers and fields usage vs. peripheral state, as target

When the peripheral acts as target, Table 523 lists the registers and their usage versus the I3C target state (disabled, idle, and active).

49.9.8  I3C broadcast DEFGPRA CCC transfer, as target

Figure 660 illustrates I3C broadcast DEFGPRA CCC, as communicated on the I3C bus, and as programmed when acting as target.

Figure 660. I3C broadcast DEFGPRA CCC, as target

49.9.9  I3C direct GETSTATUS CCC response, as target

When the I3C acts as target, the hardware returns two data bytes on reception of GETSTATUS CCC, with format 1 (without defining byte or with defining byte TGTSTAT = 0x00), or format 2 (with defining byte PRECR = 0x91).

The returned 2-byte STATUS[15:0] with format 1 on the I3C bus is then as follows:

- STATUS[15:14] = 00 (unused)
- STATUS[13] = 1 if a missed start was detected since the former GETSTATUS CCC, else 0
- STATUS[12] = 1 if an overrun/underrun error was detected since the former GETSTATUS CCC, else 0
- STATUS[11] = 1 if an SCL stable for more than 125 µs was detected during an SDR read since the former GETSTATUS CCC, else 0
- STATUS[10:8] = 000 to 110: encoded value x = 0 to 6, corresponding to a target error TEx if a protocol error was detected since the former GETSTATUS CCC (if STATUS[5] = 1), else 000
- STATUS[7:6] = 00 (ready to prepare for hand-off procedure)
- STATUS[5] = 1 if a protocol error was detected since the former GETSTATUS CCC, else 0
- STATUS[4] = 0 (reserved)
- STATUS[3:1] = 000 (unused)
• STATUS[0] = 1 if there is a pending interrupt (if an IBI is configured in the I3C_CR register, and IBIEN = 1 and DAVAL = 1 in the I3C_DEVRO0.register, and the IBI is not yet acknowledged by the controller neither disabled via DISEC), else 0

The returned 2-byte STATUS[15:0] with format 2 on the I3C bus is then as follows:

• STATUS[15:8] = 0000 0000 (unused)
• STATUS[7:2] = 0000 (unused)
• STATUS[1] = 1 if a received DEFTGTS or a received DEFRGPA CCC is still under software processing, and the related event is not yet cleared by software (DEFF = 1 or GRPF = 1 in the I3C_EVR register); the controller must wait before issuing a GETACCR CCC (else it is not acknowledged)
• STATUS[0] = 1 if a DEFTGTS or DEFRGPA CCC may have been missed. This bit is asserted if a missed start is detected (WKPF = 1 in the I3C_EVR register), de-asserted if DEFF = 1 or GRPF = 1 in the I3C_EVR register.

Completion of a GETSTATUS CCC of format 1 is reported by STAF = 1 in the I3C_EVR register, and the corresponding interrupt if enabled (if STAIE = 1 in the I3C_IER register).

Completion of a GETSTATUS CCC of format 2 is reported by GETF = 1 in the I3C_EVR register, and the corresponding interrupt if enabled (if GETIE = 1 in the I3C_IER register).
49.9.10 I3C private read/write transfer, as controller

Figure 661 illustrates private read/write transfer, as communicated on the I3C bus, and as programmed when acting as controller.

Figure 661. I3C private read/write messages, as controller

49.9.11 I3C private read/write transfer, as target

Figure 662 illustrates I3C private read/write transfer, as communicated on the I3C bus, and as programmed when acting as target.
**Figure 662. I3C private read/write messages, as target**

**I3C private write** (when IP is acting as target)

- **S**: Start
- **Sr**: Start of previous private or I2C transfer
- **ACK**: Acknowledge
- **T**: Transition bit

1. Controller (& target) drive(s) SDA low/high Z in open-drain (arbitrable header)
2. Controller drives SDA in open-drain
3. Controller drives SDA in push-pull
4. Target drives SDA in push-pull
5. Previous private or I2C transfer

---

**Legend**

- **Controller (A & target) drive(s) SDA low/high Z in open-drain (arbitrable header):**
- **Controller drives SDA in open-drain:**
- **Controller drives SDA in push-pull:**
- **Target drives SDA in push-pull:**
- **Transition bit (parity bit for write data) from controller (drives SDA in push-pull):**
- **Transition bit (end of data for read data) from controller and/or target (drive SDA low/high Z in open-drain):**
- **Acknowledgments from the addressed target(s) (drive(s) SDA low in open-drai) with hand-off (switch back SDA control to controller):**
- **Acknowledgments from the addressed target(s) (drive(s) SDA low in open-drain) without hand-off (continue driving SDA):**

*(T): Target is not able to acknowledge an addressed private read/write if it is emitted without arbitrable header (i.e., after a start) and if it occurs at the same SCL clock cycle as an IBI request from this target. In order to avoid such an address-based arbitration collision, the controller should emit a private read/write with arbitrable header when the IBI request is enabled.
49.9.12 Legacy I²C read/write transfer, as controller

Figure 663 illustrates legacy I²C read/write transfer, as communicated on the I3C bus, and as programmed when acting as controller.

Figure 663. Legacy I²C read/write messages, as controller
49.9.13 **I3C IBI transfer, as controller/target**

*Figure 664 illustrates IBI (in-band interrupt) transfer, as communicated on the I3C bus, and as programmed when acting as target or received as controller.***

![Diagram of I3C IBI transfer, as controller/target](image-url)

### Legend

- **Controller drives SDA in push-pull**
- Target drives SDA in push-pull
- Target drives SDA in open-drain
- Target drives SDA in open-drain (start condition)
- Target drives SDA in open-drain (target initiates a start)
- Controller provides SCL clocking
- Controller drives SCL in push-pull
- Controller drives SCL in open-drain
- Controller drives SCL in push-pull (start condition)
- Controller drives SCL in open-drain (start condition)
- Controller drives SCL in push-pull (start condition)
- Controller drives SCL in open-drain (start condition)

(*) Target is not able to acknowledge an addressed private read/write if it is emitted without arbitrable header (i.e. after a start), and if it occurs at the same SCL clock cycle as an IBI request from this target. To avoid such an addressed arbitration collision, the controller should send a private read/write with arbitrable header when the IBI request is emitted.

(**) Repeated start (Sr) if there is a pending transfer to execute and if I3C_DEVRi.SUSP = 0, else stop (P) in push-pull.
When the peripheral acts as controller, the I3C_IBIDR register is used to receive the IBI data payload. Consequently, the IBI request from the target must not exceed a 4-byte data payload. If there is more information to be exchanged in the context of this in-band interrupt, the controller software must issue a private read.

### 49.9.14 I3C hot-join request transfer, as controller/target

*Figure 665* illustrates hot-join request transfer, as communicated on the I3C bus, and as programmed when acting as target or received as controller.

**Figure 665. Hot-join request transfer, as controller/target**
49.9.15 I3C controller-role request transfer, as controller/target

Figure 666 illustrates controller-role request transfer, as communicated on the I3C bus, and as programmed when acting as target or received as controller.

Figure 666. Controller-role request transfer, as controller/target

```
LEGEND

Controller drives SDA in push-pull
Target drives SDA low/high-Z in open-drain (and controller in open-drain high-Z)
Start request
Target initiates a start by driving SDA low in open-drain while SCL is high and waits for controller to pull SCL low

Controller drives SDA in open-drain (start condition)
CAS
Target provides SCL clocking after tSCL

Target is not able to acknowledge an addressed private read/write if it is emitted without arbitrable header (i.e. after a start) and if it occurs at the same SCL clock cycle as an IBI request from this target. In order to avoid such an address-based arbitration collision, the controller should emit a private read/write with arbitrable header when the IBI request is enabled.

Repeated start (Sr) if there is a pending transfer to execute, else stop (P)

(): Target is not able to acknowledge an addressed private read/write if it is emitted without arbitrable header (i.e. after a start) and if it occurs at the same SCL clock cycle as an IBI request from this target. In order to avoid such an address-based arbitration collision, the controller should emit a private read/write with arbitrable header when the IBI request is enabled.

(): Repeated start (Sr) if there is a pending transfer to execute, else stop (P)
```
49.10  I3C FIFOs management, as controller

49.10.1  C-FIFO management, as controller

When controller, as illustrated in figures of Section 49.9, C-FIFO can be used during any of the following transfers:

- broadcast CCC (*Figure 654, Figure 655, Figure 656*)
- direct read/write CCC (*Figure 656*)
  - command part, first message
  - data part, next message(s)
- private read/write (*Figure 661*)
- legacy I2C read/write (*Figure 663*)
- software-initiated error recovery (SCL forced to be stopped until next header message followed by HDR exit pattern)

*Figure 667* illustrates the management of the C-FIFO for queuing control word(s) on the I3C bus, when the I3C peripheral acts as controller.

---

1. This feature is implementation-dependent and can be unavailable. Refer to *Section 49.3.4.*
First, the software must initialize the C-FIFO management via CDMAEN in the I3C_CFGR register, to be written either:

- directly by the software (if CDMAEN = 0) at the control word level:
  - via polling mode (CFNFIE = 0 in the I3C_IER register): waiting for a next control word is requested by the hardware (CFNFF = 1 in the I3C_IER register) before an explicit write to the I3C_CR register
  - via enabled interrupt notification if CFNFIE = 1
- by the allocated DMA channel (if CDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_tc_dma):
  - as configured at block level, the DMA is automatically pushing-on/writing control word(s) into the I3C_CR register from its memory source buffer, until the frame completion (a stop is emitted on the I3C bus after the last message of the frame), unless a transfer error occurs.

In any case, if C-FIFO is empty and a restart must be emitted with a new control word, a C-FIFO underrun is reported (ERRF = 1 in the I3C_EVR register and COVR = 1 in the I3C_SER register). If enabled by ERRIE = 1 in the I3C_IER register, an interrupt is generated.

The DMA mode for the C-FIFO management can be modified when the I3C peripheral is not in active state.

When controller, if a transfer error occurs (ERRF = 1 in the I3C_EVR register), the C-FIFO is flushed automatically by the hardware.

49.10.2 TX-FIFO management, as controller

When controller, as shown in figures of Section 49.9, TX-FIFO can be used during any of the following transfers:

- broadcast or direct CCC (including ENTDAA and RSTACT), if a defining/sub-command byte or if data byte(s) are present (Figure 654, Figure 655, Figure 656)
- private write (Figure 661)
- legacy I2C write (Figure 663)

Figure 668 illustrates the management of the TX-FIFO for queuing data bytes or word(s) to be transmitted on the I3C bus, when the I3C peripheral acts as controller.
First, the software must initialize the TX-FIFO management via the following fields in the I3C_CFGR register:

- **TXDMAEN**: enable/disable DMA mode for TX-FIFO
- **TXTHRES**: push-on data byte(s) or word(s) into TX-FIFO
- **TMODE**: enable/disable TX-FIFO and C-FIFO preload

Then, depending upon bit TXDMAEN in the I3C_CFGR register, the TX-FIFO is written either:

- directly by the software (if TXDMAEN = 0) at the byte/word level:
  - via polling mode (TXFNFIE = 0 in the I3C_IER register): waiting for a next data byte/word is requested by the hardware (TXFNFF = 1 in the I3C_IER register) before an explicit write to the I3C_TDR or I3C_TDWR register, depending upon bit TXTHRES in the I3C_CFGR register
  - via enabled interrupt notification if TXFNFIE = 1
- by the allocated DMA channel (if TXDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_tx_dma):
  - as configured at DMA block level, the DMA is automatically pushing-on/writing data bytes/words to the I3C_TDR or I3C_TDWR register (depending upon bit TXTHRES in the I3C_CFGR register) from its memory source buffer, until the frame completion (a stop is emitted on the I3C bus after the last message of the frame), unless a transfer error occurs.
An I3C message begins from a start or a repeated start, and ends with a stop or a repeated start. At message level, the last data byte/word to be transmitted is flagged by TXLASTF = 1 in the I3C_EVR register. When an I3C frame is described with multiple messages (separated by a repeated start), this event can be used by the software to update the pointer to the buffer where the byte(s)/word(s) of the next message is/are stored.

When frame completion is reported (FCF = 1 in the I3C_EVR register, and the corresponding interrupt is enabled), the TX-FIFO is empty.

If the TX-FIFO is empty and a data byte must be transmitted on the I3C bus, a TX-FIFO underrun is reported (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register). If enabled by ERRIE = 1 in the I3C_IER register, an interrupt is generated.

The configuration for the TX-FIFO management can be modified when the I3C peripheral is not in active state.

When controller, if a transfer error occurs (ERRF = 1), the TX-FIFO is automatically flushed by the hardware.

**No C-FIFO/TX-FIFO preload**

As defined in Table 516, C-FIFO size is two words, TX-FIFO size is 8 bytes.

When no C-FIFO/TX-FIFO preload is configured (TMODE = 0 in the I3C_CFGR register), the I3C peripheral emits a start on the I3C bus as soon as the first control word is written into the C-FIFO. Then, it decodes the I3C_CR register, and requires a next data byte/word to be written, if needed within this message. As soon as a next control word is detected as required by the hardware to be transmitted on the I3C bus (if a repeated start must be emitted on the I3C bus or if the C-FIFO gets available room), this control word is requested to be written into the C-FIFO until the last message (MEND = 1 in the I3C_CR register).

Similarly, as soon as another data byte/word is detected as required by the hardware to be transmitted on the I3C bus (if a repeated start must be emitted on the I3C bus, and if TX-FIFO is not full, and if data byte(s)/word(s) must be transmitted during this I3C message), this data byte/word must be written in the TX-FIFO.

**C-FIFO and TX-FIFO preload**

When C-FIFO/TX-FIFO preload is configured (TMODE = 1 in the I3C_CFGR register), before emitting a start on the bus, the I3C peripheral waits for loading as much as possible both the C-FIFO and the TX-FIFO, as follows:

- wait for a first control word to be written into the C-FIFO
- wait for data byte(s)/word(s) to be written in the TX-FIFO, if any, as defined by the first control word (if RNW = 0 and DCNT[15:0] = 0 in the I3C_CR register), and up to the TX-FIFO size
- If TX-FIFO is not full and if the first control word is not the last of the frame (MEND = 0 in the I3C_CR register):
  - Wait for a second control word to be written into the C-FIFO, then C-FIFO is full.
  - If TX-FIFO is not full, wait for data byte(s)/word(s) to be written in the TX-FIFO, if any, as defined by the second control word (RNW = 0 and DCNT[15:0] = 0 in the I3C_CR register), and up to the TX-FIFO size.

Then, as soon as a next control word is detected as required by the hardware to be transmitted on the I3C bus (if a repeated start must be emitted on the I3C bus), this control...
word is requested to be written into the C-FIFO until the last message (MEND = 1 in the I3C_CR register).

Similarly, as soon as a next data byte/word is detected as required by the hardware to be transmitted on the I3C bus (if a repeated start must be emitted on the I3C bus and if TX-FIFO is not full and if data byte(s)/word(s) are to be transmitted during this I3C message), this data byte/word must be written in the TX-FIFO.

49.10.3 RX-FIFO management, as controller

When controller, as shown in figures of Section 49.9, RX-FIFO is used during any of the following transfers:

- broadcast ENTDAA CCC (Figure 655)
- direct CCC read (Figure 654), including direct RSTACT CCC read (Figure 656)
- private read (Figure 661)
- legacy I2C read (Figure 663)

Figure 669 illustrates the management of the RX-FIFO for queuing and popping-out data bytes or word(s) as received from the I3C bus, when the I3C peripheral acts as controller.

Figure 669. RX-FIFO management, as controller
First, the software must initialize the RX-FIFO management via the following fields of the I3C_CFGR register:

- **RXDMAEN**: enable/disable DMA mode for RX-FIFO
- **RXTHRES**: pop-out data byte(s) or word(s) from RX-FIFO

Then, depending on RXDMAEN, the RX-FIFO is read either:

- directly by the software (RXDMAEN = 0) at the byte/word level:
  - via polling mode (RXFNEIE = 0 in the I3C_IER register): waiting for a next data byte/word is requested by the hardware (RXFNEF = 1 in the I3C_IER register) before an explicit read to the I3C_RDR or I3C_RDWR register, depending upon bit RXTHRES in the I3C_CFG register
  - via enabled interrupt notification if RXFNEIE = 1 in the I3C_IER register
- by the allocated DMA channel (if RXDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_rx_dma):
  - as configured at DMA block level, the DMA automatically pops-out/reads data bytes/words from the I3C_RDR or I3C_RDWR register (depending upon bit RXTHRES), and writes them into its memory destination buffer, until the frame completion (a stop is emitted on the I3C bus after the last message of the frame), unless a transfer error occurs.

An I3C message begins from a start or a repeated start, and ends with a stop or a repeated start. At message level, the last received data byte/word from the I3C bus is flagged by IRXLASTF = 1 in the I3C_EV register. When an I3C frame is described with multiple messages (separated by a repeated start), this event can be used by the software for updating the pointer to the buffer where is/are stored the data byte(s)/word(s) of the next message.

If RX-FIFO is full and a data byte is received on the I3C bus, an RX-FIFO overrun is reported (ERRF = 1 in the I3C_EV register and DOVR = 1 in the I3C_SER register). If enabled by ERRIE = 1 in the I3C_IER register, an interrupt is generated.

The configuration for the RX-FIFO management can be modified when the I3C peripheral is not in active state.

**Early read termination from the target**

A private read message can be early completed (also known as prematurely ended) by the addressed target.

- **If RXDMAEN = 1:**
  - the software must allocate, for the DMA request i3c_rx_dma, a DMA channel x, capable of peripheral early termination (refer to DMA implementation section).
  - The software must configure the DMA channel x to enable the DMA peripheral-flow control mode via PFREQ = 1 in the DMA_CxTR2 register, to be able to perform a(n) (early or not) DMA block completion.
  - Then, on block completion, the software can read BR1.BNDT[15:0] in DMA_Cx and/or DMA_CxSAR register(s), to get the effective number of DMA transferred bytes.
- **If RXDMAEN = 0:**
  - at message level, the last received data byte/word from the I3C bus is flagged by RXFNEF = 1 and RXLASTF = 1 in the I3C_EV register.
In any case, if the S-FIFO is disabled (if SMODE = 0 in the I3C_CFGR register), the software is notified that an early read termination occurs by RXTGTENDF = 1 in the I3C_EVR register, and the corresponding interrupt if enabled. Then, software can read the status register I3C_SR to check information related to the last message, and get the number of received data bytes on the prematurely ended read transfer (XDCNT[15:0] in the I3C_SR register).

In any case, if the S-FIFO is enabled (SMODE = 1 in the I3C_CFGR register), the software or the DMA (depending upon SDMAEN in the I3C_CFGR register) must read for each message the status register I3C_SR. The number of effective received data bytes on the prematurely ended read message is reported by XDCNT[15:0] (and then ABT = 1) in the I3C_SR register.

For more information, refer to I3C status register (I3C_SR) and Section 49.10.4.

49.10.4 S-FIFO management, as controller

When controller, S-FIFO can be used by the software to be able to read the I3C status register (I3C_SR) for each transferred message.

Reading status register with disabled S-FIFO

If SMODE = 0 in the I3C_CFGR register, the S-FIFO is disabled and the status register can be read as a usual register:

• the register content is overwritten by hardware when is transforee a new message
• I3C_SR contains the status of the last transferred message
• SCL clock is not stalled if status register is not read.

If SMODE = 0, for the specific case of a private read prematurely ended by the target:

• the software is notified by the flag RXTGTENDF = 1 in the I3C_EVR register and the corresponding interrupt if enabled.
• Then, until that the software has cleared the event flag write and set CRXTGTENDF = 1 in the I3C_CEVR register:
  – no more data byte can be received on the I3C bus and written by the hardware into I3C_RDR/I3C_RDWR registers
  – I3C_SR cannot be updated
  – SCL clock is stalled if needed

Typically, I3C_SR can be read when FCF = 1, or ERRF = 1, or RXTGTENDF = 1 in the I3C_EVR register. XDCNT[15:0] in the I3C_SR register can be read to get the effective number of received data bytes on a private read, after an early termination from the target (refer to Section 49.10.3).

Reading status register with enabled S-FIFO

If SMODE = 1 in the I3C_CFGR register, the S-FIFO is enabled. Figure 670 illustrates the management of the S-FIFO for queuing and popping-out a status word for each executed message on the I3C bus, when the I3C peripheral acts as controller.
First, the software must initialize the S-FIFO management via the SDMAEN field (enable/disable DMA mode for S-FIFO) in the I3C_CFGR register. Then, depending on SDMAEN, the S-FIFO is read either:

- directly by the software (if SDMAEN = 0):
  - via polling mode (SFNEIE = 0 in the I3C_IER register): waiting for a next status word is requested by the hardware (SFNEF = 1 in the I3C_IER register) before an explicit read to the I3C_SR register
  - via enabled interrupt notification (SFNEIE = 1)
- by the allocated DMA channel (if SDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_rs_dma):
  - as configured at DMA block level, the DMA is automatically popping-out/reading status words from the I3C_SR register and writing them into its memory destination buffer, until the frame completion (a stop is emitted on the I3C bus after the last message of the frame), unless a transfer error occurs.

Each message status must be read, else an overrun error is asserted by the hardware (ERRF = 1 in the I3C_EVR register and COVR = 1 in the I3C_SER register) when the S-FIFO is full and a next message status must be written. The corresponding interrupt is raised if enabled by ERRIE = 1 in the I3C_IER register.

The frame completion (FCF = 1 in the I3C_EVR register) is reported only when the S-FIFO is empty.
The configuration for the S-FIFO management can be modified when the I3C peripheral is not in active state.

49.11 I3C FIFOs management, as target

49.11.1 RX-FIFO management, as target

When target, as shown in figures of Section 49.9, the RX-FIFO is used during any of the following received and acknowledged transfers:
- broadcast DEFTGTS CCC (Figure 659)
- broadcast DEFGRPA CCC (Figure 660)
- private write (Figure 662)

Figure 671 illustrates the management of the RX-FIFO for queuing and popping-out data bytes or word(s) as received from the I3C bus, when the I3C peripheral acts as target.
First, the software must initialize the RX-FIFO management via the following I3C_CFRG register fields:

- RXDMAEN: enable/disable DMA mode for RX-FIFO
- RXTHRES: pop-out data byte(s) or word(s) from RX-FIFO

Then, depending on RXDMAEN, the RX-FIFO is read either:

- directly by the software (if RXDMAEN = 0) at the byte/word level:
  - via polling mode (RXFNEIE = 0 in the I3C_IER register): waiting for a next data byte/word is requested by the hardware (RXFNEF = 1 in the I3C_IER register) before an explicit read to the I3C_RDR or I3C_RDWR registers, depending upon RXTHRES in the I3C_CGFR register
  - via enabled interrupt notification if RXFNEIE = 1
- by the allocated DMA channel (if RXDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_rx_dma):
  - as configured at DMA block level, the DMA is automatically popping-out/reading data bytes/words from the I3C_RDR or I3C_RDWR register (depending upon RXTHRES) and writing them into its memory destination buffer, until the transfer completion (in the I3C_EVR register, FCF = 1 in case of private write, or GRPF = 1 in case of a DEFFRPA CCC, or DEFF = 1 in case of DEFTGTS CCC), unless a transfer error occurs.

If RX-FIFO is full and a new data byte is received on the I3C bus, a RX-FIFO overrun is reported (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register) and the corresponding interrupt if enabled.

When the transfer is completed (in the I3C_EVR register, FCF = 1, or GRPF = 1, or DEFF = 1):

- RX-FIFO is empty
- Until software has not processed the RX data buffer corresponding to the completed private write / DEFTGTS / DEFFRPA transfer (meaning until software has not cleared the corresponding flag write and set CFCF / CDEFF / CGRPF to 1 in the I3C_CEVR register), if a next private write / DEFTGTS CCC / DEFFRPA CCC is received and a data byte must be written by the hardware into the RX-FIFO, a transfer error is reported with a RX-FIFO overrun (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register) and the corresponding interrupt if enabled.

The configuration for the RX-FIFO management can be modified when the I3C peripheral is not in active state.

### 49.11.2 TX-FIFO management, as target

#### Main scheme

When target, as shown in figures of Section 49.9, the TX-FIFO is used only during a private read (Figure 662).

Figure 672 illustrates the management of the TX-FIFO for queuing and pushing-on data bytes or word(s) to be transmitted on the I3C bus, when the I3C peripheral acts as target.
First, the software must initialize the TX-FIFO management and write I3C_CFGR with

- TXDMAEN: enable/disable DMA mode for TX-FIFO
- TXTHRES: push-on data byte(s) or word(s) to TX-FIFO

Then, before receiving a private read on the I3C bus, the software must configure the I3C target transmit configuration register (I3C_TGTTDR) to preload the TX-FIFO with a number of data bytes (write TGTTDCNT[15:0] and PRELOAD = 1 in a single access), so that data bytes from the target are ready to be transmitted on the I3C bus:

- If PRELOAD = 1 and TGTTDCNT[15:0] > TX-FIFO size, TX-FIFO is first preloaded up to the FIFO size.
- If PRELOAD = 1 and TGTTDCNT[15:0] ≤ TX-FIFO size, TX-FIFO is preloaded up to TGTTDCNT[15:0].

Note: TX-FIFO size is 8 bytes (refer to Table 516).
Depending upon TXDMAEN, the TX-FIFO is preloaded either:

- directly by the software (TXDMAEN = 0) at the byte/word level:
  - via polling mode (TXFNFIE = 0 in the I3C_IER register): waiting for a next data byte/word is requested by the hardware (TXFNFF = 1 in the I3C_IER register) before an explicit write to the I3C_TDR or I3C_TDWR register, depending upon TXTHRES in the I3C_CFGFR register
  - via enabled interrupt notification if TXFNFIE = 1

- by the allocated DMA channel (TXDMAEN = 1) to the corresponding DMA request from the I3C peripheral (i3c_tx_dma):
  - as configured at DMA block level, the DMA is automatically pushing-onwriting data bytes/words to the I3C_TDR or I3C_TDWR register (depending upon TXTHRES) from its memory source buffer, until the transfer completion (FCF = 1 in the IEC_EVR register), unless a transfer error occurs.

Then, in the same way, either directly by the software or by the allocated DMA channel, if there are remaining TGTTDCNT[15:0] in the I3C_TGTTDR register to be loaded into TX-FIFO for continuing the private read (set PRELOAD = 1 and TGTTDCNT[15:0] > TX-FIFO size), and provided that the private read is not yet completed by the controller:

- If TXTHRES = 0: when a byte is transmitted on the I3C bus, a next byte is preloaded into TX-FIFO
- If TXTHRES = 1: when four bytes are transmitted on the I3C bus, the next word is preloaded into TX-FIFO.

The private read transfer is completed (FCF = 1 in the I3C_EVR register) when either the target or the controller first terminates the data byte transfer.

On transfer completion, the software can:

- read XDCNT[15:0] in the I3C_SR register: the effective number of transmitted data bytes
- read TGTTDCNT[15:0] in the I3C_TGTTDR register: the remaining number of bytes to be loaded and transmitted on the I3C bus
- flush TX-FIFO: write and set (or not) TXFLUSH = 1 in the I3C_CFGFR register, continue (or not) for another private read, depending upon the user application

If TX-FIFO is empty and a data byte must be transmitted on the I3C bus, a TX-FIFO underrun is reported (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register). If enabled by ERRIE = 1 in the I3C_EVR register, an interrupt is generated.

The configuration for the TX-FIFO management can be modified when the I3C peripheral is not in active state.

**Alternative without I3C_TGTTDR, if less bytes than the TX-FIFO size**

Alternatively to the use of the I3C_TGTTDR register, as shown in the Figure 673, when the DMA is not used (TDMAEN = 0), provided that the number of data bytes to be read on the I3C bus is less that the TX-FIFO size, the software can directly prepare and fill the TX-FIFO with the number of bytes to be read directly by the software, by successive writes to the I3C_TDR or I3C_I3C_TDWR, depending upon TXTHRES.
49.12 I3C error management

49.12.1 Controller error management

Table 525 enumerates the I3C bus error conditions, and, for each of them, the corresponding detection, action and reporting when the I3C peripheral acts as controller.

49.13  I3C wake-up from low-power mode(s)

49.13.1  Wake-up from Stop

The user must first configure the reset and clock controller (RCC) to set up the clock data path down to the I3C peripheral: to select the source oscillator for the I3C kernel clock, the source oscillator for the I3C APB clock, and to set the clocks frequency. At initialization via the RCC, the user must enable the I3C clocks for a given I3C peripheral to be functional, separately for Run/Sleep mode and for Stop mode. For more details about RCC programming, refer to Section 11: Reset and clock control (RCC).

The I3C hardware automatically manages its own clocks gating and generates a separated clock request output signal to the RCC for its kernel clock and its APB clock, whenever the device is in Run, Sleep or Stop mode.
When entering a Stop mode, the \( V_{\text{CORE}} \) domain is supplied, by default any clock oscillator is disabled, and in any case, neither the system clock nor a peripheral clock is running in the domain.

**As controller: wake-up on an IBI without MDB, a hot-join request or a controller-role request**

When the peripheral acts as controller, before the product enters a low-power mode, the software must issue an ENTAS\(x \) CCC, generally with \( x = 0, 1, 2 \) or \( 3 \), to inform targets that the I3C controller is not expected to exit from idle state neither to communicate on the I3C bus before an interval of, respectively, \( 1 \ \mu s \), \( 100 \ \mu s \), \( 2 \) ms or \( 50 \) ms, has elapsed. This delay defines the \( T_{\text{CAS}} \) delay for the controller to set the SCL bus clock low and running, after a start condition. More specifically for a Stop mode, the CCC must be restricted to an ENTAS\(x \) with the value \( x=1, 2, \) or \( 3 \).

The general scheme for the I3C wake-up from Stop is the following:

1. First the I3C peripheral requests its kernel clock to the system:
   - On a detected start condition on the I3C bus (SDA line is detected to be driven low while SCL is high).
   - As controller, as initiated by an external I3C target device for a hot-join/in-band interrupt/controller-role request. Once the kernel clock is provided and running, the I3C hardware uses an internal timer to wait for the corresponding \( T_{\text{CAS}} \) time to elapse, then drives low SCL and continues toggling SCL to let the target perform its hot-join/in-band interrupt/controller-role request on the I3C bus.

2. The system enables the source oscillator of the I3C kernel clock, and the clock gets ready (after few microseconds from HSI). The user may keep the source oscillator ON in Stop mode to reduce this startup latency, at the expense of power consumption.
   - The I3C peripheral maintains the kernel clock request until the generation of the Stop condition on the I3C bus.

3. After that the kernel clock is running, as controller the I3C peripheral requests its APB clock to the system:
   - On the ACKed address of a received IBI request (Figure 664), and it maintains the APB clock request until that IBIF is cleared.
     
     If the IBI is without MDB: a Stop is normally generated on the I3C bus, even if the APB clock is not yet provided.
   - On the ACKed address of a received controller-role request (Figure 665), and it maintains the APB clock request until that CRF is cleared.
   - On the ACKed address of a hot-join request (Figure 666), and it maintains the APB clock request until that HJF is cleared.

4. The system is notified of the I3C APB clock request, and the power management unit of the PWR module is awaken.

5. An additional delay may be needed for the regulator, if it must increase the voltage for Run mode.

6. The system enables the system clock that drives the APB clock. There is an additional delay if the selected oscillator source for the system and APB clocks is not the same as the one driving the I3C kernel clock. If so, the system enables the source oscillator of the system clock, which gets ready after a delay.

7. With the APB clock running, the peripheral can log the I3C transfer in its status and data registers. When the bus transfer is completed, the peripheral generates the corresponding flag (IBIF/CRF/HJF), and the enabled interrupt can wake up the CPU.

**As target: wake-up on a reset pattern**
The target reset pattern is a specific scheme for a controller to wake up and possibly reset a target from a low power mode. It consists both in the RSTACT CCC and in the in-band reset pattern generation.

As target, the sequence for the I3C wake-up from Stop on a reset pattern is the following:
1. When the peripheral detects a reset pattern on the bus (14 SDA transitions while SCL is kept low), it requests its APB clock to the system to set the RSTF flag of the I3C_EVR register.
2. The system is notified of the I3C APB clock request, and the power management unit of the PWR module is awaken (after few microseconds).
3. An additional delay may be needed for the regulator, if it must increase the voltage for Run mode.
4. The system enables the source oscillator of the system clock, which gets ready after few microseconds.
5. With the APB clock running, the I3C peripheral can raise the RSTF flag of the I3C_EVR register, and the enabled interrupt can wake up the CPU.

As target: wake-up on a missed start
1. The peripheral requests its kernel clock to the system:
   - On a detected start condition on the I3C bus (SDA line is detected to be driven low while SCL is high)
   - As target, as initiated by an external I3C device, whatever controller or target.
   - If the kernel clock is not provided before that SCL is driven low by the external controller, then the I3C target detects that a I3C bus start is missed and waits for the kernel clock to be provided. It can be noted that an I3C controller message intended to be addressed to it may have been missed (and NACKed). Or may have been missed any I3C CCC or private message from the controller to another addressed target or an IBI/CR/HJF start request from another target.
2. The system enables the source oscillator of the I3C kernel clock, and the clock gets ready (after few microseconds if HSI). The user may keep the source oscillator ON in Stop mode to reduce this startup latency, at the expense of power consumption. Especially if the controller is in an Activity State of x = 0 (with a 1 µs T_{CAS} latency).
3. After that the kernel clock is running, as target, the I3C peripheral requests its APB clock to the system to raise the WKPF flag conditioned by non-user text or:
4. The system is notified of the I3C APB clock request, and the power management unit of the PWR module is awaken (after few microseconds).
5. An additional delay may be needed for the regulator, if it must increase the voltage for Run mode.
6. The system enables the system clock, which drives the APB clock. There is an additional delay if the selected oscillator source for the system and APB clocks is not the same as the one driving the I3C kernel clock. If so, the system enables the source oscillator of the system clock, which gets ready after few microseconds.
7. With the APB clock running:
   - The missed start flag (WKPF of the I3C_EVR register) is raised conditioned by non-user text: if it occurred, and the enabled interrupt can wake up the CPU. It is then known that an I3C bus transaction was missed, but not whether the target was addressed or not. The software should use a timeout in order to return to Stop mode, if it is not addressed by the controller again within this interval.
## 49.14 I3C in low-power modes

<table>

49.16 **I3C registers**

The I3C registers must be accessed with a 32-bit word aligned address.

**Note:** I3C_RDR and I3C_TDR registers must be accessed with a single significant LSB data byte for, respectively, reading RX-FIFO and writing TX-FIFO.

### 49.16.1 I3C message control register (I3C_CR)

Address offset: 0x000

Reset value: 0x0000 0000

This register must be used to control the message to emit on the I3C bus:

- when I3C acts as controller (bit[30] = MTYPE[3] = 0): if there is no CCC code to be emitted bits[29:27] = MTYPE[2:0] differ from 110; else the alternate register description Section 49.16.2 must be considered.

When I3C acts as controller:

- If the control FIFO (C-FIFO) is not full (CFNFF = 1 in the I3C_EVR register), writing into this register means pushing a new control word into the C-FIFO; either by software, or automatically by DMA, as defined by CDMAEN in the I3C_CFGR register.
- If C-FIFO is empty and a restart must be emitted with a new control word, the I3C hardware asserts the control FIFO error underrun flag (COVR = 1 in the I3C_SER register). If enabled by ERRIE = 1 in the I3C_IER register, an interrupt is generated.
- After the last message of the frame is completed (a message with MEND = 1 in the I3C_CR register), the I3C hardware asserts the frame completed flag (FCF = 1 in the I3C_EVR register) and the corresponding interrupt, if enabled.

When I3C acts as target, this register is used in register mode:

- Software writes into this register to initiate a command (IBI, controller-role or hot-join request) on the I3C bus.
- C-FIFO is disabled, and there is no DMA mode neither for control words.

Bit 31 **MEND:** Message end type/last message of a frame (when the I3C acts as controller)

- 0: this message from controller is followed by a repeated start (Sr), before another message must be emitted
- 1: this message from controller ends with a stop (P), being the last message of a frame
Bits 30:27 MTYPE[3:0]: Message type (whatever I3C acts as controller/target)

Condition: when I3C acts as I3C controller

0000: SCL clock is forced to stop until a next control word is executed

   Bits [26:0] are ignored. On a CE1 error detection (ERRF = 1 in the I3C_EVR register and CODERR[3:0] = 0001 in the I3C_SER register) where a start/restart/stop is prevented from being generated, the software must use this message type for SCL "stuck at" recovery. Refer to Table 525.

0001: header message

   Bits [26:0] are ignored. If the addressed target is not responding with an ACK to a private/direct message, as an escalation stage after a failed GETSTATUS tentative, the software must program this with EXITPTRN = 1 in the I3C_CFGR register, so that an HDR exit pattern is emitted on the bus, whatever the header is ACK-ed or NACK-ed (to avoid the target to consider that the I3C bus is in HDR mode). Refer to Table 525 and MIPI specification about escalation handling.

0010: private message (refer to Figure 661)

   Bits [23:17] (ADD[6:0]) are the emitted 7-bit dynamic address.
   Bit[16] (RNW) is the emitted RnW bit.
   Bits [15:0] (DCNT[15:0]) are the number of programmed data bytes.
   The transferred private message is:
   - \( \{S + 0b111_1110 + RnW = 0 + Sr/Sr*\} + 7\text{-bit DynAddr} + RnW + (8\text{-bit Data} + T)^* + Sr/P. \)
   - After an S (start), depending upon bit NOARBH in the I3C_CFGR register, the arbitrable header \( (0b111_1110 + RnW = 0) \) is inserted or not.
   - \( Sr* \) : after an Sr (repeated start), the hardware automatically inserts \( (0b111_1110 + RnW = 0) \) if needed, if it follows a previous message without ending by a P (stop).

0011: direct message (second part of an I3C SDR direct CCC command) (refer to Figure 654)

   Bits [23:17] (ADD[6:0]) are the emitted 7-bit dynamic address.
   Bit[16] (RNW) is the emitted RnW bit.
   Bits [15:0] (DCNT[15:0]) are the number of programmed data bytes.
   The transferred direct message is: \( Sr + 7\text{-bit DynAddr} + RnW + (8\text{-bit Data} + T)^* + Sr/P \)

0100: legacy I2C message (refer to Figure 663)

   Bits [23:17] (ADD[6:0]) are the emitted 7-bit static address.
   Bit[16] (RNW) is the emitted RnW bit.
   Bits [15:0] (DCNT[15:0]) are the number of programmed data bytes.
   The transferred legacy I2C message is:
   - \( \{S + 0b111_1110 + RnW = 0 + Sr/Sr*\} + 7\text{-bit StaAddr} + RnW + (8\text{-bit data} + T)^* + Sr/P. \)
   - After an S, depending on NOARBH, the arbitrable header \( (0b111_1110 + RnW = 0) \) is inserted or not.
   - \( Sr* \) : after an Sr (repeated start), the hardware automatically inserts \( (0b111_1110 + RnW = 0) \) if needed (if it follows a previous message without ending by a P (stop)).

Others: reserved

Condition: when I3C acts as I3C target

1000: hot-join request (W) (refer to Figure 665)

   The transferred hot-join request is \( \{S + 0b000_0010 \text{ addr} + RnW = 0 \) .
   Writing the control word initiates the hot-join request if target is allowed to do so (HJEN = 1 in the I3C_DEVR0 register), either actively after a bus idle condition via the hardware issuing a start request (SDA low) and waiting for the controller to activate SCL clock, or passively if the controller initiates a concurrent message.

1001: controller-role request (W) (refer to Figure 666)

   The transferred controller-role request is \( \{S + DA[6:0] + RnW = 0 \) (DA in the I3C_DEVR0 register).
   Writing the control word initiates the controller-role request if target is allowed to do so (CREN = 1 and DAVAL = 1 in the I3C_DEVR0 register), either actively after a bus idle condition via the hardware issuing a start request (SDA low) and waiting for the controller to activate SCL clock, or passively if the controller initiates a concurrent message.

1010: IBI (in-band interrupt) request (R) (refer to Figure 664)

   Bits [15:0] (DCNT[15:0]) are the number of the IBI data payload (including the first MDB), if any.
   The transferred IBI request is \( \{S + DA[6:0] + RnW = 1 \) + optional IBI data payload.
   Writing the control word initiates the IBI request if target is allowed to do so (IBIEN = 1 and DAVAL = 1 in the I3C_DEVR0 register), either actively after a bus idle condition via the hardware issuing a start request (SDA low) and waiting for the controller to activate SCL clock, or passively if the controller initiates a concurrent message.
   When acknowledged from controller, the transmitted IBI payload data (optional, depending upon BCR2 in the I3C_BCR register) is defined by DCNT[15:0] in the I3C_CR register and I3C_IBIDR, and must be consistently programmed vs. the IBI payload data size defined by IBIP[2:0] in the I3C_IBIDR register.

Others: reserved

Bits 26:24 Reserved, must be kept at reset value.
49.16.2 I3C message control register [alternate] (I3C_CR)

Address offset: 0x000
Reset value: 0x0000 0000

This write register description must be used to control the message for when the controller has to emit a CCC (whatever is the type of the CCC: for a CCC broadcast, a CCC direct, or a CCC Enter HDR).

This is the alternate description of register I3C_CR, for when MTYPE[3:0] = 0110. Else refer to Section 49.16.1.

If the control FIFO (also known as C-FIFO) is not full (CFNFF = 1 in the I3C_EVR register), writing into this register means pushing a new control word into the C-FIFO; either by the software or automatically by DMA, as defined by the CDMAEN bit in the I3C_CFGR register.

When the last message of the frame is completed (a message with MEND = 1 in the I3C_CR register), the I3C hardware asserts the frame completed flag (FCF = 1 in the I3C_EVR register) and the corresponding interrupt, if enabled.
Bit 31 **MEND**: Message end type/last message of a frame (when I3C acts as controller)

- 0: this message from controller is followed by a repeated start (Sr), before another message must be emitted
- 1: the message from the controller ends with a stop (P), being the last message of a frame

Bits 30:27 **MTYPE[3:0]**: Message type (when I3C acts as controller)

**Condition: when I3C acts as I3C controller**

- **0110**: broadcast/direct CCC command (refer to Table 524, Figure 654, Figure 655, Figure 656)
  - Bits[23:16] (CCC[7:0]) are the emitted 8-bit CCC code
  - Bits[15:0] (DCNT[15:0]) are the number of the CCC defining bytes, or CCC sub-command bytes, or CCC data bytes.
  - If Bit[23] = CCC[7] = 1: this is the first part of an I3C SDR direct CCC command
  - The transferred direct CCC command (first part) message is:
    - {S / S + 0b111_1110 + RnW = 0 / Sr+*} + (direct CCC + T) + (8-bit Data + T)* + Sr
    - After an S (start), depending upon NOARBH in the I3C_CFGR register, the arbitrable header (0b111_1110 + RnW = 0) is inserted or not.
    - Sr+*: after an Sr (repeated start), the hardware automatically inserts (0b111_1110 + R/W).
  - If Bit[23] = CCC[7] = 0: this is an I3C SDR broadcast CCC command (including ENTDAA).
  - The transferred broadcast CCC command message is:
    - {S / S + 0b111_1110 + RnW = 0 / Sr+*} + (broadcast CCC + T) + (8-bit Data + T)* + Sr/P
    - After an S (start), depending on NOARBH, the arbitrable header (0b111_1110 + RnW = 0) is inserted or not.
    - Sr+*: after an Sr (repeated start), the hardware automatically inserts (0b111_1110 + R/W).

**Others**: reserved

Bits 26:24 Reserved, must be kept at reset value.

Bits 23:16 **CCC[7:0]**: 8-bit CCC code (when I3C acts as controller)

- If bit[23] = CCC[7] = 1, this is the first part of an I3C SDR direct CCC command.
- If bit[23] = CCC[7] = 0, this is an I3C SDR broadcast CCC command (including ENTDAA).

Bits 15:0 **DCNT[15:0]**: Count of related data to the CCC command to transfer as CCC defining bytes, or CCC sub-command bytes, or CCC data bytes, in bytes

- Linear encoding up to 64 Kbytes - 1.
- 0x0000: no data to transfer.
- Note: Value mandatory when emitting ENTDAA broadcast CCC (refer to Figure 655).
- 0x0001: 1 byte
- Note: Value mandatory when emitting RSTACT direct/broadcast CCC (refer to Figure 656).
- 0x0002: 2 bytes
- ...
- 0xFFFF: 64 Kbytes - 1 byte
49.16.3 I3C configuration register (I3C_CFGR)

Address offset: 0x004
Reset value: 0x0000 0000

This register is used to configure:
- features that apply when the I3C acts as controller or target: RX-FIFO and TX-FIFO management (RXDMAEN, RXTHRES, RXFLUSH, TXDMAEN, TXTHRES, TXFLUSH), I3C peripheral role (CRINIT)
- dedicated features when the I3C acts as a controller: frame-based control-word triggering (TSFSET), FIFOs management (TMODE, SMODE, SFLUSH, SDMAEN, CDMAEN), and miscellaneous ones (HJACK, HKSDAEN, EXITPTRN, RSTPATRN, NOARBH)

The configuration fields CRINIT, HKSDAEN can be modified only when EN = 0. This condition is respected if they are modified at the same time when EN is set to 1 (it is not necessary to set EN later on, with another write operation).

| Bit 31 | Reserved, must be kept at reset value. |
| Bit 30 | TSFSET: Frame transfer set (software trigger) (when I3C acts as controller) |
| This bit can only be written. When I3C acts as I3C controller: |
| 0: no action |
| 1: setting this bit initiates a frame transfer by causing the hardware to assert the flag CFNFF in the I3C_EVR register (C-FIFO not full and a control word is needed) |
| Note: If this bit is not set, the other alternative for the software to initiate a frame transfer is to directly write the first control word register (I3C_CR) while C-FIFO is empty (CFEF = 1 in the I3C_EVR register). Then, if the first written control word is not tagged as a message end (MEND = 0 in the I3C_CR register), it causes the hardware to assert CFNFF. |
| Bits 29:24 | Reserved, must be kept at reset value. |
| Bit 23 | Reserved, must be kept at reset value. |
| Bit 22 | Reserved, must be kept at reset value. |
| Bit 21 | CFLUSH: C-FIFO flush (when I3C acts as controller) |
| This bit can only be written. |
| 0: no action |
| 1: flush C-FIFO |
Bit 20  **CDMAEN**: C-FIFO DMA request enable (when I3C acts as controller)
When I3C acts as controller:
0: DMA mode is disabled for C-FIFO
   - Software writes and pushes control word(s) into C-FIFO (writes I3C_CR register), as needed for a given frame
   - A next control word transfer can be written by software either via polling on the flag CFNFF = 1 in the I3C_EVR register, or via interrupt notification (enabled by CFNFIE = 1 in the I3C_IER register).
1: DMA mode is enabled for C-FIFO
   - DMA writes and pushes control word(s) into C-FIFO (writes I3C_CR register), as needed for a given frame.
   - A next control word transfer is automatically written by the programmed hardware (via the asserted C-FIFO DMA request from the I3C and the programmed DMA channel).

Bit 19  **TMODE**: Transmit mode (when I3C acts as controller)
When I3C acts as controller, this bit is used for the C-FIFO and TX-FIFO management vs. the emitted frame on the I3C bus.
0: C-FIFO and TX-FIFO are not preloaded before starting to emit a frame transfer.
   A frame transfer starts as soon as the first control word is present in C-FIFO.
1: C-FIFO and TX-FIFO are first preloaded (also TX-FIFO if needed, depending on the frame format) before starting to emit a frame transfer. Refer to Section 49.10.2 for more details.

Bit 18  **SMODE**: S-FIFO enable / status receive mode (when I3C acts as controller)
When I3C acts as controller, this bit is used to enable the FIFO for the status (S-FIFO) of the exchanged message on the I3C bus.
When I3C acts as target, this bit must be cleared.
0: S-FIFO is disabled
   - Status register (I3C_SR) is used without FIFO mechanism.
   - There is no SCL stalling if a new status register content is not read.
   - Status register must be read before being overwritten by the hardware.
   - Must have SDMAEN = 0 in the I3C_CFGR register.
1: S-FIFO is enabled.
   - Each message status must be read.
   - There is SCL stalling when the S-FIFO is full and a next message status must be read.
   - S-FIFO overrun error is reported after the maximum SCL clock stalling time.

Bit 17  **SFLUSH**: S-FIFO flush (when I3C acts as controller)
This bit can be written and used only when I3C acts as controller.
0: no action
1: flush S-FIFO
Bit 16 **SDMAEN**: S-FIFO DMA request enable (when I3C acts as controller)

This bit must be cleared if SMODE = 0 in the I3C_CFRG register (S-FIFO is disabled). In other words, DMA mode cannot be used if S-FIFO is disabled. Then the status register I3C_SR can be read or not.

This bit can be set or cleared if SMODE = 1 (S-FIFO is enabled). In other words, status register I3C_SR must be read for each message, either by software, or via an allocated DMA channel.

0: DMA mode is disabled for reading status register I3C_SR
- SMODE = 0: software can read the I3C_SR register after a completed frame (FCF = 1 in the I3C_EV register) or an error (ERRF = 1 in the I3C_EV register). Via polling on these register flags or via interrupt notification (enabled by FCIE = 1 and ERRIE = 1 in the I3C_IER register).
- SMODE = 1: software must read and pop a status word from S-FIFO (read I3C_SR register) after each asserted flag SFNEF = 1. Via polling on this register flag or via interrupt notification (enabled by SFNEIE = 1 in the I3C_IER register).

1: DMA mode is enabled for reading status register I3C_SR
- Must have SMODE = 1 in the I3C_CFRG register (S-FIFO enabled)
- DMA reads and pops status word(s) from S-FIFO (it reads I3C_SR register)
- Status word(s) are automatically read by the programmed hardware (via the asserted S-FIFO DMA request from the I3C and the programmed DMA channel).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TXTHRES**: TX-FIFO threshold (whatever I3C acts as controller/target)

This threshold defines, compared to the TX-FIFO level, when the TXFNFF flag is set in the I3C_EV register (and consequently if TXDMAEN = 1 when is asserted a DMA TX request).

0: 1-byte threshold
- TXFNFF is set when 1 byte must be written in TX-FIFO (in I3C_TDR).

1: 1-word / 4-byte threshold
- TXFNFF is set when 1 word / 4 bytes must be written in TX-FIFO (in the I3C_TDWR register). If the a number of the last transmitted data is not a multiple of 4 bytes (XDCNT[1:0] = 00 in the I3C_SR register), only the relevant 1, 2, or 3 valid LSB bytes of the last word are taken into account by the hardware, and sent on the I3C bus.

Bit 13 **TXFLUSH**: TX-FIFO flush (whatever I3C acts as controller/target)

This bit can only be written.

When the I3C acts as target, this bit can be used to flush the TX-FIFO on a private read if the controller has aborted the data read (driven low the T bit), and there is/are remaining data in the TX-FIFO (ABT = 1, and XDCNT[15:0] in the I3C_SR register < TGTTDCNT[15:0] in the I3C_TGTTDR register).

0: no action
1: flush TX-FIFO

Bit 12 **TXDMAEN**: TX-FIFO DMA request enable (whatever I3C acts as controller/target)

0: DMA mode is disabled for TX-FIFO
- Software writes and pushes a data byte/word into TX-FIFO (writes I3C_TDR or I3C_TDWR register), to be transmitted over the I3C bus.
- A next data byte/word must be written by the software either via polling on the flag TXFNFF = 1 or via interrupt notification (enabled by TXFNFIE = 1).

1: DMA mode is enabled for TX-FIFO
- DMA writes and pushes data byte(s)/word(s) into TX-FIFO (writes I3C_TDR or I3C_TDWR register).
- A next data byte/word transfer is automatically pushed by the programmed hardware (via the asserted TX-FIFO DMA request from the I3C and the programmed DMA channel).
Bit 11 Reserved, must be kept at reset value.

Bit 10 **RXTHRES**: RX-FIFO threshold (whatever I3C acts as controller/target)

This threshold defines, compared to the RX-FIFO level, when the RXFNEF flag in the I3C_EVR register is set (and consequently if RXDMAEN = 1 when is asserted a DMA RX request).

0: 1-byte threshold
RXFNEF is set when 1 byte must be read in RX-FIFO (in the I3C_RDR register).

1: 1-word/4-bytes threshold
RXFNEF is set when 1 word / 4 bytes is/are to be read in RX-FIFO (in I3C_RDWR). In the case of a number of last received data being not a multiple of 4 bytes, only the relevant 1, 2 or 3 valid LSB bytes of the last word are to be considered by the software. The number of effective received data bytes is reported by XDCNT[15:0] in the I3C_SR register.

Bit 9 **RXFLUSH**: RX-FIFO flush (whatever I3C acts as controller/target)

This bit can only be written.

0: no action
1: flush RX-FIFO

Bit 8 **RXDMAEN**: RX-FIFO DMA request enable (whatever I3C acts as controller/target)

0: DMA mode is disabled for RX-FIFO
- Software reads and pops a data byte/word from RX-FIFO (it reads I3C_RDR or I3C_RDWR register).
- A next data byte/word must be read by the software either via polling flag RXFNEF = 1 in the I3C_EVR register, or via interrupt notification (enabled by RXFNEIE = 1 in the I3C_IER register).

1: DMA mode is enabled for RX-FIFO
- DMA reads and pops data byte(s)/word(s) from RX-FIFO (reads I3C_RDR or I3C_RDWR register).
- A next data byte/word is automatically read by the programmed hardware (via the asserted RX-FIFO DMA request from the I3C and the programmed DMA channel).

Bit 7 **HJACK**: Hot-join request acknowledge (when I3C acts as a controller)

0: hot-join request is not acknowledged
After the NACK, the controller continues as initially programmed (the hot-joining target is aware of the NACK and must emit another hot-join request later on).

1: hot-join request is acknowledged
After the ACK, the controller continues as initially programmed. The software is notified by the HJ interrupt (flag HJF is set in the I3C_EVR register), and must initiate the ENTDAA sequence later on, potentially preventing other hot-join requests with a disable target events command (DISEC, with DISHJ = 1).

Bit 6 Reserved, must be kept at reset value.

Bit 5 **HKSDAEN**: High-keeper enable on SDA line (when I3C acts as a controller)

0: High-keeper is disabled
1: High-keeper is enabled, and the weak pull-up is effective on the T bit, instead of the open-drain class pull-up.

*Note*: This bit can be modified only when EN = 0 in the I3C_CFG register.
Bit 4  **EXITPTRN**: HDR exit pattern enable (when I3C acts as a controller)

This bit can be modified only when there is no on-going frame.

- **0**: HDR exit pattern is not sent after the issued message header (MTYPE[3:0] = 0001 in the I3C_CR register). This is used to send the header, to test ownership of the bus when there is a suspicion of a problem after controller-role hand-off (new controller did not assert its controller-role by accessing the previous one in less than the delay defined by the activity state).
- **1**: HDR exit pattern is sent after the issued message header (MTYPE[3:0] = 0001). This is used on a controller error detection and escalation handling, in case of a not responding target to a private message or a direct read CCC.

The HDR exit pattern is sent whatever the message header (S/Sr + 0x7E addr + W) is ACK-ed or NACK-ed.

Bit 3  **RSTPTRN**: HDR reset pattern enable (when I3C acts as a controller)

This bit can be modified only when there is no on-going frame.

- **0**: standard stop emitted at the end of a frame
- **1**: HDR reset pattern is inserted before the stop of any emitted frame that includes a RSTACT CCC command

Bit 2  **NOARBH**: No arbitrable header after a start (when I3C acts as a controller)

This bit can be modified only when there is no on-going frame.

- **0**: An arbitrable header (0b111_1110 + RnW = 0) is emitted after a start and before a legacy I2C message or an I3C SDR private read/write message (default).
- **1**: No arbitrable header
  - The target address is emitted directly after a start in case of a legacy I2C message or an I3C SDR private read/write message.
  - This is a more performing option (when the emission of the 0x7E arbitrable header is useless), but must be used only when the controller is sure that the addressed target device cannot emit concurrently an IBI or a controller-role request (to insure no misinterpretation and no potential conflict between the address emitted by the controller in open-drain mode and the same address a target device can emit after a start, for IBI or MR).

Bit 1  **CRINIT**: Initial controller/target role

This bit can be modified only when EN = 0 in the I3C_CFG register.

- **0**: target role
  - Once enabled by setting EN = 1, the peripheral initially acts as a target. I3C does not drive SCL line and does not enable SDA pull-up, until it eventually acquires the controller role.
- **1**: controller role
  - Once enabled by setting EN = 1, the peripheral initially acts as a controller. It has the I3C controller role, so drives SCL line and enables SDA pull-up, until it eventually offers the controller role to an I3C secondary controller.

Bit 0  **EN**: I3C enable (whatever I3C acts as controller/target)

- **0**: I3C is disabled
  - Except registers, the peripheral is under reset (partial reset).
  - Before clearing EN, when I3C acts as a controller, all the possible target requests must be disabled using DISEC CCC.
  - When I3C acts as a target, software must not disable the I3C, unless a partial reset is needed.
- **1**: I3C is enabled
  - In this state, some register fields cannot be modified (like CRINIT, HKSDAEN for the I3C_CFG)
49.16.4 I3C receive data byte register (I3C_RDR)

Address offset: 0x010
Reset value: 0x0000 0000

This register is used to read received data bytes from the I3C bus if the RX-FIFO is configured with a byte-based read access (RXTHRES = 0 in the I3C_CFGR register). Then:

- On read, I3C_RDR returns a 32-bit data word, with the received data byte in LSB position, and other reserved bits read as 0.
- When RXDMAEN = 1 in the I3C_CFGR register: programmed I3C and DMA automatically manage by hardware the relevant and successive reads.
- When RXDMAEN = 0: before a read, the software must wait to be notified that a next received data byte must be read via the RX-FIFO non empty flag (RXFNEF = 1 in the I3C_EVR register) or via the corresponding interrupt if enabled. Last received byte of a given message to be read is also marked with RXLASTF = 1 in the I3C_EVR register when acting as controller.
- If the RX-FIFO is full, a new byte is received and cannot be pushed into the RX-FIFO without waiting anymore, the software is notified by error flag ERRF = 1 in the I3C_EVR register and by a data overrun flag DOVRF = 1 in the I3C_SER register (and corresponding interrupt if enabled).

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **RDB[7:0]**: 8-bit received data on I3C bus.

49.16.5 I3C receive data word register (I3C_RDWR)

Address offset: 0x014
Reset value: 0x0000 0000

This register is used to read received data bytes from the I3C bus if the RX-FIFO is configured with a 32-bit word-based read access (RXTHRES = 1 in the I3C_CFGR register). Then:

- When RXDMAEN = 1 in the I3C_CFGR register: programmed I3C and DMA automatically manage by hardware the relevant and successive reads.
- When RXDMAEN = 0: before a read, the software must first wait to be notified that must be read a next received data word via the RX-FIFO non empty flag (RXFNEF = 1 in the I3C_EVR register) or via the corresponding interrupt if enabled. Last received
word/byte(s) of a given message to be read is also marked with RXLASTF = 1 in the I3C_EVR register when acting as controller.

- If the RX-FIFO holds less than four bytes, a read on I3C_RDWR returns a data word padded with null byte(s): the available byte(s) in LSB position(s) is (are) padded with zero byte(s) in MSB position(s).
- If the RX-FIFO is full and a new byte is received and cannot be pushed into the RX-FIFO without waiting anymore, the software is notified by an error flag ERRF = 1 in the I3C_EVR register and a data overrun DOVR = 1 in the I3C_SER register (and corresponding interrupt if enabled).

Bits 31:24  **RDB3[7:0]**: 8-bit received data (latest byte on I3C bus).
Bits 23:16  **RDB2[7:0]**: 8-bit received data (next byte after RDB1 on I3C bus).
Bits 15:8  **RDB1[7:0]**: 8-bit received data (next byte after RDB0 on I3C bus).
Bits 7:0  **RDB0[7:0]**: 8-bit received data (earliest byte on I3C bus).

### 49.16.6 I3C transmit data byte register (I3C_TDR)

Address offset: 0x018

Reset value: 0x0000 0000

This register is used to write data bytes to be transmitted over the I3C bus.

This register implements a byte-based write access to the transmit FIFO (TX-FIFO), and is used when TXTHRES = 0 in the I3C_CFGR register.

When the I3C acts as controller:

- When TXDMAEN = 1 and if TXTHRES = 0 in the I3C_CFGR register: programmed I3C and DMA automatically manage by hardware the relevant and successive writes.
- When TXDMAEN = 0 and if TXTHRES = 0: before a write, the software must wait to be notified that must be written a next data byte via the TX-FIFO non full flag (TXFNFF = 1 in the I3C_EVR register) or via the corresponding interrupt if enabled. Last transmitted byte of a given message to be written is also marked with TXLASTF = 1 in the I3C_EVR register.

When the I3C acts as target:

- When TXDMAEN = 1 and if TXTHRES = 0 and if PRELOAD = 1 in the I3C_TGTDDR register: programmed I3C and DMA automatically manage by hardware the relevant and successive number of writes to I3C_TDR register, according to TGTDDCNT[15:0] in the I3C_TGTDDR register.
- When TXDMAEN = 0 and if TXTHRES = 0:
  - when PRELOAD = 1 in the I3C_TGTDDR register: before a write, the software must wait to be notified that must be written a next data byte via the TX-FIFO non
full flag (TXFNFF = 1) or via the corresponding interrupt, if enabled. The last transmitted byte of the initially programmed TGTTDCNT[15:0] is also marked with TXLASTF = 1 in the I3C_EVR register.

- when PRELOAD = 0: before a write, the software must wait to be notified that can be written up to 8 next data bytes (TX-FIFO size) via the TX-FIFO empty flag (TXFEF = 1 in the I3C_EVR register), or via the corresponding interrupt if enabled. If the software needs to write another data byte, it must wait for the TX-FIFO to be empty (TXFEF = 1), and then write this data byte to be transmitted before nine SCL clock periods elapse, to avoid a data underrun error flag (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register).

If the TX-FIFO is empty and the controller cannot wait longer a data byte to be transmitted, the software is notified by an error flag ERRF = 1 in the I3C_EVR register and a data underrun flag DOF = 1 (and corresponding interrupt if enabled) in the I3C_SER register.

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 TDB0[7:0]: 8-bit data to transmit on I3C bus.

### 49.16.7 I3C transmit data word register (I3C_TDWR)

Address offset: 0x01C

Reset value: 0x0000 0000

This register is used to write 32-bit data words to be transmitted over the I3C bus.

This register implements a word-based write access to the transmit FIFO (TX-FIFO), and is used when TXTHRES = 1 in the I3C_CFGR register.

When the I3C acts as controller:

- When TXDMAEN = 1 and if TXTHRES = 1 in the I3C_CFGR register, programmed I3C and DMA automatically manage by hardware the relevant and successive writes.

- When TXDMAEN = 0 and if TXTHRES = 1: before a write, the software must wait to be notified that next data word/byte(s) must be written via the TX-FIFO non full flag (TXFNFF = 1 in the I3C_EVR register), or via the corresponding interrupt if enabled. Last transmitted word/byte(s) of a given message to be written in TX-FIFO is also marked with TXLASTF = 1 in the I3C_EVR register.

When the I3C acts as target:

- When TXDMAEN = 1 and if TXTHRES = 1 and if PRELOAD = 1 in the I3C_TGTTDDR register: programmed I3C and DMA automatically manage by hardware the relevant and successive number of writes to the I3C_TDWR register, as per TGTTDCNT[15:0]
in the I3C_TGTTDR register.

- When TXDMAEN = 0 and if TXTHRES = 1:
  - when PRELOAD = 1: before a write, the software must wait to be notified that must be written a next data word via the TX-FIFO non full flag (TXFNFF = 1 in the I3C_EVR register) or via the corresponding interrupt, if enabled. Last transmitted word of the initially programmed TGTTDCNT[15:0] in the I3C_TGTTDR register is also marked with TXLASTF = 1 in the I3C_EVR register.
  - when PRELOAD = 0: before a write, the software must wait to be notified that can be written up to two next data words (TX-FIFO size) via the TX-FIFO empty flag (TXFEF = 1 in the I3C_EVR register) or via the corresponding interrupt if enabled. If the software needs to write another data word, it must wait for TX-FIFO to be empty (TXFEF = 1), and then write the next data word to be transmitted before nine SCL clock periods elapse, to avoid a data underrun error flag (ERRF = 1 in the I3C_EVR register and DOVR = 1 in the I3C_SER register).

If the TX-FIFO is empty and the controller/target cannot wait longer a data byte to be transmitted, the software is notified by an error flag ERRF = 1 in the I3C_EVR register and a data underrun flag DOF = 1 in the I3C_SER register (and corresponding interrupt if enabled).

</tbody>
</table>

Bits 31:24 | **TDB3[7:0]**: 8-bit transmit data (latest byte on I3C bus).

Bits 23:16 | **TDB2[7:0]**: 8-bit transmit data (next byte after TDB1[7:0] on I3C bus).

Bits 15:8  | **TDB1[7:0]**: 8-bit transmit data (next byte after TDB0[7:0] on I3C bus).

Bits 7:0   | **TDB0[7:0]**: 8-bit transmit data (earliest byte on I3C bus)
**49.16.8 I3C IBI payload data register (I3C_IBIDR)**

Address offset: 0x020

Reset value: 0x0000 0000

This register is used for the IBI payload data.

When I3C acts as target:
- if BCR2 = 0 in the I3C_BCR register, this register is useless.
- if BCR2 = 1, this register must be written by software
  - to be emitted on the I3C bus as the IBI payload data, after that the IBI request (MTYPE[3:0] = 1010 in the I3C_CR register) is acknowledged by the controller; with the IBI data payload size defined by DCNT[15:0] in the I3C_CR register.
  - Maximum (static) payload data size is given by IBIP[2:0] in the I3C_MAXRLR register. it can be 1, 2, 3 or 4 bytes.
  - DCNT[15:0] must be set between 1 (for the mandatory data byte MDB[7:0]) and the maximum IBIP[2:0].

When I3C acts as controller: if IBIACK= 1 in the I3C_DEVRx register, once it acknowledges on the I3C bus the IBI request from the target x:
- if IBIDEN = 0 (BCR[2] = 0 received from target x) in the I3C_DEVRx register, this register is useless.
- if IBIDEN = 1 (BCR[2] = 1 received from target x):
  - This register is internally written by hardware from the IBI payload data received on the I3C bus (including the first mandatory data byte MDB[7:0]).
  - When the last byte of the payload is received in I3C_IBIDR (when target drives T-bit = 0), IBIF flag is set (and corresponding interrupt if enabled) in the I3C_EVR register.
  - Then, the software can identify the target x via the received and logged 7-bit address in RADD[6:0] in the I3C_RMR register.
  - The software can read this register and interpret byte(s) according to the number of bytes effectively received and logged in IBIRDCNT[2:0] in the I3C_RMR register.

49.16.9  I3C target transmit configuration register (I3C_TGTTDR)

Address offset: 0x024
Reset value: 0x0000 0000

When I3C acts as target, this register must be used to preload a number of data bytes in the TX-FIFO, so that they are ready to be transmitted on the I3C bus, when they are accepted/acknowledged by the controller, whatever the DMA mode is used or not (independently from TXDMAEN in the I3C_CFRG register).

When I3C acts as target, alternatively, if the number of data bytes to be transmitted is less than or equal to the TX-FIFO size (8 bytes), the software can directly use and write byte(s) into the I3C_TDR register (or I3C_TDWR register, depending upon TXTHRES in the I3C_CFRG register), via polling on the TX-FIFO empty flag (TXFEF = 1 in the I3C_EVR register), or via the corresponding enabled interrupt.

In any case, since an I3C target is unable to stretch/stall the SCL line, the software can identify a TX-FIFO underrun via DOR = 1 in the I3C_EVR register.

Bits 31:17  Reserved, must be kept at reset value.

Bit 16  PRELOAD: Preload of the TX-FIFO (when I3C is configured as target)
This bit must be written and asserted by software in the same access when is written and defined the number of bytes to preload into the TX-FIFO and to transmit.
This bit is cleared by hardware when all the data bytes to transmit are loaded into the TX-FIFO.
0: no TX-FIFO preload
1: TX-FIFO preload

Bits 15:0  TGTTCNT[15:0]: Transmit data counter, in bytes (when I3C is configured as target)
This bitfield must be written by software in the same access when is asserted PRELOAD, in order to define the number of bytes to preload and to transmit.
This bitfield is updated by hardware and reports, when read, the remaining number of bytes to be loaded into the TX-FIFO.
49.16.10 I3C status register (I3C_SR)

Address offset: 0x030
Reset value: 0x0000 0000

This register is used to read the status about the exchanged message on the I3C bus:

- in FIFO mode: when the I3C acts as controller and if S-FIFO is enabled via SMODE = 1 in the I3C_CFGR register:
  - Software is notified via SFNEF = 1 in the I3C_EVR register if there is a status register to be read (and corresponding interrupt if enabled), when not in DMA mode (SDMAEN = 0)
  - In DMA mode (SDMAEN = 1), programmed I3C and DMA automatically manage by hardware the relevant and successive reads.
  - Software is notified via COVR = 1 in the I3C_SER register on an S-FIFO overflow (and ERRF = 1 in the I3C_EVR register and corresponding interrupt if enabled)

- in register mode: if SMODE = 0 in the I3C_CFGR register
  - Software can use the flags FCF in the I3C_SER register and ERRF = 1 in the I3C_EVR register (and corresponding interrupt if enabled) to read this register
  - This register can be overwritten by hardware on a new message completion, without any notification.

### Bits 31:24 MID[7:0]
Message identifier/counter of a given frame (when the I3C acts as controller)
When I3C acts as controller, this bitfield identifies the control word message (I3C_CR) to whom the I3C_SR status register refers.
First message of a frame is identified with MID[7:0] = 0.
This bitfield is incremented (by hardware) on the completion of a new message control word (I3C_CR) over I3C bus. This field is reset for every new frame start.

### Bits 23:19 Reserved, must be kept at reset value.

### Bit 18 DIR: Message direction
Whatever the I3C acts as controller or target, this bit indicates the direction of the related message on the I3C bus
0: write
1: read

**Note:** ENTDAA CCC is considered as a write command.
Bit 17 **ABT**: A private read message is ended prematurely by the target (when the I3C acts as controller)

When the I3C acts as controller, this bit indicates if the private read data transmitted by the target early terminates (the target drives T bit low earlier vs. what the controller expects in terms of programmed number of read data bytes DCNT[15:0] in the I3C_CR register).

0: no early completion from the target
1: early completion from the target

Bit 16 Reserved, must be kept at reset value.

Bits 15:0 **XDCNT[15:0]**: Data counter

Condition: during the dynamic address assignment process (ENTDAA CCC)
- When the I3C acts as controller: number of targets detected on the bus
- When the I3C acts as target: number of transmitted bytes

Condition: for other transfers, during the message
- Whatever the I3C acts as controller or target: number of data bytes read from or transmitted on the I3C bus during the message

### 49.16.11 I3C status error register (I3C_SER)

Address offset: 0x034

Reset value: 0x0000 0000

This read register is used to get more information about the error when an error is raised by hardware and notified to the software via the error flag ERF = 1 in the I3C_EVR register (and corresponding interrupt if enabled).

</tbody>
</table>

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DERR**: Data error (when the I3C acts as controller)

0: no detected error
1: controller detected a data error during the controller-role hand-off procedure (GETACCCR CCC, formerly known as GETACCMST) when the received target address or/and the parity bit do no match. Active controller keeps controller-role.

Bit 9 **DNACK**: Data not acknowledged (when the I3C acts as controller)

0: no detected error
1: controller detected that a data byte is not acknowledged by a target, either during:
   i) a legacy I2C write transfer
   ii) the second trial when sending dynamic address during ENTDAA procedure
Bit 8 **ANACK**: Address not acknowledged (when the I3C is configured as controller)
   0: no detected error
   1: controller detected that the static/dynamic address was not acknowledged by a target, either during:
      i) a legacy I2C read/write transfer
      ii) a direct CCC write transfer
      iii) the second trial of a direct CCC read transfer
      iv) a private read/write transfer

Bit 7 **COVR**: C-FIFO underrun or S-FIFO overrun (when the I3C acts as controller)
   0: no detected error
   1: controller detected either:
      i) a C-FIFO underrun: control FIFO is empty and a restart must be emitted
      ii) an S-FIFO overrun: S-FIFO is full and a new message ends

Bit 6 **DOVR**: RX-FIFO overrun or TX-FIFO underrun
   0: no detected error
   1: whatever controller or target, hardware detected either:
      i) a TX-FIFO underrun: TX-FIFO is empty and a write data byte must be transmitted
      ii) a RX-FIFO overrun: RX-FIFO is full and a new data byte is received

Bit 5 **STALL**: SCL stall error (when the I3C acts as target)
   0: no detected error
   1: target detected that SCL was stable for more than 125 µs during an I3C SDR data read
      (during a direct CCC read, a private read, or an IB)

Bit 4 **PERR**: Protocol error
   0: no detected error
   1: whatever controller or target, hardware detected a protocol error, as detailed in CODERR[3:0]
Bits 3:0 **CODERR[3:0]**: Protocol error code/type
- 0000: CE0 error (transaction after sending CCC): controller detected an illegally formatted CCC
- 0001: CE1 error (monitoring error):
  - controller detected that transmitted data on the bus is different from expected
- 0010: CE2 error (no response to broadcast address):
  - controller detected a not acknowledged broadcast address (0b111_1110)
- 0011: CE3 error (failed controller-role hand-off):
  - controller detected the new controller did not drive bus after controller-role hand-off
- 1000: TE0 error (invalid broadcast address 0b111_1110 + W):
  - target detected an invalid broadcast address 0b111_1110 + W
- 1001: TE1 error (CCC code):
  - target detected a parity error on a CCC code via a parity check (vs. T bit)
- 1010: TE2 error (write data):
  - target detected a parity error on a write data via a parity check (vs. T bit)
- 1011: TE3 error (assigned address during dynamic address arbitration):
  - target detected a parity error on the assigned address during dynamic address arbitration via a parity check (vs. PAR bit)
- 1100: TE4 error (0b111_1110 + R missing after Sr during dynamic address arbitration):
  - target detected a 0b111_1110 + R missing after Sr during dynamic address arbitration
- 1101: TE5 error (transaction after detecting CCC):
  - target detected an illegally formatted CCC
- 1110: TE6 error (monitoring error):
  - target detected that transmitted data on the bus is different from expected
- others: reserved

### 49.16.12 I3C received message register (I3C_RMR)

Address offset: 0x040

Reset value: 0x0000 0000

When the I3C acts as controller, this read register is used to log the received target address, and the IBI received payload data size.

When the I3C acts as target, this read register is used to log the received CCC code

</tr>
</tbody>
</table>

Bit 31 **GRPF**: Group addressing flag (when the I3C acts as target)
When the I3C acts as target (and is typically controller-capable), this flag is asserted by hardware to indicate that the broadcast DEFGRPA CCC (define list of group addresses) has been received. Then, software can store the received data for when getting controller role.
The flag is cleared when software writes 1 into the corresponding CGRPF bit in the I3C_CR register.

Bit 30 **DEFF**: DEFTGTS flag (when the I3C acts as target)
When the I3C acts as target (and is typically controller capable), this flag is asserted by hardware to indicate that the broadcast DEFTGTS CCC (define list of targets) has been received. Then, software can store the received data for when getting the controller role.
The flag is cleared when software writes 1 into the corresponding CDEFF bit in the I3C_CEVR register.

Bit 29 **INTUPDF**: Interrupt/controller-role/hot-join update flag (when the I3C acts as target)
When the I3C acts as target, this flag is asserted by hardware to indicate that the direct or broadcast ENEC/DISEC CCC (enable/disable target events) has been received, where a target event is either an interrupt/IBI request, a controller-role request, or an hot-join request. Then, software must read respectively IBIEN, CREN, or HJEN in the I3C_DEVR0 register.
The flag is cleared when software writes 1 into the corresponding CINTUPDF bit in the I3C_CEVR register.

Bit 28 **ASUPDF**: Activity state update flag (when the I3C acts as target)
When the I3C acts as target, this flag is asserted by hardware to indicate that the direct or broadcast ENASx CCC (with x = 0...3) has been received. Then, software must read AS[1:0] in the I3C_DEVR0 register.
The flag is cleared when software writes 1 into the corresponding CASUPDF bit in the I3C_CEVR register.
Bit 27 **RSTF:** Reset pattern flag (when the I3C acts as target)

When I3C acts as target, this flag is asserted by hardware to indicate that a reset pattern has been detected (14 SDA transitions while SCL is low, followed by repeated start, then stop). Then, when not in Stop mode, software must read RSTACT[1:0] and RSTVAL in the I3C_DEVR0 register, to know the required reset level.

- If RSTVAL = 1: when the RSTF is asserted (and/or the corresponding interrupt if enabled), RSTACT[1:0] in the I3C_DEVR0 register dictates the reset action to be performed by the software, if any.
- If RSTVAL = 0: when the RSTF is asserted (and/or the corresponding interrupt if enabled), the software must issue an I3C reset after a first detected reset pattern, and a system reset on the second one.

When in Stop mode, the corresponding interrupt can be used to wake up the device.

The flag is cleared when software writes 1 into the corresponding CRSTF bit in the I3C_CEVR register.

Bit 26 **MRLUPDF:** Maximum read length update flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that a direct SETMRL CCC (set max read length) has been received. Then, software must read MRL[15:0] in the I3C_MAXRLR register to get the maximum read length value.

The flag is cleared when software writes 1 into the corresponding CMRLUPDF bit in the I3C_CEVR register.

Bit 25 **MWLUPDF:** Maximum write length update flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that a direct SETMWL CCC (set max write length) has been received. Then, software must read MWL[15:0] in the I3C_MAXRLR register to get the maximum write length value.

The flag is cleared when software writes 1 into the corresponding CMWLUPDF bit in the I3C_CEVR register.

Bit 24 **DAUPDF:** Dynamic address update flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that a dynamic address update has been received via any of the broadcast ENTDAA, RSTDAA and direct SETNEWDA CCC. Then, software must read DA[6:0] and DAVAL in the I3C_DEVR0 register to get the dynamic address update.

The flag is cleared when software writes 1 into the corresponding CDAUPDF bit in the I3C_CEVR register.

Bit 23 **STAF:** Get status flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that a direct GETSTATUS CCC of format 1 (without defining byte or with defining byte TGTSTAT) has been received.

The flag is cleared when software writes 1 into the corresponding CSTAF bit in the I3C_CEVR register.

Bit 22 **GETF:** Get flag (when the I3C acts as target)

When the I3C acts as target, this flag is asserted by hardware to indicate that any direct CCC of get type (GET*** CCC) except the GETSTATUS of format 1 (but including GETSTATUS of format 2) has been received.

The flag is cleared when software writes 1 into the corresponding CGETF bit in the I3C_CEVR register.
Bit 21 **WKPF**: Wake-up/missed start flag (when the I3C acts as target)
When the I3C acts as target, this flag is asserted by hardware to indicate that a start has been detected (an SDA falling edge followed by an SCL falling edge) but on the next SCL falling edge, the I3C kernel clock is (still) gated. Thus an I3C bus transaction may have been lost by the target.
The corresponding interrupt can be used to wake up the device from a low power (Sleep or Stop) mode.
The flag is cleared when software writes 1 into the corresponding CWKPF bit in the I3C_CEVR register.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **HJF**: Hot-join flag (when the I3C acts as controller)
When the I3C acts as controller, this flag is asserted by hardware to indicate that an hot join request has been received.
The flag is cleared when software writes 1 into the corresponding CHJF bit in the I3C_CEVR register.

Bit 18 **CRUPDF**: Controller-role update flag (when the I3C acts as target)
When the I3C acts as target, this flag is asserted by hardware to indicate that it has now gained the controller role after the completed controller-role hand-off procedure.
The flag is cleared when software writes 1 into the corresponding CCRUPDF bit in the I3C_CEVR register.

Bit 17 **CRF**: Controller-role request flag (when the I3C acts as controller)
When the I3C acts as controller, this flag is asserted by hardware to indicate that a controller-role request has been acknowledged and completed (by hardware). The software must then issue a GETACCCR CCC (get accept controller role) for the controller-role hand-off procedure.
The flag is cleared when software writes 1 into the corresponding CCRF bit in the I3C_CEVR register.

Bit 16 **IBIENDF**: IBI end flag (when the I3C acts as target)
When the I3C acts as target, this flag is asserted by hardware to indicate that an IBI transfer has been received and completed (IBI acknowledged and IBI data bytes read by controller if any).
The flag is cleared when software writes 1 into the corresponding CIBIENDF bit in the I3C_CEVR register.

Bit 15 **IBIF**: IBI flag (when the I3C acts as controller)
When the I3C acts as controller, this flag is asserted by hardware to indicate that an IBI request has been received.
The flag is cleared when software writes 1 into the corresponding CIBIF bit in the I3C_CEVR register.

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **ERRF**: Flag (whatever the I3C acts as controller/target)
This flag is asserted by hardware to indicate that an error occurred. Then, software must read I3C_SER to get the error type.
The flag is cleared when software writes 1 into the corresponding CERRF bit in the I3C_CEVR register.
Bit 10 **RXTGTENDF**: Target-initiated read end flag (when the I3C acts as controller)
When the I3C acts as controller, and only if the S-FIFO is disabled (SMODE = 0 in the I3C_CFGR register), this flag is asserted by hardware to indicate that the target has prematurely ended a read transfer. Then, software must read the status register I3C_SR to check information related to the last message and get the number of received data bytes on the prematurely read transfer (XDCNT in the I3C_SR register).
The flag is cleared when software writes 1 into the corresponding CRXTGTENDF bit in the I3C_CEVR register.

Bit 9 **FCF**: Frame complete flag (whatever the I3C acts as controller/target)
When the I3C acts as controller, this flag is asserted by hardware to indicate that a frame has been (normally) completed on the I3C bus, for example, when a stop is issued.
When the I3C acts as target, this flag is asserted by hardware to indicate that a message addressed to/by this target has been (normally) completed on the I3C bus, for example, when a next stop or repeated start is then issued by the controller.
The flag is cleared when software writes 1 into the corresponding CFCF bit in the I3C_CEVR register.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **RXLASTF**: Last read data byte/word flag (when the I3C acts as controller)
When the I3C acts as controller, this flag is asserted by hardware to indicate that the last data byte/word (depending upon RXTHRES in the I3C_CFGR register) of a message must be read from the RX-FIFO. The flag is de-asserted by hardware when the last data byte/word of a message is read.

Bit 6 **TXLASTF**: Last written data byte/word flag (whatever the I3C acts as controller/target)
This flag is asserted by hardware to indicate that the last data byte/word (depending upon TXTHRES in the I3C_CFGR register) of a message must be written to the TX-FIFO. The flag is de-asserted by hardware when the last data byte/word of a message is written.

Bit 5 **RXFNEF**: RX-FIFO not empty flag (whatever the I3C acts as controller/target)
This flag is asserted/de-asserted by hardware to indicate that a data byte must/must not be read from the RX-FIFO.
*Note*: The software must wait for RXFNEF = 1 (by polling or via the enabled interrupt) before reading from RX-FIFO (reading from I3C_RDR or I3C_RDWR, depending upon RXTHRES).

Bit 4 **TXFNFF**: TX-FIFO not full flag (whatever the I3C acts as controller/target)
This flag is asserted/de-asserted by hardware to indicate that a data byte word must/must not be written to the TX-FIFO.
*Note*: The software must wait for TXFNFF = 1 (by polling or via the enabled interrupt) before writing to TX-FIFO (writing to I3C_TDR or I3C_TDWR, depending upon TXTHRES).
*Note*: When the I3C acts as target, if the software intends to use the TXFNFF flag for writing into I3C_TDR/I3C_TDWR, it must have configured and set the TX-FIFO preload (write PRELOAD in the I3C_TGTTDR register).

Bit 3 **SFNEF**: S-FIFO not empty flag (when the I3C acts as controller)
When the I3C acts as controller, if the S-FIFO is enabled (SMODE = 1 in the I3C_CFGR register), this flag is asserted by hardware to indicate that a status word must be read from the S-FIFO. The flag is de-asserted by hardware to indicate that a status word is not to be read from the S-FIFO.
Improved inter-integrated circuit (I3C) RM0481

49.16.14 I3C interrupt enable register (I3C_IER)

Address offset: 0x054

Reset value: 0x0000 0000

This register is used to enable/disable, at bit level, an interrupt, for each of the following event/flag.

### 49.16.16 I3C own device characteristics register (I3C_DEVR0)

Address offset: 0x060

Reset value: 0x0000 0000

When the I3C peripheral acts as target, this register is used to write or read its own device characteristics.

When the I3C peripheral acts as controller, the field DA[6:0] is used to write and store its own dynamic address.

</tbody>
</table>

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **RSTVAL**: Reset action is valid (when the I3C acts as target)

This bit is asserted by hardware to indicate that the RSTACT[1:0] field has been updated on the reception of a broadcast or direct write RSTACT CCC (target reset action) and is valid. This bit is cleared by hardware when the target receives a frame start.

When the device is not in Stop mode:
- If RSTVAL = 1: when RSTF in the I3C_EVTR register is asserted (and/or the corresponding interrupt if enabled), RSTACT[1:0] in the I3C_DEVR0 register dictates the reset action to be performed by the software, if any.
- If RSTVAL = 0: when RSTF is asserted (and/or the corresponding interrupt if enabled), the software must issue an I3C reset after a first detected reset pattern, and a system reset on the second one.

When in Stop mode, the corresponding interrupt can be used to wake up the device.
Bits 23:22 RSTACT[1:0]: Reset action/level on received reset pattern (when the I3C acts as target)

This read field is used by hardware on the reception of a direct read RSTACT CCC in order to return the corresponding data byte on the I3C bus.

This read field is updated by hardware on the reception of a broadcast or direct write RSTACT CCC (target reset action).

Only the defining bytes 0x00, 0x01 and 0x02 are mapped, and RSTACT[1:0] = Defining Byte[1:0].

00: no reset action

01: first level of reset: the application software must either:

a) partially reset the peripheral, by a write and clear of the enable bit of the I3C configuration register (write EN = 0). This resets the I3C bus interface and the I3C kernel sub-parts, without modifying the content of the I3C APB registers (except the EN bit).

b) fully reset the peripheral, including all its registers, via a write and set of the I3C reset control bit of the RCC (reset and clock controller) register.

10: second level of reset: the application software must issue a warm reset, also known as a system reset. This (see Section 11: Reset and clock control (RCC)) has the same impact as a pin reset (NRST = 0):

– the software writes and sets the SYSRESETREQ control bit of the AITR register, when the device is controlled by a Cortex®-M.

– the software writes and sets SYSRST = 1 in the RCC_GRSTCSETR register, when the device is controlled by a Cortex®-A.

11: no reset action

Bits 21:20 AS[1:0]: Activity state (when the I3C acts as target)

This read field is updated by hardware on the reception of a ENTASx CCC (enter activity state, with x = 0-3):

00: activity state 0

01: activity state 1

10: activity state 2

11: activity state 3

Bit 19 HJEN: Hot-join request enable (when the I3C acts as target)

This bit is initially written by software when EN = 0, and is updated by hardware on the reception of DISEC CCC with DISHJ= 1 (cleared) and the reception of ENEC CCC with ENHJ= 1 (set). This bit can only be written by software when EN = 0 in the I3C_CFGR register.

0: hot-join request disabled

1: hot-join request enabled

Bit 18 Reserved, must be kept at reset value.

Bit 17 CREN: Controller-role request enable (when the I3C acts as target)

This bit is initially written by software when EN = 0, and is updated by hardware on the reception of DISEC CCC with DISCR = 1 (cleared) and the reception of ENEC CCC with ENCR = 1 (set). This bit can only be written by software when EN = 0 in the I3C_CFGR register.

0: controller-role request disabled

1: controller-role request enabled
Bit 16 IBIEN: IBI request enable (when the I3C acts as target)
This bit is initially written by software when EN = 0, and is updated by hardware on the
reception of DISEC CCC with DISINT = 1 (cleared) and the reception of ENEC CCC with
ENINT = 1 (set). This bit can only be written by software when EN = 0 in the I3C_CFGR
register.
0: IBI request disabled
1: IBI request enabled

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:1 DA[6:0]: 7-bit dynamic address
When the I3C acts as controller, this field can be written by software, for defining its own
dynamic address.
When the I3C acts as target, this field is updated by hardware on the reception of either the
broadcast ENTDAA CCC or the direct SETNEWDA CCC.

Bit 0 DAVAL: Dynamic address is valid (when the I3C acts as target)
When the I3C acts as controller, this bit can be written by software, for validating its own
dynamic address, for example before a controller-role hand-off.
When the I3C acts as target, this bit is asserted by hardware on the acknowledge of the
broadcast ENTDAA CCC or the direct SETNEWDA CCC, and this field is cleared by
hardware on the acknowledge of the broadcast RSTDAA CCC.

49.16.17 I3C device x characteristics register (I3C_DEVRx)
Address offset: 0x060 + 0x4 * x, (x = 1 to 4)
Reset value: 0x0000 0000
When the I3C peripheral acts as controller, this register is used to define and store some
characteristics of a device target x with their related management from the controller, to
communicate accordingly with any of this target x over the I3C bus. Then, the hardware can
autonomously identify and acknowledge an allowed IBI or/and controller-role request from a
target x, receive the expected IBI payload data if any, and notify the software via the
corresponding flag IBIF/CRF (and the corresponding interrupt if enabled) in the I3C_EVR
register.

</tbody>
</table>

Bit 31 DIS: DA[6:0] write disabled (when the I3C acts as controller)
When the I3C acts as controller, once the software sets IBIACK= 1 or CRACK= 1, this read
bit is set by hardware (DIS = 1) to lock the configured DA[6:0] and IBIDEN values.
Then, to be able to modify DA[6:0], IBIDEN or SUSP, the software must wait for DIS to be
de-asserted by hardware (polling on DIS = 0) before modifying these three assigned values
to the target x. Indeed, the target can request an IBI or a controller-role while the controller
intends to modify DA[6:0], IBIDEN or SUSP.
0: write to DA[7:0] and to IBIDEN in the I3C_DEVRx register is allowed
1: write to DA[7:0] and to IBIDEN is disabled/locked
Bits 30:20  Reserved, must be kept at reset value.

Bit 19  **SUSP**: Suspend/stop I3C transfer on received IBI (when the I3C acts as controller)

When the I3C acts as controller, this bit can be used to receive an IBI from target x with pending read notification feature (received MDB[7:5] = 3'b101).

If this bit is set, when an IBI is received and completed (IBIF = 1 in the I3C_EVR register), a stop is emitted on the I3C bus and both C-FIFO and TX-FIFO are automatically flushed by hardware. The controller execution flow is stopped, even if a next control message is programmed. When the IBI is completed, the controller software can issue a new control word, such as a private read, to the target device that initiated the IBI request.

0: C-FIFO and TX-FIFO are not flushed after an IBI request from target x is acknowledged and completed, and depending on the presence or absence of a next control word, a repeated start or a stop is emitted.
1: I3C transfer is stopped and both C-FIFO and TX-FIFO are flushed after receiving an IBI request from target x.

Bit 18  **IBIDEN**: IBI data enable (when the I3C acts as controller)

When the I3C acts as controller, this bit must be written by software to store the BCR[2] bit as received from the target x during broadcast ENTDAA or direct GETBCR CCC via the received I3C_RDR.

Writing to this field has no impact when the DIS = 1 in the I3C_DEVRx register.

0: no data byte follows the acknowledged IBI from target x.
1: the mandatory data byte MDB[7:0] follows the acknowledged IBI from target x.

Bit 17  **CRACK**: Controller-role request acknowledge (when the I3C acts as controller)

When the I3C acts as controller, this bit is written by software to define the acknowledge policy to be applied on the I3C bus on the reception of a controller-role request from target x:

0: a controller-role request from target x must be NACK-ed

After the NACK, the message continues as initially programmed (the target is aware of the NACK and can emit another controller-role request later on).

1: a controller-role request (with 7-bit dynamic address DA[6:0]) from target x must be ACKed

- The field DIS is asserted by hardware to protect DA[6:0] from being modified by software meanwhile the hardware can store internally the current DA[6:0] into the kernel clock domain.

- After the ACK, the message continues as initially programmed. The software is notified by the controller-role request flag (CRF = 1 in the I3C_EVR register) and/or the corresponding interrupt if enabled; For effectively granting the controller-role to the requesting secondary controller, software must issue a GETACCCR (formerly known as GETACCMST), followed by a stop.

- Independently of CRACK configuration for this or other devices, further controller-role request(s) are NACK-ed until controller-role request flag (CRF) and IBI flag (IBIF) in the I3C_EVR register are both cleared.
Device: Improved inter-integrated circuit (I3C) RM0481

**49.16.18 I3C maximum read length register (I3C_MAXRLR)**

Address offset: 0x090

Reset value: 0x0000 0000

When the I3C acts as target, this register is used to set or get the maximum read length value exchanged with the controller during respectively GETMRL or SETMRL CCC. This register is also used to set the IBI data payload size.

This register can be written by the software when EN = 0 in the I3C_CFR register.

When receiving a private read message, the target ends the data transmission (by driving T-bit = 0) when the count of transmitted data reaches MRL[15:0] in the I3C_MAXRLR register.

| Bit 31:19 | Reserved, must be kept at reset value. |
| Bit 18:17 | IBIP[2:0] |
| Bits 16 | IBIACK: IBI request acknowledge (when the I3C acts as controller) |
| When the I3C acts as controller, this bit is written by software to define the acknowledge policy to be applied on the I3C bus on the reception of an IBI request from target x: |
| 0: an IBI request from target x must be NACK-ed |
| - After the NACK, the message continues as initially programmed (the target is aware of the NACK and can emit another IBI request later on) |
| 1: an IBI request (with 7-bit dynamic address DA[6:0]) from target x must be ACKed |
| - The field DIS is asserted by hardware to protect DA[6:0] from being modified by software meanwhile the hardware can store internally the current DA[6:0] into the kernel clock domain. |
| - After the ACK, the controller logs the IBI payload data, if any, depending on I3C DEVRx.IBIDEN. |
| - The software is notified by the IBI flag (IBIF = 1) and/or the corresponding interrupt if enabled; |
| - Independently from IBIACK configuration for this or other devices, further IBI request(s) are NACK-ed until IBI request flag (IBIF) and controller-role request flag (CRF) are both cleared. |
| Bits 15:8 | Reserved, must be kept at reset value. |
| Bits 7:1 | DA[6:0]: Assigned I3C dynamic address to target x (when the I3C acts as controller) |
| When the I3C acts as controller, this field must be written by software to store the 7-bit dynamic address that the controller sends via a broadcast ENTDAA or a direct SETNEWDA CCC acknowledged by the target x. |
| Writing to this field has no impact when the read field DIS = 1 in the I3C DEVRx register. |
| Bit 0 | Reserved, must be kept at reset value. |
**Improved inter-integrated circuit (I3C)**

49.16.19 **I3C maximum write length register (I3C_MAXWLR)**

Address offset: 0x094  
Reset value: 0x0000 0000

When the I3C acts as target, this register is used to set or get the maximum write length value exchanged with the controller during respectively GETMWL or SETMWL CCC.

This register can be written by the software when EN = 0 in the I3C_CFGR register.

On receiving a private write message, the target stops the data reception (extra received data are not written into RX-FIFO) when the count of received data reaches MWL[15:0] in the I3C_MAXWLR register.

| Bits 31:16 | Reserved | must be kept at reset value. |
| Bits 15:0  | MWL[15:0] | Maximum data write length (when I3C acts as target) |

Other details about the register and its usage are provided in the document.
49.16.20 I3C timing register 0 (I3C_TIMINGR0)

Address offset: 0x0A0

Reset value: 0x0000 0000

When the I3C acts as controller, this register is used to configure the SCL clock signal waveform.

This register can be written by the software when EN = 0 in the I3C_CFGR register.

<table>
<thead>
<tr>
<th>Bits 31:24</th>
<th>SCLH_I2C[7:0]</th>
<th>SCLL_OD[7:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
<tr>
<td>15</td>
<td>14</td>
<td>13</td>
</tr>
</tbody>
</table>

Bits 31:24 **SCLH_I2C[7:0]**: SCL high duration, used for legacy I2C messages, in number of kernel clocks cycles:

\[ \text{ts}_{\text{SCLH I2C}} = (\text{SCLH I2C} + 1) \times \text{tI3CCLK} \]

Note: SCLH I2C is used to generate \( t_{\text{DIG H (I2C)}} \) timing when communicating with I2C devices.

Note: With I2C fm+ device \( t_{\text{DIG H min}} = 260 \text{ ns} \), with I2C fm device \( t_{\text{DIG H min}} = 600 \text{ ns} \).

Bits 23:16 **SCLL_OD[7:0]**: SCL low duration in open-drain phases, used for legacy I2C messages and for I3C open-drain phases (address phase following a start, ACK phase during controller-initiated messages, and T bit phase during direct/private/IBI payload), in number of kernel clocks cycles:

\[ \text{ts}_{\text{SCLL OD}} = (\text{SCLL OD} + 1) \times \text{tI3CCLK} \]

Note: SCLL OD is used to generate both \( t_{\text{DIG L (I2C)}} \) and \( t_{\text{DIG OD L (I3C)}} \) timings.

Note: With I2C fm+ device \( t_{\text{DIG L min}} = 500 \text{ ns} \), with I2C fm device \( t_{\text{DIG L min}} = 1320 \text{ ns} \).

Note: I3C messages: \( t_{\text{DIG OD L min}} = 200 \text{ ns} \).

Note: If a single I3C frame is gathering I2C and I3C messages, the SCL low duration during I3C open-drain phases is increased to fit I2C timings.

Bits 15:8 **SCLH_I3C[7:0]**: SCL high duration, used for I3C messages (both in push-pull and open-drain phases), in number of kernel clocks cycles:

\[ \text{ts}_{\text{SCLH I3C}} = (\text{SCLH I3C} + 1) \times \text{tI3CCLK} \]

Note: SCLH I3C is used to generate both \( t_{\text{DIG H (I3C)}} \) and \( t_{\text{DIG H MIXED}} \) timings.

Note: For mixed bus (with at least one I2C target): \( t_{\text{DIG H MIXED min}} = 32 \text{ ns} \) and \( t_{\text{DIG H MIXED max}} = 45 \text{ ns} \) (due to I2C 50 ns spike filter).

Note: For pure I3C bus (with no I2C targets): \( t_{\text{DIG H min}} = 32 \text{ ns} \).

Bits 7:0 **SCLL_PP[7:0]**: SCL low duration in I3C push-pull phases, in number of kernel clocks cycles:

\[ \text{ts}_{\text{SCLL PP}} = (\text{SCLL PP} + 1) \times \text{tI3CCLK} \]

Note: SCCLL PP is used to generate \( t_{\text{DIG L (I3C in PP)}} \) timing.

Note: \( t_{\text{DIG L min}} = 32 \text{ ns} \) (max 40/60 duty cycle at 12.5 MHz).
49.16.21 I3C timing register 1 (I3C_TIMINGR1)

Address offset: 0x0A4
Reset value: 0x0000 0000

When the I3C acts as controller, this register is used to configure some I3C timing settings.

When the I3C acts as target and is controller-capable, this register is used to configure a timing for the controller-role hand-off procedure.

This register can be written by the software when EN = 0 in the I3C_CFGR register.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:29</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
</tr>
<tr>
<td>28</td>
<td><strong>SDA_HD</strong>: SDA hold time (when the I3C acts as controller), in number of kernel clocks cycles (refer to MIPI timing SDA hold time in push-pull t\textsubscript{HD_PP}): SDA hold time = (SDA_HD + 0.5) x t\textsubscript{I3CCLK}</td>
<td></td>
</tr>
<tr>
<td>27:23</td>
<td><strong>FREE[6:0]</strong>: Number of kernel clocks cycles that is used to set some MIPI timings like bus free condition time (when the I3C acts as controller)</td>
<td></td>
</tr>
<tr>
<td>22:16</td>
<td><strong>ASNCR[1:0]</strong></td>
<td></td>
</tr>
<tr>
<td>21:16</td>
<td><strong>AVAL[7:0]</strong></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:29: Reserved, must be kept at reset value.

Bit 28: **SDA\_HD**: SDA hold time (when the I3C acts as controller), in number of kernel clocks cycles (refer to MIPI timing SDA hold time in push-pull t\textsubscript{HD_PP}): SDA hold time = (SDA\_HD + 0.5) x t\textsubscript{I3CCLK}

Note: when controller: t\textsubscript{HD\_PPmin} = min (t\textsubscript{CR}, t\textsubscript{CF}) + 3 ns.

Bits 27:23: Reserved, must be kept at reset value.

Bits 22:16: **FREE[6:0]**: Number of kernel clocks cycles that is used to set some MIPI timings like bus free condition time (when the I3C acts as controller)

When the I3C acts as controller:

1. for I3C start timing: it must wait for (bus free condition) time to be elapsed after a stop and before a start, refer to MIPI timings (I3C) t\textsubscript{CAS} and (I2C) t\textsubscript{BUF}. These timings are defined by: t\textsubscript{BUF} = t\textsubscript{CAS} = [(FREE[6:0] + 1) x 2 - (0.5 + SDA\_HD)] x t\textsubscript{I3CCLK}

Note: For pure I3C bus: t\textsubscript{CASmin} = 38.4 ns, and t\textsubscript{CASmax} = 1 \mu s, 100 \mu s, 2 ms, 50 ms for, respectively, ENTAS0, 1, 2, and 3.

Note: For mixed bus with \textsuperscript{2}C fm\_device t\textsubscript{BUFmin} = 0.5 \mu s, for mixed bus with \textsuperscript{2}C fm device t\textsubscript{BUFmin} = 1.3 \mu s.

2. for I3C repeated start timing: must wait for time to be elapsed after a repeated start (SDA is de-assserted) and before driving SCL low, refer to MIPI timing t\textsubscript{CAS}. This timing is defined by: t\textsubscript{CAS} = [(FREE[6:0] + 1) x 2 - (0.5 + SDA\_HD)] x t\textsubscript{I3CCLK}

Note: t\textsubscript{CASr, min} = 19.2 ns.

3. for I3C stop timing: must wait for time to be elapsed after that the SCL clock is driven high, and before the stop condition (SDA is asserted). This timing is defined by:

\[ t\text{CBP} = (\text{FREE}[6:0] + 1) \times t\text{I3CCLK}. \]

Note: t\textsubscript{CBPmin} = 19.2 ns.

4. for I3C repeated start timing (T-bit when controller ends read with repeated start followed by stop): must wait for time to be elapsed after that the SCL clock is driven high, and before the repeated start condition (SDA is de-assserted). This timing is defined by:

\[ t\text{CBSr} = (\text{FREE}[6:0] + 1) \times t\text{I3CCLK}. \]

Note: t\textsubscript{CBSr, min} = 19.2 ns.

Bits 15:10: Reserved, must be kept at reset value.
Bits 9:8 **ASNCR[1:0]**: Activity state of the new controller (when I3C acts as active controller)  
This field indicates the time to wait before being accessed as new target, refer AVAL[7:0].  
This field can be modified only when the I3C acts as controller.

Bits 7:0 **AVAL[7:0]**: Number of kernel clock cycles to set a time unit of 1 µs, whatever I3C acts as controller or target.  
This field is used by the hardware to build some internal timers, corresponding to the following MIPI 3IC timings:

When the I3C acts as target:
1. for bus available condition time: it must wait for (bus available condition) time to be elapsed after a stop and before issuing a start request for an IBI or a controller-role request (bus free condition is sustained for at least tAVAL). Refer to MIPI timing tAVAL = 1 µs. This timing is defined by: tAVAL = (AVAL[7:0] + 2) x tI3CCLK
2. for bus idle condition time: it must wait for (bus idle condition) time to be elapsed after that both SDA and SCL are continuously high and stable before issuing a hot-join event. Refer to MIPI v1.1 timing tIDLE = 200 µs. This timing is defined by: tIDLE = (AVAL[7:0] + 2) x 200 x tI3CCLK

When the I3C acts as controller, it cannot stall the clock beyond a maximum stall time (stall the SCL clock low), as follows:
1. on first bit of assigned address during dynamic address assignment: it cannot stall the clock beyond the MIPI timing tSTALLDAA = 15 ms. This timing is defined by:  
   tSTALLDAAmax = (AVAL[7:0] + 1) x 15000 x tI3CCLK
2. on ACK/NACK phase of I3C/I2C transfer, on parity bit of write data transfer, on transition bit of I3C read transfer: it cannot stall the clock beyond the MIPI timing tSTALL = 100 µs. This timing is defined by:  
   tSTALLmax = (AVAL[7:0] + 1) x 100 x tI3CCLK

Whatever the I3C acts as controller or as (controller-capable) target, during a controller-role hand-off procedure:
1. The new controller must wait for tNEWCRLock before pulling SDA low (issuing a start) after a completed GETACCR CCC. Then the new controller, within tCAS, can pull SCL low to activate SCL clock. The active controller must wait for the same tNEWCRLock time, or at least 100 µs, before testing if the new controller has gained control of the bus by pulling SDA low. The time to wait depends upon the value of ASNCR[1:0] in the I3C_TIMINGR1 register:
   - ASNCR[1:0] = 00:  
     tNEWCRLock = (AVAL[7:0] + 1) x tI3CCLK
   - ASNCR[1:0] = 01:  
     tNEWCRLock = (AVAL[7:0] + 1) x 100 x tI3CCLK
   - ASNCR[1:0] = 10:  
     tNEWCRLock = (AVAL[7:0] + 1) x 2000 x tI3CCLK
   - ASNCR[1:0] = 11:  
     tNEWCRLock = (AVAL[7:0] + 1) x 50000 x tI3CCLK
49.16.22  I3C timing register 2 (I3C_TIMINGR2)

Address offset: 0x0A8
Reset value: 0x0000 0000

When the I3C acts as controller, this register is used to configure and enable SCL clock stalling, to enable SCL clock low stalling, if needed by the addressed I3C or legacy I²C target(s).

This register can be written only when the I3C acts as controller.

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:8  **STALL[7:0]**: Controller clock stall time, in number of kernel clock cycles

\[ t_{SCLL\_STALL} = STALL \times t_{I3C\_CLK} \]

Bits 7:4  Reserved, must be kept at reset value.

Bit 3  **STALLA**: Controller clock stall enable on ACK phase

The SCL is stalled (during \( t_{SCLL\_STALL} \)) in the address ACK/NACK phase (before the ninth bit). This allows the target to prepare data. The ACK driven by the controller itself on a target-initiated request (IBI/HJ/CR) is not impacted by this control bit.

0: no stall

1: stall enabled

Bit 2  **STALLC**: Controller clock stall enable on PAR phase of CCC

The SCL is stalled during \( STALL \times t_{SCLL\_PP} \) in the T-bit phase of common command code (before the ninth bit). This allows the target to decode the command.

0: no stall

1: stall enabled

*Note: \( t_{SCLL\_PP} = (I3C\_TIMINGR0.SCLL\_PP[7:0] + 1) \times t_{I3C\_CLK} \)*

Bit 1  **STALLD**: Controller clock stall enable on PAR phase of Data

The SCL is stalled during \( STALL \times t_{SCLL\_PP} \) in the T-bit phase (before the ninth bit). This allows the target to read received data.

0: no stall

1: stall enabled

*Note: \( t_{SCLL\_PP} = (I3C\_TIMINGR0.SCLL\_PP[7:0] + 1) \times t_{I3C\_CLK} \)*

Bit 0  **STALLT**: Controller clock stall enable on T-bit phase of data (and on the ACK/NACK phase of data byte of a legacy I²C read)

The SCL is stalled during \( STALL \times t_{SCLL\_PP} \) in the T-bit phase (before the ninth bit). This allows the target to prepare the data to be sent.

0: no stall

1: stall enabled

*Note: \( t_{SCLL\_PP} = (I3C\_TIMINGR0.SCLL\_PP[7:0] + 1) \times t_{I3C\_CLK} \)*
49.16.23 I3C bus characteristics register (I3C_BCR)

Address offset: 0x0C0
Reset value: 0x0000 0000

When the I3C acts as target, this register is used to configure three bits used by hardware to return the data byte BCR[7:0] on reception of GETBCR or ENTDAA CCC. The returned byte BCR[7:0] on the I3C bus is then as follows:

- BCR[7] = 0 (reserved)
- BCR[6] = I3C_BCR6 (controller capable)
- BCR[5] = 1 (advanced capabilities, use GETCAPS CCC to determine which ones)
- BCR[4] = 0 (not a virtual target)
- BCR[3] = 1 (offline capable)
- BCR[2] = I3C_BCR2 (IBI payload)
- BCR[1] = 1 (IBI request capable)
- BCR[0] = I3C_BCR0 (max data speed limitation)

This register can be written by software only when EN = 0 in the I3C_CFGR register.

Bits 31:7 Reserved, must be kept at reset value.

- Bit 6 **BCR6**: Controller capable
  0: I3C target (no controller capable)
  1: I3C controller capable

Bits 5:3 Reserved, must be kept at reset value.

- Bit 2 **BCR2**: in-band interrupt (IBI) payload
  0: no data byte follows the accepted IBI
  1: at least one mandatory data byte follows the accepted IBI (and at most 4 data bytes)

- Bit 1 Reserved, must be kept at reset value.

- Bit 0 **BCR0**: max data speed limitation
  0: no limitation
  1: limitation, as described by I3C_GETMXDSR.
49.16.24 I3C device characteristics register (I3C_DCR)

Address offset: 0x0C4
Reset value: 0x0000 0000

When the I3C acts as target, this register is used to configure the device characteristics ID, which is used by hardware to return the data byte DCR[7:0] on reception of GETDCR, ENTDAA, or DEFTGTS CCC.

This register can be written by software only when EN = 0 in the I3C_CFRG register.

Bits 7:0  **DCR[7:0]:** device characteristics ID
0x00: generic device (for v1.0 devices)
others: ID to describe the type of the I3C sensor/device

*Note: The latest MIPI DCR ID assignments are available on https://www.mipi.org.*
### I3C get capability register (I3C_GETCAPR)

- **Address offset:** 0x0C8
- **Reset value:** 0x0000 0000

When the I3C acts as target, this register is used to set the IBI MDB support for pending read notification support, and is used by hardware to return the GETCAP3 byte on reception of GETCAPS CCC, format 1.

The returned byte GETCAP1[7:0] on the I3C bus is then as follows:

- GETCAP1[7:0] = 0 (no HDR)

The returned byte GETCAP2[7:0] on the I3C bus is then as follows:

- GETCAP2[7:6] = 00 (no HDR)
- GETCAP2[5:4] = 00 (no group addressing)
- GETCAP2[3:0] = 0001 (compliant with MIPI specification v1.1)

The returned byte GETCAP3[7:0] on the I3C bus is then as follows:

- GETCAP3[7] = 0 (reserved)
- GETCAP3[6] = CAPPEND in the I3C_GETCAPR register (IBI MDB support for pending read notification)
- GETCAP3[5] = 0 (no HDR)
- GETCAP3[4] = 1 (defining byte support in GETSTATUS)
- GETCAP3[3] = 1 (defining byte support in GETCAPS)
- GETCAP3[2] = 0 (no device-to-device transfer)
- GETCAP3[1] = 0 (no device-to-device transfer)
- GETCAP3[0] = 0 (no multi-lane data transfer)

This register can be written by software only when EN = 0 in the I3C_CFGR register.

<table>
<thead>
<tr>
<th>Bit 31-15</th>

49.16.26 I3C controller-role capability register (I3C_CRCAPR)

Address offset: 0x0CC
Reset value: 0x0000 0000

When the I3C acts as target, this register is used to set features the I3C supports as a secondary controller after controller-role hand-off, and is used by hardware to return the CRCAP1 byte and the CRCAP2 byte on reception of GETCAPS CCC, format 2 with the defining byte CRCAPS (0x91).

The returned CRCAP1[7:0] on the I3C bus is then as follows:
- CRCAP1[7:3] = 00000 (reserved)
- CRCAP1[2] = 0 (no multi-lane)
- CRCAP1[1] = CAPGRP in the I3C_CRCAPR register (group management)
- CRCAP1[0] = 1 (hot-join)

The returned CRCAP2[7:0] on the I3C bus is then as follows:
- CRCAP2[7:4] = 0000 (reserved)
- CRCAP2[3] = CAPDHOFF in the I3C_CRCAPR register (delayed controller-role handoff)
- CRCAP2[2] = 1 (deep sleep capable)
- CRCAP2[1] = 0 (no automatic controller-role pass-back)
- CRCAP2[0] = 1 (IBI ack capable)

This register can be written by software only when EN = 0 in the I3C_CFGR register.

49.16.27 **I3C get max data speed register (I3C_GETMXDSR)**

Address offset: 0x0D0

Reset value: 0x0000 0000

When the I3C acts as target, this register is used to return its capabilities and limitations if any. This register is used by hardware to return data byte(s) on reception of GETMXDS CCC, with format 1 (2 bytes, without maxRdTurn), format 2 (5 bytes, with MaxRdTurn), or format 3 (with defining byte WRRDTURN = 0x00: same 5 bytes as format 2, or with defining byte CRHDLY = 0x91: single byte CRHDLY1).

The returned byte MaxWr[7:0] on the I3C bus is then as follows:

- MaxWr[7:4] = 0000 (reserved)
- MaxWr[3] = 1 (defining byte WRRDTURN and CRHDLY support)
- MaxWr[2:0] = 000 (max sustained data rate for non-CCC messages sent by the controller to the target is designed to operate at 12.5 MHz)

The returned byte MaxRd[7:0] on the I3C bus is then as follows:

- MaxRd[7] = 0 (reserved)
- MaxRd[6] = 1 (stop is allowed between write and read)
- MaxRd[5:3] = 100 if TSCO = 0 (clock to data turnaround time tSCO ≤ 12 ns) in the I3C_GETMXDSR register, else 111 (tSCO > 12 ns, refer to the datasheet for more details)
- MaxRd[2:0] = 000 (max sustained data rate for non-CCC messages sent by the target to the controller is designed to operate at 12.5 MHz)

The returned 3-byte MaxRdTurn[23:0], if FMT[1:0] = 00 in the I3C_GETMXDSR register, on the I3C bus is then as follows:

- MaxRdTurn[23:0], with either the MSB (between 65 ms and 16 s), the middle byte (between 256 µs and 65 ms), or the LSB (less than 256 µs) from RDTURN[7:0] in the I3C_GETMXDSR register (others bits are 0), and depending upon FMT[1:0] in the same register.

The returned byte CRHDLY1[7:0] on the I3C bus is then as follows:

- CRHDLY1[7:3] = 00000 (reserved)
- CRHDLY1[2] = 0 if HOFFAS[1:0] = 00 in the I3C_GETMXDSR register, else 1 (set bus activity state)
- CRHDLY1[1:0] = HOFFAS[1:0] (controller-role hand-off activity state)

This register can be written by software only when EN = 0 in the I3C_CFRG register.
Bits 31:25  Reserved, must be kept at reset value.

Bit 24  **TSCO**: clock-to-data turnaround time \(t_{\text{SCO}}\)
This bit is written by software during bus initialization (EN = 0 in the I3C_CFGR register) and is used to specify the clock-to-data turnaround time \(t_{\text{SCO}}\) (vs. the value of 12 ns). This bit is used by the hardware in response to the GETMXDS CCC to return the encoded clock-to-data turnaround time via the returned MaxRd[5:3] bits.
0: \(t_{\text{SCO}} \leq 12\) ns
1: \(t_{\text{SCO}} > 12\) ns (refer to the datasheet for more details)

Bits 23:16  **RDTURN[7:0]**: programmed byte of the 3-byte MaxRdTurn (maximum read turnaround byte)
This bit is written by software during bus initialization (EN = 0) and writes the value of the selected byte (via the FMT[1:0] field) of the 3-byte MaxRdTurn, which is returned in response to the GETMXDS CCC format 2 to encode the maximum read turnaround time.

Bits 15:10  Reserved, must be kept at reset value.

Bits 9:8  **FMT[1:0]**: GETMXDS CCC format
This field is written by software during bus initialization (EN = 0) and indicates how is returned the GETMXDS format 1 (without MaxRdTurn) and format 2 (with MaxRdTurn).
This field is used to return the 2-byte format 1 (MaxWr, MaxRd) or 5-byte format 2 (MaxWr, MaxRd, 3-byte MaxRdTurn) byte in response to the GETCAPS CCC.
00: format 1 (2 bytes with MaxWr with no defining byte, MaxRd)
01: format 2: (5 bytes with MaxWr with no defining byte, MaxRd, MaxRdTurn)
- 3-byte MaxRdTurn is returned with MSB = 0, middle byte = 0 and LSB = RDTURN[7:0].
- Max read turnaround time is less than 256 µs.
10: format 2 (5 bytes with MaxWr with no defining byte, MaxRd, and middle byte of MaxRdTurn)
- 3-byte MaxRdTurn is returned with MSB = 0, middle byte = RDTURN[7:0] and LSB = 0.
- Max read turnaround time is between 256 and 65535 µs
11: format 2 (5 bytes with MaxWr with no defining byte, MaxRd, MSB of MaxRdTurn)
- 3-byte MaxRdTurn is returned with MSB = RDTURN[7:0], middle byte = 0 and LSB = 0.
- Max read turnaround time is between 65535 µs and 16 s.

Bits 7:2  Reserved, must be kept at reset value.

Bits 1:0  **HOFFAS[1:0]**: Controller hand-off activity state
This field is written by software during bus initialization (EN = 0), and indicates in which initial activity state the (other) current controller must expect the I3C bus after a controller-role hand-off to this controller-capable I3C, when returning the defining byte CRHDLY (0x91) to a GETMXDS CCC.
This 2-bit field is used to return the CRHDLY1 byte in response to the GETCAPS CCC format 3, to state the activity state of this I3C when becoming controller after a controller-role hand-off, and consequently the time the former controller must wait before testing this I3C to be confirmed its ownership.
00: activity state 0 is the initial activity state of this I3C before and when becoming controller
01: activity state 1 is the initial activity state of this I3C when becoming controller
10: activity state 2 is the initial activity state of this I3C when becoming controller
11: activity state 3 is the initial activity state of this I3C when becoming controller
49.16.28 I3C extended provisioned ID register (I3C_EPIDR)

Address offset: 0xD4
Reset value: 0x0208 0000

When the I3C acts as target, this register is used to set the 4-bit MIPI instance ID by software, and some other constant bits used for the 48-bit provisioned ID. It is also used by hardware to return the six bytes for the 48-bit provisioned ID on reception of GETPID and ENTDAA CCC.

This register can be written by software only when EN = 0 in the I3C_CFGR register.

|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x000  | I3C_CR        | MEND | MTYPE[3:0] | MIPIMID[14:0] | IDTSEL | Bits 31:17 MIPIMID[14:0]: 15-bit MIPI manufacturer ID
This read field is the 15-bit STMicroelectronics MIPI ID (0x0104). This field represents bits[47:33] of the 48-bit provisioned ID.

Bit 16 IDTSEL: provisioned ID type selector
This field is set as 0 (vendor fixed value). This field represents bit[32] of the 48-bit provisioned ID.

Note: Bits[31:16] of the provisioned ID can be 0.

Bits 15:12 MIPIID[3:0]: 4-bit MIPI Instance ID
This field is written by software to set and identify individually each instance of this I3C IP with a specific number on a single I3C bus. This field represents bits[15:12] of the 48-bit provisioned ID.

Note: Bits[11:0] of the provisioned ID can be 0.

Bits 11:0 Reserved, must be kept at reset value.

49.16.29 I3C register map

Table 529. I3C register map and reset values
| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

50 Universal synchronous/asynchronous receiver transmitter (USART/UART)

This section describes the universal synchronous asynchronous receiver transmitter (USART/UART).

50.1 Introduction

The USART offers a flexible means to perform Full-duplex data exchange with external equipments requiring an industry standard NRZ asynchronous serial data format. A very wide range of baud rates can be achieved through a fractional baud rate generator.

The USART supports both synchronous one-way and Half-duplex Single-wire communications, as well as LIN (local interconnection network), Smartcard protocol, IrDA (infrared data association) SIR ENDEC specifications, and Modem operations (CTS/RTS). Multiprocessor communications are also supported.

High-speed data communications are possible by using the DMA (direct memory access) for multibuffer configuration.

50.2 USART main features

- Full-duplex asynchronous communication
- NRZ standard format (mark/space)
- Configurable oversampling method by 16 or 8 to achieve the best compromise between speed and clock tolerance
- Baud rate generator systems
- Two internal FIFOs for transmit and receive data
  Each FIFO can be enabled/disabled by software and come with a status flag.
- A common programmable transmit and receive baud rate
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK
- Auto baud rate detection
- Programmable data word length (7, 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Synchronous Master/Slave mode and clock output/input for synchronous communications
- SPI slave transmission underrun error flag
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
• Communication control/error detection flags
• Parity control:
  – Transmits parity bit
  – Checks parity of received data byte
• Interrupt sources with flags
• Multiprocessor communications: wake-up from Mute mode by idle line detection or address mark detection
• Wake-up from Stop mode

50.3 **USART extended features**
• LIN master synchronous break send capability and LIN slave break detection capability
  – 13-bit break generation and 10/11 bit break detection when USART is hardware configured for LIN
• IrDA SIR encoder decoder supporting 3/16 bit duration for Normal mode
• Smartcard mode
  – Supports the T=0 and T=1 asynchronous protocols for smartcards as defined in the ISO/IEC 7816-3 standard
  – 0.5 and 1.5 stop bits for Smartcard operation
• Support for Modbus communication
  – Timeout feature
  – CR/LF character recognition

50.4 **USART implementation**
The table below describe USART implementation. It also includes LPUART for comparison.

50.5 **USART functional description**

50.5.1 **USART block diagram**

![USART block diagram](image)

50.5.2 **USART pins and internal signals**

**Description USART input/output pins**

- **USART bidirectional communications**
  
  USART bidirectional communications require a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):
  
  - **RX** (Receive Data Input)
    
    RX is the serial data input. Oversampling techniques are used for data recovery. They discriminate between valid incoming data and noise.
  
  - **TX** (Transmit Data Output)
    
    When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and no data needs to be transmitted, the TX pin is High. In Single-wire and Smartcard modes, this I/O is used to transmit and receive data.
• RS232 Hardware flow control mode
  The following pins are required in RS232 Hardware flow control mode:
  – **CTS** (Clear To Send)
    When driven high, this signal blocks the data transmission at the end of the current transfer.
  – **RTS** (Request To Send)
    When it is low, this signal indicates that the USART is ready to receive data.

• RS485 Hardware control mode
  The **DE** (Driver Enable) pin is required in RS485 Hardware control mode. This signal activates the Transmission mode of the external transceiver.

• Synchronous Master/Slave mode and Smartcard mode
  The following pins are required in synchronous Master/Slave mode and Smartcard mode:
  – **CK**
    This pin acts as Clock output in Synchronous master and Smartcard modes.
    It acts as Clock input in Synchronous slave mode.
    In Synchronous master mode, this pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel, data can be received synchronously on RX pin. This mechanism can be used to control peripherals featuring shift registers (for example LCD drivers). The clock phase and polarity are software programmable.
    In Smartcard mode, CK output provides the clock to the smartcard.
  – **NSS**
    This pin acts as Slave Select input in Synchronous slave mode.

Refer to [*Table 532*](#) and [*Table 533*](#) for the list of USART input/output pins and internal signals.

</tbody>
</table>

50.5.3 USART clocks

The simplified block diagram given in Figure 674 shows two fully-independent clock domains:

- The **usart_pclk** clock domain
  
  The **usart_pclk** clock signal feeds the peripheral bus interface. It must be active when accesses to the USART registers are required.

- The **usart_ker_ck** kernel clock domain.
  
  The **usart_ker_ck** is the USART clock source. It is independent from **usart_pclk** and delivered by the RCC. The USART registers can consequently be written/read even when the **usart_ker_ck** clock is stopped.
  
  When the dual clock domain feature is not supported, the **usart_ker_ck** clock is the same as the **usart_pclk** clock.

There is no constraint between **usart_pclk** and **usart_ker_ck**: **usart_ker_ck** can be faster or slower than **usart_pclk**. The only limitation is the software ability to manage the communication fast enough.

When the USART operates in SPI slave mode, it handles data flow using the serial interface clock derived from the external CK signal provided by the external master SPI device. The **usart_ker_ck** clock must be at least 3 times faster than the clock on the CK input.

50.5.4 USART character description

The word length can be set to 7, 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the USART_CR1 register (see Figure 675):

- 7-bit character length: M[1:0] = 10
- 8-bit character length: M[1:0] = 00
- 9-bit character length: M[1:0] = 01

**Note:** In 7-bit data length mode, the Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.
An **Idle character** is interpreted as an entire frame of “1”s (the number of “1”s includes the number of stop bits).

A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clock are generated when the enable bit is set for the transmitter and receiver, respectively.

A detailed description of each block is given below.

** LBCL bit controls last data clock pulse
50.5.5 USART FIFOs and thresholds

The USART can operate in FIFO mode.

The USART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN in USART_CR1 register (bit 29). This mode is supported only in UART, SPI and Smartcard modes.

Since the maximum data word length is 9 bits, the TXFIFO is 9-bit wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

Note: The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR.

The status flags are available in the USART_ISR register.

It is possible to configure the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in USART_CR3 control register.

In this case:
- The Rx interrupt is generated when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields.
  
  In this case, the RXFT flag is set in the USART_ISR register. This means that RXFTCFG data have been received: 1 data in USART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to 101, the RXFT flag is set when a number of data corresponding to the FIFO size has been received (FIFO size -1 data in the RXFIFO and 1 data in the USART_RDR). As a result, the next received data does not set the overrun flag.

- The Tx interrupt is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bits fields.

50.5.6 USART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin while the corresponding clock pulses are output on the CK pin.

Character transmission

During an USART transmission, data shifts out the least significant bit first (default configuration) on the TX pin. In this mode, the USART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register.

When FIFO mode is enabled, the data written to the transmit data register (USART_TDR) are queued in the TXFIFO.

Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be configured to 0.5, 1, 1.5 or 2.
Note: The TE bit must be set before writing the data to be transmitted to the USART_TDR. The TE bit must not be reset during data transmission. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters get frozen. The current data being transmitted are then lost. An idle frame is sent when the TE bit is enabled.

Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in USART_CR2, bits 13,12.
- **1 stop bit**: This is the default value of number of stop bits.
- **2 stop bits**: This is supported by normal USART, Single-wire and Modem modes.
- **1.5 stop bits**: To be used in Smartcard mode.

An idle frame transmission includes the stop bits.

A break transmission is 10 low bits (when \(M[1:0] = 00\)) or 11 low bits (when \(M[1:0] = 01\)) or 9 low bits (when \(M[1:0] = 10\)) followed by 2 stop bits (see Figure 676). It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

![Figure 676. Configurable stop bits](image-url)

Character transmission procedure

To transmit a character, follow the sequence below:
1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the USART_BRR register.
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAT) in USART_CR3 if multibuffer communication must take place. Configure the DMA register as explained in Section 50.5.20: Continuous communication using USART and DMA.
6. Set the TE bit in USART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART_TDR register. Repeat this for each data to be transmitted in case of single buffer.
   – When FIFO mode is disabled, writing a data to the USART_TDR clears the TXE flag.
   – When FIFO mode is enabled, writing a data to the USART_TDR adds one data to the TXFIFO. Write operations to the USART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.

8. When the last data is written to the USART_TDR register, wait until TC=1.
   – When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
   – When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.
This check is required to avoid corrupting the last transmission when the USART is disabled or enters Halt mode.

Single byte communication

• When FIFO mode is disabled
  Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware. It indicates that:
  – the data have been moved from the USART_TDR register to the shift register and the data transmission has started;
  – the USART_TDR register is empty;
  – the next data can be written to the USART_TDR register without overwriting the previous data.
This flag generates an interrupt if the TXEIE bit is set.
  When a transmission is ongoing, a write instruction to the USART_TDR register stores the data in the TDR buffer. It is then copied in the shift register at the end of the current transmission.
  When no transmission is ongoing, a write instruction to the USART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

• When FIFO mode is enabled, the TXFNF (TXFIFO not full) flag is set by hardware to indicate that:
  – the TXFIFO is not full;
  – the USART_TDR register is empty;
  – the next data can be written to the USART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the USART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.
When the TXFIFO is not full, the TXFNF flag stays at 1 even after a write operation to USART_TDR register. It is cleared when the TXFIFO is full. This flag generates an interrupt if the TXFNFIE bit is set.
Alternatively, interrupts can be generated and data can be written to the FIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed trigger level.
If a frame is transmitted (after the stop bit) and the TXE flag (TXFE in case of FIFO mode) is set, the TC flag goes high. An interrupt is generated if the TCIE bit is set in the USART_CR1 register.
After writing the last data to the USART_TDR register, it is mandatory to wait until TC is set before disabling the USART or causing the microcontroller to enter the low-power mode (see Figure 677: TC/TXE behavior when transmitting).

Figure 677. TC/TXE behavior when transmitting

Note: When FIFO management is enabled, the TXFNF flag is used for data transmission.

Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bit (see Figure 675).

If a 1 is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The USART inserts a logic 1 signal (stop) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

Idle characters

Setting the TE bit drives the USART to send an idle frame before the first data frame.

50.5.7 USART receiver

The USART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the USART_CR1 register.

Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8.
In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0X 0 X 0X 0.

Figure 678. Start bit detection when oversampling by 16 or 8

Note: If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.

The start bit is confirmed (RXNE flag set and interrupt generated if RXNEIE=1, or RXFNE flag set and interrupt generated if RXFNEIE=1 if FIFO mode enabled) if the 3 sampled bits are at 0 (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at 0 and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at 0).

The start bit is validated but the NE noise flag is set if,
   a) for both samplings, 2 out of the 3 sampled bits are at 0 (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits)
   or
   b) for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at 0.

If neither of the above conditions are met, the start detection aborts and the receiver returns to the idle state (no flag is set).
Character reception

During an USART reception, data are shifted out least significant bit first (default configuration) through the RX pin.

Character reception procedure

To receive a character, follow the sequence below:

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register USART_BRR
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAR) in USART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in Section 50.5.20: Continuous communication using USART and DMA.
6. Set the RE bit USART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received:

- When FIFO mode is disabled, the RXNE bit is set to indicate that the content of the shift register is transferred to the RDR. In other words, data have been received and can be read (as well as their associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set to indicate that the RXFIFO is not empty. Reading the USART_RDR returns the oldest data entered in the RXFIFO. When a data is received, it is stored in the RXFIFO together with the corresponding error bits.
- An interrupt is generated if the RXNEIE (RXFNEIE when FIFO mode is enabled) bit is set.
- The error flags can be set if a frame error, noise, parity or an overrun error was detected during reception.
- In Multibuffer communication mode:
  - When FIFO mode is disabled, the RXNE flag is set after every byte reception. It is cleared when the DMA reads the Receive data Register.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. A DMA request is triggered when the RXFIFO is not empty i.e. when there are data to be read from the RXFIFO.
- In Single-buffer mode:
  - When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the USART_RDR register. The RXNE flag can also be cleared by programming RXFRQ bit to 1 in the USART_RQR register. The RXNE flag must be cleared before the end of the reception of the next character to avoid an overrun error.
  - When FIFO mode is enabled, the RXFNE is set when the RXFIFO is not empty. After every read operation from USART_RDR, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by programming RXFRQ bit to 1 in USART_RQR. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character, to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set. Alternatively, interrupts can be
generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

**Break character**

When a break character is received, the USART handles it as a framing error.

**Idle character**

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.

**Overrun error**

- **FIFO mode disabled**
  
  An overrun error occurs if a character is received and RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte reception. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:
  - the ORE bit is set;
  - the RDR content is not lost. The previous data is available by reading the USART_RDR register.
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXNEIE or the EIE bit is set.

- **FIFO mode enabled**
  
  An overrun error occurs when the shift register is ready to be transferred and the receive FIFO is full. Data can not be transferred from the shift register to the USART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty. An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:
  - The ORE bit is set.
  - The first entry in the RXFIFO is not lost. It is available by reading the USART_RDR register.
  - The shift register is overwritten. After that point, any data received during overrun is lost.
  - An interrupt is generated if either the RXFNEIE or EIE bit is set.

The ORE bit is reset by setting the ORECFF bit in the USART_ICR register.

*Note:* The ORE bit, when set, indicates that at least 1 data has been lost.

When the FIFO mode is disabled, there are two possibilities

- if RXNE=1, then the last valid data is stored in the receive register (RDR) and can be read,
- if RXNE=0, the last valid data has already been read and there is nothing left to be read in the RDR register. This case can occur when the last valid data is read in the RDR register at the same time as the new (and lost) data is received.
Selecting the clock source and the appropriate oversampling method

The choice of the clock source is done through the Clock Control system (see Section: Reset and Clock Control (RCC)). The clock source must be selected through the UE bit before enabling the USART.

The clock source must be selected according to two criteria:

- Possible use of the USART in low-power mode
- Communication speed.

The clock source frequency is usart_ker_ck.

When the dual clock domain and the wake-up from low-power mode features are supported, the usart_ker_ck clock source can be configurable in the RCC (see Section: Reset and Clock Control (RCC)). Otherwise the usart_ker_ck clock is the same as usart_pclk.

The usart_ker_ck clock can be divided by a programmable factor, defined in the USART_PRES register.

Some usart_ker_ck sources enable the USART to receive data while the MCU is in low-power mode. Depending on the received data and wake-up mode selected, the USART wakes up the MCU, when needed, in order to transfer the received data, by performing a software read to the USART_RDR register or by DMA.

For the other clock sources, the system must be active to enable USART communications.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver implements different user-configurable oversampling techniques (except in Synchronous mode) for data recovery by discriminating between valid incoming data and noise. This enables obtaining the best a trade-off between the maximum communication speed and noise/clock inaccuracy immunity.

The oversampling method can be selected by programming the OVER8 bit in the USART_CR1 register either to 16 or 8 times the baud rate clock (see Figure 680 and Figure 681).

Depending on the application:

- select oversampling by 8 (OVER8=1) to achieve higher speed (up to usart_ker_ck_pres/8). In this case the maximum receiver tolerance to clock deviation is reduced (refer to Section 50.5.9: Tolerance of the USART receiver to clock deviation on page 2248)
- select oversampling by 16 (OVER8=0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum
usr

The majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NE bit is set.

• A single sample in the center of the received bit

Depending on the application:

– select the three sample majority vote method (ONEBIT=0) when operating in a noisy environment and reject the data when a noise is detected (refer to Table 534) because this indicates that a glitch occurred during the sampling.

– select the single sample method (ONEBIT=1) when the line is noise-free to increase the receiver tolerance to clock deviations (see Section 50.5.9: Tolerance of the USART receiver to clock deviation on page 2248). In this case the NE bit is never set.

When noise is detected in a frame:

• The NE bit is set at the rising edge of the RXNE bit (RXFNE in case of FIFO mode enabled).

• The invalid data is transferred from the Shift register to the USART_RDR register.

• No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case of FIFO mode enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The NE bit is reset by setting NFCF bit in ICR register.

Note: Noise error is not supported in SPI mode.

Oversampling by 8 is not available in the Smartcard, IrDA and LIN modes. In those modes, the OVER8 bit is forced to 0 by hardware.

Figure 680. Data sampling when oversampling by 16
Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:

- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the USART_RDR register (RXFIFO in case FIFO mode is enabled).
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case FIFO mode is enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The FE bit is reset by writing 1 to the FECF in the USART_ICR register.

Note: Framing error is not supported in SPI mode.
Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of USART_CR: it can be either 1 or 2 in Normal mode and 0.5 or 1.5 in Smartcard mode.

- **0.5 stop bit (reception in Smartcard mode):** no sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.
- **1 stop bit:** sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- **1.5 stop bits (Smartcard mode)**
  When transmitting in Smartcard mode, the device must check that the data are correctly sent. The receiver block must consequently be enabled (RE =1 in USART_CR1) and the stop bit is checked to test if the Smartcard has detected a parity error.
  
  In the event of a parity error, the Smartcard forces the data signal low during the sampling (NACK signal), which is flagged as a framing error. The FE flag is then set through RXNE flag (RXFNE if the FIFO mode is enabled) at the end of the 1.5 stop bit. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bit can be broken into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through (refer to Section 50.5.17: USART receiver timeout on page 2261 for more details).
  
  - **2 stop bits**
    Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. The framing error flag is set if a framing error is detected during the first stop bit. The second stop bit is not checked for framing error. The RXNE flag (RXFNE if the FIFO mode is enabled) is set at the end of the first stop bit.

**50.5.8 USART baud rate generation**

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the USART_BRR register.

**Equation 1: baud rate for standard USART (SPI mode included) (OVER8 = 0 or 1)**

In case of oversampling by 16, the baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{\text{usart_ker_ck_pres}}{\text{USARTDIV}}
\]

In case of oversampling by 8, the baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{2 \times \text{usart_ker_ck_pres}}{\text{USARTDIV}}
\]

**Equation 2: baud rate in Smartcard, LIN and IrDA modes (OVER8 = 0)**

The baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{\text{usart_ker_ck_pres}}{\text{USARTDIV}}
\]
USARTDIV is an unsigned fixed point number that is coded on the USART_BRR register.

- When $\text{OVER8} = 0$, $\text{BRR} = \text{USARTDIV}$.
- When $\text{OVER8} = 1$
  - $\text{BRR}[2:0] = \text{USARTDIV}[3:0]$ shifted 1 bit to the right.
  - $\text{BRR}[3]$ must be kept cleared.
  - $\text{BRR}[15:4] = \text{USARTDIV}[15:4]$

**Note:** The baud counters are updated to the new value in the baud registers after a write operation to USART_BRR. Hence the baud rate register value must not be changed during communication.

*In case of oversampling by 16 and 8, USARTDIV must be greater than or equal to 16.*

**How to derive USARTDIV from USART_BRR register values**

**Example 1**
To obtain 9600 bauds with $\text{usart\_ker\_ck\_pres} = 8$ MHz:

- In case of oversampling by 16:
  - $\text{USARTDIV} = 8\,000\,000/9600$
  - $\text{BRR} = \text{USARTDIV} = 0\text{d}833 = 0x0341$

- In case of oversampling by 8:
  - $\text{USARTDIV} = 2 \times 8\,000\,000/9600$
  - $\text{USARTDIV} = 1666.66$ (0d1667 = 0x683)
  - $\text{BRR}[3:0] = 0x3 >> 1 = 0x1$
  - $\text{BRR} = 0x681$

**Example 2**
To obtain 921.6 kbauds with $\text{usart\_ker\_ck\_pres} = 48$ MHz:

- In case of oversampling by 16:
  - $\text{USARTDIV} = 48\,000\,000/921\,600$
  - $\text{BRR} = \text{USARTDIV} = 0\text{x}52 = 0x34$

- In case of oversampling by 8:
  - $\text{USARTDIV} = 2 \times 48\,000\,000/921\,600$
  - $\text{USARTDIV} = 104$ (0d104 = 0x68)
  - $\text{BRR}[3:0] = \text{USARTDIV}[3:0] >> 1 = 0x8 >> 1 = 0x4$
  - $\text{BRR} = 0x64$
50.5.9 Tolerance of the USART receiver to clock deviation

The USART asynchronous receiver operates correctly only if the total clock system deviation is less than the tolerance of the USART receiver.

The causes which contribute to the total deviation are:

- DTRA: deviation due to the transmitter error (which also includes the deviation of the transmitter’s local oscillator)
- DQUANT: error due to the baud rate quantization of the receiver
- DREC: deviation of the receiver local oscillator
- DTCL: deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[ \text{DTRA} + \text{DQUANT} + \text{DREC} + \text{DTCL} + \text{DWU} < \text{USART receiver tolerance} \]

where

- DWU is the error due to sampling point deviation when the wake-up from low-power mode is used.

when \( M[1:0] = 01 \):

\[ \text{DWU} = \frac{t_{\text{WUUSART}}}{11 \times \text{Tbit}} \]

when \( M[1:0] = 00 \):

\[ \text{DWU} = \frac{t_{\text{WUUSART}}}{10 \times \text{Tbit}} \]

when \( M[1:0] = 10 \):

\[ \text{DWU} = \frac{t_{\text{WUUSART}}}{9 \times \text{Tbit}} \]

\( t_{\text{WUUSART}} \) is the time between the detection of the start bit falling edge and the instant when the clock (requested by the peripheral) is ready and reaching the peripheral, and the regulator is ready.

The USART receiver can receive data correctly at up to the maximum tolerated deviation specified in Table 535, Table 536, depending on the following settings:

- 9-, 10- or 11-bit character length defined by the M bits in the USART_CR1 register
- Oversampling by 8 or 16 defined by the OVER8 bit in the USART_CR1 register
- Bits BRR[3:0] of USART_BRR register are equal to or different from 0000.
- Use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART_CR3 register.
Note: The data specified in Table 535 and Table 536 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = 00 (11-bit times when M= 01 or 9-bit times when M = 10).

### 50.5.10 USART auto baud rate detection

The USART can detect and automatically set the USART_BRR register value based on the reception of one character. Automatic baud rate detection is useful under two circumstances:

- The communication speed of the system is not known in advance.
- The system is using a relatively low accuracy clock source and this mechanism enables the correct baud rate to be obtained without measuring the clock deviation.

The clock source frequency must be compatible with the expected communication speed.

- When oversampling by 16, the baud rate ranges from `usart_ker_ck_pres/65535` and `usart_ker_ck_pres/16`.
- When oversampling by 8, the baud rate ranges from `usart_ker_ck_pres/65535` and `usart_ker_ck_pres/8`.

Before activating the auto baud rate detection, the auto baud rate detection mode must be selected through the ABRMOD[1:0] field in the USART_CR2 register. There are four modes based on different character patterns. In these auto baud rate modes, the baud rate is measured several times during the synchronization data reception and each measurement is compared to the previous one.
These modes are the following:

- **Mode 0**: Any character starting with a bit at 1.
  In this case the USART measures the duration of the start bit (falling edge to rising edge).

- **Mode 1**: Any character starting with a 10xx bit pattern.
  In this case, the USART measures the duration of the Start and of the 1st data bit. The measurement is done falling edge to falling edge, to ensure a better accuracy in the case of slow signal slopes.

- **Mode 2**: A 0x7F character frame (it may be a 0x7F character in LSB first mode or a 0xFE in MSB first mode).
  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 6 (based on the measurement done from falling edge to falling edge: BR6). Bit0 to bit6 are sampled at BRs while further bits of the character are sampled at BR6.

- **Mode 3**: A 0x55 character frame.
  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 0 (based on the measurement done from falling edge to falling edge: BR0), and finally at the end of bit 6 (BR6). Bit 0 is sampled at BRs, bit 1 to bit 6 are sampled at BR0, and further bits of the character are sampled at BR6. In parallel, another check is performed for each intermediate RX line transition. An error is generated if the transitions on RX are not sufficiently synchronized with the receiver (the receiver being based on the baud rate calculated on bit 0).

Prior to activating the auto baud rate detection, the USART_BRR register must be initialized by writing a non-zero baud rate value.

The automatic baud rate detection is activated by setting the ABREN bit in the USART_CR2 register. The USART then waits for the first character on the RX line. The auto baud rate operation completion is indicated by the setting of the ABRF flag in the USART_ISR register. If the line is noisy, the correct baud rate detection cannot be guaranteed. In this case the BRR value may be corrupted and the ABRE error flag is set. This also happens if the communication speed is not compatible with the automatic baud rate detection range (bit duration not between 16 and 65536 clock periods (oversampling by 16) and not between 8 and 65536 clock periods (oversampling by 8)).

The auto baud rate detection can be re-launched later by resetting the ABRF flag (by writing a 0). When FIFO management is disabled and an auto baud rate error occurs, the ABRE flag is set through RXNE and FE bits.

When FIFO management is enabled and an auto baud rate error occurs, the ABRE flag is set through RXFNE and FE bits.

If the FIFO mode is enabled, the auto baud rate detection must be made using the data on the first RXFIFO location. So, prior to launching the auto baud rate detection, make sure that the RXFIFO is empty by checking the RXFNE flag in USART_ISR register.

*Note:* The BRR value might be corrupted if the USART is disabled (UE=0) during an auto baud rate operation.
**50.5.11 USART multiprocessor communication**

It is possible to perform USART multiprocessor communications (with several USARTs connected in a network). For instance one of the USARTs can be the master with its TX output connected to the RX inputs of the other USARTs, while the others are slaves with their respective TX outputs logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations, it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non-addressed devices can be placed in Mute mode by means of the muting function. To use the Mute mode feature, the MME bit must be set in the USART_CR1 register.

*Note:* When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two usart_ker_ck cycles), otherwise Mute mode might remain active.

When the Mute mode is enabled:
- none of the reception status bits can be set;
- all the receive interrupts are inhibited;
- the RWU bit in USART_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the USART_RQR register, under certain conditions.

The USART can enter or exit from Mute mode using one of two methods, depending on the WAKE bit in the USART_CR1 register:
- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

**Idle line detection (WAKE=0)**

The USART enters Mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

The USART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the USART_ISR register. An example of Mute mode behavior using Idle line detection is given in *Figure 682.*
Figure 682. Mute mode using Idle line detection

Note: If the MMRQ is set while the IDLE character has already elapsed, Mute mode is not entered (RWU is not set).
If the USART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

4-bit/7-bit address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a 1, otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART_CR2 register.

Note: In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The USART enters Mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the USART enters Mute mode. When FIFO management is enabled, the software must ensure that there is at least one empty location in the RXFIFO before entering Mute mode.

The USART also enters Mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The USART exits from Mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: When FIFO management is enabled, when MMRQ is set while the receiver is sampling last bit of a data, this data may be received before effectively entering in Mute mode

An example of Mute mode behavior using address mark detection is given in Figure 683.
50.5.12 USART Modbus communication

The USART offers basic support for the implementation of Modbus/RTU and Modbus/ASCII protocols. Modbus/RTU is a Half-duplex, block-transfer protocol. The control part of the protocol (address recognition, block integrity control and command interpretation) must be implemented in software.

The USART offers basic support for the end of the block detection, without software overhead or other resources.

Modbus/RTU

In this mode, the end of one block is recognized by a “silence” (idle line) for more than 2 character times. This function is implemented through the programmable timeout function.

The timeout function and interrupt must be activated, through the RTOEN bit in the USART_CR2 register and the RTOIE in the USART_CR1 register. The value corresponding to a timeout of 2 character times (for example 22 x bit time) must be programmed in the RTO register. When the receive line is idle for this duration, after the last stop bit is received, an interrupt is generated, informing the software that the current block reception is completed.

Modbus/ASCII

In this mode, the end of a block is recognized by a specific (CR/LF) character sequence. The USART manages this mechanism using the character match function.

By programming the LF ASCII code in the ADD[7:0] field and by activating the character match interrupt (CMIE = 1), the software is informed when a LF has been received and can check the CR/LF in the DMA buffer.
50.5.13 USART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART_CR1 register. Depending on the frame length defined by the M bits, the possible USART frame formats are as listed in Table 537.

1. Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).

Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit is equal to 0 if even parity is selected (PS bit in USART_CR1 = 0).

Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit is equal to 1 if odd parity is selected (PS bit in USART_CR1 = 1).

Parity checking in reception

If the parity check fails, the PE flag is set in the USART_ISR register and an interrupt is generated if PEIE is set in the USART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the USART_ICR register.

Parity generation in transmission

If the PCE bit is set in USART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).
50.5.14 USART LIN (local interconnection network) mode

This section is relevant only when LIN mode is supported. Refer to Section 50.4: USART implementation on page 2229.

The LIN mode is selected by setting the LINEN bit in the USART_CR2 register. In LIN mode, the following bits must be kept cleared:
- CLKEN in the USART_CR2 register,
- STOP[1:0], SCEN, HDSEL and IREN in the USART_CR3 register.

LIN transmission

The procedure described in Section 50.5.5 has to be applied for LIN Master transmission. It must be the same as for normal USART transmission with the following differences:
- Clear the M bit to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBKRQ bit sends 13 zero bits as a break character. Then 2 bits of value ‘1’ are sent to enable the next start detection.

LIN reception

When LIN mode is enabled, the break detection circuit is activated. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE=1 in USART_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART_CR2) or 11 (when LBDL=1 in USART_CR2) consecutive bits are detected as 0, and are followed by a delimiter character, the LBDF flag is set in USART_ISR. If the LBDIE bit=1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a ‘1’ is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN=0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN=1), as soon as a framing error occurs (i.e. stop bit detected at 0, which is the case for any break frame), the receiver stops until the break detection circuit receives either a ‘1’, if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown on the Figure 684: Break detection in LIN mode (11-bit break length - LBDL bit is set) on page 2256.

Examples of break frames are given on Figure 685: Break detection in LIN mode vs. Framing error detection on page 2257.

50.5.15 **USART synchronous mode**

**Master mode**

The Synchronous master mode is selected by programming the CLKEN bit in the USART_CR2 register to 1. In Synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in Master mode. The CK pin is the output of the USART transmitter clock. No clock pulses are sent to the CK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART_CR2 register, clock pulses are, or are not, generated during the last valid data bit (address mark). The CPOL bit in the USART_CR2 register is used to select the clock polarity, and the CPHA bit in the USART_CR2 register is used to select the phase of the external clock (see Figure 686, Figure 687 and Figure 688).

During the Idle state, preamble and send break, the external CK clock is not activated.

In Synchronous master mode, the USART transmitter operates exactly like in Asynchronous mode. However, since CK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In Synchronous master mode, the USART receiver operates in a different way compared to Asynchronous mode. If RE is set to 1, the data are sampled on CK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A given setup and a hold time must be respected (which depends on the baud rate: 1/16 bit time).
Note: In Master mode, the CK pin operates in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE=1) and data are being transmitted (USART_TDR data register written). This means that it is not possible to receive synchronous data without transmitting data.

Figure 686. USART example of synchronous master transmission

Figure 687. USART data clock timing diagram in Synchronous master mode (M bits =00)
Figure 688. USART data clock timing diagram in Synchronous master mode (M bits = 01)

Slave mode

The Synchronous slave mode is selected by programming the SLVEN bit in the USART_CR2 register to 1. In Synchronous slave mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in Slave mode. The CK pin is the input of the USART in Slave mode.

Note: When the peripheral is used in SPI slave mode, the frequency of peripheral clock source (usart_ker_ck_pres) must be greater than 3 times the CK input frequency.

The CPOL bit and the CPHA bit in the USART_CR2 register are used to select the clock polarity and the phase of the external clock, respectively (see Figure 689).

An underrun error flag is available in Slave transmission mode. This flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value to USART_TDR.

The slave supports the hardware and software NSS management.
Slave Select (NSS) pin management

The hardware or software slave select management can be set through the DIS_NSS bit in the USART_CR2 register:

- Software NSS management (DIS_NSS = 1)
  SPI slave is always selected and NSS input pin is ignored.
  The external NSS pin remains free for other application uses.

- Hardware NSS management (DIS_NSS = 0)
  The SPI slave selection depends on NSS input pin. The slave is selected when NSS is low and deselected when NSS is high.

Note: The LBCL (used only on SPI master mode), CPOL and CPHA bits have to be selected when the USART is disabled (UE=0) to ensure that the clock pulses function correctly.

In SPI slave mode, the USART must be enabled before starting the master communications (or between frames while the clock is stable). Otherwise, if the USART slave is enabled while the master is in the middle of a frame, it becomes desynchronized with the master.

The data register of the slave needs to be ready before the first edge of the communication clock or before the end of the ongoing communication, otherwise the SPI slave transmits zeros.

SPI Slave underrun error

When an underrun error occurs, the UDR flag is set in the USART_ISR register, and the SPI slave goes on sending the last data until the underrun error flag is cleared by software.

The underrun flag is set at the beginning of the frame. An underrun error interrupt is triggered if EIE bit is set in the USART_CR3 register.

The underrun error flag is cleared by setting bit UDRCF in the USART_ICR register.
In case of underrun error, it is still possible to write to the TDR register. Clearing the underrun error enables sending new data.

If an underrun error occurred and there is no new data written in TDR, then the TC flag is set at the end of the frame.

**Note:** An underrun error may occur if the moment the data is written to the USART_TDR is too close to the first CK transmission edge. To avoid this underrun error, the USART_TDR must be written 3 usec before the first CK edge.

### 50.5.16 USART single-wire Half-duplex communication

Single-wire Half-duplex mode is selected by setting the HDSEL bit in the USART_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN and IREN bits in the USART_CR3 register.

The USART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in USART_CR3.

As soon as HDSEL is written to 1:

- The TX and RX lines are internally connected.
- The RX pin is no longer used.
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal USART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data are written in the data register while the TE bit is set.

### 50.5.17 USART receiver timeout

The receiver timeout feature is enabled by setting the RTOEN bit in the USART_CR2 control register.

The timeout duration is programmed using the RTO bitfields in the USART_RTOR register.

The receiver timeout counter starts counting:

- from the end of the stop bit if STOP = 00 or STOP = 11
- from the end of the second stop bit if STOP = 10.
- from the beginning of the stop bit if STOP = 01.

When the timeout duration has elapsed, the RTOF flag in the USART_ISR register is set. A timeout is generated if RTOIE bit in USART_CR1 register is set.
50.5.18 USART Smartcard mode

This section is relevant only when Smartcard mode is supported. Refer to Section 50.4: USART implementation on page 2229.

Smartcard mode is selected by setting the SCEN bit in the USART_CR3 register. In Smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- HDSEL and IREN bits in the USART_CR3 register.

The CLKEN bit can also be set to provide a clock to the Smartcard.

The Smartcard interface is designed to support asynchronous Smartcard protocol as defined in the ISO 7816-3 standard. Both T=0 (character mode) and T=1 (block mode) are supported.

The USART must be configured as:

- 8 bits plus parity: M=1 and PCE=1 in the USART_CR1 register
- 1.5 stop bits when transmitting and receiving data: STOP=11 in the USART_CR2 register. It is also possible to choose 0.5 stop bit for reception.

In T=0 (character) mode, the parity error is indicated at the end of each character during the guard time period.

Figure 690 shows examples of what can be seen on the data line with and without parity error.

![Figure 690. ISO 7816-3 asynchronous protocol](image)

When connected to a Smartcard, the TX output of the USART drives a bidirectional line that is also driven by the Smartcard. The TX pin must be configured as open drain.

Smartcard mode implements a single wire half duplex communication protocol.

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register starts shifting on the next baud clock edge. In Smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.

- In transmission, if the Smartcard detects a parity error, it signals this condition to the USART by driving the line low (NACK). This NACK signal (pulling transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The USART can handle automatic re-sending of data according to the protocol.
The number of retries is programmed in the SCARCNT bitfield. If the USART continues receiving the NACK after the programmed number of retries, it stops transmitting and signals the error as a framing error. The TXE bit (TXFNF bit in case FIFO mode is enabled) may be set using the TXFRQ bit in the USART_RQR register.

- Smartcard auto-retry in transmission: A delay of 2.5 baud periods is inserted between the NACK detection by the USART and the start bit of the repeated character. The TC bit is set immediately at the end of reception of the last repeated character (no guardtime). If the software wants to repeat it again, it must insure the minimum 2 baud periods required by the standard.

- If a parity error is detected during reception of a frame programmed with a 1.5 stop bit period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the Smartcard that the data transmitted to the USART has not been correctly received. A parity error is NACKed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted (to be used in T=1 mode). If the received character is erroneous, the RXNE (RXFNE in case FIFO mode is enabled)/receive DMA request is not activated. According to the protocol specification, the Smartcard must resend the same character. If the received character is still erroneous after the maximum number of retries specified in the SCARCNT bitfield, the USART stops transmitting the NACK and signals the error as a parity error.

- Smartcard auto-retry in reception: the BUSY flag remains set if the USART NACKs the card but the card doesn’t repeat the character.

- In transmission, the USART inserts the Guard Time (as programmed in the Guard Time register) between two successive characters. As the Guard Time is measured after the stop bit of the previous character, the GT[7:0] register must be programmed to the desired CGT (Character Guard Time, as defined by the 7816-3 specification) minus 12 (the duration of one character).

- The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In Smartcard mode an empty transmit shift register triggers the Guard Time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the Guard Time counter reaches the programmed value TC is asserted high. The TCBGT flag can be used to detect the end of data transfer without waiting for guard time completion. This flag is set just after the end of frame transmission and if no NACK has been received from the card.

- The de-assertion of TC flag is unaffected by Smartcard mode.

- If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK is not detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.

- On the receiver side, if a parity error is detected and a NACK is transmitted the receiver does not detect the NACK as a start bit.

Note: Break characters are not significant in Smartcard mode. A 0x00 data with a framing error is treated as data and not as a break.

No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.

Figure 691 shows how the NACK signal is sampled by the USART. In this example the USART is transmitting data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.
The USART can provide a clock to the Smartcard through the CK output. In Smartcard mode, CK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the USART_GTPR register. CK frequency can be programmed from usart_ker_ck_pres/2 to usart_ker_ck_pres/62, where usart_ker_ck_pres is the peripheral input clock divided by a programmed prescaler.

**Block mode (T=1)**

In T=1 (block) mode, the parity error transmission can be deactivated by clearing the NACK bit in the UART_CR3 register.

When requesting a read from the Smartcard, in block mode, the software must program the RTOR register to the BWT (block wait time) - 11 value. If no answer is received from the card before the expiration of this period, a timeout interrupt is generated. If the first character is received before the expiration of the period, it is signaled by the RXNE/RXFNE interrupt.

**Note:** The RXNE/RXFNE interrupt must be enabled even when using the USART in DMA mode to read from the Smartcard in block mode. In parallel, the DMA must be enabled only after the first received byte.

After the reception of the first character (RXNE/RXFNE interrupt), the RTO register must be programmed to the CWT (character wait time -11 value), in order to enable the automatic check of the maximum wait time between two consecutive characters. This time is expressed in baud time units. If the Smartcard does not send a new character in less than the CWT period after the end of the previous character, the USART signals it to the software through the RTOF flag and interrupt (when RTOIE bit is set).

**Note:** As in the Smartcard protocol definition, the BWT/CWT values must be defined from the beginning (start bit) of the last character. The RTO register must be programmed to BWT -11 or CWT -11, respectively, taking into account the length of the last character itself.

A block length counter is used to count all the characters received by the USART. This counter is reset when the USART is transmitting. The length of the block is communicated by the Smartcard in the third byte of the block (prologue field). This value must be programmed to the BLEN field in the USART_RTOR register. When using DMA mode, before the start of the block, this register field must be programmed to the minimum value.
(0x0). With this value, an interrupt is generated after the 4th received character. The software must read the LEN field (third byte), its value must be read from the receive buffer.

In interrupt driven receive mode, the length of the block may be checked by software or by programming the BLEN value. However, before the start of the block, the maximum value of BLEN (0xFF) may be programmed. The real value is programmed after the reception of the third character.

If the block is using the LRC longitudinal redundancy check (1 epilogue byte), the BLEN=LEN. If the block is using the CRC mechanism (2 epilog bytes), BLEN=LEN+1 must be programmed. The total block length (including prologue, epilogue and information fields) equals BLEN+4. The end of the block is signaled to the software through the EOBF flag and interrupt (when EOBIE bit is set).

In case of an error in the block length, the end of the block is signaled by the RTO interrupt (Character Wait Time overflow).

Note: The error checking code (LRC/CRC) must be computed/verified by software.

Direct and inverse convention

The Smartcard protocol defines two conventions: direct and inverse.

The direct convention is defined as: LSB first, logical bit value of 1 corresponds to a H state of the line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=0, DATAINV=0 (default values).

The inverse convention is defined as: MSB first, logical bit value 1 corresponds to an L state on the signal line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=1, DATAINV=1.

Note: When logical data values are inverted (0=H, 1=L), the parity bit is also inverted in the same way.

In order to recognize the card convention, the card sends the initial character, TS, as the first character of the ATR (Answer To Reset) frame. The two possible patterns for the TS are: LHHL LLL LLH and LHHL HHH LLH.

- (H) LHHL LLL LLH sets up the inverse convention: state L encodes value 1 and moment 2 conveys the most significant bit (MSB first). When decoded by inverse convention, the conveyed byte is equal to ‘3F’.
- (H) LHHL HHH LLH sets up the direct convention: state H encodes value 1 and moment 2 conveys the least significant bit (LSB first). When decoded by direct convention, the conveyed byte is equal to ‘3B’.

Character parity is correct when there is an even number of bits set to 1 in the nine moments 2 to 10.

As the USART does not know which convention is used by the card, it needs to be able to recognize either pattern and act accordingly. The pattern recognition is not done in hardware, but through a software sequence. Moreover, supposing that the USART is configured in direct convention (default) and the card answers with the inverse convention, TS = LHHL LLL LLH => the USART received character is equal to 03 and the parity is odd.
Therefore, two methods are available for TS pattern recognition:

**Method 1**
The USART is programmed in standard Smartcard mode/direct convention. In this case, the TS pattern reception generates a parity error interrupt and error signal to the card.
- The parity error interrupt informs the software that the card did not answer correctly in direct convention. Software then reprograms the USART for inverse convention
- In response to the error signal, the card retries the same TS character, and it is correctly received this time, by the reprogrammed USART

Alternatively, in answer to the parity error interrupt, the software may decide to reprogram the USART and to also generate a new reset command to the card, then wait again for the TS.

**Method 2**
The USART is programmed in 9-bit/no-parity mode, no bit inversion. In this mode it receives any of the two TS patterns as:
- (H) LHHL LLL LLH = 0x103 -> inverse convention to be chosen
- (H) LHHL HHH LLH = 0x13B -> direct convention to be chosen

The software checks the received character against these two patterns and, if any of them match, then programs the USART accordingly for the next character reception.

If none of the two is recognized, a card reset may be generated in order to restart the negotiation.

### 50.5.19 USART IrDA SIR ENDEC block

This section is relevant only when IrDA mode is supported. Refer to *Section 50.4: USART implementation on page 2229*.

IrDA mode is selected by setting the IREN bit in the USART_CR3 register. In IrDA mode, the following bits must be kept cleared:
- LINEN, STOP and CLKEN bits in the USART_CR2 register,
- SCEN and HDSEL bits in the USART_CR3 register.

The IrDA SIR physical layer specifies use of a Return to Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see *Figure 692*).

The SIR Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only bit rates up to 115.2 kbauds for the SIR ENDEC. In Normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to the USART. The decoder input is normally high (marking state) in the Idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.
- IrDA is a half duplex communication protocol. If the Transmitter is busy (when the USART is sending data to the IrDA encoder), any data on the IrDA receive line is ignored by the IrDA decoder and if the Receiver is busy (when the USART is receiving decoded data from the USART), data on the TX from the USART to IrDA is not
encoded. While receiving data, transmission must be avoided as the data to be transmitted may be corrupted.

- A 0 is transmitted as a high pulse and a 1 is transmitted as a 0. The width of the pulse is specified as 3/16th of the selected bit period in Normal mode (see Figure 693).
- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.
- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.
- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.
- The IrDA specification requires the acceptance of pulses greater than 1.41 µs. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the USART_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than 2 periods are accepted as a pulse. The IrDA encoder/decoder doesn't work when PSC=0.
- The receiver can communicate with a low-power transmitter.
- In IrDA mode, the stop bits in the USART_CR2 register must be configured to ‘1 stop bit’.

**IrDA low-power mode**

- **Transmitter**
  In low-power mode, the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz. Generally, this value is 1.8432 MHz (1.42 MHz < PSC< 2.12 MHz). A low-power mode programmable divisor divides the system clock to achieve this value.

- **Receiver**
  Receiving in low-power mode is similar to receiving in Normal mode. For glitch detection the USART must discard pulses of duration shorter than 1/PSC. A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power baud clock (PSC value in the USART_GTPR).

**Note:**
A pulse of width less than two and greater than one PSC period(s) may or may not be rejected.

The receiver set up time must be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half duplex protocol).
Figure 692. IrDA SIR ENDEC block diagram

Figure 693. IrDA data modulation (3/16) - Normal mode
50.5.20 Continuous communication using USART and DMA

The USART is capable of performing continuous communications using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

Note: Refer to Section 50.4: USART implementation on page 2229 to determine if the DMA mode is supported. If DMA is not supported, use the USART as explained in Section 50.5.7. To perform continuous communications when the FIFO is disabled, clear the TXE/ RXNE flags in the USART_ISR register.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the USART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to section Direct memory access controller (DMA)) to the USART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

1. Write the USART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the USART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register
5. Configure DMA interrupt generation after half/full transfer as required by the application.
6. Clear the TC flag in the USART_ISR register by setting the TCCF bit in the USART_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In Transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the USART communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or before the system enters a low-power mode when the peripheral clock is disabled. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

Note: The DMAT bit must not be cleared before the DMA end of transfer.
**Reception using DMA**

DMA mode can be enabled for reception by setting the DMAR bit in USART_CR3 register. Data are loaded from the USART_RDR register to an SRAM area configured using the DMA peripheral (refer to *section Direct memory access controller (DMA)*) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from USART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

**Note:** *The DMAR bit must not be cleared before the DMA end of transfer.*

Software configures the DMA to receive 3 data blocks and enables the USART

Error flagging and interrupt generation in multibuffer communication

If any error occurs during a transaction in Multibuffer communication mode, the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

50.5.21 RS232 Hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The Figure 696 shows how to connect 2 devices in this mode:

Figure 696. Hardware flow control between 2 USARTs

Note: When FIFO management is enabled, the DMA request is triggered by Receive FIFO not empty (i.e. RXFNE = 1).
RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits to 1 in the USART_CR3 register.

**RS232 RTS flow control**

If the RTS flow control is enabled (RTSE=1), then RTS is deasserted (tied low) as long as the USART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame. *Figure 697* shows an example of communication with RTS flow control enabled.

*Figure 697. RS232 RTS flow control*

![RS232 RTS flow control diagram](image)

**Note:** When FIFO mode is enabled, RTS is asserted only when RXFIFO is full.

**RS232 CTS flow control**

If the CTS flow control is enabled (CTSE = 1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE=0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE = 1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART_CR3 register is set. *Figure 698* shows an example of communication with CTS flow control enabled.
For correct behavior, CTS must be deasserted at least 3 USART clock source periods before the end of the current character. In addition it must be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

**RS485 driver enable**

The driver enable feature is enabled by setting bit DEM in the USART_CR3 control register. This enables the user to activate the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the start bit. It is programmed using the DEAT [4:0] bitfields in the USART_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bitfields in the USART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the USART_CR3 control register.

In USART, the DEAT and DEDT are expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
50.5.22 USART low-power management

The USART has advanced low-power mode functions, that enables transferring properly data even when the usart_pclk clock is disabled.

The USART is able to wake up the MCU from low-power mode when the UESM bit is set. When the usart_pclk is gated, the USART provides a wake-up interrupt (USART_wkup) if a specific action requiring the activation of the usart_pclk clock is needed:

- If FIFO mode is disabled
  usart_pclk clock has to be activated to empty the USART data register.
  In this case, the USART interrupt source is RXNE set to 1. The RXNEIE bit must be set before entering low-power mode.

- If FIFO mode is enabled
  usart_pclk clock has to be activated to:
  - to fill the TXFIFO
  - or to empty the RXFIFO
  In this case, the USART interrupt source can be:
    - RXFIFO not empty. In this case, the RXFIEE bit must be set before entering low-power mode.
    - RXFIFO full. In this case, the RXFFIE bit must be set before entering low-power mode, the number of received data corresponds to the RXFIFO size, and the RXFF flag is not set.
    - TXFIFO empty. In this case, the TXFEIE bit must be set before entering low-power mode.

This enables sending/receiving the data in the TXFIFO/RXFIFO during low-power mode.

To avoid overrun/underrun errors and transmit/receive data in low-power mode, the USART interrupt source can be one of the following events:

- TXFIFO threshold reached. In this case, the TXFTIE bit must be set before entering low-power mode.
- RXFIFO threshold reached. In this case, the RXFTIE bit must be set before entering low-power mode.

For example, the application can set the threshold to the maximum RXFIFO size if the wake-up time is less than the time required to receive a single byte across the line.

Using the RXFIFO full, TXFIFO empty, RXFIFO not empty and RXFIFO/TXFIFO threshold interrupts to wake up the MCU from low-power mode enables doing as many USART transfers as possible during low-power mode with the benefit of optimizing consumption.

Alternatively, a specific USART_wkup interrupt can be selected through the WUS bitfields.

When the wake-up event is detected, the WUF flag is set by hardware and a USART_wkup interrupt is generated if the WUFIE bit is set.
Before entering low-power mode, make sure that no USART transfers are ongoing. Checking the BUSY flag cannot ensure that low-power mode is never entered when data reception is ongoing.

The WUF flag is set when a wake-up event is detected, independently of whether the MCU is in low-power or Active mode.

When entering low-power mode just after having initialized and enabled the receiver, the REACK bit must be checked to make sure the USART is enabled.

When DMA is used for reception, it must be disabled before entering low-power mode and re-enabled when exiting from low-power mode.

When the FIFO is enabled, waking up from low-power mode on address match is only possible when Mute mode is enabled.

**Using Mute mode with low-power mode**

If the USART is put into Mute mode before entering low-power mode:

- Wake-up from Mute mode on idle detection must not be used, because idle detection cannot work in low-power mode.
- If the wake-up from Mute mode on address match is used, then the low-power mode wake-up source must also be the address match. If the RXNE flag was set when entering the low-power mode, the interface remains in Mute mode upon address match and wake up from low-power mode.

**Note:** When FIFO management is enabled, Mute mode can be used with wake-up from low-power mode without any constraints (i.e. the two points mentioned above about Mute and low-power mode are valid only when FIFO management is disabled).

**Wake-up from low-power mode when USART kernel clock (usart_ker_ck) is OFF in low-power mode**

If during low-power mode, the usart_ker_ck clock is switched OFF when a falling edge on the USART receive line is detected, the USART interface requests the usart_ker_ck clock to be switched ON thanks to the usart_ker_ck_req signal. usart_ker_ck is then used for the frame reception.

If the wake-up event is verified, the MCU wakes up from low-power mode and data reception goes on normally.

If the wake-up event is not verified, usart_ker_ck is switched OFF again, the MCU is not woken up and remains in low-power mode, and the kernel clock request is released.

The example below shows the case of a wake-up event programmed to “address match detection” and FIFO management disabled.
Figure 699 shows the USART behavior when the wake-up event is verified.

Figure 699. Wake-up event verified (wake-up event = address match, FIFO disabled)

Figure 700 shows the USART behavior when the wake-up event is not verified.

Figure 700. Wake-up event not verified (wake-up event = address match, FIFO disabled)

Note: The figures above are valid when address match or any received frame is used as wake-up event. If the wake-up event is the start bit detection, the USART sends the wake-up event to the MCU at the end of the start bit.
Determining the maximum USART baud rate that enables to correctly wake up the microcontroller from low-power mode

The maximum baud rate that enables to correctly wake up the microcontroller from low-power mode depends on the wake-up time parameter (refer to the device datasheet) and on the USART receiver tolerance (see Section 50.5.9: Tolerance of the USART receiver to clock deviation).

Let us take the example of OVER8 = 0, M bits = 01, ONEBIT = 0 and BRR[3:0] = 0000.

In these conditions, according to Table 535: Tolerance of the USART receiver when BRR[3:0] = 0000, the USART receiver tolerance equals 3.41%.

\[
D_{WUmax} = \frac{t_{WUUSART}}{11 \times T_{bitmin}}
\]

\[
T_{bitmin} = \frac{t_{WUUSART}}{11 \times D_{WUmax}}
\]

where \(t_{WUUSART}\) is the wake-up time from low-power mode.

If we consider the ideal case where DTRA, DQUANT, DREC and DTCL parameters are at 0%, the maximum value of DWU is 3.41%. In fact, we need to consider at least the \(\text{uart}_\text{ker}_\text{ck}\) inaccuracy (DREC).

For example, if HSI is used as \(\text{uart}_\text{ker}_\text{ck}\), and the HSI inaccuracy is of 1%, then we obtain:

\[
D_{WUmax} = \text{USART receiver tolerance} - \text{DREC} = 3.41\% - 1\% = 2.41\%
\]

\[
T_{bitmin} = \frac{3 \mu s}{11 \times 2.41\%} = 11.32 \mu s.
\]

As a result, the maximum baud rate enables to wake up correctly from low-power mode is: \(1/11.32 \mu s = 88.36\) kbauds.

50.6 USART in low-power modes

Table 538. Effect of low-power modes on the USART

1. The USART can wake up the device from Stop mode only if the peripheral instance supports the wake-up from Stop mode feature. Refer to Section 50.4: USART implementation for the list of supported Stop modes.

2. RXFF flag is asserted if the USART receives n+1 data (n being the RXFIFO size): n data in the RXFIFO and 1 data in USART_RDR. In Stop mode, USART_RDR is not clocked. As a result, this register is not written and once n data are received and written in the RXFIFO, the RXFF interrupt is asserted (RXFF flag is not set).

3. When OVRDIS = 0.
50.8 USART registers

Refer to Section 1.2 on page 101 for a list of abbreviations used in register descriptions.
The peripheral registers have to be accessed by words (32 bits).

50.8.1 USART control register 1 (USART_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

Bit 31 RXFFIE: RXFIFO Full interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when RXFF=1 in the USART_ISR register

Bit 30 TXFEIE: TXFIFO empty interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when TXFE=1 in the USART_ISR register

Bit 29 FIFOEN: FIFO mode enable
This bit is set and cleared by software.
0: FIFO mode is disabled.
1: FIFO mode is enabled.
This bitfield can only be written when the USART is disabled (UE=0).

Note: FIFO mode can be used on standard UART communication, in SPI Master/Slave mode and in Smartcard modes only. It must not be enabled in IrDA and LIN modes.

Bit 28 M1: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.
M[1:0] = 00: 1 start bit, 8 Data bits, n Stop bit
M[1:0] = 01: 1 start bit, 9 Data bits, n Stop bit
M[1:0] = 10: 1 start bit, 7 Data bits, n Stop bit
This bit can only be written when the USART is disabled (UE=0).

Note: In 7-bits data length mode, the Smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.
Bit 27 **EOBIE**: End of Block interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the EOBF flag is set in the USART_ISR register
*Note*: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 26 **RTOIE**: Receiver timeout interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the RTOF bit is set in the USART_ISR register.
*Note*: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Section 50.4: USART implementation on page 2229.

Bits 25:21 **DEAT[4:0]**: Driver Enable assertion time
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
This bitfield can only be written when the USART is disabled (UE=0).
*Note*: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bits 20:16 **DEDT[4:0]**: Driver Enable deassertion time
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DDT and DEAT times have both elapsed.
This bitfield can only be written when the USART is disabled (UE=0).
*Note*: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 15 **OVER8**: Oversampling mode
0: Oversampling by 16
1: Oversampling by 8
This bit can only be written when the USART is disabled (UE=0).
*Note*: In LIN, IrDA and Smartcard modes, this bit must be kept cleared.

Bit 14 **CMIE**: Character match interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the CMF bit is set in the USART_ISR register.

Bit 13 **MME**: Mute mode enable
This bit enables the USART Mute mode function. When set, the USART can switch between active and Mute mode, as defined by the WAKE bit. It is set and cleared by software.
0: Receiver in Active mode permanently
1: Receiver can switch between Mute mode and Active mode.

Bit 12 **M0**: Word length
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1)description).
This bit can only be written when the USART is disabled (UE=0).

---

**RM0481 Universal synchronous/asynchronous receiver transmitter (USART/UART)**
Bit 11 **WAKE**: Receiver wake-up method
This bit determines the USART wake-up method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the USART is disabled (UE=0).

Bit 10 **PCE**: Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and the parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the USART is disabled (UE=0).

Bit 9 **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the USART is disabled (UE=0).

Bit 8 **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever PE=1 in the USART_ISR register

Bit 7 **TXFNFIE**: TXFIFO not full interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TXFNF =1 in the USART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TC=1 in the USART_ISR register

Bit 5 **RXFNEIE**: RXFIFO not empty interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever ORE=1 or RXFNE=1 in the USART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever IDLE=1 in the USART_ISR register
Bit 3  **TE:** Transmitter enable

This bit enables the transmitter. It is set and cleared by software.

0: Transmitter is disabled
1: Transmitter is enabled

*Note:* During transmission, a low pulse on the TE bit (0 followed by 1) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.

In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.

Bit 2  **RE:** Receiver enable

This bit enables the receiver. It is set and cleared by software.

0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1  **UESM:** USART enable in low-power mode

When this bit is cleared, the USART cannot wake up the MCU from low-power mode.

When this bit is set, the USART can wake up the MCU from low-power mode.

This bit is set and cleared by software.

0: USART not able to wake up the MCU from low-power mode.
1: USART able to wake up the MCU from low-power mode.

*Note:* It is recommended to set the UESM bit just before entering low-power mode, and clear it when exiting low-power mode.

Bit 0  **UE:** USART enable

When this bit is cleared, the USART prescalers and outputs are stopped immediately, and all current operations are discarded. The USART configuration is kept, but all the USART_ISR status flags are reset. This bit is set and cleared by software.

0: USART prescaler and outputs disabled, low-power mode
1: USART enabled

*Note:* To enter low-power mode without generating errors on the line, the TE bit must be previously reset and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.

The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

In Smartcard mode, (SCEN = 1), the CK is always available when CLKEN = 1, regardless of the UE bit value.
50.8.2 USART control register 1 [alternate] (USART_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

FIFO mode disabled

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 FIFOEN: FIFO mode enable
This bit is set and cleared by software.
0: FIFO mode is disabled.
1: FIFO mode is enabled.

This bitfield can only be written when the USART is disabled (UE=0).

Note: FIFO mode can be used on standard UART communication, in SPI Master/Slave mode and in Smartcard modes only. It must not be enabled in IrDA and LIN modes.

Bit 28 M1: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.
M[1:0] = 00: 1 start bit, 8 Data bits, n Stop bit
M[1:0] = 01: 1 start bit, 9 Data bits, n Stop bit
M[1:0] = 10: 1 start bit, 7 Data bits, n Stop bit

This bit can only be written when the USART is disabled (UE=0).

Note: In 7-bits data length mode, the Smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

Bit 27 EOBIE: End of Block interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the EOBF flag is set in the USART_ISR register

Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 26 RTOIE: Receiver timeout interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the RTOF bit is set in the USART_ISR register.

Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Section 50.4: USART implementation on page 2229.
Bits 25:21 \textbf{DEAT[4:0]}: Driver Enable assertion time

This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

This bitfield can only be written when the USART is disabled (UE=0).

\textit{Note:} If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bits 20:16 \textbf{DEDT[4:0]}: Driver Enable deassertion time

This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

If the USART TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.

This bitfield can only be written when the USART is disabled (UE=0).

\textit{Note:} If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 15 \textbf{OVER8}: Oversampling mode

0: Oversampling by 16
1: Oversampling by 8

This bit can only be written when the USART is disabled (UE=0).

\textit{Note:} In LIN, IrDA and Smartcard modes, this bit must be kept cleared.

Bit 14 \textbf{CMIE}: Character match interrupt enable

This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the CMF bit is set in the USART_ISR register.

Bit 13 \textbf{MME}: Mute mode enable

This bit enables the USART Mute mode function. When set, the USART can switch between active and Mute mode, as defined by the WAKE bit. It is set and cleared by software.
0: Receiver in Active mode permanently
1: Receiver can switch between Mute mode and Active mode.

Bit 12 \textbf{M0}: Word length

This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).

This bit can only be written when the USART is disabled (UE=0).

Bit 11 \textbf{WAKE}: Receiver wake-up method

This bit determines the USART wake-up method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark

This bitfield can only be written when the USART is disabled (UE=0).

Bit 10 \textbf{PCE}: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if \(M=1\); 8th bit if \(M=0\)) and the parity is checked on the received data. This bit is set and cleared by software.

Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled

This bitfield can only be written when the USART is disabled (UE=0).
Bit 9 **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the USART is disabled (UE=0).

Bit 8 **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever PE=1 in the USART_ISR register

Bit 7 **TXEIE**: Transmit data register empty
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TXE =1 in the USART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TC=1 in the USART_ISR register

Bit 5 **RXNEIE**: Receive data register not empty
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever ORE=1 or RXNE=1 in the USART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever IDLE=1 in the USART_ISR register

Bit 3 **TE**: Transmitter enable
This bit enables the transmitter. It is set and cleared by software.
0: Transmitter is disabled
1: Transmitter is enabled

**Note:** During transmission, a low pulse on the TE bit (0 followed by 1) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.

In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.
Bit 2 **RE**: Receiver enable
This bit enables the receiver. It is set and cleared by software.
0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: USART enable in low-power mode
When this bit is cleared, the USART cannot wake up the MCU from low-power mode.
When this bit is set, the USART can wake up the MCU from low-power mode.
This bit is set and cleared by software.
0: USART not able to wake up the MCU from low-power mode.
1: USART able to wake up the MCU from low-power mode.

*Note*: It is recommended to set the UESM bit just before entering low-power mode, and clear it when exiting low-power mode.

Bit 0 **UE**: USART enable
When this bit is cleared, the USART prescalers and outputs are stopped immediately, and all current operations are discarded. The USART configuration is kept, but all the USART_ISR status flags are reset. This bit is set and cleared by software.
0: USART prescaler and outputs disabled, low-power mode
1: USART enabled

*Note*: To enter low-power mode without generating errors on the line, the TE bit must be previously reset and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.
The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.
In Smartcard mode, (SCEN = 1), the CK is always available when CLKEN = 1, regardless of the UE bit value.

Bits 31:24  **ADD[7:0]: Address of the USART node**

These bits give the address of the USART node in Mute mode or a character code to be recognized in low-power or Run mode:

- In Mute mode: they are used in multiprocessor communication to wake up from Mute mode with 4-bit/7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. In 4-bit address mark detection, only ADD[3:0] bits are used.
- In low-power mode: they are used for wake up from low-power mode on character match. When WUS[1:0] is programmed to 0b00 (WUF active on address match), the wake-up from low-power mode is performed when the received character corresponds to the character programmed through ADD[6:0] or ADD[3:0] bitfield (depending on ADDM7 bit), and WUF interrupt is enabled by setting WUFIE bit. The MSB of the character sent by transmitter should be equal to 1.
- In Run mode with Mute mode inactive (for example, end-of-block detection in ModBus protocol): the whole received character (8 bits) is compared to ADD[7:0] value and CMF flag is set on match. An interrupt is generated if the CMIE bit is set.

These bits can only be written when the reception is disabled (RE = 0) or when the USART is disabled (UE = 0).

Bit 23  **RTOEN**: Receiver timeout enable

This bit is set and cleared by software.

0: Receiver timeout feature disabled.
1: Receiver timeout feature enabled.

When this feature is enabled, the RTOF flag in the USART_ISR register is set if the RX line is idle (no reception) for the duration programmed in the RTOR (receiver timeout register).

**Note**: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bits 22:21  **ABRMOD[1:0]: Auto baud rate mode**

These bits are set and cleared by software.

00: Measurement of the start bit is used to detect the baud rate.
01: Falling edge to falling edge measurement (the received frame must start with a single bit = 1 -> Frame = Start10xxxxxx)
10: 0x7F frame detection.
11: 0x55 frame detection

This bitfield can only be written when ABREN = 0 or the USART is disabled (UE=0).

**Note**: If DATAINV=1 and/or MSBFIRST=1 the patterns must be the same on the line, for example 0xAA for MSBFIRST)

If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 20  **ABREN**: Auto baud rate enable

This bit is set and cleared by software.

0: Auto baud rate detection is disabled.
1: Auto baud rate detection is enabled.

**Note**: If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 19  **MSBFIRST**: Most significant bit first

This bit is set and cleared by software.

0: data is transmitted/received with data bit 0 first, following the start bit.
1: data is transmitted/received with the MSB (bit 7/8) first, following the start bit.

This bitfield can only be written when the USART is disabled (UE=0).
Bit 18 **DATAINV**: Binary data inversion
This bit is set and cleared by software.
0: Logical data from the data register are send/received in positive/direct logic. (1=H, 0=L)
1: Logical data from the data register are send/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.
This bitfield can only be written when the USART is disabled (UE=0).

Bit 17 **TXINV**: TX pin active level inversion
This bit is set and cleared by software.
0: TX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
1: TX pin signal values are inverted. (VDD =0/mark, Gnd=1/idle).
This enables the use of an external inverter on the TX line.
This bitfield can only be written when the USART is disabled (UE=0).

Bit 16 **RXINV**: RX pin active level inversion
This bit is set and cleared by software.
0: RX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
1: RX pin signal values are inverted. (VDD =0/mark, Gnd=1/idle).
This enables the use of an external inverter on the RX line.
This bitfield can only be written when the USART is disabled (UE=0).

Bit 15 **SWAP**: Swap TX/RX pins
This bit is set and cleared by software.
0: TX/RX pins are used as defined in standard pinout
1: The TX and RX pins functions are swapped. This enables to work in the case of a cross-wired connection to another UART.
This bitfield can only be written when the USART is disabled (UE=0).

Bit 14 **LINEN**: LIN mode enable
This bit is set and cleared by software.
0: LIN mode disabled
1: LIN mode enabled
The LIN mode enables the capability to send LIN synchronous breaks (13 low bits) using the SBKRQ bit in the USART_CR1 register, and to detect LIN Sync breaks.
This bitfield can only be written when the USART is disabled (UE=0).

*Note*: If the USART does not support LIN mode, this bit is reserved and must be kept at reset value.
Refer to Section 50.4: USART implementation on page 2229.

Bits 13:12 **STOP[1:0]**: stop bits
These bits are used for programming the stop bits.
00: 1 stop bit
01: 0.5 stop bit.
10: 2 stop bits
11: 1.5 stop bits
This bitfield can only be written when the USART is disabled (UE=0).
Bit 11 **CLKEN**: Clock enable
This bit enables the user to enable the CK pin.
0: CK pin disabled
1: CK pin enabled
This bit can only be written when the USART is disabled (UE=0).

**Note:** If neither Synchronous mode nor Smartcard mode is supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

In Smartcard mode, in order to provide correctly the CK clock to the smartcard, the steps below must be respected:

- **UE** = 0
- **SCEN** = 1
- GTPR configuration
- **CLKEN** = 1
- **UE** = 1

Bit 10 **CPOL**: Clock polarity
This bit enables the user to select the polarity of the clock output on the CK pin in Synchronous mode. It works in conjunction with the CPHA bit to produce the desired clock/data relationship

0: Steady low value on CK pin outside transmission window
1: Steady high value on CK pin outside transmission window

This bit can only be written when the USART is disabled (UE=0).

**Note:** If Synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 9 **CPHA**: Clock phase
This bit is used to select the phase of the clock output on the CK pin in Synchronous mode. It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see Figure 680 and Figure 681)

0: The first clock transition is the first data capture edge
1: The second clock transition is the first data capture edge

This bit can only be written when the USART is disabled (UE=0).

**Note:** If Synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 8 **LBCL**: Last bit clock pulse
This bit is used to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the CK pin in Synchronous mode.

0: The clock pulse of the last data bit is not output to the CK pin
1: The clock pulse of the last data bit is output to the CK pin

**Caution:** The last bit is the 7th or 8th or 9th data bit transmitted depending on the 7 or 8 or 9 bit format selected by the M bit in the USART_CR1 register.

This bit can only be written when the USART is disabled (UE=0).

**Note:** If Synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LBDIE**: LIN break detection interrupt enable
Break interrupt mask (break detection using break delimiter).
0: Interrupt is inhibited
1: An interrupt is generated whenever LBDF=1 in the USART_ISR register

**Note:** If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.
Bit 5 **LBDL**: LIN break detection length
- This bit is for selection between 11 bit or 10 bit break detection.
  0: 10-bit break detection
  1: 11-bit break detection
- This bit can only be written when the USART is disabled (UE=0).

**Note**: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 4 **ADDM7**: 7-bit Address Detection/4-bit Address Detection
- This bit is for selection between 4-bit address detection or 7-bit address detection.
  0: 4-bit address detection
  1: 7-bit address detection (in 8-bit data mode)
- This bit can only be written when the USART is disabled (UE=0)

**Note**: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.

Bit 3 **DIS_NSS**: When the DIS_NSS bit is set, the NSS pin input is ignored.
- 0: SPI slave selection depends on NSS input pin.
- 1: SPI slave is always selected and NSS input pin is ignored.

**Note**: When SPI slave mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **SLVEN**: Synchronous Slave mode enable
- When the SLVEN bit is set, the Synchronous slave mode is enabled.
  0: Slave mode disabled.
  1: Slave mode enabled.

**Note**: When SPI slave mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

**Note**: The CPOL, CPHA and LBCL bits must not be written while the transmitter is enabled.
Bits 31:29 **TXFTCFG[2:0]**: TXFIFO threshold configuration

- 000: TXFIFO reaches 1/8 of its depth
- 001: TXFIFO reaches 1/4 of its depth
- 010: TXFIFO reaches 1/2 of its depth
- 011: TXFIFO reaches 3/4 of its depth
- 100: TXFIFO reaches 7/8 of its depth
- 101: TXFIFO becomes empty
- Remaining combinations: Reserved

Bit 28 **RXFTIE**: RXFIFO threshold interrupt enable

- This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when Receive FIFO reaches the threshold programmed in RXFTCFG.

Bits 27:25 **RXFTCFG[2:0]**: Receive FIFO threshold configuration

- 000: Receive FIFO reaches 1/8 of its depth
- 001: Receive FIFO reaches 1/4 of its depth
- 010: Receive FIFO reaches 1/2 of its depth
- 011: Receive FIFO reaches 3/4 of its depth
- 100: Receive FIFO reaches 7/8 of its depth
- 101: Receive FIFO becomes full
- Remaining combinations: Reserved

Bit 24 **TCBGTIE**: Transmission Complete before guard time, interrupt enable

- This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever TCBGT=1 in the USART_ISR register

**Note**: If the USART does not support the Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 23 **TXFTIE**: TXFIFO threshold interrupt enable

- This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when TXFIFO reaches the threshold programmed in TXFTCFG.

Bit 22 **WUFIE**: Wake-up from low-power mode interrupt enable

- This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever WUF=1 in the USART_ISR register

**Note**: WUFIE must be set before entering in low-power mode.

**If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.**
Bits 21:20 **WUS[1:0]**: Wake-up from low-power mode interrupt flag selection

This bitfield specifies the event which activates the WUF (wake-up from low-power mode flag).
- 00: WUF active on address match (as defined by ADD[7:0] and ADDM7)
- 01: Reserved.
- 10: WUF active on start bit detection
- 11: WUF active on RXNE/RXFNE.

This bitfield can only be written when the USART is disabled (UE=0).

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bits 19:17 **SCARCNT[2:0]**: Smartcard auto-retry count

This bitfield specifies the number of retries for transmission and reception in Smartcard mode.

In Transmission mode, it specifies the number of automatic retransmission retries, before generating a transmission error (FE bit set).

In Reception mode, it specifies the number of erroneous reception trials, before generating a reception error (RXNE/RXFNE and PE bits set).

This bitfield must be programmed only when the USART is disabled (UE=0).

When the USART is enabled (UE=1), this bitfield may only be written to 0x0, in order to stop retransmission.

- 0x0: retransmission disabled - No automatic retransmission in Transmission mode.
- 0x1 to 0x7: number of automatic retransmission attempts (before signaling error)

*Note: If Smartcard mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 16 Reserved, must be kept at reset value.

Bit 15 **DEP**: Driver enable polarity selection

- 0: DE signal is active high.
- 1: DE signal is active low.

This bit can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 14 **DEM**: Driver enable mode

This bit enables the user to activate the external transceiver control, through the DE signal.

- 0: DE function is disabled.
- 1: DE function is enabled. The DE signal is output on the RTS pin.

This bit can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Section 50.4: USART implementation on page 2229.*

Bit 13 **DDRE**: DMA Disable on Reception Error

- 0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data is transferred. (used for Smartcard mode)
- 1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE/RXFNE is case FIFO mode is enabled) before clearing the error flag.

This bit can only be written when the USART is disabled (UE=0).

*Note: The reception errors are: parity error, framing error or noise error.*
Bit 12 **OVRDIS**: Overrun Disable
This bit is used to disable the receive overrun detection.
0: Overrun Error Flag, ORE, is set when received data is not read before receiving new data.
1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the USART_RDR register. When FIFO mode is enabled, the RXFIFO is bypassed and data are written directly in USART_RDR register. Even when FIFO management is enabled, the RXNE flag is to be used.
This bit can only be written when the USART is disabled (UE=0).

*Note*: This control bit enables checking the communication flow w/o reading the data

Bit 11 **ONEBIT**: One sample bit method enable
This bit enables the user to select the sample method. When the one sample bit method is selected the noise detection flag (NE) is disabled.
0: Three sample bit method
1: One sample bit method
This bit can only be written when the USART is disabled (UE=0).

Bit 10 **CTSE**: CTS interrupt enable
0: Interrupt is inhibited
1: An interrupt is generated whenever CTSIF=1 in the USART_ISR register

*Note*: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 9 **CTSE**: CTS enable
0: CTS hardware flow control disabled
1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0).
If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.
This bit can only be written when the USART is disabled (UE=0)

*Note*: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 8 **RTSE**: RTS enable
0: RTS hardware flow control disabled
1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is deasserted (pulled to 0) when data can be received.
This bit can only be written when the USART is disabled (UE=0).

*Note*: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 7 **DMAT**: DMA enable transmitter
This bit is set/reset by software
1: DMA mode is enabled for transmission
0: DMA mode is disabled for transmission

Bit 6 **DMAR**: DMA enable receiver
This bit is set/reset by software
1: DMA mode is enabled for reception
0: DMA mode is disabled for reception
Bit 5 **SCEN**: Smartcard mode enable

This bit is used for enabling Smartcard mode.

- 0: Smartcard mode disabled
- 1: Smartcard mode enabled

This bitfield can only be written when the USART is disabled (UE=0).

**Note:** If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 4 **NACK**: Smartcard NACK enable

- 0: NACK transmission in case of parity error is disabled
- 1: NACK transmission during parity error is enabled

This bitfield can only be written when the USART is disabled (UE=0).

**Note:** If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 3 **HDSEL**: Half-duplex selection

Selection of Single-wire Half-duplex mode

- 0: Half-duplex mode is not selected
- 1: Half-duplex mode is selected

This bit can only be written when the USART is disabled (UE=0).

Bit 2 **IRLP**: IrDA low-power

This bit is used for selecting between normal and low-power IrDA modes

- 0: Normal mode
- 1: Low-power mode

This bit can only be written when the USART is disabled (UE=0).

**Note:** If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 1 **IREN**: IrDA mode enable

This bit is set and cleared by software.

- 0: IrDA disabled
- 1: IrDA enabled

This bit can only be written when the USART is disabled (UE=0).

**Note:** If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 0 **EIE**: Error interrupt enable

Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error noise flag or SPI slave underrun error (FE=1 or ORE=1 or NE=1 or UDR = 1 in the USART_ISR register).

- 0: Interrupt inhibited
- 1: interrupt generated when FE=1 or ORE=1 or NE=1 or UDR = 1 (in SPI slave mode) in the USART_ISR register.
50.8.5  **USART baud rate register (USART_BRR)**

This register can only be written when the USART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

50.8.7 USART receiver timeout register (USART_RTOR)

Address offset: 0x14

Reset value: 0x0000 0000

| Bits 31:16 | Reserved, must be kept at reset value. |
| Bits 15:8 | GT[7:0]: Guard time value |
| This bitfield is used to program the Guard time value in terms of number of baud clock periods. |
| This is used in Smartcard mode. The Transmission Complete flag is set after this guard time value. |
| This bitfield can only be written when the USART is disabled (UE=0). |
| **Note:** If Smartcard mode is not supported, this bit is reserved and must be kept at reset value. |
| Refer to Section 50.4: USART implementation on page 2229. |

| Bits 7:0 | PSC[7:0]: Prescaler value |
| **Condition:** IrDA low-power and normal IrDA mode |
| PSC[7:0] = IrDA Normal and Low-power baud rate |
| This bitfield is used for programming the prescaler for dividing the USART source clock to achieve the low-power frequency: |
| The source clock is divided by the value given in the register (8 significant bits): |
| 00000000: Reserved - do not program this value |
| 00000001: divides the source clock by 1 |
| 00000010: divides the source clock by 2 |
| ... |
| **Condition:** Smartcard mode |
| PSC[4:0]: Prescaler value |
| This bitfield is used for programming the prescaler for dividing the USART source clock to provide the Smartcard clock. |
| The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency: |
| 00000: Reserved - do not program this value |
| 00001: divides the source clock by 2 |
| 00010: divides the source clock by 4 |
| 00011: divides the source clock by 6 |
| ... |
| This bitfield can only be written when the USART is disabled (UE=0). |
| **Note:** Bits [7:5] must be kept cleared if Smartcard mode is used. |
| This bitfield is reserved and forced by hardware to 0 when the Smartcard and IrDA modes are not supported. Refer to Section 50.4: USART implementation on page 2229. |
Bits 31:24 BLEN[7:0]: Block Length
This bitfield gives the Block length in Smartcard T=1 Reception. Its value equals the number of information characters + the length of the Epilogue Field (1-LEC/2-CRC) - 1.
Examples:
BLEN = 0 -> 0 information characters + LEC
BLEN = 1 -> 0 information characters + CRC
BLEN = 255 -> 254 information characters + CRC (total 256 characters))
In Smartcard mode, the Block length counter is reset when TXE=0 (TXFE = 0 in case FIFO mode is enabled).
This bitfield can be used also in other modes. In this case, the Block length counter is reset when RE=0 (receiver disabled) and/or when the EOBCF bit is written to 1.
Note: This value can be programmed after the start of the block reception (using the data from the LEN character in the Prologue Field). It must be programmed only once per received block.

Bits 23:0 RTO[23:0]: Receiver timeout value
This bitfield gives the Receiver timeout value in terms of number of bit duration.
In Standard mode, the RTOF flag is set if, after the last received character, no new start bit is detected for more than the RTO value.
In Smartcard mode, this value is used to implement the CWT and BWT. See Smartcard chapter for more details. In the standard, the CWT/BWT measurement is done starting from the start bit of the last received character.
Note: This value must only be programmed once per received character.

Note: RTOR can be written on-the-fly. If the new value is lower than or equal to the counter, the RTOF flag is set.
This register is reserved and forced by hardware to "0x00000000" when the Receiver timeout feature is not supported. Refer to Section 50.4: USART implementation on page 2229.

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 TXFRQ: Transmit data flush request
When FIFO mode is disabled, writing 1 to this bit sets the TXE flag. This enables to discard the transmit data. This bit must be used only in Smartcard mode, when data have not been sent due to errors (NACK) and the FE flag is active in the USART_ISR register. If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value.

When FIFO is enabled, TXFRQ bit is set to flush the whole FIFO. This sets the TXFE flag (Transmit FIFO empty, bit 23 in the USART_ISR register). Flushing the Transmit FIFO is supported in both UART and Smartcard modes.

Note: In FIFO mode, the TXFNF flag is reset during the flush request until TxxFIFO is empty in order to ensure that no data are written in the data register.

Bit 3 RXFRQ: Receive data flush request
Writing 1 to this bit empties the entire receive FIFO i.e. clears the bit RXFNE. This enables to discard the received data without reading them, and avoid an overrun condition.

Bit 2 MMCRQ: Mute mode request
Writing 1 to this bit puts the USART in Mute mode and resets the RWU flag.

Bit 1 SBKREQ: Send break request
Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

Note: When the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software must wait for the TXE flag assertion before setting the SBKREQ bit.

Bit 0 ABFRREQ: Auto baud rate request
Writing 1 to this bit resets the ABRF and ABRE flags in the USART_ISR and requests an automatic baud rate measurement on the next received data frame.

Note: If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

50.8.9 USART interrupt and status register (USART_ISR)
Address offset: 0x1C
Reset value: 0x0XX0 00C0
XX = 28 if FIFO/Smartcard mode enabled
XX = 08 if FIFO enabled and Smartcard mode disabled

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

FIFO mode enabled

Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **TXFT**: TXFIFO threshold flag

This bit is set by hardware when the TXFIFO reaches the threshold programmed in TXFTCFG of USART_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit =1 (bit 31) in the USART_CR3 register.

0: TXFIFO does not reach the programmed threshold.
1: TXFIFO reached the programmed threshold.

Bit 26  **RXFT**: RXFIFO threshold flag

This bit is set by hardware when the threshold programmed in RXFTCFG in USART_CR3 register is reached. This means that there are (RXFTCFG - 1) data in the Receive FIFO and one data in the USART_RDR register. An interrupt is generated if the RXFTIE bit =1 (bit 27) in the USART_CR3 register.

0: Receive FIFO does not reach the programmed threshold.
1: Receive FIFO reached the programmed threshold.

**Note:** When the RXFTCFG threshold is configured to 101, RXFT flag is set if 16 data are available i.e. 15 data in the RXFIFO and 1 data in the USART_RDR. Consequently, the 17th received data does not cause an overrun error. The overrun error occurs after receiving the 18th data.

Bit 25  **TCBGT**: Transmission complete before guard time flag

This bit is set when the last data written in the USART_TDR has been transmitted correctly out of the shift register.

It is set by hardware in Smartcard mode, if the transmission of a frame containing data is complete and if the smart card did not send back any NACK. An interrupt is generated if TCBGTIE=1 in the USART_CR3 register.

This bit is cleared by software, by writing 1 to the TCBGTCF in the USART_ICR register or by a write to the USART_TDR register.

0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card)
1: Transmission is complete successfully (before Guard time completion and there is no NACK from the smart card).

**Note:** If the USART does not support the Smartcard mode, this bit is reserved and kept at reset value. If the USART supports the Smartcard mode and the Smartcard mode is enabled, the TCBGT reset value is 1. Refer to Section 50.4: USART implementation on page 2229.

Bit 24  **RXFF**: RXFIFO Full

This bit is set by hardware when the number of received data corresponds to RXFIFO size + 1 (RXFIFO full + 1 data in the USART_RDR register.

An interrupt is generated if the RXFFIE bit =1 in the USART_CR1 register.

0: RXFIFO not full.
1: RXFIFO Full.

Bit 23  **TXFE**: TXFIFO Empty

This bit is set by hardware when TXFIFO is Empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the USART_RQR register.

An interrupt is generated if the TXFEIE bit =1 (bit 30) in the USART_CR1 register.

0: TXFIFO not empty.
1: TXFIFO empty.
Bit 22  **REACK**: Receive enable acknowledge flag
This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.
It can be used to verify that the USART is ready for reception before entering low-power mode.

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 21  **TEACK**: Transmit enable acknowledge flag
This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.
It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the USART_CR1 register, in order to respect the TE=0 minimum period.

Bit 20  **WUF**: Wake-up from low-power mode flag
This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the USART_ICR register. An interrupt is generated if WUFIE=1 in the USART_CR3 register.

*Note: When UESM is cleared, WUF flag is also cleared.*
If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 19  **RWU**: Receiver wake-up from Mute mode
This bit indicates if the USART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.
When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.
0: Receiver in Active mode
1: Receiver in Mute mode

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 18  **SBKF**: Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.
0: No break character transmitted
1: Break character transmitted

Bit 17  **CMF**: Character match flag
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register. An interrupt is generated if CMIE=1 in the USART_CR1 register.
0: No Character match detected
1: Character match detected

Bit 16  **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
0: USART is idle (no reception)
1: Reception on going
Bit 15  **ABRF**: Auto baud rate flag
This bit is set by hardware when the automatic baud rate has been set (RXFNE is also set, generating an interrupt if RXFNEIE = 1) or when the auto baud rate operation was completed without success (ABRE=1) (ABRE, RXFNE and FE are also set in this case)
It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART_RQR register.
*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 14  **ABRE**: Auto baud rate error
This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed)
It is cleared by software, by writing 1 to the ABRRQ bit in the USART_RQR register.
*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 13  **UDR**: SPI slave underrun error flag
In Slave transmission mode, this flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value into USART_TDR. This flag is reset by setting UDRCF bit in the USART_ICR register.
0: No underrun error
1: underrun error
*Note: If the USART does not support the SPI slave mode, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 12  **EOBF**: End of block flag
This bit is set by hardware when a complete block has been received (for example T=1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.
An interrupt is generated if EOBIE = 1 in the USART_CR1 register.
It is cleared by software, writing 1 to EOBCF in the USART_ICR register.
0: End of Block not reached
1: End of Block (number of characters) reached
*Note: If Smartcard mode is not supported, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 11  **RTOF**: Receiver timeout
This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.
An interrupt is generated if RTOIE=1 in the USART_CR2 register.
In Smartcard mode, the timeout corresponds to the CWT or BWT timings.
0: Timeout value not reached
1: Timeout value reached without any data reception
*Note: If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set.
The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF is set.
If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.*
Bit 10  **CTS**: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
0: CTS line set
1: CTS line reset
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 9  **CTSIF**: CTS interrupt flag
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.
An interrupt is generated if CTSIE=1 in the USART_CR3 register.
0: No change occurred on the CTS status line
1: A change occurred on the CTS status line
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 8  **LBDF**: LIN break detection flag
This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDCF in the USART_ICR.
An interrupt is generated if LBDIE = 1 in the USART_CR2 register.
0: LIN Break not detected
1: LIN break detected
*Note: If the USART does not support LIN mode, this bit is reserved and kept at reset value.*
Refer to Section 50.4: USART implementation on page 2229.

Bit 7  **TXFNF**: TXFIFO not full
TXFNF is set by hardware when TXFIFO is not full meaning that data can be written in the USART_TDR. Every write operation to the USART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data can not be written into the USART_TDR.
An interrupt is generated if the TXFNFIE bit =1 in the USART_CR1 register.
0: Transmit FIFO is full
1: Transmit FIFO is not full
*Note: The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF must be checked prior to writing in TXFIFO (TXFNF and TXFE is set at the same time). This bit is used during single buffer transmission.*

Bit 6  **TC**: Transmission complete
This bit indicates that the last data written in the USART_TDR has been transmitted out of the shift register. The TC flag behaves as follows:
- When TDN = 0, the TC flag is set when the transmission of a frame containing data is complete and when TXE/TXFE is set.
- When TDN is equal to the number of data in the TXFIFO, the TC flag is set when TXFIFO is empty and TDN is reached.
- When TDN is greater than the number of data in the TXFIFO, TC remains cleared until the TXFIFO is filled again to reach the programmed number of data to be transferred.
- When TDN is less than the number of data in the TXFIFO, TC is set when TDN is reached even if the TXFIFO is not empty.
An interrupt is generated if TCIE=1 in the USART_CR1 register.
TC bit is cleared by software by writing 1 to the TCCF in the USART_ICR register or by writing to the USART_TDR register.
Bit 5  **RXFNE**: RXFIFO not empty

RXFNE bit is set by hardware when the RXFIFO is not empty, meaning that data can be read from the USART_RDR register. Every read operation from the USART_RDR frees a location in the RXFIFO.

RXFNE is cleared when the RXFIFO is empty. The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register.

An interrupt is generated if RXFNEIE=1 in the USART_CR1 register.

0: Data is not received
1: Received data is ready to be read.

Bit 4  **IDLE**: Idle line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE=1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART_ICR register.

0: No Idle line is detected
1: Idle line is detected

*Note: The IDLE bit is not set again until the RXFNE bit has been set (i.e. a new idle line occurs).*

If Mute mode is enabled (MME=1), IDLE is set if the USART is not mute (RWU=0), whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.

Bit 3  **ORE**: Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the USART_RDR register while RXFF = 1. It is cleared by a software, writing 1 to the ORECF, in the USART_ICR register.

An interrupt is generated if RXFNEIE=1 in the USART_CR1 register, or EIE = 1 in the USART_CR3 register.

0: No overrun error
1: Overrun error is detected

*Note: When this bit is set, the USART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.*

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the USART_CR3 register.
Bit 2  **NE**: Noise detection flag

This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NFCF bit in the USART_ICR register.

0: No noise is detected
1: Noise is detected

*Note:* This bit does not generate an interrupt as it appears at the same time as the RXFNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

When the line is noise-free, the NE flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to Section 50.5.9: Tolerance of the USART receiver to clock deviation on page 2248).

This error is associated with the character in the USART_RDR.

Bit 1  **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART_ICR register.

When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the USART_CR3 register.

0: No Framing error is detected
1: Framing error or break character is detected

*Note:* This error is associated with the character in the USART_RDR.

Bit 0  **PE**: Parity error

This bit is set by hardware when a parity error occurs in Reception mode. It is cleared by software, writing 1 to the PECF in the USART_ICR register.

An interrupt is generated if PEIE = 1 in the USART_CR1 register.

0: No parity error
1: Parity error

*Note:* This error is associated with the character in the USART_RDR.

### 50.8.10 USART interrupt and status register [alternate] (USART_ISR)

Address offset: 0x1C

Reset value: 0x0000 00C0

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

#### FIFO mode disabled

RM0481 Universal synchronous/asynchronous receiver transmitter (USART/UART)
Bits 31:26  Reserved, must be kept at reset value.

Bit 25  TCBGT: Transmission complete before guard time flag

This bit is set when the last data written in the USART_TDR has been transmitted correctly out of the shift register.

It is set by hardware in Smartcard mode, if the transmission of a frame containing data is complete and if the smartcard did not send back any NACK. An interrupt is generated if TCBGTE=1 in the USART_CR3 register.

This bit is cleared by software, by writing 1 to the TCBGTCF in the USART_ICR register or by a write to the USART_TDR register.

0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card)
1: Transmission is complete successfully (before Guard time completion and there is no NACK from the smart card).

Note: If the USART does not support the Smartcard mode, this bit is reserved and kept at reset value. If the USART supports the Smartcard mode and the Smartcard mode is enabled, the TCBGT reset value is 1. Refer to Section 50.4: USART implementation on page 2229.

Bits 24:23  Reserved, must be kept at reset value.

Bit 22  REACK: Receive enable acknowledge flag

This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.

It can be used to verify that the USART is ready for reception before entering low-power mode.

Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 21  TEACK: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.

It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the USART_CR1 register, in order to respect the TE=0 minimum period.

Bit 20  WUF: Wake-up from low-power mode flag

This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the USART_ICR register. An interrupt is generated if WUFIE=1 in the USART_CR3 register.

Note: When UESM is cleared, WUF flag is also cleared.

If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bit 19  RWU: Receiver wake-up from Mute mode

This bit indicates if the USART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.

When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.

0: Receiver in Active mode
1: Receiver in Mute mode

Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.
Bit 18 **SBKF**: Send break flag  
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.  
0: No break character transmitted  
1: Break character transmitted

Bit 17 **CMF**: Character match flag  
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register.  
An interrupt is generated if CMIE=1 in the USART_CR1 register.  
0: No Character match detected  
1: Character match detected

Bit 16 **BUSY**: Busy flag  
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).  
0: USART is idle (no reception)  
1: Reception on going

Bit 15 **ABRF**: Auto baud rate flag  
This bit is set by hardware when the automatic baud rate has been set (RXNE is also set, generating an interrupt if RXNEIE = 1) or when the auto baud rate operation was completed without success (ABRE=1) (ABRE, RXNE and FE are also set in this case).  
It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART_RQR register.  
*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 14 **ABRE**: Auto baud rate error  
This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed).  
It is cleared by software, by writing 1 to the ABRRQ bit in the USART_RQR register.  
*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 13 **UDR**: SPI slave underrun error flag  
In Slave transmission mode, this flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value into USART_TDR. This flag is reset by setting UDRCF bit in the USART_ICR register.  
0: No underrun error  
1: underrun error  
*Note: If the USART does not support the SPI slave mode, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 12 **EOBF**: End of block flag  
This bit is set by hardware when a complete block has been received (for example T=1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.  
An interrupt is generated if EOBIE = 1 in the USART_CR1 register.  
It is cleared by software, writing 1 to EOBCF in the USART_ICR register.  
0: End of Block not reached  
1: End of Block (number of characters) reached  
*Note: If Smartcard mode is not supported, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*
Bit 11 **RTOF**: Receiver timeout
This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.
An interrupt is generated if RTOIE=1 in the USART_CR2 register.
In Smartcard mode, the timeout corresponds to the CWT or BWT timings.
0: Timeout value not reached
1: Timeout value reached without any data reception

*Note: If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set. The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF is set.*

If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.

Bit 10 **CTS**: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
0: CTS line set
1: CTS line reset

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 9 **CTSIF**: CTS interrupt flag
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.
An interrupt is generated if CTSIE=1 in the USART_CR3 register.
0: No change occurred on the CTS status line
1: A change occurred on the CTS status line

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 8 **LBDF**: LIN break detection flag
This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDCF in the USART_ICR.
An interrupt is generated if LBDIE = 1 in the USART_CR2 register.
0: LIN Break not detected
1: LIN break detected

*Note: If the USART does not support LIN mode, this bit is reserved and kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 7 **TXE**: Transmit data register empty
TXE is set by hardware when the content of the USART_TDR register has been transferred into the shift register. It is cleared by writing to the USART_TDR register. The TXE flag can also be set by writing 1 to the TXFRQ in the USART_RQR register, in order to discard the data (only in Smartcard T=0 mode, in case of transmission failure).
An interrupt is generated if the TXEIE bit =1 in the USART_CR1 register.
0: Data register full
1: Data register full
Bit 6 **TC**: Transmission complete

This bit indicates that the last data written in the USART_TDR has been transmitted out of the shift register. The TC flag is set when the transmission of a frame containing data is complete and when TXE is set.

An interrupt is generated if TCIE=1 in the USART_CR1 register.

TC bit is cleared by software by writing 1 to the TCCF in the USART_ICR register or by writing to the USART_TDR register.

Bit 5 **RXNE**: Read data register not empty

RXNE bit is set by hardware when the content of the USART_RDR shift register has been transferred to the USART_RDR register. It is cleared by reading from the USART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register.

An interrupt is generated if RXNEIE=1 in the USART_CR1 register.

0: Data is not received
1: Received data is ready to be read.

Bit 4 **IDLE**: Idle line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE=1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART_ICR register.

0: No Idle line is detected
1: Idle line is detected

Note: *The IDLE bit is not set again until the RXNE bit has been set (i.e. a new idle line occurs).*

If Mute mode is enabled (MME=1), IDLE is set if the USART is not mute (RWU=0), whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.

Bit 3 **ORE**: Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the USART_RDR register while RXNE=1. It is cleared by a software, writing 1 to the ORECF, in the USART_ICR register.

An interrupt is generated if RXNEIE=1 in the USART_CR1 register, or EIE = 1 in the USART_CR3 register.

1: Overrun error is detected

Note: *When this bit is set, the USART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.*

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the USART_CR3 register.

Bits 31:21 Reserved, must be kept at reset value.

**Bit 20** WUCF: Wake-up from low-power mode clear flag

Writing 1 to this bit clears the WUF flag in the USART_ISR register.

**Note:** If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.

Bits 19:18 Reserved, must be kept at reset value.

**Bit 2** NE: Noise detection flag

This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NFCF bit in the USART_ICR register.

0: No noise is detected
1: Noise is detected

**Note:** This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

When the line is noise-free, the NE flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to Section 50.5.9: Tolerance of the USART receiver to clock deviation on page 2248). This error is associated with the character in the USART_RDR.

**Bit 1** FE: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART_ICR register. When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame). An interrupt is generated if EIE = 1 in the USART_CR3 register.

0: No Framing error is detected
1: Framing error or break character is detected

**Note:** This error is associated with the character in the USART_RDR.

**Bit 0** PE: Parity error

This bit is set by hardware when a parity error occurs in Reception mode. It is cleared by software, writing 1 to the PECF in the USART_ICR register. An interrupt is generated if PEIE = 1 in the USART_CR1 register.

0: No parity error
1: Parity error

**Note:** This error is associated with the character in the USART_RDR.
Bit 17 **CMCF**: Character match clear flag
Writing 1 to this bit clears the CMF flag in the USART_ISR register.

Bits 16:14 Reserved, must be kept at reset value.

Bit 13 **UDRF**: SPI slave underrun clear flag
Writing 1 to this bit clears the UDRF flag in the USART_ISR register.
*Note: If the USART does not support SPI slave mode, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229*

Bit 12 **EOBCF**: End of block clear flag
Writing 1 to this bit clears the EOBF flag in the USART_ISR register.
*Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 11 **RTOCF**: Receiver timeout clear flag
Writing 1 to this bit clears the RTOF flag in the USART_ISR register.
*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CTSCF**: CTS clear flag
Writing 1 to this bit clears the CTSIF flag in the USART_ISR register.
*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 8 **LBDCF**: LIN break detection clear flag
Writing 1 to this bit clears the LBDF flag in the USART_ISR register.
*Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 50.4: USART implementation on page 2229.*

Bit 7 **TCBGTCF**: Transmission complete before Guard time clear flag
Writing 1 to this bit clears the TCBGT flag in the USART_ISR register.

Bit 6 **TCCF**: Transmission complete clear flag
Writing 1 to this bit clears the TC flag in the USART_ISR register.

Bit 5 **TXFECF**: TXFIFO empty clear flag
Writing 1 to this bit clears the TXFE flag in the USART_ISR register.

Bit 4 **IDLECF**: Idle line detected clear flag
Writing 1 to this bit clears the IDLE flag in the USART_ISR register.

Bit 3 **ORECF**: Overrun error clear flag
Writing 1 to this bit clears the ORE flag in the USART_ISR register.

Bit 2 **NECF**: Noise detected clear flag
Writing 1 to this bit clears the NE flag in the USART_ISR register.

Bit 1 **FE CF**: Framing error clear flag
Writing 1 to this bit clears the FE flag in the USART_ISR register.

Bit 0 **PECF**: Parity error clear flag
Writing 1 to this bit clears the PE flag in the USART_ISR register.

Bits 31:9  Reserved, must be kept at reset value.

Bits 8:0  RDR[8:0]: Receive data value
Contains the received data character.
The RDR register provides the parallel interface between the input shift register and the internal bus (see Figure 674).
When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

50.8.13  USART transmit data register (USART_TDR)

Bits 31:9  Reserved, must be kept at reset value.

Bits 8:0  TDR[8:0]: Transmit data value
Contains the data character to be transmitted.
The USART_TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 674).
When transmitting with the parity enabled (PCE bit set to 1 in the USART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

Note: This register must be written only when TXE/TXFNF=1.
50.8.14  **USART prescaler register (USART_PRESC)**

This register can only be written when the USART is disabled (UE=0).

Address offset: 0x2C

Reset value: 0x0000 0000

**W** **R** **R** **R**  **PRESCALER[3:0]**

**Bits 31:4**  Reserved, must be kept at reset value.

**Bits 3:0**  **PRESCALER[3:0]:** Clock prescaler

The USART input clock can be divided by a prescaler factor:

- 0000: input clock not divided
- 0001: input clock divided by 2
- 0010: input clock divided by 4
- 0011: input clock divided by 6
- 0100: input clock divided by 8
- 0101: input clock divided by 10
- 0110: input clock divided by 12
- 0111: input clock divided by 16
- 1000: input clock divided by 32
- 1001: input clock divided by 64
- 1010: input clock divided by 128
- 1011: input clock divided by 256

Remaining combinations: Reserved

**Note:**  When PRESCALER is programmed with a value different of the allowed ones, programmed prescaler value is equal to 1011 i.e. input clock divided by 256.

Refer to Section 2.3 on page 111 for the register boundary addresses.
51 Low-power universal asynchronous receiver transmitter (LPUART)

This section describes the low-power universal asynchronous receiver transmitter (LPUART).

51.1 Introduction

The LPUART is an UART which enables bidirectional UART communications with a limited power consumption. Only 32.768 kHz LSE clock is required to enable UART communications up to 9600 bauds. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock.

Even when the microcontroller is in low-power mode, the LPUART can wait for an incoming UART frame while having an extremely low energy consumption. The LPUART includes all necessary hardware support to make asynchronous serial communications possible with minimum power consumption.

It supports Half-duplex Single-wire communications and modem operations (CTS/RTS).

It also supports multiprocessor communications.

DMA (direct memory access) can be used for data transmission/reception.

51.2 LPUART main features

- Full-duplex asynchronous communications
- NRZ standard format (mark/space)
- Programmable baud rate
- From 300 bauds to 9600 bauds using a 32.768 kHz clock source.
- Higher baud rates can be achieved by using a higher frequency clock source
- Two internal FIFOs to transmit and receive data
  Each FIFO can be enabled/disabled by software and come with status flags for FIFOs states.
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK.
- Programmable data word length (7 or 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
• Transfer detection flags:
  – Receive buffer full
  – Transmit buffer empty
  – Busy and end of transmission flags
• Parity control:
  – Transmits parity bit
  – Checks parity of received data byte
• Four error detection flags:
  – Overrun error
  – Noise detection
  – Frame error
  – Parity error
• Interrupt sources with flags
• Multiprocessor communications: wake-up from Mute mode by idle line detection or address mark detection
• Wake-up from Stop mode

51.3 LPUART implementation

The table below describe LPUART implementation. It also includes USARTs and UARTs for comparison.

51.4 LPUART functional description

51.4.1 LPUART block diagram

Figure 701. LPUART block diagram
51.4.2 LPUART pins and internal signals

Description LPUART input/output pins

- LPUART bidirectional communications
  LPUART bidirectional communications requires a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):
  - **RX** (Receive Data Input):
    RX is the serial data input.
  - **TX** (Transmit Data Output)
    When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In Single-wire mode, this I/O is used to transmit and receive the data.

- RS232 hardware flow control mode
  The following pins are required in RS232 Hardware flow control mode:
  - **CTS** (Clear To Send)
    When driven high, this signal blocks the data transmission at the end of the current transfer.
  - **RTS** (Request to send)
    When it is low, this signal indicates that the USART is ready to receive data.

- RS485 hardware flow control mode
  The **DE** (Driver Enable) pin is required in RS485 Hardware control mode. This signal activates the transmission mode of the external transceiver.

Refer to Table 543 and Table 544 for the list of LPUART input/output pins and internal signals.

</tbody>
</table>
51.4.3 LPUART clocks

The simplified block diagram given in Figure 701 shows two fully independent clock domains:

- **The lpuart_pclk clock domain**
  
  The `lpuart_pclk` clock signal feeds the peripheral bus interface. It must be active when accesses to the LPUART registers are required.

- **The lpuart_ker_ck kernel clock domain**

  The `lpuart_ker_ck` is the LPUART clock source. It is independent of the `lpuart_pclk` and delivered by the RCC. So, the LPUART registers can be written/read even when the `lpuart_ker_ck` is stopped.

  When the dual clock domain feature is not supported, the `lpuart_ker_ck` is the same as the `lpuart_pclk` clock.

  There is no constraint between `lpuart_pclk` and `lpuart_ker_ck`: `lpuart_ker_ck` can be faster or slower than `lpuart_pclk`, with no more limitation than the ability for the software to manage the communication fast enough.

51.4.4 LPUART character description

The word length can be set to 7 or 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the LPUART_CR1 register (see Figure 675).

- 7-bit character length: M[1:0] = ‘10
- 8-bit character length: M[1:0] = 00
- 9-bit character length: M[1:0] = 01

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An **Idle character** is interpreted as an entire frame of “1”s. (The number of “1”’s includes the number of stop bits).

A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clocks are generated when the enable bit is set for the transmitter and receiver, respectively.

The details of each block is given below.

** LBCL bit controls last data clock pulse
51.4.5 LPUART FIFOs and thresholds

The LPUART can operate in FIFO mode.

The LPUART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN bit (bit 29) in LPUART_CR1 register.

Since 9 bits the maximum data word length is 9 bits, the TXFIFO is 9-bits wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

*Note:* The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR.

The status flags are available in the LPUART_ISR register.

It is possible to define the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in LPUART_CR3 control register.

In this case:

- The Rx interrupt is generated when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bitfields.

  In this case, the RXFT flag is set in the LPUART_ISR register. This means that RXFTCFG data have been received: 1 data in LPUART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to ‘101, the RXFT flag is set when a number of data corresponding to the FIFO size has been received: FIFO size - 1 data in the RXFIFO and 1 data in the LPUART_RDR. As a result, the next received data does not set the overrun flag.

- The Tx interrupt is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bitfields.

51.4.6 LPUART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin.

**Character transmission**

During an LPUART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the LPUART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see *Figure 701*).

When FIFO mode is enabled, the data written to the LPUART_TDR register are queued in the TXFIFO.

Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be 1 or 2.
Note: The TE bit must be set before writing the data to be transmitted to the LPUART_TDR. The TE bit must not be reset during data transmission. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters is frozen. The current data being transmitted are lost.
An idle frame is sent after the TE bit is enabled.

Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in LPUART_CR2 (bits 13, 12).

- **1 stop bit**: This is the default value of number of stop bits.
- **2 Stop bits**: This is supported by normal LPUART, Single-wire and Modem modes.

An idle frame transmission includes the stop bits.

A break transmission is 10 low bits (when M[1:0] = 00) or 11 low bits (when M[1:0] = 01) or 9 low bits (when M[1:0] = 10) followed by 2 stop bits. It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

**Figure 703. Configurable stop bits**

8-bit Word length (M[1:0]=00 bit is reset)

Character transmission procedure

To transmit a character, follow the sequence below:
1. Program the M bits in LPUART_CR1 to define the word length.
2. Select the desired baud rate using the LPUART_BRR register.
3. Program the number of stop bits in LPUART_CR2.
4. Enable the LPUART by writing the UE bit in LPUART_CR1 register to 1.
5. Select DMA enable (DMAT) in LPUART_CR3 if Multi buffer Communication is to take place. Configure the DMA register as explained in Section 51.4.13: Continuous communication using DMA and LPUART.
6. Set the TE bit in LPUART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the LPUART_TDR register. Repeat this operation for each data to be transmitted in case of single buffer.
   - When FIFO mode is disabled, writing a data in the LPUART_TDR clears the TXE flag.
   - When FIFO mode is enabled, writing a data in the LPUART_TDR adds one data to the TXFIFO. Write operations to the LPUART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.

8. When the last data is written to the LPUART_TDR register, wait until TC=1. This indicates that the transmission of the last frame is complete.
   - When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
   - When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.

This check is required to avoid corrupting the last transmission when the LPUART is disabled or enters Halt mode.

Single byte communication

- When FIFO mode disabled:
  Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware to indicate that:
  - the data have been moved from the LPUART_TDR register to the shift register and data transmission has started;
  - the LPUART_TDR register is empty;
  - the next data can be written to the LPUART_TDR register without overwriting the previous data.

  The TXE flag generates an interrupt if the TXEIE bit is set.

  When a transmission is ongoing, a write instruction to the LPUART_TDR register stores the data in the TDR register, which is copied to the shift register at the end of the current transmission.

  When no transmission is ongoing, a write instruction to the LPUART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

- When FIFO mode is enabled, the TXFNF (TXFIFO Not Full) flag is set by hardware to indicate that:
  - the TXFIFO is not full;
  - the LPUART_TDR register is empty;
  - the next data can be written to the LPUART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the
LPUART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.

When the TXFIFO is not full, the TXFNF flag stays at 1 even after a write in LPUART_TDR. It is cleared when the TXFIFO is full. This flag generates an interrupt if TXFNEIE bit is set.

Alternatively, interrupts can be generated and data can be written to the TXFIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed threshold.

If a frame is transmitted (after the stop bit) and the TXE flag (TXFE is case of FIFO mode) is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the LPUART_CR1 register.

After writing the last data in the LPUART_TDR register, it is mandatory to wait for TC=1 before disabling the LPUART or causing the microcontroller to enter the low-power mode (see Figure 704: TC/TXE behavior when transmitting).

Figure 704. TC/TXE behavior when transmitting

Note: When FIFO management is enabled, the TXFNF flag is used for data transmission.

Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bits (see Figure 702).

If a 1 is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The LPUART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.
When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

**Idle characters**

Setting the TE bit drives the LPUART to send an idle frame before the first data frame.

### 51.4.7 LPUART receiver

The LPUART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the LPUART.CR1 register.

**Start bit detection**

In the LPUART, the start bit is detected when a falling edge occurs on the Rx line, followed by a sample taken in the middle of the start bit to confirm that it is still 0. If the start sample is at 1, then the noise error flag (NE) is set, then the start bit is discarded and the receiver waits for a new start bit. Else, the receiver continues to sample all incoming bits normally.

**Character reception**

During an LPUART reception, data are shifted in least significant bit first (default configuration) through the RX pin. In this mode, the LPUART.RDR register consists of a buffer (RDR) between the internal bus and the received shift register.

**Character reception procedure**

To receive a character, follow the sequence below:

1. Program the M bits in LPUART.CR1 to define the word length.
2. Select the desired baud rate using the baud rate register LPUART.BRR
3. Program the number of stop bits in LPUART.CR2.
4. Enable the LPUART by writing the UE bit in LPUART.CR1 register to 1.
5. Select DMA enable (DMAR) in LPUART.CR3 if multibuffer communication is to take place. Configure the DMA register as explained in [Section 51.4.13: Continuous communication using DMA and LPUART](#).
6. Set the RE bit LPUART.CR1. This enables the receiver which begins searching for a start bit.

When a character is received:

- When FIFO mode is disabled, the RXNE bit is set. It indicates that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set indicating that the RXFIFO is not empty. Reading the LPUART.RDR returns the oldest data entered in the RXFIFO.
When a data is received, it is stored in the RXFIFO, together with the corresponding error bits.

- An interrupt is generated if the RXNEIE (RXFNEIE in case of FIFO mode) bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.
- In Multibuffer communication mode:
  - When FIFO mode is disabled, the RXNE flag is set after every byte received and is cleared by the DMA read of the Receive Data Register.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. DMA request is triggered by RXFIFO is not empty i.e. there is a data in the RXFIFO to be read.
- In Single-buffer mode:
  - When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every read operation from the LPUART_RDR register, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by writing 1 to the RXFRQ bit in the LPUART_RQR register. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set. Alternatively, interrupts can be generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

**Break character**

When a break character is received, the USART handles it as a framing error.

**Idle character**

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.
Overrun error

- FIFO mode disabled
  An overrun error occurs when a character is received when RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte received.
  An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:
  - the ORE bit is set;
  - the RDR content is not lost. The previous data is available when a read to LPUART_RDR is performed;
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXNEIE bit or EIE bit is set.

- FIFO mode enabled
  An overrun error occurs when the shift register is ready to be transferred when the receive FIFO is full.
  Data can not be transferred from the shift register to the LPUART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty.
  An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:
  - the ORE bit is set;
  - the first entry in the RXFIFO is not lost. It is available when a read to LPUART_RDR is performed.
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXFNEIE bit or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the ICR register.

Note: The ORE bit, when set, indicates that at least 1 data has been lost. T
When the FIFO mode is disabled, there are two possibilities
- if RXNE=1, then the last valid data is stored in the receive register (RDR) and can be read,
- if RXNE=0, then the last valid data has already been read and there is nothing left to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.

Selecting the clock source

The choice of the clock source is done through the Clock Control system (see Section Reset and clock controller (RCC)). The clock source must be selected through the UE bit, before enabling the LPUART.

The clock source must be selected according to two criteria:
- Possible use of the LPUART in low-power mode
- Communication speed.

The clock source frequency is lpuart_ker_ck.
When the dual clock domain and the wake-up from low-power mode features are supported, the lpuart_ker_ck clock source can be configured in the RCC (see Section Reset and clock controller (RCC)). Otherwise, the lpuart_ker_ck is the same as lpuart_pclk.

The lpuart_ker_ck can be divided by a programmable factor in the LPUART_PRES register.

**Figure 705. lpuart_ker_ck clock divider block diagram**

Some lpuart_ker_ck sources enable the LPUART to receive data while the MCU is in low-power mode. Depending on the received data and Wake-up mode selection, the LPUART wakes up the MCU, when needed, in order to transfer the received data by software reading the LPUART_RDR register or by DMA.

For the other clock sources, the system must be active to enable LPUART communications.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver samples each incoming bit as close as possible to the middle of the bit-period. Only a single sample is taken of each of the incoming bits.

*Note: There is no noise detection for data.*

**Framing error**

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:
- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the LPUART_RDR register.
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication, an interrupt is issued if the EIE bit is set in the LPUART_CR3 register.

The FE bit is reset by writing 1 to the FECF in the LPUART_ICR register.
Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of LPUART_CR2; it can be either 1 or 2 in Normal mode.

- **1 stop bit**: sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- **2 stop bits**: sampling for the 2 stop bits is done in the middle of the second stop bit. The RXNE and FE flags are set just after this sample i.e. during the second stop bit. The first stop bit is not checked for framing error.

51.4.8 LPUART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the LPUART_BRR register.

\[
Tx/Rx \text{ baud} = \frac{256 \times \text{lpuart_ker_ck_pres}}{\text{LPUARTDIV}}
\]

LPUARTDIV is defined in the LPUART_BRR register.

**Note:** The baud counters are updated to the new value in the baud registers after a write operation to LPUART_BRR. Hence the baud rate register value must not be changed during communication.

It is forbidden to write values lower than 0x300 in the LPUART_BRR register. f\(_{\text{CK}}\) must range from 3 x baud rate to 4096 x baud rate.

The maximum baud rate that can be reached when the LPUART clock source is the LSE, is 9600 bauds. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock. For example, if the LPUART clock source frequency is 100 MHz, the maximum baud rate that can be reached is about 33 Mbauds.

</table>
51.4.9 Tolerance of the LPUART receiver to clock deviation

The asynchronous receiver of the LPUART works correctly only if the total clock system deviation is less than the tolerance of the LPUART receiver. The causes which contribute to the total deviation are:

- **DTRA**: deviation due to the transmitter error (which also includes the deviation of the transmitter's local oscillator)
- **DQUANT**: error due to the baud rate quantization of the receiver
- **DREC**: deviation of the receiver local oscillator
- **DTCL**: deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[
DTRA + DQUANT + DREC + DTCL + DWU < \text{LPUART receiver tolerance}
\]

where

- **DWU** is the error due to sampling point deviation when the wake-up from low-power mode is used.

When \(M[1:0] = 01\):

\[
DWU = \frac{t_{WULPUART}}{11 \times \text{Tbit}}
\]

When \(M[1:0] = 00\):

\[
DWU = \frac{t_{WULPUART}}{10 \times \text{Tbit}}
\]

When \(M[1:0] = 10\):

\[
DWU = \frac{t_{WULPUART}}{9 \times \text{Tbit}}
\]

\(t_{WULPUART}\) is the time between the detection of the start bit falling edge and the instant when the clock (requested by the peripheral) is ready and reaching the peripheral, and the regulator is ready.

The LPUART receiver can receive data correctly at up to the maximum tolerated deviation specified in Table 547:

- Number of Stop bits defined through STOP[1:0] bits in the LPUART_CR2 register
- LPUART_BRR register value.

Note: The data specified in Table 547 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = 00 (11-bit times when M=’01 or 9-bit times when M = ‘10).

51.4.10 LPUART multiprocessor communication

It is possible to perform LPUART multiprocessor communications (with several LPUARTs connected in a network). For instance one of the LPUARTs can be the master, with its TX output connected to the RX inputs of the other LPUARTs. The others are slaves, with their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant LPUART service overhead for all non addressed receivers.

The non addressed devices can be placed in Mute mode by means of the muting function. To use the Mute mode feature, the MME bit must be set in the LPUART_CR1 register.

Note: When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two lpuart_ker_ck cycles), otherwise Mute mode might remain active.

When the Mute mode is enabled:
- none of the reception status bits can be set;
- all the receive interrupts are inhibited;
- the RWU bit in LPUART_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the LPUART_RQR register, under certain conditions.

The LPUART can enter or exit from Mute mode using one of two methods, depending on the WAKE bit in the LPUART_CR1 register:
- Idle Line detection if the WAKE bit is reset,
- Address mark detection if the WAKE bit is set.

Idle line detection (WAKE=0)

The LPUART enters Mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

The LPUART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the LPUART_ISR register. An example of Mute mode behavior using Idle line detection is given in Figure 706.
Figure 706. Mute mode using Idle line detection

Note: If the MMRQ is set while the IDLE character has already elapsed, Mute mode is not entered (RWU is not set).

If the LPUART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

4-bit/7-bit address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a 1 otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the LPUART_CR2 register.

Note: In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The LPUART enters Mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the LPUART enters Mute mode.

The LPUART also enters Mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The LPUART exits from Mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: When FIFO management is enabled, when MMRQ bit is set while the receiver is sampling the last bit of a data, this data may be received before effectively entering in Mute mode.

An example of Mute mode behavior using address mark detection is given in Figure 707.
51.4.11 LPUART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the LPUART_CR1 register. Depending on the frame length defined by the M bits, the possible LPUART frame formats are as listed in Table 548.

### Table 548: LPUART frame formats

<tr>
<td>10</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

2. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).

### Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame which is made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit is equal to 0 if even parity is selected (PS bit in LPUART_CR1 = 0).

### Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit is equal to 1 if odd parity is selected (PS bit in LPUART_CR1 = 1).
Parity checking in reception

If the parity check fails, the PE flag is set in the LPUART_ISR register and an interrupt is generated if PEIE is set in the LPUART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the LPUART_ICR register.

Parity generation in transmission

If the PCE bit is set in LPUART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

51.4.12 LPUART Single-Wire Half-Duplex Communication

Single-wire Half-duplex mode is selected by setting the HDSEL bit in the LPUART_CR3 register.

The LPUART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in LPUART_CR3.

As soon as HDSEL is written to 1:
- The TX and RX lines are internally connected.
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal LPUART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data is written in the data register while the TE bit is set.

Note: In LPUART communications, in the case of 1-stop bit configuration, the RXNE flag is set in the middle of the stop bit.

51.4.13 Continuous Communication Using DMA and LPUART

The LPUART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

Note: Refer to Section 50.4: USART implementation on page 2229 to determine if the DMA mode is supported. If DMA is not supported, use the LPUSRT as explained in Section 50.5.7. To perform continuous communication. When FIFO is disabled, clear the TXE/RXNE flags in the LPUART_ISR register.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the LPUART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to Section Direct memory access controller) to the LPUART_TDR register whenever the TXFNF flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for LPUART transmission, use the following procedure (x denotes the channel number):
1. Write the LPUART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.

2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the LPUART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.

3. Configure the total number of bytes to be transferred to the DMA control register.

4. Configure the channel priority in the DMA register.

5. Configure DMA interrupt generation after half/ full transfer as required by the application.

6. Clear the TC flag in the LPUART_ISR register by setting the TCCF bit in the LPUART_ICR register.

7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In Transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the LPUART communication is complete. This is required to avoid corrupting the last transmission before disabling the LPUART or entering low-power mode. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

Note: The DMAT bit must not be cleared before the DMA end of transfer.

![Figure 708. Transmission using DMA](image-url)
Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in LPUART_CR3 register. Data are loaded from the LPUART_RDR register to a SRAM area configured using the DMA peripheral (refer to section Direct memory access controller (DMA)) whenever a data byte is received. To map a DMA channel for LPUART reception, use the following procedure:

1. Write the LPUART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from LPUART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

Note: The DMAR bit must not be cleared before the DMA end of transfer.

Figure 709. Reception using DMA

Note: When FIFO management is enabled, the DMA request is triggered by Receive FIFO not empty (i.e. RXFNE = 1).

Error flagging and interrupt generation in multibuffer communication

If any error occurs during a transaction in Multibuffer communication mode, the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt.
enable bit (EIE bit in the LPUART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

51.4.14 RS232 Hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The Figure 710 shows how to connect 2 devices in this mode:

Figure 710. Hardware flow control between 2 LPUARTs

RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the LPUART_CR3 register).

RS232 RTS flow control

If the RTS flow control is enabled (RTSE=1), then RTS is deasserted (tied low) as long as the LPUART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame. Figure 711 shows an example of communication with RTS flow control enabled.

Figure 711. RS232 RTS flow control

Note: When FIFO mode is enabled, RTS is asserted only when RXFIFO is full.
RS232 CTS flow control

If the CTS flow control is enabled (CTSE = 1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE=0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE = 1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the LPUART_CR3 register is set. Figure 712 shows an example of communication with CTS flow control enabled.

![Figure 712. RS232 CTS flow control](image)

Note: For correct behavior, CTS must be deasserted at least 3 LPUART clock source periods before the end of the current character. In addition it must be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

RS485 driver enable

The driver enable feature is enabled by setting bit DEM in the LPUART_CR3 control register. This enables activating the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the start bit. It is programmed using the DEAT [4:0] bitfields in the LPUART_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bitfields in the LPUART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the LPUART_CR3 control register.
The LPUART DEAT and DEDT are expressed in LPUART clock source (f\(_{\text{CK}}\)) cycles:

- The Driver enable assertion time equals
  - \((1 + (\text{DEAT} \times P)) \times f_{\text{CK}}, \text{if } P \neq 0\)
  - \((1 + \text{DEAT}) \times f_{\text{CK}}, \text{if } P = 0\)
- The Driver enable de-assertion time equals
  - \((1 + (\text{DEDT} \times P)) \times f_{\text{CK}}, \text{if } P \neq 0\)
  - \((1 + \text{DEDT}) \times f_{\text{CK}}, \text{if } P = 0\)

where \(P = \text{BRR}[20:11]\)

### 51.4.15 LPUART low-power management

The LPUART has advanced low-power mode functions that enable it to transfer properly data even when the lpuart_pclk clock is disabled. The LPUART is able to wake up the MCU from low-power mode when the UESM bit is set. When the usart_pclk is gated, the LPUART provides a wake-up interrupt (usart_wkup) if a specific action requiring the activation of the usart_pclk clock is needed:

- If FIFO mode is disabled
  - lpuart_pclk clock has to be activated to empty the LPUART data register.
  - In this case, the lpuart_wkup interrupt source is the RXNE set to 1. The RXNEIE bit must be set before entering low-power mode.
- If FIFO mode is enabled
  - lpuart_pclk clock has to be activated
    - to fill the TXFIFO
    - or to empty the RXFIFO
  - In this case, the lpuart_wkup interrupt source can be:
    - RXFIFO not empty. In this case, the RXFNEIE bit must be set before entering low-power mode.
    - RXFIFO full. In this case, the RXFFIE bit must be set before entering low-power mode, the number of received data corresponds to the RXFIFO size, and the RXFF flag is not set.
    - TXFIFO empty. In this case, the TXFEIE bit must be set before entering low-power mode.
  - This enables sending/receiving the data in the TXFIFO/RXFIFO during low-power mode.
  - To avoid overrun/underrun errors and transmit/receive data in low-power mode, the lpuart_wkup interrupt source can be one of the following events:
    - TXFIFO threshold reached. In this case, the TXFTIE bit must be set before entering low-power mode.
    - RXFIFO threshold reached. In this case, the RXFTIE bit must be set before entering low-power mode.
  - For example, the application can set the threshold to the maximum RXFIFO size if the wake-up time is less than the time to receive a single byte across the line.
  - Using the RXFIFO full, TXFIFO empty, RXFIFO not empty and RXFIFO/TXFIFO threshold interrupts to wake up the MCU from low-power mode enables doing as many LPUART transfers as possible during low-power mode with the benefit of optimizing consumption.
Alternatively, a specific `lpuart_wkup` interrupt may be selected through the WUS bitfields. When the wake-up event is detected, the WUF flag is set by hardware and `lpuart_wkup` interrupt is generated if the WUFIE bit is set.

**Note:**

Before entering low-power mode, make sure that no LPUART transfer is ongoing. Checking the BUSY flag cannot ensure that low-power mode is never entered when data reception is ongoing.

The WUF flag is set when a wake-up event is detected, independently of whether the MCU is in low-power or in an active mode.

When entering low-power mode just after having initialized and enabled the receiver, the REACK bit must be checked to ensure the LPUART is actually enabled.

When DMA is used for reception, it must be disabled before entering low-power mode and re-enabled upon exit from low-power mode.

When FIFO is enabled, the wake-up from low-power mode on address match is only possible when Mute mode is enabled.

**Using Mute mode with low-power mode**

If the LPUART is put into Mute mode before entering low-power mode:

- Wake-up from Mute mode on idle detection must not be used, because idle detection cannot work in low-power mode.
- If the wake-up from Mute mode on address match is used, then the low-power mode wake-up source from must also be the address match. If the RXNE flag was set when entering the low-power mode, the interface remains in Mute mode upon address match and wake up from low-power mode.

**Note:**

When FIFO management is enabled, Mute mode is used with wake-up from low-power mode without any constraints (i.e. the two points mentioned above about mute and low-power mode are valid only when FIFO management is disabled).

**Wake-up from low-power mode when LPUART kernel clock lpuart_ker_ck is OFF in low-power mode**

If during low-power mode, the lpuart_ker_ck clock is switched OFF, when a falling edge on the LPUART receive line is detected, the LPUART interface requests the lpuart_ker_ck clock to be switched ON thanks to the lpuart_ker_ck_req signal. The lpuart_ker_ck is then used for the frame reception.

If the wake-up event is verified, the MCU wakes up from low-power mode and data reception goes on normally.

If the wake-up event is not verified, the usart_ker_ck is switched OFF again, the MCU is not waken up and stays in low-power mode and the kernel clock request is released.

The example below shows the case of wake-up event programmed to “address match detection” and FIFO management disabled.

_Figure 713_ shows the behavior when the wake-up event is verified.
Figure 713. Wake-up event verified (wake-up event = address match, FIFO disabled)

- Address match event WUF = '1'
- LPUART sends a wakeup event to the MCU
- Data reception goes on

Figure 714 shows the behavior when the wake-up event is not verified.

Figure 714. Wake-up event not verified (wake-up event = address match, FIFO disabled)

- Address does not match

Note: The above figures are valid when address match or any received frame is used as wake-up event. In the case the wake-up event is the start bit detection, the LPUART sends the wake-up event to the MCU at the end of the start bit.
Determining the maximum LPUART baud rate that enables to correctly wake up the MCU from low-power mode

The maximum baud rate that enables to correctly wake up the MCU from low-power mode depends on the wake-up time parameter (refer to the device datasheet) and on the LPUART receiver tolerance (see Section 51.4.9: Tolerance of the LPUART receiver to clock deviation).

Let us take the example of OVER8 = 0, M bits = 01, ONEBIT = 0 and BRR [3:0] = 0000. In these conditions, according to Table 547: Tolerance of the LPUART receiver, the LPUART receiver tolerance equals 3.41%.

\[
D_{WU\text{max}} = \frac{t_{\text{WULPUART}}}{(11 \times T_{\text{bit Min}})}
\]

\[
T_{\text{bit Min}} = \frac{t_{\text{WULPUART}}}{(11 \times D_{WU\text{max}})}
\]

where \(t_{\text{WULPUART}}\) is the wake-up time from low-power mode.

If we consider the ideal case where DTRA, DQUANT, DREC and DTCL parameters are at 0%, the maximum value of DWU is 3.41%. In reality, we need to consider at least the lpuart_ker_ck inaccuracy.

For example, if HSI is used as lpuart_ker_ck, and the HSI inaccuracy is of 1%, then we obtain:

\[
t_{\text{WULPUART}} = 3 \mu\text{s} \text{ (values provided only as examples; for correct values, refer to the device datasheet).}
\]

\[
D_{WU\text{max}} = 3.41\% - 1\% = 2.41\%
\]

\[
T_{\text{bit min}} = \frac{3 \mu\text{s}}{(11 \times 2.41\%)} = 11.32 \mu\text{s}.
\]

As a result, the maximum baud rate that enables to wake up correctly from low-power mode is: \(1/11.32 \mu\text{s} = 88.36 \text{kbauds}.

### 51.5 LPUART in low-power modes

<table>

</table>
1. The LPUART can wake up the device from Stop mode only if the peripheral instance supports the Wake-up from Stop mode feature. Refer to Section 51.3: LPUART implementation for the list of supported Stop modes.

2. RXFF flag is asserted if the LPUART receives n+1 data (n being the RXFIFO size): n data in the RXFIFO and 1 data in LPUART_RDR. In Stop mode, LPUART_RDR is not clocked. As a result, this register is not written and once n data are received and written in the RXFIFO, the RXFF interrupt is asserted (RXFF flag is not set).

3. When OVRDIS = 0.

51.7 LPUART registers

Refer to Section 1.2 on page 101 for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

51.7.1 LPUART control register 1 (LPUART_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

**FIFO mode enabled**

**Bit 31 RXFIE:** RXFIFO Full interrupt enable

- This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated when RXFF=1 in the LPUART_ISR register

**Bit 30 TXFEIE:** TXFIFO empty interrupt enable

- This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated when TXFE=1 in the LPUART_ISR register

**Bit 29 FIFOEN:** FIFO mode enable

- This bit is set and cleared by software.
- 0: FIFO mode is disabled.
- 1: FIFO mode is enabled.
Bit 28  **M1**: Word length

This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.

- M[1:0] = 00: 1 Start bit, 8 Data bits, n Stop bit
- M[1:0] = 01: 1 Start bit, 9 Data bits, n Stop bit
- M[1:0] = '10: 1 Start bit, 7 Data bits, n Stop bit

This bit can only be written when the LPUART is disabled (UE=0).

*Note:* In 7-bit data length mode, the Smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

Bits 27:26  Reserved, must be kept at reset value.

Bits 25:21  **DEAT[4:0]**: Driver Enable assertion time

This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in lpuart_ker_ck clock cycles. For more details, refer to Section 50.5.21: RS232 Hardware flow control and RS485 Driver Enable. This bitfield can only be written when the LPUART is disabled (UE=0).

Bits 20:16  **DEDT[4:0]**: Driver Enable deassertion time

This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in lpuart_ker_ck clock cycles. For more details, refer to Section 51.4.14: RS232 Hardware flow control and RS485 Driver Enable. If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed. This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 15  Reserved, must be kept at reset value.

Bit 14  **CMIE**: Character match interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register.

Bit 13  **MME**: Mute mode enable

This bit activates the Mute mode function of the LPUART. When set, the LPUART can switch between the active and Mute modes, as defined by the WAKE bit. It is set and cleared by software.

- 0: Receiver in Active mode permanently
- 1: Receiver can switch between Mute mode and Active mode.

Bit 12  **M0**: Word length

This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description). This bit can only be written when the LPUART is disabled (UE=0).

Bit 11  **WAKE**: Receiver wake-up method

This bit determines the LPUART wake-up method from Mute mode. It is set or cleared by software.

- 0: Idle line
- 1: Address mark

This bitfield can only be written when the LPUART is disabled (UE=0).
Bit 10  **PCE**: Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if \(M=1\); 8th bit if \(M=0\)) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
- 0: Parity control disabled
- 1: Parity control enabled

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 9  **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
- 0: Even parity
- 1: Odd parity

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 8  **PEIE**: PE interrupt enable
This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated whenever PE=1 in the LPUART_ISR register

Bit 7  **TXFNFIE**: TXFIFO not full interrupt enable
This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated whenever TXFNF =1 in the LPUART_ISR register

Bit 6  **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated whenever TC=1 in the LPUART_ISR register

Bit 5  **RXFNEIE**: RXFIFO not empty interrupt enable
This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated whenever ORE=1 or RXFNE=1 in the LPUART_ISR register

Bit 4  **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated whenever IDLE=1 in the LPUART_ISR register

Bit 3  **TE**: Transmitter enable
This bit enables the transmitter. It is set and cleared by software.
- 0: Transmitter is disabled
- 1: Transmitter is enabled

**Note:** During transmission, a low pulse on the TE bit (0 followed by 1) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. To ensure the required duration, the software can poll the TEACK bit in the LPUART_ISR register.

In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.
Bit 2 \textbf{RE:} Receiver enable

This bit enables the receiver. It is set and cleared by software.

0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 \textbf{UESM:} LPUART enable in low-power mode

When this bit is cleared, the LPUART cannot wake up the MCU from low-power mode.
When this bit is set, the LPUART can wake up the MCU from low-power mode.
This bit is set and cleared by software.
0: USART not able to wake up the MCU from low-power mode.
1: USART able to wake up the MCU from low-power mode.

\textit{Note:} It is recommended to set the UESM bit just before entering low-power mode, and clear it when exiting low-power mode.

Bit 0 \textbf{UE:} LPUART enable

When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART_ISR are reset. This bit is set and cleared by software.
0: LPUART prescaler and outputs disabled, low-power mode
1: LPUART enabled

\textit{Note:} To enter low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART_ISR to be set before resetting the UE bit.
The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

### 51.7.2 LPUART control register 1 [alternate] (LPUART\_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

\textbf{FIFO mode disabled}

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **FIFOEN**: FIFO mode enable
   This bit is set and cleared by software.
   0: FIFO mode is disabled.
   1: FIFO mode is enabled.

Bit 28 **M1**: Word length
   This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.
   \[ M[1:0] = \begin{cases} 00 & \text{1 Start bit, 8 Data bits, n Stop bit} \\ 01 & \text{1 Start bit, 9 Data bits, n Stop bit} \\ 10 & \text{1 Start bit, 7 Data bits, n Stop bit} \end{cases} \]
   This bit can only be written when the LPUART is disabled (UE=0).

**Note:** In 7-bit data length mode, the Smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:21 **DEAT[4:0]**: Driver Enable assertion time
   This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in lpuart_ker_ck clock cycles. For more details, refer **Section 50.5.21: RS232 Hardware flow control and RS485 Driver Enable**.
   This bitfield can only be written when the LPUART is disabled (UE=0).

Bits 20:16 **DEDT[4:0]**: Driver Enable deassertion time
   This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in lpuart_ker_ck clock cycles. For more details, refer **Section 51.4.14: RS232 Hardware flow control and RS485 Driver Enable**.
   If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.
   This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **CMIE**: Character match interrupt enable
   This bit is set and cleared by software.
   0: Interrupt is inhibited
   1: A LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register.

Bit 13 **MME**: Mute mode enable
   This bit activates the Mute mode function of the LPUART. When set, the LPUART can switch between the active and Mute modes, as defined by the WAKE bit. It is set and cleared by software.
   0: Receiver in Active mode permanently
   1: Receiver can switch between Mute mode and Active mode.

Bit 12 **M0**: Word length
   This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
   This bit can only be written when the LPUART is disabled (UE=0).
Bit 11 **WAKE**: Receiver wake-up method

This bit determines the LPUART wake-up method from Mute mode. It is set or cleared by software.

- 0: Idle line
- 1: Address mark

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 10 **PCE**: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software.

- 0: Parity control disabled
- 1: Parity control enabled

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 9 **PS**: Parity selection

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.

- 0: Even parity
- 1: Odd parity

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 8 **PEIE**: PE interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated whenever PE=1 in the LPUART_ISR register

Bit 7 **TXEIE**: Transmit data register empty

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated whenever TXE =1 in the LPUART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated whenever TC=1 in the LPUART_ISR register

Bit 5 **RXNEIE**: Receive data register not empty

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated whenever ORE=1 or RXNE=1 in the LPUART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated whenever IDLE=1 in the LPUART_ISR register
Bit 3 TE: Transmitter enable
This bit enables the transmitter. It is set and cleared by software.
0: Transmitter is disabled
1: Transmitter is enabled

Note: During transmission, a low pulse on the TE bit (0 followed by 1) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to ‘1’. To ensure the required duration, the software can poll the TEACK bit in the LPUART_ISR register.
In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.

Bit 2 RE: Receiver enable
This bit enables the receiver. It is set and cleared by software.
0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 UESM: LPUART enable in low-power mode
When this bit is cleared, the LPUART cannot wake up the MCU from low-power mode.
When this bit is set, the LPUART can wake up the MCU from low-power mode.
This bit is set and cleared by software.
0: USART not able to wake up the MCU from low-power mode.
1: USART able to wake up the MCU from low-power mode.

Note: It is recommended to set the UESM bit just before entering low-power mode, and clear it when exiting low-power mode.

Bit 0 UE: LPUART enable
When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART_ISR are reset. This bit is set and cleared by software.
0: LPUART prescaler and outputs disabled, low-power mode
1: LPUART enabled

Note: To enter low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART_ISR to be set before resetting the UE bit.
The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

51.7.3 LPUART control register 2 (LPUART_CR2)
Address offset: 0x04
Reset value: 0x0000 0000
Bits 31:24 **ADD[7:0]**: Address of the LPUART node

These bits give the address of the LPUART node in Mute mode or a character code to be recognized in low-power or Run mode:

- In Mute mode: they are used in multiprocessor communication to wake up from Mute mode with 4-bit/7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. In 4-bit address mark detection, only ADD[3:0] bits are used.

- In low-power mode: they are used for wake up from low-power mode on character match. When WUS[1:0] is programmed to 0b00 (WUF active on address match), the wake-up from low-power mode is performed when the received character corresponds to the character programmed through ADD[6:0] or ADD[3:0] bitfield (depending on ADDM7 bit), and WUF interrupt is enabled by setting WUFIE bit. The MSB of the character sent by transmitter should be equal to 1.

- In Run mode with Mute mode inactive (for example, end-of-block detection in ModBus protocol): the whole received character (8 bits) is compared to ADD[7:0] value and CMF flag is set on match. An interrupt is generated if the CMIE bit is set. These bits can only be written when the reception is disabled (RE = 0) or when the USART is disabled (UE = 0).

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **MSBFIRST**: Most significant bit first

This bit is set and cleared by software.

- 0: data is transmitted/received with data bit 0 first, following the start bit.
- 1: data is transmitted/received with the MSB (bit 7/8) first, following the start bit.

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 18 **DATAINV**: Binary data inversion

This bit is set and cleared by software.

- 0: Logical data from the data register are send/received in positive/direct logic. (1=H, 0=L)
- 1: Logical data from the data register are send/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 17 **TXINV**: TX pin active level inversion

This bit is set and cleared by software.

- 0: TX pin signal works using the standard logic levels (V_DD =1/idle, Gnd=0/mark)
- 1: TX pin signal values are inverted. ((V_DD =0/mark, Gnd=1/idle). This enables the use of an external inverter on the TX line.

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 16 **RXINV**: RX pin active level inversion

This bit is set and cleared by software.

- 0: RX pin signal works using the standard logic levels (V_DD =1/idle, Gnd=0/mark)
- 1: RX pin signal values are inverted. ((V_DD =0/mark, Gnd=1/idle). This enables the use of an external inverter on the RX line.

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 15 **SWAP**: Swap TX/RX pins

This bit is set and cleared by software.

- 0: TX/RX pins are used as defined in standard pinout
- 1: The TX and RX pins functions are swapped. This enables to work in the case of a cross-wired connection to another UART.

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 14 Reserved, must be kept at reset value.
Bits 13:12 STOP[1:0]: STOP bits
  These bits are used for programming the stop bits.
  00: 1 stop bit
  01: Reserved.
  10: 2 stop bits
  11: Reserved
  This bitfield can only be written when the LPUART is disabled (UE=0).

Bits 11:5 Reserved, must be kept at reset value.

Bit 4 ADDM7: 7-bit Address Detection/4-bit Address Detection
  This bit is for selection between 4-bit address detection or 7-bit address detection.
  0: 4-bit address detection
  1: 7-bit address detection (in 8-bit data mode)
  This bit can only be written when the LPUART is disabled (UE=0)
  Note: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address
  (ADD[5:0] and ADD[7:0]) respectively.

Bits 3:0 Reserved, must be kept at reset value.

51.7.4 LPUART control register 3 (LPUART_CR3)

Address offset: 0x08

Reset value: 0x0000 0000

Note: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.
Bits 31:29 **TXFTCFG[2:0]**: TXFIFO threshold configuration
- 000: TXFIFO reaches 1/8 of its depth.
- 001: TXFIFO reaches 1/4 of its depth.
- 110: TXFIFO reaches 1/2 of its depth.
- 100: TXFIFO reaches 7/8 of its depth.
- 101: TXFIFO becomes empty.
- Remaining combinations: Reserved.

Bit 28 **RXFTIE**: RXFIFO threshold interrupt enable
This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated when Receive FIFO reaches the threshold programmed in RXFTCFG.

Bits 27:25 **RXFTCFG[2:0]**: Receive FIFO threshold configuration
- 000: Receive FIFO reaches 1/8 of its depth.
- 001: Receive FIFO reaches 1/4 of its depth.
- 110: Receive FIFO reaches 1/2 of its depth.
- 011: Receive FIFO reaches 3/4 of its depth.
- 100: Receive FIFO reaches 7/8 of its depth.
- 101: Receive FIFO becomes full.
- Remaining combinations: Reserved.

Bit 24 Reserved, must be kept at reset value.

Bit 23 **TXFTIE**: TXFIFO threshold interrupt enable
This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated when TXFIFO reaches the threshold programmed in TXFTCFG.

Bit 22 **WUFIE**: Wake-up from low-power mode interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever WUF=1 in the LPUART_ISR register

Note: **WUFIE must be set before entering in low-power mode.**
If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 51.3: LPUART implementation on page 2317.

Bits 21:20 **WUS[1:0]**: Wake-up from low-power mode interrupt flag selection
This bitfield specifies the event which activates the WUF (Wake-up from low-power mode flag).
- 00: WUF active on address match (as defined by ADD[7:0] and ADDM7)
- 01: Reserved.
- 10: WUF active on start bit detection
- 11: WUF active on RXNE/RXFNE.

This bitfield can only be written when the LPUART is disabled (UE=0).

Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 51.3: LPUART implementation on page 2317.

Bits 19:16 Reserved, must be kept at reset value.
Bit 15 **DEP**: Driver enable polarity selection
0: DE signal is active high.
1: DE signal is active low.
This bit can only be written when the LPUART is disabled (UE=0).

Bit 14 **DEM**: Driver enable mode
This bit enables the user to activate the external transceiver control, through the DE signal.
0: DE function is disabled.
1: DE function is enabled. The DE signal is output on the RTS pin.
This bit can only be written when the LPUART is disabled (UE=0).

Bit 13 **DDRE**: DMA Disable on Reception Error
0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data is transferred.
1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE before clearing the error flag.
This bit can only be written when the LPUART is disabled (UE=0).

Note: The reception errors are: parity error, framing error or noise error.

Bit 12 **OVRDIS**: Overrun Disable
This bit is used to disable the receive overrun detection.
0: Overrun Error Flag, ORE is set when received data is not read before receiving new data.
1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the LPUART_RDR register.
This bit can only be written when the LPUART is disabled (UE=0).

Note: This control bit enables checking the communication flow w/o reading the data.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **CTSIE**: CTS interrupt enable
0: Interrupt is inhibited
1: An interrupt is generated whenever CTSIF=1 in the LPUART_ISR register

Bit 9 **CTSE**: CTS enable
0: CTS hardware flow control disabled
1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0). If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.
This bit can only be written when the LPUART is disabled (UE=0)

Bit 8 **RTSE**: RTS enable
0: RTS hardware flow control disabled
1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is deasserted (pulled to 0) when data can be received.
This bit can only be written when the LPUART is disabled (UE=0).

Bit 7 **DMAT**: DMA enable transmitter
This bit is set/reset by software
0: DMA mode is disabled for transmission

Bit 6 **DMAR**: DMA enable receiver

This bit is set/reset by software

- 1: DMA mode is enabled for reception
- 0: DMA mode is disabled for reception

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **HDSEL**: Half-duplex selection

Selection of Single-wire Half-duplex mode

- 0: Half-duplex mode is not selected
- 1: Half-duplex mode is selected

This bit can only be written when the LPUART is disabled (UE=0).

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **EIE**: Error interrupt enable

Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error or noise flag (FE=1 or ORE=1 or NE=1 in the LPUART_ISR register).

- 0: Interrupt is inhibited
- 1: An interrupt is generated when FE=1 or ORE=1 or NE=1 in the LPUART_ISR register.

**51.7.5 LPUART baud rate register (LPUART_BRR)**

This register can only be written when the LPUART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C

Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **BRR[19:0]**: LPUART baud rate division (LPUARTDIV)

Note: It is forbidden to write values lower than 0x300 in the LPUART_BRR register.

Provided that LPUART_BRR must be ≥ 0x300 and LPUART_BRR is 20 bits, a care must be taken when generating high baud rates using high fck values. fck must be in the range [3 x baud rate..4096 x baud rate].
51.7.6  LPUART request register (LPUART_RQR)

Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **TXFT**: TXFIFO threshold flag  
This bit is set by hardware when the TXFIFO reaches the threshold programmed in TXFTCFG in LPUART_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFIE bit = 1 (bit 31) in the LPUART_CR3 register.  
0: TXFIFO does not reach the programmed threshold.  
1: TXFIFO reached the programmed threshold.

Bit 26  **RXFT**: RXFIFO threshold flag  
This bit is set by hardware when the RXFIFO reaches the threshold programmed in RXFTCFG in LPUART_CR3 register i.e. the Receive FIFO contains RXFTCFG data. An interrupt is generated if the RXFTIE bit = 1 (bit 27) in the LPUART_CR3 register.  
0: Receive FIFO does not reach the programmed threshold.  
1: Receive FIFO reached the programmed threshold.

Bit 25  Reserved, must be kept at reset value.

Bit 24  **RXFF**: RXFIFO Full  
This bit is set by hardware when the number of received data corresponds to RXFIFO size + 1 (RXFIFO full + 1 data in the LPUART_RDR register. An interrupt is generated if the RXFFIE bit = 1 in the LPUART_CR1 register.  
0: RXFIFO is not Full.  
1: RXFIFO is Full.

Bit 23  **TXFE**: TXFIFO Empty  
This bit is set by hardware when TXFIFO is Empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the LPUART_RQR register. An interrupt is generated if the TXFEIE bit = 1 (bit 30) in the LPUART_CR1 register.  
0: TXFIFO is not empty.  
1: TXFIFO is empty.

Bit 22  **REACK**: Receive enable acknowledge flag  
This bit is set/reset by hardware, when the Receive Enable value is taken into account by the LPUART.  
It can be used to verify that the LPUART is ready for reception before entering low-power mode.  
**Note**: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.

Bit 21  **TEACK**: Transmit enable acknowledge flag  
This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART.  
It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the LPUART_CR1 register, in order to respect the TE=0 minimum period.

Bit 20  **WUF**: Wake-up from low-power mode flag  
This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the LPUART_ICR register. An interrupt is generated if WUFEIE = 1 in the LPUART_CR3 register.  
**Note**: When UESM is cleared, WUF flag is also cleared.  
**If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 51.3: LPUART implementation on page 2317.**
Bit 19 **RWU**: Receiver wake-up from Mute mode
This bit indicates if the LPUART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART_CR1 register.
When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART_RQR register.
0: Receiver in Active mode
1: Receiver in Mute mode
*Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*

Bit 18 **SBKF**: Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRO bit in the LPUART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.
0: No break character transmitted
1: Break character transmitted

Bit 17 **CMF**: Character match flag
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART_ICR register.
An interrupt is generated if CMIE=1 in the LPUART_CR1 register.
0: No Character match detected
1: Character match detected

Bit 16 **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
0: LPUART is idle (no reception)
1: Reception on going

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CTS**: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
0: CTS line set
1: CTS line reset
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 9 **CTSIF**: CTS interrupt flag
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART_ICR register.
An interrupt is generated if CTSIE=1 in the LPUART_CR3 register.
0: No change occurred on the CTS status line
1: A change occurred on the CTS status line
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 8 Reserved, must be kept at reset value.
Bit 7  **TXFNF**: TXFIFO not full  
TXFNF is set by hardware when TXFIFO is not full, and so data can be written in the LPUART_TDR. Every write in the LPUART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data can not be written into the LPUART_TDR.

The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF must be checked prior to writing in TXFIFO (TXFNF and TXFE are set at the same time).

An interrupt is generated if the TXFNFIE bit = 1 in the LPUART_CR1 register.

0: Data register is full/Transmit FIFO is full.
1: Data register/Transmit FIFO is not full.

*Note*: This bit is used during single buffer transmission.

Bit 6  **TC**: Transmission complete  
This bit indicates that the last data written in the LPUART_TDR has been transmitted out of the shift register. The TC flag behaves as follows:

- When TDN = 0, the TC flag is set when the transmission of a frame containing data is complete and when TXF is set.
- When TDN is equal to the number of data in the TXFIFO, the TC flag is set when TXFIFO is empty and TDN is reached.
- When TDN is greater than the number of data in the TXFIFO, TC remains cleared until the TXFIFO is filled again to reach the programmed number of data to be transferred.
- When TDN is less than the number of data in the TXFIFO, TC is set when TDN is reached even if the TXFIFO is not empty.

An interrupt is generated if TCIE=1 in the LPUART_CR1 register.

TC bit is cleared by software by writing 1 to the TCCF in the LPUART_ICR register or by writing to the LPUART_TDR register.

Bit 5  **RXFNE**: RXFIFO not empty  
RXFNE bit is set by hardware when the RXFIFO is not empty, and so data can be read from the LPUART_RDR register. Every read of the LPUART_RDR frees a location in the RXFIFO.

It is cleared when the RXFIFO is empty.

The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.

An interrupt is generated if RXFNEIE=1 in the LPUART_CR1 register.

0: Data is not received
1: Received data is ready to be read.

Bit 4  **IDLE**: Idle line detected  
This bit is set by hardware when an Idle line is detected. An interrupt is generated if IDLEIE=1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.

0: No Idle line is detected
1: Idle line is detected

*Note*: The IDLE bit is not set again until the RXFNE bit has been set (i.e. a new idle line occurs).

If Mute mode is enabled (MME=1), IDLE is set if the LPUART is not mute (RWU=0), whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.
Bit 3  **ORE**: Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the LPUART_RDR register while RXFF = 1. It is cleared by a software, writing 1 to the ORECF, in the LPUART_ICR register.

An interrupt is generated if RXFNEIE=1 in the LPUART_CR1 register, or EIE = 1 in the LPUART_CR3 register.

1: Overrun error is detected

*Note:* When this bit is set, the LPUART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the LPUART_CR3 register.

Bit 2  **NE**: Start bit noise detection flag

This bit is set by hardware when noise is detected on the start bit of a received frame. It is cleared by software, writing 1 to the NFCF bit in the LPUART_ICR register.

0: No noise is detected
1: Noise is detected

*Note:* This bit does not generate an interrupt as it appears at the same time as the RXFNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

This error is associated with the character in the LPUART_RDR.

Bit 1  **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the LPUART_ICR register.

When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the LPUART_CR3 register.

0: No Framing error is detected
1: Framing error or break character is detected

*Note:* This error is associated with the character in the LPUART_RDR.

Bit 0  **PE**: Parity error

This bit is set by hardware when a parity error occurs in Reception mode. It is cleared by software, writing 1 to the PECF in the LPUART_ICR register.

An interrupt is generated if PEIE = 1 in the LPUART_CR1 register.

0: No parity error
1: Parity error

*Note:* This error is associated with the character in the LPUART_RDR.
51.7.8 LPUART interrupt and status register [alternate] (LPUART_ISR)

Address offset: 0x1C
Reset value: 0x0000 00C0

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

### FIFO mode disabled

Bits 31:23 Reserved, must be kept at reset value.

- **Bit 22** REACK: Receive enable acknowledge flag
  - This bit is set/reset by hardware, when the Receive Enable value is taken into account by the LPUART.
  - It can be used to verify that the LPUART is ready for reception before entering low-power mode.
  - **Note:** If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.

- **Bit 21** TEACK: Transmit enable acknowledge flag
  - This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART.
  - It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the LPUART_CR1 register, in order to respect the TE=0 minimum period.

- **Bit 20** WUF: Wake-up from low-power mode flag
  - This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the LPUART_ICR register. An interrupt is generated if WUFIE=1 in the LPUART_CR3 register.
  - **Note:** When UESM is cleared, WUF flag is also cleared.
  - If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 51.3: LPUART implementation on page 2317.

- **Bit 19** RWU: Receiver wake-up from Mute mode
  - This bit indicates if the LPUART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART_CR1 register.
  - When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART_RQR register.
  - **0:** Receiver in Active mode
  - **1:** Receiver in Mute mode
  - **Note:** If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.
Bit 18 **SBKF**: Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the LPUART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.
0: No break character transmitted
1: Break character transmitted

Bit 17 **CMF**: Character match flag
This bit is set by hardware, when the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART_ICR register.
An interrupt is generated if CMIE=1 in the LPUART_CR1 register.
0: No Character match detected
1: Character match detected

Bit 16 **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
0: LPUART is idle (no reception)
1: Reception ongoing

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CTS**: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
0: CTS line set
1: CTS line reset
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 9 **CTSF**: CTS interrupt flag
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART_ICR register.
An interrupt is generated if CTSIE=1 in the LPUART_CR3 register.
0: No change occurred on the CTS status line
1: A change occurred on the CTS status line
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 8 Reserved, must be kept at reset value.

Bit 7 **TXE**: Transmit data register empty
TXE is set by hardware when the content of the LPUART_TDR register has been transferred into the shift register. It is cleared by a write to the LPUART_TDR register.
An interrupt is generated if the TXEIE bit =1 in the LPUART_CR1 register.
0: Data register is full/Transmit FIFO is full.
1: Data register/Transmit FIFO is not full.
*Note: This bit is used during single buffer transmission.*

Bit 6 **TC**: Transmission complete
This bit indicates that the last data written in the USART_TDR has been transmitted out of the shift register. The TC flag is set when the transmission of a frame containing data is complete and when TXE is set.
An interrupt is generated if TCIE=1 in the LPUART_CR1 register.
TC bit is cleared by software by writing 1 to the TCCF in the USART_ICR register or by writing to the USART_TDR register.
Bit 5 RXNE: Read data register not empty
RXNE bit is set by hardware when the content of the LPUART_RDR shift register has been transferred to the LPUART_RDR register. It is cleared by a read to the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register. The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register. An interrupt is generated if RXNEIE=1 in the LPUART_CR1 register.
0: Data is not received
1: Received data is ready to be read.

Bit 4 IDLE: Idle line detected
This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE=1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.
0: No Idle line is detected
1: Idle line is detected

Note: The IDLE bit is not set again until the RXNE bit has been set (i.e. a new idle line occurs).

If Mute mode is enabled (MME=1), IDLE is set if the LPUART is not mute (RWU=0), whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.

Bit 3 ORE: Overrun error
This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the LPUART_RDR register while RXNE=1 (RXFF = 1 in case FIFO mode is enabled). It is cleared by a software, writing 1 to the ORECF, in the LPUART_ICR register.
An interrupt is generated if RXNEIE=1 in the LPUART_CR1 register, or EIE = 1 in the LPUART_CR3 register.
1: Overrun error is detected

Note: When this bit is set, the LPUART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.
This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the LPUART_CR3 register.
Bit 2 **NE**: Start bit noise detection flag

This bit is set by hardware when noise is detected on the start bit of a received frame. It is cleared by software, writing 1 to the NFCF bit in the LPUART_ICR register.

0: No noise is detected
1: Noise is detected

*Note:* This bit does not generate an interrupt as it appears at the same time as the RXNE/RXFNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

In FIFO mode, this error is associated with the character in the LPUART_RDR.

Bit 1 **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the LPUART_ICR register.

When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame). An interrupt is generated if EIE = 1 in the LPUART_CR3 register.

0: No Framing error is detected
1: Framing error or break character is detected

*Note:* In FIFO mode, this error is associated with the character in the LPUART_RDR.

Bit 0 **PE**: Parity error

This bit is set by hardware when a parity error occurs in Reception mode. It is cleared by software, writing 1 to the PECF in the LPUART_ICR register.

An interrupt is generated if PEIE = 1 in the LPUART_CR1 register.

0: No parity error
1: Parity error

*Note:* In FIFO mode, this error is associated with the character in the LPUART_RDR.

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **WUCF**: Wake-up from low-power mode clear flag

Writing 1 to this bit clears the WUF flag in the USART_ISR register.

*Note:* If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 51.3: LPUART implementation on page 2317.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CMCF**: Character match clear flag

Writing 1 to this bit clears the CMF flag in the LPUART_ISR register.

Bits 16:10 Reserved, must be kept at reset value.

---

**Notes:**

The LPUART interrupt flag clear register (LPUART_ICR) is used to clear various interrupt flags in the LPUART module. Each bit in the register corresponds to a specific interrupt or error condition in the LPUART module. Writing a 1 to a bit in this register clears the corresponding flag in the LPUART_ISR register, which may cause an interrupt to occur. The register is located at address offset 0x20 and its reset value is 0x0000 0000.

### Additional Notes:

- **NE (Start bit noise detection flag):** This flag is set by hardware when noise is detected on the start bit of a received frame. It is cleared by software by setting the NFCF bit in the LPUART_ICR register.

- **FE (Framing error):** This flag is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software by setting the FECF bit in the LPUART_ICR register.

- **PE (Parity error):** This flag is set by hardware when a parity error occurs in Reception mode. It is cleared by software by setting the PECF bit in the LPUART_ICR register.

- **WUCF (Wake-up from low-power mode clear flag):** Writing 1 to this bit clears the WUF flag in the USART_ISR register. If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value.

- **CMCF (Character match clear flag):** Writing 1 to this bit clears the CMF flag in the LPUART_ISR register.

---

**References:**

- Section 51.3: LPUART implementation on page 2317.
Bit 9 **CTSCF**: CTS clear flag  
Writing 1 to this bit clears the CTSIF flag in the LPUART_ISR register.

Bit 8 Reserved, must be kept at reset value.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TCCF**: Transmission complete clear flag  
Writing 1 to this bit clears the TC flag in the LPUART_ISR register.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IDLECF**: Idle line detected clear flag  
Writing 1 to this bit clears the IDLE flag in the LPUART_ISR register.

Bit 3 **ORECF**: Overrun error clear flag  
Writing 1 to this bit clears the ORE flag in the LPUART_ISR register.

Bit 2 **NECF**: Noise detected clear flag  
Writing 1 to this bit clears the NE flag in the LPUART_ISR register.

Bit 1 **FECF**: Framing error clear flag  
Writing 1 to this bit clears the FE flag in the LPUART_ISR register.

Bit 0 **PECF**: Parity error clear flag  
Writing 1 to this bit clears the PE flag in the LPUART_ISR register.

### 51.7.10 LPUART receive data register (LPUART_RDR)

</tbody>
</table>

**Bits 31:9** Reserved, must be kept at reset value.

**Bits 8:0** **RDR[8:0]**: Receive data value  
Contains the received data character.  
The RDR register provides the parallel interface between the input shift register and the internal bus (see Figure 701).  
When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.
51.7.11 LPUART transmit data register (LPUART_TDR)

Address offset: 0x28
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **TDR[8:0]**: Transmit data value

Contains the data character to be transmitted.

The TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 701).

When transmitting with the parity enabled (PCE bit set to 1 in the LPUART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

*Note: This register must be written only when TXE/TXFNF=1.*

51.7.12 LPUART prescaler register (LPUART_PRESC)

This register can only be written when the LPUART is disabled (UE=0).

Address offset: 0x2C
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **PRESCALER[3:0]**

The value in this register is used to divide the baud rate generator clock before being applied to the baud rate generator. This register is only accessible when the LPUART is disabled (UE=0).
Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **PRESCALER[3:0]:** Clock prescaler

The LPUART input clock can be divided by a prescaler:

- 0000: input clock not divided
- 0001: input clock divided by 2
- 0010: input clock divided by 4
- 0011: input clock divided by 6
- 0100: input clock divided by 8
- 0101: input clock divided by 10
- 0110: input clock divided by 12
- 0111: input clock divided by 16
- 1000: input clock divided by 32
- 1001: input clock divided by 64
- 1010: input clock divided by 128
- 1011: input clock divided by 256

Remaining combinations: Reserved.

Note: When PRESCALER is programmed with a value different of the allowed ones, programmed prescaler value is equal to 1011 i.e. input clock divided by 256.

51.7.13 LPUART register map

### Table 551. LPUART register map and reset values

52 Serial peripheral interface (SPI)

52.1 Introduction

The serial peripheral interface (SPI) can be used to communicate with external devices while using the specific synchronous protocol. The SPI protocol supports half-duplex, full-duplex and simplex synchronous, serial communication with external devices. The interface can be configured as master or slave and is capable of operating in multi slave or multi master configurations. The device configured as master provides communication clock (SCK) to the slave device. The Slave select (SS) and ready (RDY) signals can be applied optionally just to setup communication with concrete slave and to assure it handles the data flow properly. The Motorola data format is used by default, but some other specific modes are supported as well.

52.2 SPI main features

- Full-duplex synchronous transfers on three lines
- Half-duplex synchronous transfer on two lines (with bidirectional data line)
- Simplex synchronous transfers on two lines (with unidirectional data line)
- From 4- up to 32-bit data size selection or fixed to 8-bit multiples
- Multi master or multi slave mode capability
- Dual clock domain, the peripheral kernel clock is independent from the APB bus clock
- Baud rate prescaler up to kernel frequency/2 or bypass from RCC in Master mode
- Protection of configuration and setting
- Hardware or software management of SS for both master and slave
- Adjustable minimum delays between data and between SS and data flow
- Configurable SS signal polarity and timing, MISO x MOSI swap capability
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Programmable number of data within a transaction to control SS and CRC
- Dedicated transmission and reception flags with interrupt capability
- SPI Motorola and TI formats support
- Hardware CRC feature can verify integrity of the communication at the end of transaction by:
  - Adding CRC value in Tx mode
  - Automatic CRC error checking for Rx mode
- Error detection with interrupt capability in case of data overrun, CRC error, data underrun, the mode fault and frame error, depending upon the operating mode
- Two multiples of 8-bit embedded Rx and Tx FIFOs (FIFO size depends on instance)
- Configurable FIFO thresholds (data packing)
- Capability to handle data streams by system DMA controller
- Configurable behavior for slave underrun condition (support of cascaded circular buffers)
- Optional status pin RDY signalizing the slave device ready to handle the data flow
52.3 **SPI implementation**

*Table 552* describes the SPI implementation. The instances are applied either with a full set or a limited set of features.

52.4 SPI functional description

52.4.1 SPI block diagram

The SPI enables a synchronous, serial communication between the MCU and external devices. The application software can manage the communication by polling the status flag or using a dedicated SPI interrupt. The main SPI elements and their interactions are shown in Figure 715.

Figure 715. SPI/I2S block diagram

The simplified scheme of Figure 715 shows three fully independent clock domains:

- the **spi_pclk** clock domain
- the **spi_ker_ck** kernel clock domain
- the serial interface clock domain

All the control and status signals between these domains are strictly synchronized. There is no specific constraint concerning the frequency ratio between these clock signals. The user has to consider a ratio compatible with the data flow speed to avoid data underrun or overrun events.
The \textbf{spi\_pclk} clock signal feeds the peripheral bus interface. It must be active when accesses to the SPI registers are required.

The SPI working in Slave mode handles a data flow using the serial interface clock derived from the external SCK signal provided by the external master SPI device. This is why the SPI slave is able to receive and send data even when the \textbf{spi\_pclk} and \textbf{spi\_ker\_ck} clock signals are inactive. As a consequence, a specific slave logic working within the serial interface clock domain needs some additional traffic to be setup correctly (for example when underrun or overrun is evaluated, see \textit{Section 52.5.2} for details). This cannot be done when the bus becomes idle. In some cases the slave even requires the clock generator working (see \textit{Section 52.5.1}).

When the SPI works as master, it needs \textbf{spi\_ker\_ck} kernel clock coming from RCC active during communication to feed the serial interface clock via the clock generator where it can be divided by prescaler or bypassed optionally. The signal is then provided to slaves via the SCK pin and internally to the serial interface domain of the master.

\textbf{52.4.2 SPI pins and internal signals}

Up to five I/O pins are dedicated to SPI communication with external devices.

- **MISO:** master in / slave out data. In the general case, this pin is used to transmit data in Slave mode and receive data in Master mode.
- **MOSI:** master out / slave in data. In the general case, this pin is used to transmit data in Master mode and receive data in Slave mode.
- **SCK:** serial clock output pin for SPI masters and input pin for SPI slaves.
- **SS:** slave select pin. Depending on the SPI and SS settings, this pin can be used to either:
  - select an individual slave device for communication
  - synchronize the data frame, or
  - detect a conflict between multiple masters
  See \textit{Section 52.4.7} for details.
- **RDY:** optional status pin signaling slave FIFO occupancies and so the slave availability to continue the transaction without any risk of data flow corruption. It can be checked by master to control temporal suspension of the ongoing communication.

All these pins (except RDY) are shared in the I2S mode. This mode features additional I2S specific MCK signal. For more details about I2S signals see \textit{Section 52.9.2}.

The SPI bus enables the communication between one master device and one or more slave devices. The bus consists of at least two wires: one for the clock signal and the other for synchronous data transfer. Other signals are optional and can be added depending on the data exchange between SPI nodes and their communication control management.

Refer to \textit{Table 553} and \textit{Table 554} for the list of SPI input / output pins and internal signals.

\begin{table}[h]

\end{table}
52.4.3 SPI communication general aspects

The SPI allows the MCU to communicate using different configurations, depending on the device targeted and the application requirements. These configurations use 2 or 3 wires (with software SS management) or 3 or 4 wires (with hardware SS management). The communication is always initiated and controlled by the master. The master provides a clock signal on the SCK line and selects or synchronizes slave(s) for communication by SS line when it is managed by hardware. The data between the master and the slave flow on the MOSI and/or MISO lines.

52.4.4 Communications between one master and one slave

The communication flow may use one of 3 possible modes: the full-duplex (3 wires) mode, half-duplex (2 wires) mode or the simplex (2 wires) mode. The SS signal is optional in single master-slave configuration and is often not connected between the two communication nodes. Nevertheless, the SS signal can be helpful in this configuration to synchronize the data flow and it is used by default for some specific SPI modes (for example the TI mode).

The next optional RDY signal can help to assure correct management of all the transacted data at slave side.
Full-duplex communication

By default, the SPI is configured for full-duplex communication (bits COMM[1:0] = 00 in the SPI_CFG2 register). In this configuration, the shift registers of the master and slave are linked using two unidirectional lines between the MOSI and the MISO pins. During the SPI communication, the data are shifted synchronously on the SCK clock edges provided by the master. The master transmits the data to be sent to the slave via the MOSI line and receives data from the slave via the MISO line simultaneously. When the data frame transfer is complete (all the bits are shifted) the information between the master and slave is exchanged.

Figure 716. Full-duplex single master/ single slave application

1. To apply SS pins interconnection is not mandatory to make the SPI interface working (see Section 52.4.7 for details).
2. RDY signal provided by slave can be read by master optionally.

Half-duplex communication

The SPI can communicate in half-duplex mode by setting COMM[1:0] = 11 in the SPI_CFG2 register. In this configuration, one single cross connection line is used to link the shift registers of the master and slave together. During this communication, the data are synchronously shifted between the shift registers on the SCK clock edge in the transfer direction selected reciprocally by both master and slave with the HDDIR bit in their SPI_CR1 registers. Note that the SPI must be disabled when changing direction of the communication. In this configuration, the MISO pin at master and the MOSI pin at slave are free for other application uses and act as GPIOs.
1. To apply SS pins interconnection is not mandatory to make the SPI interface working (see Section 52.4.7 for details).

2. In this configuration, the MISO pin at master and MOSI pin at slave can be used as GPIOs.

3. A critical situation can happen when the communication direction is not changed synchronously between two nodes working in bidirectional mode. The new transmitter accesses the common data line while the former transmitter still keeps an opposite value on the line (the value depends on the SPI configuration and communicated data). The nodes can conflict temporarily with opposite output levels on the line until the former transmitter changes its data direction setting. It is suggested to insert a serial resistance between MISO and MOSI pins in this mode to protect the conflicting outputs and limit the current flow between them.

4. RDY signal provided by slave can be read by master optionally.

**Simplex communications**

The SPI can communicate in simplex mode by setting the SPI in transmit-only or in receive-only using the COMM[1:0] field in the SPI_CFG2 register. In this configuration, only one line is used for the transfer between the shift registers of the master and slave. The remaining MISO or MOSI pins pair is not used for communication and can be used as standard GPIOs.

- **Transmit-only mode:** COMM[1:0] = 01
  The master in transmit-only mode generates the clock as long as there are data available in the TxFIFO and the master transfer is ongoing.
  The slave in transmit-only mode sends data as long as it receives a clock on the SCK pin and the SS pin (or software managed internal signal) is active (see Section 52.4.7).

- **Receive-only mode:** COMM[1:0] = 10
  In Master mode, the MOSI output is disabled and may be used as GPIO. The clock signal is generated continuously as long as the SPI is enabled and the CSTART bit in the SPI_CR1 register is set. The clock is stopped either by software explicitly requesting this by setting the CSUSP bit in the SPI_CR1 register or automatically when the RxFIFO is full, when the MASRX bit in the SPI_CR1 is set.
  In slave configuration, the MISO output is disabled and the pin can be used as a GPIO. The slave continues to receive data from the MOSI pin while its slave select signal is active (see Section 52.4.7).

**Note:** In whatever Master and Slave modes, the data pin dedicated for transmission can be replaced by the data pin dedicated for reception and vice versa by changing the IOSWP bit value in the SPI_CFG2 register (This bit may only be modified when the SPI is disabled).

Any simplex communication can be replaced by a variant of the half duplex communication with a constant setting of the transaction direction (bidirectional mode is enabled, while the HDDIR bit is never changed) or by full duplex control when unused data line and corresponding data flow is ignored.
Figure 718. Simplex single master / single slave application (master in transmit-only / slave in receive-only mode)

1. SS pins interconnection is not mandatory to make the SPI interface working (see Section 52.4.7).
2. In this configuration, both the MISO pins can be used as GPIOs.
3. RDY signal provided by slave can be read by master optionally.

52.4.5 Standard multislave communication

In a configuration with two or more independent slaves, the master uses a star topology with dedicated GPIO pins to manage the chip select lines for each slave separately (see Figure 719.). The master must select one of the slaves individually by pulling low the GPIO connected to the slave SS input (only one slave can control data on common MISO line at a given time). When this is done, a communication between the master and the selected slave is established. Except the simplicity, the advantage of this topology is that a specific SPI configuration can be applied for each slave as all the communication sessions are performed separately just within single master-slave pair. Optionally, when there is no need to read any information from slaves, the master can transmit the same information to the multiple slaves.
1. Master single SS pin hardware output functionality cannot support this topology (to be replaced by set of GPIOs under SW control) and user should avoid SPI AF setting at the pin (see Section 52.4.7 for details).

2. If the application cannot assure that no more than a single SS active signal is provided by the master at a given time, it is better to configure MISO pins into open-drain configuration with an external pull up on the MISO line to prevent conflicts between interconnected outputs of the slaves. Else, a push-pull configuration can be applied without extra resistor (see I/O alternate function input/output (GPIO) section).

3. RDY signals can be read by master from the slaves optionally.

The master can handle the SPI communication with all the slaves in time when a circular topology is applied (see Figure 720). All the slaves behave like simple shift registers applied in serial chain under control of common slave select (SS) and clock (SCK) signals. All the information is shifted simultaneously around the circle while returning back to the master. Sessions have fixed the length where the number of data frames transacted by the master is equal to the number of slaves.

Then when a first data frame is transacted in the chain, the master just sends the information dedicated for the last slave node in the chain, via the first slave node input, while the first information received by the master comes from the last node output at this time. Correspondingly, the lastly transacted data finishing the session is dedicated for the first slave node while its firstly outgoing data just reaches the master input, after its circling
around the chain passing through all the other slaves during the session.
The data format configuration and clock setting must be the same for all the nodes in the
chain in this topology. As the receive and transmit shift registers are separated internally, a
trick with intentional underrun must be applied to the TxFIFO slaves when the information is
transacted between the receiver and the transmitter by hardware.
In this case, the transmission underrun feature is configured in a mode repeating lastly
received data frame (UDRCFG=1). A session can start optionally with a single data pattern
written into the TxFIFO by each slave (usually slave status information is applied) before the
session starts. In this case the underrun happens in fact after this first data frame is
transacted. To be able to clear the internal underrun condition immediately and restart the
session by the TxFIFO content again, the user must disable and enable the SPI between
the sessions and must fill the TxFIFO by a new single data pattern (to overcome the
propagating delay of the clearing raised in case the underrun is cleared in a standard way
by the UDRC bit).

Figure 720. Master and three slaves connected in circular (daisy chain) topology

1. The underrun feature is used by the slaves in this configuration when the slaves are able to transmit data
   received previously into the Rx shift register once their TxFIFOs become empty.
2. RDY signals can be read by master optionally either separately or configured as open drain outputs (while
   RDIOP=0) and connected together with a pull up resistor as a common chain ready status overdriven by
   the slowest device.
52.4.6 Multimaster communication

Unless the SPI bus is not designed primarily for a multimaster capability, it is possible to use a built-in feature that detects a potential conflict between two nodes trying to master the bus at the same time. For this detection, the SS pin is used configured in hardware input mode. The connection of more than two SPI nodes working in this mode is impossible, as only one node can apply its output on a common data line at a given time.

When the nodes are not active, both stay in Slave mode by default. When a node wants to take control on the bus, it switches itself into Master mode and applies active level on the slave select input of the other node via the dedicated GPIO pin. After the session is completed, the active slave select signal is released and the node mastering the bus temporary returns back to passive Slave mode waiting for a next session to start.

If both nodes raise their mastering request at the same time, a bus conflict event appears (see mode fault MODF event). The user can apply some simple arbitration process (for example postpone next attempt by predefined different time-outs applied in both nodes).

Figure 721. Multimaster application

1. The SS pin is configured at hardware input mode at both nodes. Its active level enables the MISO line output control as passive node is configured as a slave.

2. The RDY signal is not used in this communication.

52.4.7 Slave select (SS) pin management

In Slave mode, the SS works as a standard ‘chip select’ input and lets the slave communicate with the master. In Master mode, the SS can be used either as an output or an input. As an input it can prevent a multi master bus collision, and as an output it can drive a slave select signal of a single slave. The SS signal can be managed internally (software management of the SS input) or externally when both the SS input and output are associated with the SS pin (hardware SS management). The user can configure which level of this input/output external signal (present on the SS pin) is considered as active one by the SSIOP bit setting. SS level is considered as active if it is equal to SSIOP.
The hardware or software slave select management can be set using the SSM bit in the SPI_CFG2 register:

- **Software SS management (SSM = 1):** in this configuration, slave select information is driven internally by the SSI bit value in the register SPI_CR1. The external SS pin is free for other application uses (as GPIO or other alternate function).

- **Hardware SS management (SSM = 0):** in this case, there are two possible configurations. The configuration used depends on the SS output configuration (SSOE bit in register SPI_CFG2).
  - **SS output enable (SSOE = 1):** this configuration is only used when the MCU is set as master. The SS pin is managed by the hardware. The functionality is tied to CSTART and EOT control. As a consequence, the master must apply proper TSIZE>0 setting to control the SS output correctly. Even if SPI AF is not applied at the SS pin (it can be used as a standard GPIO then), keep anyway SSOE = 1 to assure default SS input level and prevent any mode fault evaluation at input of the master SS internal logic applicable at a multimaster topology exclusively.
    a) When SSOM = 0 and SP = 000, the SS signal is driven to the active level as soon as the master transfer starts (CSTART = 1) and it is kept active until its EOT flag is set or the transmission is suspended.
    b) When SP = 001, a pulse is generated as defined by the TI mode.
    c) When SSOM = 1, SP = 000 and MIDI > 1 the SS is pulsed inactive between data frames, and kept inactive for a number of SPI clock periods defined by the MIDI value decremented by one (1 to 14).
    d) SS input is forced to non active state internally at master to prevent its any mode fault.
  - **SS output disable (SSM = 0, SSOE = 0):**
    a) If the micro-controller is acting as the master on the bus, this configuration allows multi master capability. If the SS pin is pulled into an active level in this mode, the SPI enters Master mode fault state and the SPI device is automatically reconfigured in Slave mode (MASTER = 0).
    b) In Slave mode, the SS pin works as a standard ‘chip select’ input and the slave is selected while the SS line is at its active level.

**Note:** The purpose of automatic switching into Slave mode at mode fault condition is to avoid the possible conflicts on data and clock line. As the SPE is automatically reset in this condition, both Rx and Tx FIFOs are flushed and current data is lost.

When the SPI slave is enabled in the hardware SS management mode, all the traffic is ignored even in case of the SS is found at active level. They are ignored until the slave detects a start of the SS signal (transition from non-active to active level) just synchronizing the slave with the master. This is because the hardware management mode cannot be used when the external SS pin is fixed. There is no such protection in the SS software management. Then the SSI bit must be changed when there is no traffic on the bus and the SCK signal is at idle state level between transfers exclusively in this case.
When the hardware output SS control is applied (SSM = 0, SSOE = 1), by configuration of the MIDI[3:0] and MSSI[3:0] bitfields, the user can control the timing of the SS signal between data frames and can insert an extra delay at the beginning of every transaction (to separate the SS and clock starts). This can be useful when the slave needs to slow down the flow to obtain sufficient room for correct data handling (see Figure 723).

**Figure 723. Data flow timing control (SSOE = 1, SSOM = 0, SSM = 0)**

2. CPHA = 0, CPOL = 0, SSIOP = 0, LSBFRST = 0.

Additionally, bit SSOM = 1 setting invokes specific mode which interleaves pulses between data frames if there is a sufficient space to provide them (MIDI[3:0] must be set greater then one SPI period). Some configuration examples are shown in Figure 724.
Figure 724. SS interleaving pulses between data (S$OE = 1$, SS$OM = 1$, SSM = 0)
2. SS interleaves between data when MIDI[3:0] > 1 wide of the interleaving pulse is always one SCK period less then gap provided between frames (defined by MIDI parameter). If MIDI is set the frames are separated by single SCK period but no interleaving pulse appears on SS.

52.4.8 Ready pin (RDY) management

The status of the slave capability to handle data, can be checked on the RDY pin. By default, a low level indicates that the slave is not ready for transaction. The reason can be that slave's TxFIFO is empty, RxFIFO full or the SPI is disabled. An active level of the signal can be selected by the RDIOP bit. If the master continues or starts to communicate with the slave when it indicates a not ready status, the transaction fails great probably.

The logic to control the RDY output is rather complex, tied closely with TSIZE and DSIZE settings. The RDY reaction is more pessimistic and sensitive to TxFIFO becoming nearly empty and/or RxFIFO nearly full during a frame transaction. This pessimistic logic is suppressed at the end of a transaction only when RDY stays active, despite TxFIFO becomes fully empty and/or RxFIFO becomes fully occupied. The target is to prevent any data corruption and inform master in time that it is necessary to suspend the transaction temporarily till the next transacted data can be processed safely again. When RDY signal input is enabled at master side, master suspends the communication once the slave indicates not ready status. This prevents the master to complete transaction of an ongoing frame which just empties slave's TxFIFO or full fills its RxFIFO till a next data is written and/or read there (despite the frame still can be completed without any constraint). It can make a problem if TSIZE = 0 configuration is applied at slave because slave then never evaluates end of transaction (which suppresses the not ready status just when the last data is sent). Then the user has to release the RxFIFO and/or write additional (even dummy) data to TxFIFO by software at slave side to release the not RDY signal, unblock ST master and so enable it to continue at the communication suspended at middle of a frame occasionally.

When RDY is not used by the master, it must be disabled (RDIOM = 0). Then an internal logic of the master simulates the slave status always ready. In this case, the RDIOP bit setting has no meaning.

Due to synchronization between clock domains and evaluation of the RDY logic on both master and slave sides, the RDY pin feature is not reliable and cannot be used when the size of data frames is configured shorter than 8-bit.

52.4.9 Communication formats

During SPI communication, receive and transmit operations are performed simultaneously. The serial clock (SCK) synchronizes the shifting and sampling of the information on the data lines. The communication format depends on the clock phase, the clock polarity and the data frame format. To be able to communicate together, the master and slave devices must follow the same communication format and be synchronized correctly.

Clock phase and polarity controls

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPI_CFG2 register. The CPOL (clock polarity) bit controls the idle state value of the clock when no data are being transferred. This bit affects both Master and Slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.
If the CPHA bit is set, the second edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set). Data are latched on each occurrence of this clock transition type. If the CPHA bit is reset, the first edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is set, rising edge if the CPOL bit is reset). Data are latched on each occurrence of this clock transition type.

The combination of the CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edges (dotted lines in Figure 725).

Figure 725, shows an SPI full-duplex transfer with the four combinations of the CPHA and CPOL bits.

Note: Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit. The idle state of SCK must correspond to the polarity selected in the SPI_CFG2 register (by pulling the SCK pin up if CPOL = 1 or pulling it down if CPOL = 0).

Figure 725. Data clock timing diagram

1. The order of data bits depends on LSBFRST bit setting.
Data frame format

The SPI shift register can be set up to shift out MSB-first or LSB-first, depending on the value of the LSBFIRST bit in SPI_CFG2 register.

At instance with full feature set, the data frame size is chosen by using the DSIZE[4:0] bits at SPI_CFG1 register. It can be set from 4-bit up to 32-bit length and the setting applies for both transmission and reception. When the SPI_TXDR/SPI_RXDR registers are accessed, data frames are always right-aligned into either a byte (if the data fit into a byte), a half-word or a word (see Figure 726).

If the access is a multiple of the configured data size, data packing is applied automatically. During communication, only bits within the data frame are clocked and transferred.

Figure 726. Data alignment when data size is not equal to 8-, 16- or 32-bit

<table>
<thead>
<tr>
<th>DSIZE &lt;= 8-bits</th>
<th>9-bits &lt;= DSIZE &lt;= 16-bits</th>
<th>17-bits &lt;= DSIZE &lt;= 32-bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>data is right aligned on byte Example: DSIZE[4:0]=00011</td>
<td>data is right aligned on half-word Example: DSIZE[4:0]=01101</td>
<td>data is right aligned on word Example: DSIZE[4:0]=11010</td>
</tr>
</tbody>
</table>

Note: The minimum data length is 4 bits. If a data length of less than 4 bits is selected, it is forced to an 4-bit data frame size.

At the instance with limited set of features, data size is fixed to multiply 8-bit up to maximum data length (depends on instance) in according to DSIZE[4:3] bits value. If the SPI_TXDR or SPI_RXDR are accessed by wider access (a multiply of the configured the data size), data packing is applied automatically.

52.4.10 Configuring the SPI

The configuration procedure is almost the same for the master and the slave. For specific mode setups, follow the dedicated chapters. When a standard communication must be initialized, perform these steps:

1. Write the proper GPIO registers: configure GPIO alternate functions at MOSI, MISO, SCK, SS and RDY pins if applied.
2. Write into the SPI_CFG1 and SPI_CFG2 registers and set up proper values of all 'not reserved' bits and bitfields, prior SPI is enabled, with the following exceptions:
   a) The SSOM, MASRX, SSOE, RDIOM, MBR[2:0], BPASS, MIDI[3:0], MSSI[3:0] bits are taken into account in Master mode only, the MSSI[3:0] bits take effect when the SSOE bit is set, the RDIOP bit takes no effect when the RDIOM bit is not set in Master mode. When slave is configured at TI mode, MBR[2:0] setting is considered, too.
   b) UDRCFG is taken into account in Slave mode only.
   c) CRCSIZE[4:0] is required if CRCEN is set.
d) CPOL, CPHA, LSBFRST, SSOM, SSOE, SSIOP, SSM, RDIOP, RDIOM, MSSI and MIDI are not required in TI mode.
e) Once the AFCNTR bit is set in the SPI_CFG2 register, all the SPI outputs start to be propagated onto the associated GPIO pins regardless the peripheral enable. So any later configuration changes of the SPI_CFG1 and SPI_CFG2 registers can affect the level of signals on these pins.

3. Write to the SPI_CR2 register to select the length of the transfer, if it is not known TSIZE must be programmed to zero.
4. Write to SPI_CRCPOLY and into TCRCINI, RCRCINI and CRC33_17 bits at the SPI_CR1 register to configure the CRC polynomial and CRC calculation if needed.
5. Configure DMA streams dedicated for the SPI Tx and Rx in DMA registers if the DMA streams are used (see chapter Communication using DMA).
6. Configure SSI, HDDIR and MASRX at SPI_CR1 register if required.
7. Program the IOLOCK bit in the SPI_CFG1 register if the configuration protection is required (for safety).

52.4.11 Enabling the SPI

It is recommended to configure and enable the SPI slave before the master sends the clock. But there is no impact if the configuration and enabling procedure is done while a traffic is ongoing on the bus, assuming that the SS signal is managed by hardware at slave or kept inactive by slave’s software when the software management of the SS signal is applied (see Section 52.4.7). The data register of the slave transmitter should contain data to be sent before the master starts its clocking. The SCK signal must be settled to the idle state level corresponding to the selected polarity, before the SPI slave is selected by SS, else the following transaction may be desynchronized.

When the SPI slave is enabled at the hardware SS management mode, all the traffics are ignored even in case of the SS is found at active level. They are ignored until the slave detects a start of the SS signal (its transition from non-active to active level) just synchronizing the slave with the master. This is why the hardware management mode cannot be used when external SS pin is fixed. There is no such protection at the SS software management. In this case, the SSI bit must be changed when there is no traffic on the bus and the SCK signal is at idle state level between transfers exclusively in this case.

The master in full duplex (or in any transmit-only mode) starts to communicate when the SPI is enabled, the CSTART bit is set and the TxFIFO is not empty, or with the next write to TxFIFO.

In any master receive-only mode, the master starts to communicate and the clock starts running after the SPI is enabled and the CSTART bit is set.

For handling DMA, see Section 52.4.15.

52.4.12 SPI data transmission and reception procedures

The setting of data communication format follows the basic principle that sure number of data with a flexible size must be transferred within a session (transaction) while, optionally, the data handling can be cumulated effectively into a single access of the SPI data registers (data packing) or even grouped into a sequence of such services if data is collected at consistent bigger data packets. The data handling services are based upon FIFO packet occupancy events. This is why the complete data packet must be serviced exclusively upon a dedicated packet flag.
To understand better the next detailed content of this section, the user should capture the configuration impact and meaning of the following items at first:

**Data size (DSIZE)** - defines data frame (sets the number of bits at single data frame).

**FIFO threshold (FTHLV)** - defines data packet, sets the number of data frames at single data packet and so the occurrence of the packet occupancy events to handle SPI data registers either by software or by DMA.

**Data access** – a way how to handle the SPI data register content when the transfer data between the application and the SPI FIFOs upon a packet event. It depends on the packet size configuration. Optionally, multiply data can be handled effectively by a single access of the register (by data packing) or by sequence of such accesses (when servicing a bigger data packet).

**FIFO size** – capacity or space to absorb available data. It depends on the data size and the internal hardware efficiency how the data is compressed and organized within this space. The FTHLV setting must respect the FIFO capacity to store two data packets at least.

**Transaction size (TSIZE)** – defines total number of data frames involved at a transaction session overall possibly covered by several data packet services. There is no need to align this number with the packet size (handling of a last not aligned data packet is supported if TSIZE is programmed properly).

**Data handling via RxFIFO and TxFIFO**

All SPI data transactions pass through the embedded FIFOs organized by bytes (N x 8-bit). The size of the FIFOs (N) is dependent on the product and the peripheral instance. This enables the SPI to work in a continuous flow, and prevents overruns when the data frame size is short or the interrupt/DMA latency is too long. Each direction has its own FIFO called TxFIFO and RxFIFO, respectively.

The handling of the FIFOs content is based on servicing data packet events exclusively raised by dedicated FIFO packet occupancy flags (TXP, RXP or DXP). The flags occurrence depends on the data exchange mode (duplex, simplex), the data frame size (number of bits in the frame) and how data are organized at data packets. The frequency of the packet events can be decreased significantly when data are organized into packets via defining the FIFOs threshold. Several data frames grouped at packet can be then handled effectively based on a single FIFO occupancy packet event either by a single SPI data register access or their sequence what consumes less system performance. The user can control the access type by casting the data register address to force a concrete CPU instruction applied for the register read or write. The access then can be 8-bit, 16-bit or 32-bit but single data frame must be always accessed at least. It is crucial to keep the setting of the packet size (FTHVL) and the data size (DSIZE) always balanced with the applied data registers access (no matter if a single access or their sequence is applied) just to apply and complete service of a single data packet upon its event. This principle, occurrence and clearing capabilities of the FIFO occupancy flags are common no matter if DMA, interrupt, or polling is applied.

A read access to the SPI_RXDR register returns the oldest value stored in the RxFIFO that has not been read yet. A write access to the SPI_TXDR stores the written data in the TxFIFO at the end of a send queue.

A read access to the SPI_RXDR register must be managed by the RXP event. This flag is set by hardware when at least one complete data packet (defined as receiver threshold by FTHVL[3:0] bits at the SPI_CFG1 register) is available at the reception FIFO while reception is active. The RXP is cleared as soon as less data than complete single packet is available in the RxFIFO, when reading SPI_RXDR by software or by DMA.
The RXP triggers an interrupt if the RXPIE bit is set and/or a DMA request if the RXDMAEN bit is set.

Upon setting of the RXP flag, the application performs the due number of SPI data register reads to download the content of one data packet. Once a complete data packet is downloaded, the application software or DMA checks the RXP value to see if other packets are pending into the receive FIFO and, if so, downloads them packet by packet until the RXP reads 0. RxFIFO can store up to N data frames (for frame size ≤ 8-bit), N/2 data frames (for 8-bit < frame ≤ 16-bit), N/3 data frames (for 16-bit < frame ≤ 24-bit) or N/4 data frames (if data frame > 24-bit) where N is the size of the FIFO in bytes.

At the end of a reception, it may happen that some data are still available in the RxFIFO, without reaching the FTHLV level, thus the RXP is not set. In this case, the number of remaining RX data frames in the FIFO is indicated by RXWNE and RXPLVL fields in the SPI_SR register. It happens when the number of the last data received in a transfer cannot fully accomplish the configured packet size; in case the transfer size and the packet size are not aligned. Nevertheless the application software can still perform the standard number of reads from the RxFIFO used for the previous complete data packets without drawbacks: only the consistent data (completed data frames) are popped from the RxFIFO while redundant reads (or any uncompleted data) are reading 0. Thanks to that, the application software can treat all the data in a transfer in the same way, and is off-loaded to foresee the reception of the last data in a transfer and to calculate the due number of reads to be popped from RxFIFO.

In a similar way, the write access of a data frame to be transmitted is managed by the TXP event. This flag is set by hardware when there is enough space for the application to push at least one complete data packet (defined at FTHLV[3:0] bits at SPI_CFG1 register) into the transmission FIFO while transmission is active. The TXP is cleared as soon as the TxFIFO is filled by software and/or by the DMA. The space currently available for any next complete data packet is lost. This can lead to oscillations of the TXP signal when data are released out from the TxFIFO while a new packet is stored frame by frame. Any write to the TxFIFO is ignored when there is no sufficient room to store at least a single data frame (TXP event is not respected), when TXTF is set or when the SPI is disabled.

The TXP triggers an interrupt if the TXPIE bit is set and/or with a DMA request if the TXDMAEN bit is set. The TXPIE mask is cleared by hardware when the TXTF flag is set.

Upon setting of the TXP flag, the application performs the due number of SPI data register writes to upload the content of one entire data packet. Once new complete data packet is uploaded, the application software or DMA checks the TXP value to see if other packets can be pushed into the TxFIFO and, if so, uploads them packet by packet until TXP reads 0.

The number of last data in a transfer can be shorter than the configured packet size in the case when the transfer size and the packet size are not aligned. Nevertheless the application software can still perform the standard number of data register writes used for the previous packets without drawbacks: only the consistent data are pushed into the TxFIFO while redundant writes are discarded. Thanks to that, the application software can treat all the data in a transfer in the same way and is off-loaded to foresee the transmission of the last data in a transfer and from calculating the due number of writes to push the last data into TxFIFO. Just for the last data case, the TXP event is asserted by SPI once there is enough space into TxFIFO to store remaining data to complete current transfer.

Both TXP and RXP events can be polled or handled by interrupts. The DXP bit can be monitored as a common TXP and RXP event at full-duplex mode.
Upon setting of the DXP flag the application performs the due number of writes to the SPI data register to upload the content of one entire data packet for transmission, followed by the same number of reads from the SPI data register to download the content of one data packet. Once one data packet is uploaded and one is downloaded, the application software or DMA checks the DXP value to see if other packets can be pushed and popped in sequence and, if so, uploads/downloads them packet by packet until DXP reads 0.

The DXP triggers an interrupt if the DXPIE bit is set. The DXPIE mask is cleared by hardware when the TXTF flag is set.

The DXP is useful in full-duplex communication in order to optimize performance in data uploading/downloading, and reducing the number of interrupts or DMA sequences required to support an SPI transfer thus minimizing the request for CPU bandwidth and system power especially when SPI is operated in Stop mode.

When relay on the DXP interrupt exclusively, the user must consider the drawback of such a simplification when TXP and RXP events are serviced by common procedures because the TXP services are delayed by purpose in this case. This is due to fact that the TXP events precedes the reception RXP ones normally to allow the TXP servicing prior transaction of the last frame fully emptying the TxFIFO else master cannot provide a continuous SCK clock flow and the slave can even face an underrun condition. The possible solution is to prefill the TxFIFO by few data packets ahead prior the session starts and to handle all the data received after the TXTF event by EOT exclusively at the end of the transaction (as TXTF suppresses the DXP interrupts at the end of the transaction). In case of CRC computation is enabled, the user must calculate with additional space to accommodate the CRC frame at RxFIFO when relying on EOT exclusively at the end of transaction.

Another way to manage the data exchange is to use DMA (see Section 52.4.15).

If the next data is received when the RxFIFO is full, an overrun event occurs (see description of OVR flag in Section 52.5.2). An overrun event can be polled or handled by an interrupt.

This may happen in Slave mode or in a master receive mode when MASRX = 0. If MASRX bit is set at a master receiver, the generated clock stops automatically when the RxFIFO is full, therefore overrun is prevented.

Both RxFIFO and TxFIFO content is kept flushed and cannot be accessed when SPI is disabled (SPE = 0).

Transaction handling

A few data frames can be passed at single sequence to complete a message. The user can handle a number of data within a message thanks to the value stored into TSIZE. In principle, the transaction of a message starts when the SPI is enabled by setting CSTART bit and finishes when the total number of required data is transacted. The end of transaction controls the CRC and the hardware SS management when applied. To restart the internal state machine properly, SPI is strongly suggested to be disabled and re-enabled before next transaction starts despite its setting is not changed.

If TSIZE is kept at zero while CSTART is set, an endless transaction is initialized (no control of transfer size is applied). During an endless transaction, the number of transacted data aligned with FIFOs threshold is supported exclusively. If the number of data (or its grouping into packets) is unpredictable, the user must keep the FIFO threshold setting (packet size) at single data (FTHLV = 0) to assure that each data frame raises its own packet event to be serviced by the application or DMA. The transaction can be suspended at any time thanks
to CSUSP which clears the CSTART bit. SPI must be always disabled after such software suspension and re-enabled before the next transaction starts.

When the transmission is enabled, a sequence begins and continues while any data is present in the TxFIFO of the master. The clock signal is provided permanently by the master until TxFIFO becomes empty, then it stops, waiting for additional data.

In receive-only modes, half-duplex (COMM[1:0] = 11, HDDIR = 0) or simplex (COMM[1:0] = 10) modes, the master starts the sequence when the SPI is enabled and the transaction is released by setting the CSTART bit. The clock signal is provided by the master and it does not stop until either SPI or receive-only mode is disabled/suspended by the master. The master receives data frames permanently up to this moment. The reception can be suspended either by software control, writing 1 to the CSUSP bit in the SPI_CR1 register, or automatically when MASRX = 1 and RxFIFO becomes full or upon the RDY status if this signal is applied (see Section 52.4.8). The reception is automatically stopped also when the number of frames programmed in TSIZE has been completed.

In order to disable the master receive-only mode, the SPI must first be suspended. When the SPI is suspended, the current frame is completed, before changing the configuration.

**Caution:** If the SPE bit is cleared in Master mode, while the reception is ongoing without any suspending, the clock is stopped without completing the current frame, and the RxFIFO is flushed.

While the master can provide all the transactions in continuous mode (SCK signal is continuous) it must respect the slave capability to handle data flow and its content at anytime. If the slave features the RDY signal option, the master can monitor the RDY signal issued by the slave, to control the communication flow. If the RDY pin is not used, the slave is considered always ready for communication with the master.

When necessary, the master must slow down the communication and provide either a slower clock or separate frames or data sessions with sufficient delays by MIDI[3:0] bits setting or provide an initial delay by setting MSS[1:0], which postpones any transaction start to give slave sufficient room for preparing data. Be aware data from the slave are always transacted and processed by the master even if the slave cannot prepare it correctly in time. It is preferable for the slave to use DMA, especially when data frames are short, FIFO is accessed by bytes and the SPI bus rate is high.

In order to add some software control on the SPI communication flow from a slave transmitter node, a specific value written in the SPI_UDRDR (SPI Underrun Data Register) may be used. On slave side, when TxFIFO becomes empty, this value is sent out automatically as next data and may be interpreted by software on the master receiver side (either simply dropped or interpreted as a XOFF like command, in order to suspend the master receiver by software).

In the multislave star topology, only a single slave only can be enabled for output data at a given time. The slave just selected for the communication with the master needs to detect a change of its SS input into active level before communication with the master starts. In a single slave system it is not necessary to control the slave with SS, but it is often better to provide the pulse here too, to synchronize the slave with the beginning of each data sequence. The SS can be managed by both software and hardware (Section 52.4.7).

### 52.4.13 Disabling the SPI

To disable the SPI, it is mandatory to follow the disable procedures described in this paragraph.
In the Master mode, it is important to do this before the system enters a low-power mode when the peripheral clock is stopped, otherwise, ongoing transactions may be corrupted.

In Slave mode, the SPI communication can continue when the \texttt{spi\_pclk} and \texttt{spi\_ker\_ck} clocks are stopped, without interruption, until any end of communication or data service request condition is reached. The \texttt{spi\_pclk} can generally be stopped by setting the system into Stop mode. Refer to the RCC section for further information.

The master in full-duplex or transmit-only mode can finish any transaction when it stops providing data for transmission. In this case, the clock stops after the last data transaction. TXC flag can be polled (or interrupt enabled with EOTIE = 1) in order to wait for the last data frame to be sent.

When the master is in any receive-only mode, in order to stop the peripheral, the SPI communication must first be suspended, by setting the CSUSP bit to 1.

The data received but not read remain stored in RxFIFO when the SPI is suspended.

After such a software suspension, SPI must be always disabled to restart the internal state machine properly.

When SPI is disabled, RxFIFO is flushed. To prevent losing unread data, the user must ensure that RxFIFO is empty when disabling the SPI, by reading all remaining data (as indicated by the RXP, RXWNE and RXPLVL fields in the SPI\_SR register).

The standard disable procedure is based on polling EOT and/or TXC status to check if a transmission session is (fully) completed. This check can be done in specific cases, too, when it is necessary to identify the end of ongoing transactions, for example:

- When the master handles SS signal by a GPIO not related to SPI (for example at case of multislave star topology) and it has to provide proper end of SS pulse for slave, or
- When transaction streams from DMA or FIFO are completed while the last data frame or CRC frame transaction is still ongoing in the peripheral bus.

When TSIZE>0, EOT and TXC signals are equal so polling of EOT is reliable at whatever SPI communication mode to check end of the bus activity. When TSIZE = 0, the user has to check TXC, SUSP or FIFO occupancy flags in according with the applied SPI mode and the way of the data flow termination.

The correct disable procedure in Master mode, except when receive-only mode is used, is:

1. Wait until TXC = 1 and/or EOT = 1 (no more data to transmit and last data frame sent). When CRC is used, it is sent automatically after the last data in the block is processed. TXC/EOT is set when CRC frame is completed in this case. When a transmission is suspended the software has to wait till CSTART bit is cleared.
2. Read all RxFIFO data (until RXWNE = 0 and RXPLVL = 00).
3. Disable the SPI (SPE = 0).

The correct disable procedure for master receive-only modes is:

1. Wait on EOT or break the receive flow by suspending SPI (CSUSP = 1).
2. Wait until SUSP = 1 (the last data frame is processed) if receive flow is suspended.
3. Read all RxFIFO data (until RXWNE = 0 and RXPLVL = 00).
4. Disable the SPI (SPE = 0).

In Slave mode, any on going data are lost when disabling the SPI.
Controlling the I/Os

As soon as the SPI is disabled, the associated and enabled AF outputs can still be driven by the device depending on the AFCNTR setting. When active output control is applied (AFCNTR = 1) and SPI is just been disabled (SPE = 0), the enabled outputs associated with SPI control signals (like SS and SCK at master and RDY at slave) can toggle immediately to inactive level (according to SSIOP and CPOL settings at master and RDIOP at slave respectively). The data line output (MOSI at master and MISO at slave) can instead change its level immediately at dependency on the actual TxFIFO content with the effect of potentially making invalid and no more guaranteed the value of the latest transacted bit on the bus. If necessary, the user has to take care about proper data hold time at the data line and avoid any eventual fast SPI disable just after the last data transaction is completed.

Note: Despite stability of the latest bit is guaranteed by design during the sampling edge of the clock, some devices can require even extension of this data bit stability interval during the sampling. It can be done for example by inserting small software delay between EOT event occurrence and SPI disable action.

52.4.14 Data packing

From user point of view there are two ways of data packing which can overlay each other:

- Type of access when data are written to TxFIFO or read from RxFIFO
  Multiple data can be pushed or fetched effectively by single access if data size is multiplied less than the access performed upon SPI_TXDR or SPI_RXDR registers.
- Number of data to be handled during the single software service
  It is convenient to group data into packets and cumulate the FIFO services overall the data packet content exclusively instead of handling data frame by frame separately. The user can define packets by FIFO threshold settings. Then all the FIFO occupancy events are related to that threshold level while required services are signalized by proper flags with interrupt and/or wake up capabilities.

When the data frame size fits into one byte (less than or equal to 8 bits), the data packing is used automatically when any read or write 16-bit or 32-bit access is performed on the SPI_RXDR/SPI_TXDR register. The multiple data frame pattern is handled in parallel in this case. At first, the SPI operates using the pattern stored in the LSB of the accessed word, then with the other data stored in the MSB.

Figure 727 provides an example of data packing mode sequence handling at full feature set instance. While DSIZE[4:0] is configured to 4-bit there, two or four data frames are written in the TxFIFO after the single 16-bit or 32-bit access the SPI_TXDR register of the transmitter. When the data frame size is between 9-bit and 16-bit, data packing is used automatically when a 32-bit access is done. Least significant half-word is used first. (regardless of the LSBFRST value)

This sequence can generate two or four RXP events in the receiver if the RxFIFO threshold is set frame (and data is read on a frame basis, unpacked), or it can generate a single RXP event if the FTHLV[3:0] field in the SPI_CFG1 register is programmed to a multiple of the frames to be read in a packed mode (16-bit or 32-bit read access).

The data are aligned in accordance with Figure 726. The valid bits are performed on the bus exclusively. Unused bits are not cared at transmitter while padded by zeros at receiver.

When short data frames (< 8-bit or < 16-bit) are used together with a larger data access mode (16-bit or 32-bit), the FTHLV value must be programmed as a multiple of the number...
of frames/data access (multiple of 4 if 32-bit access is used to up to 8-bit frames or multiple of 2 if 16-bit access is used to up to 8-bit frames or 32-bit access to up to 16-bit frames.).

The RxFIFO threshold setting must always be higher or equal at least than the following read access size, as spurious extra data would be read otherwise.

The FIFO data access less than the configured data size is forbidden. One complete data frame must be always accessed at minimum.

A specific problem appears if an incomplete data packet is available at FIFO: less than threshold set at FTHLV bits.

There are two ways of dealing with this problem:

A. without using TSIZE field

On transmitter side, writing the last data frame of any odd sequence with an 8-bit/16-bit access to SPI_TXDR is enough.

On receiver side, the remaining data may be read by any access. Any extra data read are padded with zeros. Polling the RXWNE and RXPLVL may be used to detect when the RX data are available in the RxFIFO. (A time out may be used at system level in order to detect the polling)

B. using the TSIZE field

On transmitter side, the transaction is stopped by the master when it faces EOT event.

In reception, the RXP flag is not set when EOT is set. In the case when the number of data to be received (TSIZE) is not a multiple of packet size, the number of remaining data is indicated by the RXWNE and RXPLVL fields in the SPI_SR register. The remaining data can be read by any access. Any extra read is padded by zeros.

Figure 727. Packing data in FIFO for transmission and reception at full feature set instance

1. DSIZE[4:0] is configured to 4-bit, data is right aligned, valid bits are performed only on the bus, their order depends on LSBFRST, if it is set, the order is reversed at all the data frames.

52.4.15 Communication using DMA (direct memory addressing)

To operate at its maximum speed and to facilitate the data register read/write process required to avoid overrun, the SPI features a DMA capability, which implements a simple request/acknowledge protocol.
A DMA access is requested when the TXDMAEN or RXDMAEN enable bits in the SPI_CFG1 register are set. Separate requests must be issued to the Tx and Rx buffers to fulfill service of the defined packet.

- In transmission, a series of DMA requests is triggered each time TXP is set to 1. The DMA then performs series of writes to the SPI_TXDR register.
- In reception, a series of DMA requests is triggered each time RXP is set to 1. The DMA then performs series of reads from the SPI_RXDR register. When EOT is set at the end of transaction and last data packet is incomplete then DMA request is activated automatically in according with RXWNE and RXPLVL[1:0] setting to read rest of data.

If the SPI is programmed in receive-only mode, UDR is never set.

If the SPI is programmed in a transmit mode, TXP and UDR can be eventually set at slave side, because transmit data may not be available. In this case, some data are sent on the TX line according with the UDR management selection.

When the SPI is used at a simplex mode, the user must enable the adequate DMA channel only while keeping the complementary unused channel disabled.

If the SPI is programmed in transmit-only mode, RXP and OVR are never set.

If the SPI is programmed in full-duplex mode, RXP and OVR are eventually set, because received data are not read.

In transmission mode, when the DMA or the user has written all the data to be transmitted (the TXTF flag is set at SPI_SR register), the EOT (or TXC at case TSIZE = 0) flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or before disabling the spi_pclk in Master mode. The software must first wait until EOT = 1 and/or TXC = 1.

When starting communication using DMA, to prevent DMA channel management raising error events, these steps must be followed in order:
1. Enable DMA Rx buffer in the RXDMAEN bit in the SPI_CFG1 register, if DMA Rx is used.
2. Enable DMA requests for Tx and Rx in DMA registers, if the DMA is used.
3. Enable DMA Tx buffer in the TXDMAEN bit in the SPI_CFG1 register, if DMA Tx is used.
4. Enable the SPI by setting the SPE bit.

To close communication it is mandatory to follow these steps in order:
1. Disable DMA request for Tx and Rx in the DMA registers, if the DMA issued.
2. Disable the SPI by following the SPI disable procedure.
3. Disable DMA Tx and Rx buffers by clearing the TXDMAEN and RXDMAEN bits in the SPI_CFG1 register, if DMA Tx and/or DMA Rx are used.

Data packing with DMA

If the transfers are managed by DMA (TXDMAEN and RXDMAEN set in the SPI_CFG1 register) the packing mode is enabled/disabled automatically depending on the PSIZE value configured for SPI TX and the SPI RX DMA channel.

If the DMA channel PSIZE value is equal to 16-bit and the SPI data size is less than or equal to 8-bit, then the packing mode is enabled. Similarly, If the DMA channel PSIZE value is equal to 32-bit and the SPI data size is less than or equal to 16-bit, then the packing mode is
enabled. The DMA then automatically manages the write operations to the SPI_TXDR register.

Regardless data packing mode is used and the number of data to transfer is not a multiple of the DMA data size (16-bit or 32-bit) while the frame size is smaller, DMA completes the transfer automatically in according with the TSIZE field setting.

Alternatively, last data frames may be written by software, in the single/unpacked mode.

To configure any DMA data access less than the configured data size is forbidden. One complete data frame must be always accessed at minimum.

52.5  SPI specific modes and control

52.5.1  TI mode

With a specific SP[2:0] bit field setting of the SPI_CFG2 register, the SPI can be configured compliant with the TI protocol. The SCK and SS signals polarity, phase and flow as well as the bits order are fixed so the setting of CPOL, CPHA, LSBFRST, SSOM, SSOE, SSIOP, SSM, RDIOP, RDIOM, MSSI and MIDI is not required when the SPI is in TI mode configuration. The SS signal synchronizes the protocol by pulses over the LSB data bit as it is shown in Figure 728.

![Figure 728. TI mode transfer](image)

In Slave mode, the clock generator is used to define time when the slave output at MISO pin becomes to HiZ when the current transaction finishes. The master baud rate setting (MBR[2:0] at SPI_CFG1) is applied and any baud rate can be used to determine this moment with optimal flexibility. The delay for the MISO signal to become HiZ (TRELEASE) depends on internal re-synchronization, too, which takes next additional 2-4 periods of the clock signal feeding the generator. It is given by formula:

\[
\frac{T_{baud}}{2} + 2 \times T_{spi\_ker\_ck} \leq T_{release} \leq \frac{T_{baud}}{2} + 4 \times T_{spi\_ker\_ck}
\]

If the slave detects misplaced SS pulse during data transaction the TIFRE flag is set.
52.5.2 SPI error flags

An SPI interrupt is generated if one of the following error flags is set and interrupt is enabled by setting the corresponding Interrupt Enable bit.

**Overrun flag (OVR)**

An overrun condition occurs when data are received by a master or slave and the RxFIFO has not enough space to store these received data. This can happen if the software or the DMA did not have enough time to read the previously received data (stored in the RxFIFO).

When an overrun condition occurs, the OVR flag is set and the newly received value does not overwrite the previous one in the RxFIFO. The newly received value is discarded and all data transmitted subsequently are lost. OVR flag triggers an interrupt if OVRIE bit is set.

Clearing the OVR bit is done by a writing 1 to the OVRC bit in the SPI_IFCR. To prevent any next overrun event the clearing should be done after RxFIFO is emptied by software reads. It is suggested to release the RxFIFO space as much as possible, this means to read out all the available data packets based on RXP flag indication.

In Master mode, the user can prevent the RxFIFO overrun by automatic communication suspend (MASRX bit).

**Underrun flag (UDR)**

In a slave-transmitting mode, the underrun condition is captured internally by hardware if no data is available for transmission in the slave TxFIFO commonly. The UDR flag setting is then propagated into the status register by hardware (see note below). UDR triggers an interrupt if the UDRIE bit is set.

Underrun detection logic and system behavior depends on the UDRCFG bit. When an underrun is detected by slave, it can provide out either a constant pattern stored by the user at the UDRDR register or the data received previously from the master. When the first configuration (UDRCFG = 0) is applied, the underrun condition is evaluated whenever master starts to communicate a new data frame while TxFIFO is empty. Then single additional dummy (accidental) data is always inserted between last valid data and constant pattern defined at the UDRDR register (see Figure 729). The second configuration (UDRCFG = 1) can be used at circular topography structure (see Figure 720). Assuming that TxFIFO is not empty when master starts the communication, the underrun condition is evaluated just once the FIFO becomes empty during the next data flow. Valid data from TxFIFO is then upended by the lastly received data immediately.

The standard transmission is re-enabled once the software clears the UDR flag and this clearing is propagated into SPI logic by hardware. The user should write some data into TxFIFO prior clearing the UDR flag to prevent any next underrun condition occurrence capture.

The data transacted by slave is unpredictable especially when the transaction starts or continues while TxFIFO is empty and underrun condition is either not yet captured or just cleared. Typically, this is the case when SPI is just enabled or when a transaction with a defined size just starts. First bits can be corrupted in this case, as well, when slave software writes first data into the empty TxFIFO too close prior the data transaction starts (propagation of the data into TxFIFO takes few APB clock cycles).
Figure 729. Optional configurations of slave detecting underrun condition

Note: The hardware propagation of an UDR event needs additional traffic on the bus. It always takes few extra SPI clock cycles after the event happens (both underrun captured by hardware and cleared by software). If clearing of the UDR flag by software is applied close to the end of data frame transaction or when SCK line is at idle in between the frames, next extra underrun pattern is sent initially by slave prior the valid data from Tx FIFO becomes transacted again. The user can prevent this by SPI disable/enable action between sessions to restart the underrun logic and so initiate the next session by the valid data.

Mode fault (MODF)

Mode fault occurs when the master device has its internal SS signal (SS pin in SS hardware mode, or SSI bit in SS software mode) pulled low. This automatically affects the SPI interface in the following ways:

- The MODF bit is set and the SPI interrupt is triggered if the MODFIE bit is set.
- The SPE bit is forced to zero till MODF bit is set. This disables SPI and blocks all the peripheral outputs except the MODF interrupt request if enabled.
- The MASTER bit is cleared, thus forcing the device into Slave mode.

MODF is cleared by writing 1 to the MODFC bit in the SPI_IFCR.

To avoid any multiple slave conflicts in a system comprising several MCUs, the SS pin must be pulled to its non-active level before re-enabling the SPI, by setting the SPE bit.
As a security, hardware does not allow the SPE bit to be set while the MODF bit is set. In a slave device the MODF bit cannot be set except as the result of a previous multi master conflict.

A correct software procedure when master overtakes the bus at multi master system should be the following one:

- Switch into Master mode while SSOE = 0 (potential conflict can appear when another master occupies the bus. MODF is raised in this case, preventing any next node switching into Master mode)
- Put GPIO pin dedicated for another master SS control into active level
- Perform data transaction
- Put GPIO pin dedicated for another master SS control into non active level
- Switch back to Slave mode

**CRC error (CRCE)**

This flag is used to verify the validity of the value received when the CRCEN bit in the SPI_CFG1 register is set. The CRCE flag in the SPI_SR register is set if the value received in the shift register does not match the receiver SPI_RXCRC value, after the last data is received (as defined by TSIZE). The CRCE flag triggers an interrupt if CRCEIE bit is set. Clearing the bit CRCE is done by a writing 1 to the CRCEC bit in the SPI_IFCR.

**TI mode frame format error (TIFRE)**

A TI mode frame format error is detected when an SS pulse occurs during an ongoing communication when the SPI is operating in Slave mode and configured to conform to the TI mode protocol. When this error occurs, the TIFRE flag is set in the SPI_SR register. The SPI is not disabled when an error occurs, the SS pulse is ignored, and the SPI waits for the next SS pulse before starting a new transfer. The data may be corrupted since the error detection may result in the loss of few data frames.

The TIFRE flag is cleared by writing 1 to the TIFREC bit in the SPI_IFCR. If the TIFREIE bit is set, an interrupt is generated on the SS error detection. As data consistency is no longer guaranteed, communication should be re-initiated by software between master and slave.

### 52.5.3 CRC computation

Two separate 33-bit or two separate 17-bit CRC calculators are implemented to check the reliability of transmitted and received data. For instances with full feature set, the SPI offers CRC polynomial length from 5 to 33 bits when maximum data size is 32-bit and from 9 to 17 bits for the peripheral instances with data size limited to 16 bits. For instances with limited set of features, the CRC polynomial length can be set either to 9 or 17 only when data size is limited to 16 bit and optionally to 33 when data size is extended to 32-bit. The length of the polynomial is defined by the most significant bit of the value stored at the CRCPOLY register. It must be set greater than data frame length defined at DSIZE field. When maximum data size is applied, the CRC33_17 bit must be set additionally to define the most significant bit of the polynomial string while keep its size always greater than data. The CRCSIZE field in the SPI_CFG1 then defines how many the most significant bits from CRC calculation registers are transacted and compared as CRC frame. It is defined independently from the data frame length, but it must be either equal or an integer multiple of the data frame size while its size cannot exceed the maximum data size of the instance.

To fully benefit from the CRC calculation capability, the polynomial length setting must correspond to the CRC pattern size, else the bits unused at the calculation are transacted...
and expected all zero at the end of the CRC pattern if its size is set greater then the polynomial length.

**CRC principle**

The CRC calculation is enabled by setting the CRCEN bit in the SPI_CFG1 register before the SPI is enabled (SPE = 1). The CRC value is then calculated using the CRC polynomial defined by the CRCPOLY register and CRC33_17 bit. When SPI is enabled, the CRC polynomial can be changed but only in case when there is no traffic on the bus.

The CRC computation is done, bit by bit, on the sampling clock edge defined by the CPHA and CPOL bits in the SPI_CR1 register. The calculated CRC value is checked automatically at the end of the data block defined by the SPI_CR2 register exclusively.

When a mismatch is detected between the CRC calculated internally on the received data and the CRC received from the transmitter, a CRCE flag is set to indicate a data corruption error. The right procedure for handling the CRC depends on the SPI configuration and the chosen transfer management.

**CRC transfer management**

Communication starts and continues normally until the last data frame must be sent or received in the SPI_DR register.

The length of the transfer must be defined by TSIZE. When the desired number of data is transacted, the TXCRC is transmitted and the data received on the line are compared to the RXCRC value.

No matter what is the CRCSIZE configuration, TSIZE cannot be set neither to 0xFFFF at full feature set instance nor to 0x3FF value at limited feature one if CRC is enabled.

In transmission, the CRC computation is frozen during CRC transaction and the TXCRC are transmitted, in a frame of length equal to the CRCSIZE field value.

In reception, the RXCRC is also frozen when desired number of data is transacted. Information to be compared with the RXCRC register content is then received in a frame of length equal to the CRCSIZE value.

Once the CRC frame is completed, an automatic check is performed comparing the received CRC value and the value calculated in the SPI_RXCRC register. The software has to check the CRCE flag in the SPI_SR register to determine if the data transfers were corrupted or not. Software clears the CRCE flag by writing 1 to the CRCEC.

The user takes no care about any flushing redundant CRC information, it is done automatically.

**Resetting the SPI_TXCRC and SPI_RXCRC values**

The SPI_TXCRC and SPI_RXCRC values are initialized automatically when new data is sampled after a CRC phase. This allows the use of DMA circular mode in order to transfer data without any interruption (several data blocks covered by intermediate CRC checking phases). Initialization patterns for receiver and transmitter can be configured either to zero or to all ones in dependency on setting bits TCRCINI and RCRCINI at SPI_CR1 register.

The CRC values are reset when the SPI is disabled.
52.6 SPI low-power modes

1. Refer to Section 52.3: SPI implementation for information about wake-up from Stop mode support per instance as well as Standby mode availability. If an instance is not functional in a Stop mode, it must be disabled before entering this Stop mode.

52.7 SPI interrupts

Table 556 gives an overview of the SPI events capable to generate interrupts if enabled. Some of them feature wake up from Low-power mode capability, additionally. Most of them can be enabled and disabled independently while using specific interrupt enable control bits. The flags associated with the events are cleared by specific methods. Refer to description of SPI registers for more details about the event flags. When SPI is disabled, all the pending interrupt requests are blocked to prevent their propagation into the interrupt services, except the MODF interrupt request.

52.8 I2S main features

- Full duplex communication
- Simplex communication (only transmitter or receiver)
- Master or slave operations
- 8-bit programmable linear prescaler
- Data length may be 16, 24 or 32 bits\(^{a}\)
- Channel length can be 16 or 32 in master, any value in slave
- Programmable clock polarity
- Error flags signaling for improved reliability: Underrun, Overrun and Frame Error
- Embedded Rx and TxFIFOs
- Supported I2S protocols:
  - I2S Philips standard
  - MSB-Justified standard (Left-Justified)
  - LSB-Justified standard (Right-Justified)
  - PCM standard (with short and long frame synchronization)
- Data ordering programmable (LSb or MSb first)
- DMA capability for transmission and reception
- Master clock can be output to drive an external audio component:
  - \(F_{MCK} = 256 \times F_{WS}\) for all I2S modes
  - \(F_{MCK} = 128 \times F_{WS}\) for all PCM modes

Note: \(F_{MCK}\) is the master clock frequency and \(F_{WS}\) is the audio sampling frequency.

52.9 I2S functional description

52.9.1 I2S general description

The block diagram shown on Figure 715 also applies for I2S mode.

The SPI/I2S block can work on I2S/PCM mode, when the bit I2SMOD is set. A dedicated register (SPI_I2SCFGR) is available for configuring the dedicated I2S parameters, which include the clock generator, and the serial link interface.

---

\(^{a}\) Not always available, refer to Section 52.3: SPI implementation in order to check if 24 and 32-bit data width are supported.
The I2S/PCM function uses the clock generator to produce the communication clock when the SPI/I2S is set in master mode. This clock generator is also the source of the master clock output (MCK).

Resources such as RxFIFO, TxFIFO, DMA and parts of interrupt signaling are shared with SPI function. The low-power mode function is also available in I2S mode, refer to Section 52.6: SPI low-power modes and Section 52.10: I2S interrupts.

52.9.2 Pin sharing with SPI function

The I2S shares four common pins with the SPI:
- SDO: Serial Data Output (mapped on the MOSI pin) to transmit the audio samples in master, and to receive the audio sample in slave. Refer to Section : Serial data line swapping on page 2414.
- SDI: Serial Data Input (mapped on the MISO pin) to receive the audio samples in master, and to transmit the audio sample in slave. Refer to Section : Serial data line swapping on page 2414.
- WS: Word Select (mapped on the SS pin) is the frame synchronization. It is configured as output in master mode, and as input for slave mode.
- CK: Serial Clock (mapped on the SCK pin) is the serial bit clock. It is configured as output in master mode, and as input for slave mode.

An additional pin can be used when a master clock output is needed for some external audio devices:
- MCK: Master Clock (mapped separately) is used when the I2S is configured in master mode.

52.9.3 Bitfields usable in I2S/PCM mode

When the I2S/PCM mode is selected (I2SMOD = '1'), some bitfields are no longer relevant, and must be forced to a specific value in order to guarantee the behavior of the I2S/PCM function. Table 557 shows the list of bits and fields available in the I2S/PCM mode, and indicates which must be forced to a specific value.

<table>

</table>
52.9.4 Slave and master modes

The SPI/I2S block supports master and slave mode for both I2S and PCM protocols. In master mode, both CK, WS and MCK signals are set to output. In slave mode, both CK and WS signals are set to input. The signal MCK cannot be used in slave mode.

In order to improve the robustness of the SPI/I2S block in slave mode, the peripheral re-synchronizes each reception and transmission on WS signal. This means that:

- In I2S Philips standard, the shift-in or shift-out of each data is triggered one bit clock after each transition of WS.
- In I2S MSB justified standard, the shift-in or shift-out of each data is triggered as soon as a transition of WS is detected.
- In PCM short standard, the shift-in or shift-out of each data is triggered one bit clock after the active edge of WS.
- In PCM long standard, the shift-in or shift-out of each data is triggered as soon as the active edge of WS is detected.

Note: This re-synchronization mechanism is not available for the I2S LSB justified standard.

Note as well that there is no need to provide a kernel clock when the SPI/I2S is configured in slave mode.

52.9.5 Supported audio protocols

The I2S/PCM interface supports four audio standards, configurable using the I2SSTD[1:0] and PCMSYNC bits in the SPI_I2SCFGR register.

In the I2S protocol, the audio data are time-multiplexed on two channels: the left channel and the right channel. The WS signal is used to indicate which channel must be considered as the left, and which one is the right.

In I2S master mode, four frames formats are supported:

- 16-bit data packed in a 16-bit channel
- 16-bit data packed in a 32-bit channel
- 24-bit data packed in a 32-bit channel
- 32-bit data packed in a 32-bit channel

**Table 557. Bitfields usable in PCM/I2S mode (continued)**

</tr>
</tbody>
</table>
In PCM master mode, three frames formats are supported:

- 16-bit data packed in a 16-bit channel
- 16-bit data packed in a 32-bit channel
- 24-bit data packed in a 32-bit channel\(^{(a)}\)

The figure hereafter shows the main definition used in this section: data length, channel length and frame length.

**Figure 730. Waveform examples**

For simplicity sake, in the next figures, SDI represents the serial data input and SDO the serial data output. Refer to Section 52.3: SPI implementation in order to check if 24 and 32-bit data width are supported.

**I^2S Philips standard**

The I^2S Philips standard is selected by setting I2SSTD to 0b00. This standard is supported in master and slave mode.

In this standard, the WS signal toggles one CK clock cycle before the first bit (MSb in I^2S Philips standard) is available. A falling edge transition of WS indicates that the next data transferred is the left channel, and a rising edge transition indicates that the next data transferred is the right channel.

---

\(a\). Not always available, refer to Section 52.3: SPI implementation in order to check if 24 and 32-bit data width are supported.
1. Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10). Refer to Section 52.3: SPI implementation for the supported data sizes.

CKPOL is cleared in order to match the I2S Philips protocol. See Selection of the CK sampling edge for information concerning the handling of WS signal.

Figure 731 shows an example of waveform generated by the SPI/I2S in the case where the channel length is equal to the data length. More precisely, this is true when CHLEN = 0 and DATLEN = 0b00 or when CHLEN = 1 and DATLEN = 0b10.

See Control of the WS Inversion for information concerning the handling of WS signal.

1. Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10). Refer to Section 52.3: SPI implementation for the supported data sizes.

In the case where the channel length is bigger than the data length, the remaining bits are not significant when the SPI/I2S is configured in transmit mode. This is applicable for both master and slave mode.
MSB justified standard

For this standard, the WS signal toggles when the first data bit is provided. The data transferred represents the left channel if WS is high, and the right channel if WS is low.

Figure 733. Master MSB Justified 16-bit or 32-bit full-accuracy length

1. Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10), Refer to Section 52.3: SPI implementation to check the supported data size.

CKPOL is cleared in order to match the I2S MSB justified protocol. See Selection of the CK sampling edge for information concerning the handling of WS signal.

See Control of the WS Inversion for information concerning the handling of WS signal.

Figure 734. Master MSB justified 16 or 24-bit data length

1. Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10), Refer to Section 52.3: SPI implementation to check the supported data size.

In the case where the channel length is bigger than the data length, the remaining bits are not significant when the SPI/I2S is configured in master transmit mode. In slave transmit the remaining bits are forced to the value of the first bit of the next data to be generated in order to avoid timing issues (see Figure 735).
1. Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10), Refer to Section 52.3: SPI implementation to check the supported data size.

**LSB justified standard**

This standard is similar to the MSB justified standard in master mode (no difference for the 16 and 32-bit full-accuracy frame formats). The LSB justified 16 or 32-bit full-accuracy format give similar waveforms than MSB justified mode (see Figure 733) because the channel and data have the same length.

*Note: In the LSB justified format, only 16 and 32-bit channel length are supported in master and slave mode. This is due to the fact that it is not possible to transfer properly the data if the channel length is not known by transmitter and receiver side.*

**Figure 736. LSB justified 16 or 24-bit data length**

1. Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10), Refer to Section 52.3: SPI implementation to check the supported data size.

CKPOL is cleared in order to match the I2S LSB justified protocol. See Selection of the CK sampling edge for information concerning the handling of WS signal.

See Control of the WS Inversion for information concerning the handling of WS signal.
PCM standard

For the PCM standard, there is no need to use channel-side information. The two PCM modes (short and long frame) are available and can be selected using the PCMSYNC bit in SPI_I2SCFGR register.

In PCM long frame:
- The assertion time of WS signal is fixed to 13 cycles of CK in master mode,
- The first data bit is received or transmitted as soon as the WS signal is asserted.

In PCM short frame:
- The assertion time of WS signal is fixed to one cycle of CK in master mode,
- The first data bit is received or transmitted one cycle of CK after the WS assertion.

For both PCM modes:
- The first data bit is MSb or LSb depending on LSBFIRST bit value.
- The CK sampling edge can be selected thanks to CKPOL bit.
- The WS signal can be inverted thanks to WSINV bit. See Control of the WS Inversion for information concerning the handling of WS signal.

Figure 737. Master PCM when the frame length is equal the data length

A data size of 16 or 24 bits can be used when the channel length is set to 32 bits.

Figure 738. Master PCM standard waveforms (16 or 24-bit data length)

1. Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10), Refer to Section 52.3: SPI Implementation to check the supported data size.
If the PCM protocol is used in slave mode, frame lengths can be different from 16 or 32 bits. As shown in Figure 739, in slave mode various pulse widths of WS can be accepted as the start of frame is detected by a rising edge of WS. The only constraint is that the WS must go back to its inactive state for at least one CK cycle.

**Figure 739. Slave PCM waveforms**

1. Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10). Refer to Section 52.3: SPI implementation to check the supported data size.

**Note:** In the case where the channel length is bigger than the data length, in slave PCM long, the transmission of the remaining bits are forced to the value of the first bit of the next data to be generated if the TXFIFO contains the next data to be transmitted.

**Note:** In slave mode, CHLEN must be always programmed properly (whatever FIXCH value). For example, if CHLEN is cleared (16-bit length), the data transfer is truncated to 16 bits even if DATLEN is different from 0. To avoid this situation, CHLEN must be set, if DATLEN = 1 or 2.

### 52.9.6 Additional serial interface flexibility

#### Variable frame length in slave

In slave mode, channel lengths different from 16 or 32 bits can be accepted, as long as the channel length is bigger than the data length. This is true for all protocols except for I2S LSB justified protocol.
Data ordering

For all data formats and communication standards, it is possible to select the data ordering (MSb or LSb first) thanks to the bit LSBFRST located into SPI/I2S configuration register 2 (SPI_CFG2).

Selection of the CK sampling edge

The CKPOL bit located into SPI/I2S configuration register (SPI_I2SCFGR) allows the user to choose the sampling edge polarity of the CK for slave and master modes, for all protocols.

- When CKPOL = 0, serial data SDO and WS (when master) are changed on the falling edge of CK and the serial data SDI and WS (when slave) are read on the rising edge.
- When CKPOL = 1, serial data SDO and WS (when master) are changed on the rising edge of CK and the serial data SDI and WS (when slave) are read on the falling edge.

Control of the WS Inversion

It is possible to invert the default WS signal polarity for master and slave modes, for all protocols, by setting WSINV. By default the WS polarity is the following:

- In I2S Philips Standard, WS is LOW for left channel, and HIGH for right channel
- In MSB/LSB justified mode, WS is HIGH for left channel, and LOW for right channel
- In PCM mode, the start of frame is indicated by a rising edge of WS.

When WSINV is set, the WS polarity is inverted, then:

- In I2S Philips Standard, WS is HIGH for left channel, and LOW for right channel
- In MSB/LSB justified mode, WS is LOW for left channel, and HIGH for right channel
- In PCM mode, the start of frame is indicated by a falling edge of WS.

WSINV is located into SPI/I2S configuration register (SPI_I2SCFGR).

Control of the I/Os

The SPI/I2S block allows the settling of the WS and CK signals to their inactive state before enabling the SPI/I2S thanks to the AFCNTR bit of SPI/I2S configuration register 2 (SPI_CFG2).

This can be done by programming CKPOL and WSINV using the following sequence:

Assuming that AFCNTR is initially cleared:

- Set I2SMOD = 1, (In order to inform the hardware that the CK and WS polarity is controlled via CKPOL and WSINV).
- Set bits CKPOL and WSINV to the wanted value.
- Set AFCNTR = 1.
  Then the inactive level of CK and WS I/Os is set according to CKPOL and WSINV values, even if the SPI/I2S is not yet enabled.
- Then performs the activation sequence of the I2S/PCM

Table 558 shows the level of WS and CK signals, when the AFCNTR bit is set, and before the SPI/I2S block is enabled (i.e. inactive level). Note that the level of WS depends also on the protocol selected.
Table 558. WS and CK level before SPI/I2S is enabled when AFCNTR = 1

Note: The bit AFCNTR must not be set, when the SPI2S is in slave mode.

Serial data line swapping

The direction of SDI and SDO depends on the IOSWP bit of SPI/I2S configuration register 2 (SPI_CFG2), and on the slave/master mode. Table 559 gives details on this feature.

52.9.7 Startup sequence

When the bit SPE is cleared, the user is not allowed to read and write into the SPI_RXDR and SPI_TXDR registers, but the access to other registers is allowed.

When the application wants to use the SPI/I2S block the user has to proceed as follow:

1. Ensure that the SPE is cleared, otherwise write SPE to 0.
2. Program all the configuration and control registers according to the wanted configuration. Refer to Section 52.9.16 for detailed programming examples.
3. Clear all the status flags by setting the USPC, TIFREC, OVRC and UDRC bits of SPI_IFCR register. Note that if the flag SUSP is not cleared (via SUSPC bit) the CSTART control bit has no effect.
4. Set the SPE bit, in order to activate the SPI/I2S block. When this bit is set, the serial interface is still disabled, but the DMA and interrupt services are working, allowing for example, the data transfer into the TxFIFO. The generation of MCK can also be started when SPE goes to 1.
5. Set bit CSTART, in order to activate the serial interface.

As shown in Figure 740, in I2S Philips standard master TX, the generation of the WS and CK signals starts after a resynchronization delay (SYNC_DLY2) when CSTART goes to 1.
and the TxFIFO is not empty. Note that the bit clock CK is activated 4 rising edges before the falling edge of WS in order to ensure that the external slave device can detect properly WS transition. Other standards behave similarly.

**Figure 740. Startup sequence, I2S Philips standard, master**

1. As shown in the figure, MCK can be enabled as soon as the bit SPE is set. It is generated after a synchronization delay (SYNC_DLY1). See MCK generation in Section 52.9.9: Clock generator for more information.

2. Note that the level of WS and CK signals are controlled by the SPI/I2S block during the configuration phase as soon as the AFCNTR bit is set. Due to clock domain resynchronization, the CSTART bit is taken into account by the hardware after about 3 periods of CK clock (SYNC_DLY2).

**Note:** Due to clock domain resynchronization, the CSTART bit is taken into account by the hardware after about 3 periods of CK clock (SYNC_DLY2).

In slave mode, once the bit CSTART is set, the data transfer starts when the start-of-frame condition is met:

- For I2S Philips standard, the start-of-frame condition is a falling edge of WS signal. The transmission/reception starts one bit clock later. If WSINV = 1, then the start-of-frame condition is a rising edge.
- For other protocols, the start-of-frame condition is a rising edge of WS signal. The transmission/reception starts at rising edge of WS for MSB aligned protocol. The transmission/reception starts one bit clock later for PCM protocol. If WSINV = 1, then the start-of-frame condition is a falling edge.

**Figure 741** shows an example of startup sequence in I2S Philips standard, slave mode.
2416/3119 RM0481 Rev 1

Figure 741. Startup sequence, I2S Philips standard, slave

![Diagram of startup sequence](image)

Note: Due to clock domain resynchronization, the CSTART bit is taken into account by the hardware after 2 periods of CK clock (SYNC_DLY).

52.9.8 Stop sequence

The application can stop the I2S/PCM transfers by clearing the SPE bit. In that case the communication is stopped immediately, without waiting for the end of the current frame.

In master mode it is also possible to stop the I2S/PCM transfers at the end of the current frame. For that purpose, the user has to set the bit CSUSP, and polls the CSTART bit until it goes to 0. The CSTART bit goes to 0 when the current stereo (if an I2S mode was selected) or mono sample are completely shifted in or out. Then the SPE bit can be cleared.

The Figure 742 shows an example of stop sequence in the case of master mode. The CSUSP bit is set, during the transmission of left sample, the transfer continue until the last bit of the right sample is transferred. Then CSTART and CSUSP go back to 0, CK and WS signals go back to their inactive state, and the user can clear SPE bit.

![Diagram of stop sequence](image)

Note: In slave mode, the stop sequence is only controlled by the SPE bit.
52.9.9 Clock generator

When the I2S or PCM is configured in master mode, the user needs to program the clock generator in order to produce the Frame Synchronization (WS), the bit clock (CK) and the master clock (MCK) at the desired frequency.

If the I2S or PCM is used in slave mode, there is no need to configure the clock generator.

The frequency generated on MCK, CK and WS depends mainly on I2SDIV, ODD, CHLEN and MCKOE. The bit MCKOE indicates if a master clock need to be generated or not. The master clock has a frequency 256 or 128 times higher than the frame synchronization. This master clock is often required to provide a reference clock to external audio codecs.

Note: In master mode, there is no specific constraints on the ratio between the bus clock rate (Fpclk) and the bit clock (FCK). The bus clock frequency must be high enough in order to support the data throughput.

When the master clock is generated (MCKOE = 1), the frequency of the frame synchronization is given by the following formula in I2S mode:

\[ F_{WS} = \frac{F_{i2s\_clk}}{256 \times \{2 \times I2SDIV\} + ODD} \]

and by this formula in PCM mode:

\[ F_{WS} = \frac{F_{i2s\_clk}}{128 \times \{2 \times I2SDIV\} + ODD} \]

In addition, the frequency of the MCK (F_{MCK}) is given by the formula:

\[ F_{MCK} = \frac{F_{i2s\_clk}}{(2 \times I2SDIV) + ODD} \]

When the master clock is disabled (MCKOE = 0), the frequency of the frame synchronization is given by the following formula in I2S mode:

\[ F_{WS} = \frac{F_{i2s\_clk}}{32 \times (CHLEN + 1) \times \{2 \times I2SDIV\} + ODD} \]
And by this formula in PCM mode:

\[ F_{WS} = \frac{F_{i2s\_clk}}{16 \times (CHLEN + 1) \times (2 \times I2SDIV + ODD)} \]

Where \( F_{WS} \) is the frequency of the frame synchronization, and \( F_{i2s\_clk} \) is the frequency of the kernel clock provided to the SPI/I2S block.

**Note:**
- CHLEN and ODD can be either 0 or 1.
- \( I2SDIV \) can take any values from 0 to 255 when ODD = 0, but when ODD = 1, the value \( I2SDIV = 1 \) is not allowed.
- When \( I2SDIV = 0 \), then \((2 \times I2SDIV) + ODD\) is forced to 1.

**Note:** When \((2 \times I2SDIV) + ODD\) is odd, the duty cycle of MCK or the CK signals are not 50%. Care must be taken when odd ratio is used: it can impact margin on setup and hold time. For example if \((2 \times I2SDIV) + ODD\) = 5, then the duty cycle can be 40%.

*Table 560* provides examples of clock generator programming for I2S modes.

### MCK generation

The master clock MCK is generated when the following conditions are met:
- \( I2SMOD \) must be equal to 1,
- \( I2SCFG \) must select a master mode,
- \( MCKOE \) must be set,
- \( SPE \) must be set

### 52.9.10 Internal FIFOs

The I2S interface can use a dedicated FIFO for the RX and the TX path. The samples to transmit can be written into the TxFIFO via the SPI_TXDR register. The reading of RxFIFO is performed via the SPI_RXDR register.

#### Data alignment and ordering

It is possible to select the data alignment into the SPI_RXDR and SPI_TXDR registers thanks to the DATFMT bit.

Note as well that the format of the data located into the SPI_RXDR or SPI_TXDR depends as well on the way those registers are accessed via the APB bus. **Figure 744** shows the allowed settings between APB access sizes, DATFMT and DATLEN.

**Note:** *Caution must be taken when the APB access size is 32 bits, and DATLEN = 0. For read operation the RxFIFO must contain at least two data, otherwise the read data are invalid. In the same way, for write operation, the TxFIFO must have at least two empty locations, otherwise a data can be lost.*

<td>0b10</td>
<td>31 valid sample 0</td>
<td>31 valid sample 0</td>
</tr>
</tbody>
</table>

1. In I2S mode, the sample N represents the left sample, and the sample N+1 is the right sample.

2. Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10). Refer to Section 52.3: SPI implementation to check the supported data size.
It is possible to generate an interrupt or a DMA request according to a programmable FIFO threshold levels. The FIFO threshold is common to RX and TxFIFOs can be adjusted via FTHLV.

In I2S mode, the left and right audio samples are interleaved into the FIFOs. It means that for transmit operations, the user has to start to fill-up the TxFIFO with a left sample, followed by a right sample, and so on. For receive mode, the first data read from the RxFIFO is supposed to represent a left channel, the next one is a right channel, and so on.

Note that the read and write pointers of the FIFOs are reset when the bit SPE is cleared.

Refer to Section 52.9.11 and Section 52.9.15 for additional information.

**FIFO size optimization**

The basic element of the FIFO is the byte. This allows an optimization of the FIFO locations. For example when the data size is fixed to 24 bits, each audio sample takes 3 basic FIFO elements.

For example, a FIFO with 16 basic elements can have a depth of:
- 8 samples, if the DATLEN = 0 (16 bits),
- 5 samples, if the DATLEN = 1 (24 bits)(a),
- 4 samples, if the DATLEN = 2 (32 bits)(a).

### 52.9.11 FIFOs status flags

Two status flags are provided for the application to fully monitor the state of the I2S interface. Both flags can generate an interrupt request. The receive interrupt is generated if RXPIE bit is enabled, the transmit interrupt is generated if TXPIE bit is enabled. Those bits are located into the SPI_IER register.

**TxFIFO threshold reached (TXP)**

When set, this flag indicates that the TxFIFO contains at least FTHLV empty locations. thus FTHLV new data to be transmitted can be written into SPI_TXDR. The TXP flag is reset when the amount of empty locations is lower than FTHLV. Note that TXP = 1, when the I2S is disabled (SPE bit is reset).

**RxFIFO threshold reached (RXP)**

When set, this flag indicates that there is at least FTHLV valid data into the RxFIFO, thus the user can read those data via SPI_RXDR. It is reset when the RxFIFO contains less than FTHLV data.

See Section 52.10 for additional information on interrupt function in I2S mode.

### 52.9.12 Handling of underrun situation

In transmit mode, an underrun situation is detected when a new data needs to be loaded into the shift register while the TxFIFO is already empty. In such a situation the UDR flag is set, and at least one audio frame contains unexpected data.

---

(a) Not always available, refer to Section 52.3: SPI implementation in order to check if 24 and 32-bit data width are supported.
For I2S modes, there is a hardware mechanism to prevent misalignment situations (left and right channel swapped). When an underrun situation is detected, the last valid data present in the shift register is repeated if the real channel length matches the length selected by the CHLEN bit. In the other cases, an undefined data is repeated. Typically, if the block is programmed in slave TX mode, and the external master audio device is using channel lengths other than 16 or 32 bits, the repeated data value is undefined in case of underrun.

The following figure shows the case where an underrun occurs and the peripheral re-plays the last valid data on left and right channels as long as conditions of restart are not met. The transmission restarts:

- When there is enough data into the TxFIFO, and
- When the UDR flag is cleared by the software, and
- When the restart condition is met:
  - if the underrun occurs when a right channel data needs to be transmitted, the transmission restarts when a right channel needs to be transmitted, or
  - if the underrun occurs when a left channel data needs to be transmitted, the transmission restarts when a left channel needs to be transmitted.

![Figure 745. Handling of underrun situation](image)

When the block is configured in one of the PCM modes, the transmission restarts at the start of the next frame, when there is enough data in the TxFIFO, and the UDR flag is cleared.

The UDR flag can trigger an interrupt if the UDRIE bit in the SPI_IER register is set. The UDR bit is cleared by writing UDRC bit of SPI_IFCR register to 1.

**Note:**

An underrun situation can occur in master or slave mode. In master mode, when an underrun occurs, the WS, CK and MCK signal are not gated.

Due to resynchronization, any change on the UDR flag is taken into account by the hardware after at least 2 periods of CK clock.

### 52.9.13 Handling of overrun situation

In receive mode, an overrun situation is detected when the shift register needs to store a new data into the RxFIFO, while the RxFIFO is full. In such a situation the OVR flag is set, and the incoming data is lost.
In I2S mode, there is a hardware mechanism in to prevent misalignment situations (left and right channel swapped). As shown in the following figure, when an overrun occurs, the peripheral stops writing data into the Rx_FIFO as long as restart conditions are not met.

The reception restarts when there is enough room into the Rx_FIFO, and the OVR flag is cleared, the block starts by writing next the right channel into the Rx_FIFO if the overrun occurs when a right channel data is received or by writing the next left channel if the overrun occurs when a left channel data is received.

![Figure 746. Handling of overrun situation](image)

When the block is configured in PCM mode, after an overrun error, the block stops writing data in the Rx_FIFO as long as conditions of restart are not met. When there is enough room in the Rx_FIFO, and the OVR flag is cleared, the next received data are written in the Rx_FIFO.

An interrupt can be generated if the OVRIE bit of the SPI_IER register is set. The OVR bit is cleared by writing OVRC bit of SPI_IFCR register to 1.

**Note:** An overrun situation can occur in master or slave mode. In master mode when an overrun occurs, the WS, CK and MCK signal are not gated.

### 52.9.14 Frame error detection

When configured in slave mode, the SPI/I2S block detects two kinds of frame errors:
- A frame synchronization received while the shift-in or shift-out of the previous data is not completed (early frame error). This mode is selected with FIXCH = 0.
- A frame synchronization occurring at an unexpected position. This mode is selected with FIXCH = 1.

In slave mode, if the frame length provided by the external master device is different from 32 or 64 bits, the user has to clear FIXCH. As the SPI/I2S synchronize each transfer with the WS there is no misalignment risk, but in a noisy environment, if a glitch occurs in the CK signal, a sample may be affected and the application is not aware of this.

If the frame length provided by the external master device is equal to 32 or 64 bits, then the user can set FIXCH and adjust accordingly CHLEN. As the SPI/I2S synchronize each transfer with the WS there is still no misalignment risk, and if the amount of bit clock between each channel boundary is different from CHLEN, the frame error flag (TIFRE) is set.
Figure 747 shows an example of frame error detection. The SPI/I2S block is in slave mode and the amount of bit clock periods for left channel are not enough to shift-in or shift-out the data. The figure shows that the on-going transfer is interrupted and the next one is started in order to remain aligned to the WS signal.

Figure 747. Frame error detection, with FIXCH=0

An interrupt can be generated if the TIFREIE bit is set. The frame error flag (TIFRE) is cleared by writing the TIFREC bit of the SPI_IFCR register to 1.

It is possible to extend the coverage of the frame error flag by setting the bit FIXCH. When this bit is set, then the SPI/I2S is expecting fixed channel lengths in slave mode. This means that the expected channel length can be 16 or 32 bits, according to CHLEN. As shown in Figure 748, in this mode the SPI/I2S block is able to detect if the WS signal is changing at the expected moment (too early or too late).

Note: Figure 747 and Figure 748 show the mechanism for the slave transmit mode, but this is also true for slave receive and slave full-duplex.

Figure 748. Frame error detection, with FIXCH=1

The frame error detection can be generally due to noisy environment disturbing the good reception of WS or CK signals.

Note: The SPI/I2S is not able to recover properly if an overrun and an early frame occur within the same frame. In this case the user has to disable and re-enable the SPI/I2S.
52.9.15 DMA interface

The I2S/PCM mode shares the same DMA requests lines than the SPI function. There is a separated DMA channel for TX and RX paths. Each DMA channel can be enabled via RXDMAEN and TXDMAEN bits of SPI_CFG1 register.

In receive mode, the DMA interface is working as follow:
1. The hardware evaluates the RxFIFO level,
2. If the RxFIFO contains at least FTHLV samples, then FTHLV DMA requests are generated,
   – When the FTHLV DMA requests are completed, the hardware loops to step 1
3. If the RxFIFO contains less than FTHLV samples, no DMA request is generated, and the hardware loop to step 1

In transmit mode, the DMA interface is working as follow:
1. The hardware evaluates the TxFIFO level,
2. If the TxFIFO contains at least FTHLV empty locations, then FTHLV DMA requests are generated,
   – When the FTHLV DMA requests are completed, the hardware loops to step 1
3. If the TxFIFO contains less than FTHLV empty locations, no DMA request is generated, and the hardware loop to step 1

52.9.16 Programming examples

Master I2S Philips standard, full-duplex

This example shows how to program the interface for supporting the I2S Philips standard protocol in master full-duplex mode, with a sampling rate of 48 kHz, using the master clock. The assumption has been taken that the SPI/I2S is receiving a kernel clock (i2s_clk) of 61.44 MHz from the clock controller of the circuit. In the example above we took the assumption that the external audio codec needs to be programmed, for example via an I2C interface before starting the transfer. In addition, it is supposed that this external audio codec needs the MCK to accept I2C commands.
**Procedure**

1. Via the RCC block, enable the bus interface and the kernel clocks, assert and release the reset signal if needed.
2. Program the AFMUX in order to select the wanted I/Os. In the current example MCK, CK, WS, SDO, SDI are needed.
3. Program the clock generator to provide the MCK clock, and to have a frame synchronization rate at exactly 48 kHz. Set i2SDIV to 2, ODD to 1, and MCKOE to 1.
4. Program the serial interface protocol: CKPOL = 0, WSINV = 0, CHLEN = 1 (32 bits per channel) DATLEN = 1 (24 bits), I2SSTD = 0 (I2S Philips standard), I2SCFG = 5 (master Full-duplex), I2SMOD = 1, for I2S/PCM mode.
5. Adjust the FIFO threshold, by setting the wanted value into FTHLV. For example, if a threshold of 2 audio samples is required, FTHLV = 1.
6. If the application wishes to perform data transfer via DMA, set the bits TXDMAEN and RXDMAEN.
7. Clear all interrupt enable fields located in SPI_IER register.
8. Clear all status flags, by setting SUSPC, TIFREC, OVRC, UDRC of SPI_IFCR register.
9. Set SPE bit, then the MCK is generated. In the example presented here, the TxFIFO is not filled-up as soon as SPE = 1. The application can then configure the external audio codec via an I2C interface even if audio samples to transmit are not yet available. An **Alternative sequence** is proposed hereafter.
10. When the application wants to start the data transfer:
   - If the data transfer uses DMA:
     - Program the DMA peripheral: two channels, one for RX and one for TX
     - Initialize the memory buffer with valid audio samples for TX path – Enable the DMA channels,
     - Enable interrupt events such as UDRIE and OVRIE if needed in order to detect transfer errors.
     - Enable the DMA channel. If TXDMAEN was set, the TxFIFO is filled-up.
   - If the data transfer is done via interrupt:
     - Enable the interrupt events UDRIE, OVRIE, TXPIE and RXPIE (by writing 1). An interrupt request is immediately activated allowing the interrupt handler to fill-up the TxFIFO.
11. Finally, the SPI/I2S serial interface can be enabled by setting the bit CSTART. CSTART bit is located into SPI_CR1 register.

**Alternative sequence**

- Steps 1 to 8 similar to the previous sequence.
- If the data transfer uses DMA:
  - Program the DMA peripheral: two channels, one for RX and one for TX
  - Initialize the memory buffer with valid audio samples for TX path
  - Enable interrupt events such as UDRIE and OVRIE if needed in order to detect transfer errors.
  - Enable the DMA channels,
- If the data transfer is done via interrupt:
Enable the interrupt events UDRIE, OVRIE, TXPIE and RXPIE (by writing 1). An interrupt request is immediately activated allowing the interrupt handler to fill-up the TxFIFO.

- Set SPE, as soon as this bit is set to one the following actions may happen:
  - If the interrupt generation is enabled, the SPI/I2S generates an interrupt request allowing the interrupt handler to fill-up the TxFIFO.
  - If the DMA transfer are enabled, the SPI/I2S generates DMA requests in order to fill-up the TxFIFO
  - The MCK is generated. The application can then configure the external audio codec via an I2C interface.

- Finally, the SPI/I2S serial interface can be enabled by setting the bit CSTART. CSTART bit is located into SPI_CR1 register.

Stop Procedure in master mode

1. Set the bit CSUSP, in order to stop on-going transfers
2. Check the value of CSTART bit until it goes to 0
3. Clear the SUSP flag by setting SUSPC
4. Stop DMA peripheral, bus clock...
5. Clear bit SPE in order to disable the SPI/I2S block

Slave I2S Philips standard, receive

This example shows how to program the interface for supporting the I2S Philips standard protocol in slave receiver mode, with a sampling rate of 48 kHz. Note that in slave mode the SPI/I2S block cannot control the sample rate of the received samples. In this example we took the assumption that the external master device is delivering an I2S frame structure with a channel length of 24 bits. So we cannot use the capability offered for frame error detection when FIXCH is set.

Procedure

1. Via the RCC block, enable the bus interface and the kernel clocks, assert and release the reset signal if needed,
2. Program the AFMUX in order to select the wanted I/Os. In the current example CK, WS, SDI,
3. Program the serial interface protocol: CKPOL = 0, WSINV = 0, LSBFRST = 0, FIXCH = 0 (because channel length is different from 16 and 32 bits), DATLEN = 0 (16 bits), I2SSTD = 0 (Philips protocol), I2SCFG = 1 (slave RX), I2SMOD = 1, for I2S mode.
4. Adjust the FIFO threshold, by setting the wanted value into FTHLV. For example if a threshold of 2 audio samples is required, FTHLV = 1.
5. Clear all status flag registers.
6. Enable the flags that generate an interrupt such as OVRIE and TIFRE.
7. If the data transfer uses DMA:
   - Program the DMA peripheral: one RX channel
   - Enable the DMA channel,
   - In the SPI/I2S block, enable the DMA by setting the RXDMAEN bit.
8. If the data transfer is done via interrupt, then the user has to enable the interrupt by setting the RXPIE bit.
9. Set SPE.
10. Finally the user can set the bit CSTART in order to enable the serial interface. The SPI/I2S starts to store data into the RxFIFO on the next occurrence of left data transmitted by the external master device.

Stop Procedure in slave mode
1. Clear bit SPE in order to disable the SPI/I2S block
2. Stop DMA peripheral, bus clock...

52.10 I2S interrupts

In PCM/I2S mode an interrupt (spi_it) or a wake-up event signal (spi_wkup) can be generated according to the events described in the Table 561.

Interrupt events can be enabled and disabled separately.

RM0481 Rev 1 2427/3119
Bits 31:17  Reserved, must be kept at reset value.

Bit 16  **IOLOCK**: locking the AF configuration of associated I/Os
   This bit can be changed by software only when SPI is disabled (SPE = 0). It is cleared by
   hardware if a MODF event occurs
   0: AF configuration is not locked
   1: AF configuration is locked
   When this bit is set, SPI_CFG2 register content cannot be modified. This bit is write-
   protected when SPI is enabled (SPE = 1).

Bit 15  **TCRCINI**: CRC calculation initialization pattern control for transmitter
   0: all zero pattern is applied
   1: all ones pattern is applied

Bit 14  **RCRCINI**: CRC calculation initialization pattern control for receiver
   0: All zero pattern is applied
   1: All ones pattern is applied

Bit 13  **CRC33_17**: 32-bit CRC polynomial configuration
   0: Full size (33-bit or 17-bit) CRC polynomial is not used
   1: Full size (33-bit or 17-bit) CRC polynomial is used

Bit 12  **SSI**: internal SS signal input level
   This bit has an effect only when the SSM bit is set. The value of this bit is forced onto the
   peripheral SS input internally and the I/O value of the SS pin is ignored.

Bit 11  **HDDIR**: Rx/Tx direction at Half-duplex mode
   In Half-Duplex configuration the HDDIR bit establishes the Rx/Tx direction of the data
   transfer. This bit is ignored in Full-Duplex or any Simplex configuration.
   0: SPI is receiver
   1: SPI is transmitter

Bit 10  **CSUSP**: master suspend request
   This bit reads as zero.
   In Master mode, when this bit is set by software, the CSTART bit is reset at the end of the
   current frame and communication is suspended. The user has to check SUSP flag to check
   end of the frame transaction.
   The Master mode communication must be suspended (using this bit or keeping TXDR
   empty) before going to Low-power mode.
   After software suspension, SUSP flag must be cleared and SPI disabled and re-enabled
   before the next transaction starts.

Bit 9  **CSTART**: master transfer start
   This bit can be set by software if SPI is enabled only to start an SPI or I2S/PCM
   communication. In SPI mode, it is cleared by hardware when end of transfer (EOT) flag is set
   or when a transaction suspend request is accepted. In I2S/PCM mode, it is also cleared by
   hardware as described in the Section 52.9.8: Stop sequence.
   0: master transfer is at idle
   1: master transfer is ongoing or temporary suspended by automatic suspend
   In SPI mode, the bit is taken into account at master mode only. If transmission is enabled,
   communication starts or continues only if any data is available in the transmission FIFO.
Bit 8 **MASRX**: master automatic suspension in Receive mode

This bit is set and cleared by software to control continuous SPI transfer in master receiver mode and automatic management in order to avoid overrun condition.

0: SPI flow/clock generation is continuous, regardless of overrun condition. (data are lost)
1: SPI flow is suspended temporarily on RxFIFO full condition, before reaching overrun condition. The SUSP flag is set when the SPI communication is suspended.

When SPI communication is suspended by hardware automatically, it may happen that few bits of next frame are already clocked out due to internal synchronization delay.

This is why, the automatic suspension is not quite reliable when size of data drops below 8 bits. In this case, a safe suspension can be achieved by combination with delay inserted between data frames applied when MIDI parameter keeps a non zero value; sum of data size and the interleaved SPI cycles should always produce interval at length of 8 SPI clock periods at minimum. After software clearing of the SUSP bit, the communication resumes and continues by subsequent bits transaction without any next constraint. Prior the SUSP bit is cleared, the user must release the RxFIFO space as much as possible by reading out all the data packets available at RxFIFO based on the RXP flag indication to prevent any subsequent suspension.

**Bits 7:1** Reserved, must be kept at reset value.

Bit 0 **SPE**: serial peripheral enable

This bit is set by and cleared by software.

0: Serial peripheral disabled.
1: Serial peripheral enabled

When SPE = 1, SPI data transfer is enabled, SPI_CFG1 and SPI_CFG2 configuration registers, CRCPOLY, UDRDR, IOLOCK bit in the SPI_CR1 register are write protected. They can be changed only when SPE = 0.

When SPE = 0 any SPI operation is stopped and disabled, all the pending requests of the events with enabled interrupt are blocked except the MODF interrupt request (but their pending still propagates the request of the spi_plck clock), the SS output is deactivated at master, the RDY signal keeps not ready status at slave, the internal state machine is reseted, all the FIFOs content is flushed, CRC calculation initialized, receive data register is read zero. SPE is cleared and cannot be set when MODF error flag is active.

Bit 31 **BPASS**: bypass of the prescaler at master baud rate clock generator
- 0: bypass is disabled
- 1: bypass is enabled

Bits 30:28 **MBR[2:0]**: master baud rate prescaler setting
- 000: SPI master clock/2
- 001: SPI master clock/4
- 010: SPI master clock/8
- 011: SPI master clock/16
- 100: SPI master clock/32
- 101: SPI master clock/64
- 110: SPI master clock/128
- 111: SPI master clock/256

*Note: MBR setting is considered at slave working at TI mode, too (see Section 52.5.1: TI mode).*

Bits 27:23 Reserved, must be kept at reset value.

Bit 22 **CRCEN**: hardware CRC computation enable
- 0: CRC calculation disabled
- 1: CRC calculation enabled

Bit 21 Reserved, must be kept at reset value.
Bits 20:16 **CRCSIZE[4:0]**: length of CRC frame to be transacted and compared

Most significant bits are taken into account from polynomial calculation when CRC result is transacted or compared. The length of the polynomial is not affected by this setting.

- 00000: reserved
- 00001: reserved
- 00010: reserved
- 00011: 4-bits
- 00100: 5-bits
- 00101: 6-bits
- 00110: 7-bits
- 00111: 8-bits
- .....  
- 11101: 30-bits
- 11110: 31-bits
- 11111: 32-bits

The value must be set equal or multiply of data size (DSIZE[4:0]). Its maximum size corresponds to DSIZE maximum at the instance.

*Note: The most significant bit at CRCSIZE bit field is reserved at the peripheral instances where data size is limited to 16-bit.*

Bit 15 **TXDMAEN**: Tx DMA stream enable

- 0: Tx DMA disabled
- 1: Tx DMA enabled

Bit 14 **RXDMAEN**: Rx DMA stream enable

- 0: Rx-DMA disabled
- 1: Rx-DMA enabled

Bits 13:10 Reserved, must be kept at reset value.
Bit 9 **UDRCFG**: behavior of slave transmitter at underrun condition

0: slave sends a constant pattern defined by the user at the SPI_UDRDR register
1: Slave repeats lastly received data from master. When slave is configured at transmit only mode (COMM[1:0] = 01), all zeros pattern is repeated.

For more details see Figure 729: Optional configurations of slave detecting underrun condition.

Bits 8:5 **FTHLV[3:0]**: FIFO threshold level

Defines number of data frames at single data packet. Size of the packet should not exceed 1/2 of FIFO space.

- 0000: 1-data
- 0001: 2-data
- 0010: 3-data
- 0011: 4-data
- 0100: 5-data
- 0101: 6-data
- 0110: 7-data
- 0111: 8-data
- 1000: 9-data
- 1001: 10-data
- 1010: 11-data
- 1011: 12-data
- 1100: 13-data
- 1101: 14-data
- 1110: 15-data
- 1111: 16-data

SPI interface is more efficient if configured packet sizes are aligned with data register access parallelism:

- If SPI data register is accessed as a 16-bit register and DSIZE ≤ 8 bit, better to select FTHLV = 2, 4, 6.
- If SPI data register is accessed as a 32-bit register and DSIZE > 8 bit, better to select FTHLV = 2, 4, 6, while if DSIZE ≤ 8bit, better to select FTHLV = 4, 8, 12.

*Note: FTHLV[3:2] bits are reserved at instances with limited set of features*
Bits 4:0 **DSIZE[4:0]**: number of bits in a single SPI data frame
- 00000: not used
- 00001: not used
- 00010: not used
- 00011: 4 bits
- 00100: 5 bits
- 00101: 6 bits
- 00110: 7 bits
- 00111: 8 bits
- ....
- 11101: 30 bits
- 11110: 31 bits
- 11111: 32 bits

*Note:* Maximum data size can be limited up to 16-bits at some instances. At instances with limited set of features, **DSIZE[2:0]** bits are reserved and must be kept at reset state. **DSIZE[4:3]** bits then control next settings of data size:
- 00xxx: 8-bits
- 01xxx: 16-bits
- 10xxx: 24-bits
- 11xxx: 32-bits.

### 52.11.4 SPI/I2S configuration register 2 (SPI_CFG2)

STI
Bit 31 **AFCNTR**: alternate function GPIOs control
This bit is taken into account when SPE = 0 only
0: The peripheral takes no control of GPIOs while it is disabled
1: The peripheral keeps always control of all associated GPIOs
When SPI must be disabled temporarily for a specific configuration reason (for example CRC reset, CPHA or HDDIR change) setting this bit prevents any glitches on the associated outputs configured at alternate function mode by keeping them forced at state corresponding to the current SPI configuration.

*Note*: This bit can be also used in PCM and I2S modes.

*Note*: The bit AFCNTR must not be set, when the block is in slave mode.

Bit 30 **SSOM**: SS output management in Master mode
This bit is taken into account in Master mode when SSOE is enabled. It allows the SS output to be configured between two consecutive data transfers.
0: SS is kept at active level till data transfer is completed, it becomes inactive with EOT flag
1: SPI data frames are interleaved with SS non active pulses when MIDI[3:0]>1

Bit 29 **SSOE**: SS output enable
This bit is taken into account in Master mode only
0: SS output is disabled and the SPI can work in multimaster configuration
1: SS output is enabled. The SPI cannot work in a multimaster environment. It forces the SS pin at inactive level after the transfer is completed or SPI is disabled with respect to SSOM, MIDI, MSSI, SSIOP bits setting

Bit 28 **SSIOP**: SS input/output polarity
0: low level is active for SS signal
1: high level is active for SS signal

Bit 27 Reserved, must be kept at reset value.

Bit 26 **SSM**: software management of SS signal input
0: SS input value is determined by the SS PAD
1: SS input value is determined by the SSI bit
When master uses hardware SS output (SSM = 0 and SSOE = 1) the SS signal input is forced to not active state internally to prevent master mode fault error.

Bit 25 **CPOL**: clock polarity
0: SCK signal is at 0 when idle
1: SCK signal is at 1 when idle

Bit 24 **CPHA**: clock phase
0: the first clock transition is the first data capture edge
1: the second clock transition is the first data capture edge

Bit 23 **LSBFRST**: data frame format
0: MSB transmitted first
1: LSB transmitted first

*Note*: This bit can be also used in PCM and I2S modes.

Bit 22 **MASTER**: SPI Master
0: SPI Slave
1: SPI Master
Bits 21:19 **SP[2:0]**: serial protocol
- 000: SPI Motorola
- 001: SPI TI
- others: reserved, must not be used

Bits 18:17 **COMM[1:0]**: SPI Communication Mode
- 00: full-duplex
- 01: simplex transmitter
- 10: simplex receiver
- 11: half-duplex

Bit 16 Reserved, must be kept at reset value.

Bit 15 **IOSWP**: swap functionality of MISO and MOSI pins
- 0: no swap
- 1: MOSI and MISO are swapped
  When this bit is set, the function of MISO and MOSI pins alternate functions are inverted.
  Original MISO pin becomes MOSI and original MOSI pin becomes MISO.
  *Note: This bit can be also used in PCM and I2S modes to swap SDO and SDI pins.*

Bit 14 **RDIOP**: RDY signal input/output polarity
- 0: high level of the signal means the slave is ready for communication
- 1: low level of the signal means the slave is ready for communication

Bit 13 **RDIOM**: RDY signal input/output management
- 0: RDY signal is defined internally fixed as permanently active (RDIOP setting has no effect)
- 1: RDY signal is overtaken from alternate function input (at master case) or output (at slave case) of the dedicated pin (RDIOP setting takes effect)

  *Note: When DSIZE at the SPI_CFG1 register is configured shorter than 8-bit, the RDIOM bit must be kept at zero.*

Bits 12:8 Reserved, must be kept at reset value.

Bits 7:4 **MIDI[3:0]**: master Inter-Data Idleness
  Specifies minimum time delay (expressed in SPI clock cycles periods) inserted between two consecutive data frames in Master mode.
- 0000: no delay
- 0001: 1 clock cycle period delay
- ... 1111: 15 clock cycle periods delay

  *Note: This feature is not supported in TI mode.*

Bits 3:0 **MSSI[3:0]**: Master SS Idleness
  Specifies an extra delay, expressed in number of SPI clock cycle periods, inserted additionally between active edge of SS opening a session and the beginning of the first data frame of the session in Master mode when SSOE is enabled.
- 0000: no extra delay
- 0001: 1 clock cycle period delay added
- ... 1111: 15 clock cycle periods delay added

  *Note: This feature is not supported in TI mode.*
  *To include the delay, the SPI must be disabled and re-enabled between sessions.*
### 52.11.5 SPI/I2S interrupt enable register (SPI_IER)

52.11.6 SPI/I2S status register (SPI_SR)

Address offset: 0x14

Reset value: 0x0000 1002

All the flags of this register are not cleared automatically when the SPI is re-enabled. They require specific clearing access exclusively via the flag clearing register as noted in the bits descriptions below.

<table>
<thead>
<tr>
<th>Bit 31:16 CTSIZE[15:0]</th>
<th>number of data frames remaining in current TSIZE session</th>
</tr>
</thead>
<tbody>
<tr>
<td>r r r r r r r r r r r r r r</td>
<td>The value is not quite reliable when traffic is ongoing on bus .</td>
</tr>
<tr>
<td>Note: CTSIZE[15:0] bits are not available in instances with limited set of features.</td>
<td></td>
</tr>
</tbody>
</table>

Bit 15 RXWNE: RxFIFO word not empty
0: less than four bytes of RxFIFO space is occupied by data
1: at least four bytes of RxFIFO space is occupied by data

Note: This bit value does not depend on DSIZE setting and keeps together with RXPLVL[1:0] information about RxFIFO occupancy by residual data.

Bits 14:13 RXPLVL[1:0]: RxFIFO packing level
When RXWNE = 0 and data size is set up to 16-bit, the value gives number of remaining data frames persisting at RxFIFO.
00: no next frame is available at RxFIFO
01: 1 frame is available
10: 2 frames are available*
11: 3 frames are available*

Note: (*) Possible value when data size is set up to 8-bit only.
When data size is greater than 16-bit, these bits are always read as 00. In that consequence, the single data frame received at the FIFO cannot be detected neither by RXNE nor by RXPLVL bits if data size is set from 17 to 24 bits. The user must then apply other methods to detect the number of data received, such as monitor the EOT event when TSIZE > 0 or RXP events when FTHLV = 0.

Bit 12 TXC: TxFIFO transmission complete
The flag behavior depends on TSIZE setting.
When TSIZE = 0, the TXC is changed by hardware exclusively and it raises each time the TxFIFO becomes empty and there is no activity on the bus.
If TSIZE ≠ 0 there is no specific reason to monitor TXC as it just copies the EOT flag value including its software clearing. The TXC generates an interrupt when EOTIE is set.
This flag is set when SPI is reset or disabled.
0: current data transaction is still ongoing, data is available in TxFIFO or last frame transmission is on going.
1: last TxFIFO frame transmission complete
Bit 11 **SUSP**: suspension status

In Master mode, SUSP is set by hardware either as soon as the current frame is completed after CSUSP request is done or at master automatic suspend receive mode (MASRX bit is set at SPI_CR1 register) on RxFIFO full condition.

SUSP generates an interrupt when EOTIE is set.

This bit must be cleared prior SPI is disabled and this is done by writing 1 to SUSPC bit of SPI_IFCR exclusively.

- **0**: SPI not suspended (Master mode active or other mode).
- **1**: Master mode is suspended (current frame completed).

Bit 10 **Reserved**, must be kept at reset value.

Bit 9 **MODF**: mode fault

- **0**: no mode fault
- **1**: mode fault detected.

When MODF is set, SPE and IOLOCK bits of SPI_CR1 register are reset and setting SPE again is blocked until MODF is cleared.

This bit is cleared by writing 1 to MODFC bit of SPI_IFCR exclusively.

Bit 8 **TIFRE**: TI frame format error

- **0**: no TI Frame Error
- **1**: TI frame error detected

This bit is cleared by writing 1 to TIFREC bit of SPI_IFCR exclusively.

Bit 7 **CRCE**: CRC error

- **0**: no CRC error
- **1**: CRC error detected

This bit is cleared when SPI is re-enabled or by writing 1 to CRCEC bit of SPI_IFCR optionally.

Bit 6 **OVR**: overrun

- **0**: no overrun
- **1**: overrun detected

This bit is cleared when SPI is re-enabled or by writing 1 to OVRC bit of SPI_IFCR optionally.

Bit 5 **UDR**: underrun

- **0**: no underrun
- **1**: underrun detected

This bit is cleared when SPI is re-enabled or by writing 1 to UDRC bit of SPI_IFCR optionally.

**Note**: In SPI mode, the UDR flag applies to Slave mode only. In I2S/PCM mode, (when available) this flag applies to Master and Slave mode.

Bit 4 **TXTF**: transmission transfer filled

- **0**: upload of TxFIFO is ongoing or not started
- **1**: TxFIFO upload is finished

TXTF is set by hardware as soon as all of the data packets in a transfer have been submitted for transmission by application software or DMA, that is when TSIZE number of data have been pushed into the TxFIFO.

This bit is cleared by software write 1 to TXTFC bit of SPI_IFCR exclusively.

TXTF flag triggers an interrupt if TXTFIE bit is set.

TXTF setting clears the TXPIE and DXPIE masks so to off-load application software from calculating when to disable TXP and DXP interrupts.
Bit 3 EOT: end of transfer
EOT is set by hardware as soon as a full transfer is complete, that is when SPI is re-enabled or when TSIZE number of data have been transmitted and/or received on the SPI. EOT is cleared when SPI is re-enabled or by writing 1 to EOTC bit of SPI_IFCR optionally. EOT flag triggers an interrupt if EOTIE bit is set.
If DXF flag is used until TXTF flag is set and DXPIE is cleared, EOT can be used to download the last packets contained into Rx FIFO in one-shot.
0: transfer is ongoing or not started
1: transfer complete
In master, EOT event terminates the data transaction and handles SS output optionally. When CRC is applied, the EOT event is extended over the CRC frame transaction.
To restart the internal state machine properly, SPI is strongly suggested to be disabled and re-enabled before next transaction starts despite its setting is not changed.

Bit 2 DXP: duplex packet
0: TxFIFO is Full and/or RxFIFO is Empty
1: both TxFIFO has space for write and RxFIFO contains for read a single packet at least
DXP flag is set whenever both TXP and RXP flags are set regardless SPI mode.

Bit 1 TXP: Tx-packet space available
0: not enough free space at TxFIFO to host next data packet
1: enough free space at TxFIFO to host at least one data packet
TXP flag can be changed only by hardware. Its value depends on the physical size of the FIFO and its threshold (FTHLV[3:0]), data frame size (DSIZE[4:0] in SPI mode and respective DATLEN[1:0] in I2S/PCM mode), and actual communication flow. If the data packet is stored by performing consecutive write operations to SPI_TXDR, TXP flag must be checked again once a complete data packet is stored at TxFIFO. TXP is set despite SPI TxFIFO becomes inaccessible when SPI is reset or disabled.

Bit 0 RXP: Rx-packet available
0: RxFIFO is empty or an incomplete data packet is received
1: RxFIFO contains at least one data packet
The flag is changed by hardware. It monitors the total number of data currently available at RxFIFO if SPI is enabled. RXP value depends on the FIFO threshold (FTHLV[3:0]), data frame size (DSIZE[4:0] in SPI mode and DATLEN[1:0] in I2S/PCM mode), and actual communication flow. If the data packet is read by performing consecutive read operations from SPI_RXDR, RXP flag must be checked again once a complete data packet is read out from RxFIFO.

52.11.7 SPI/I2S interrupt/status flags clear register (SPI_IFCR)
Address offset: 0x18
Reset value: 0x0000 0000
Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **SUSPC**: Suspend flag clear
Writing a 1 into this bit clears SUSP flag in the SPI_SR register

Bit 10 Reserved, must be kept at reset value.

Bit 9 **MODFC**: mode fault flag clear
Writing a 1 into this bit clears MODF flag in the SPI_SR register

Bit 8 **TIFREC**: Ti frame format error flag clear
Writing a 1 into this bit clears TIFRE flag in the SPI_SR register

Bit 7 **CRCCEC**: CRC error flag clear
Writing a 1 into this bit clears CRCE flag in the SPI_SR register

Bit 6 **OVRC**: overrun flag clear
Writing a 1 into this bit clears OVR flag in the SPI_SR register

Bit 5 **UDRC**: underrun flag clear
Writing a 1 into this bit clears UDR flag in the SPI_SR register

Bit 4 **TXTFC**: transmission transfer filled flag clear
Writing a 1 into this bit clears TXTF flag in the SPI_SR register

Bit 3 **EOTC**: end of transfer flag clear
Writing a 1 into this bit clears EOT flag in the SPI_SR register

Bits 2:0 Reserved, must be kept at reset value.

**52.11.8 SPI/I2S transmit data register (SPI_TXDR)**

Address offset: 0x20

Reset value: 0x0000 0000

**TXDR[15:0]**

Bits 31:0 **TXDR[31:0]**: transmit data register

The register serves as an interface with TxFIFO. A write to it accesses TxFIFO.

**Note:** In SPI mode, data is always right-aligned. Alignment of data at I2S mode depends on DATLEN and DATFMT setting. Unused bits are ignored when writing to the register, and read as zero when the register is read.

**Note:** DR can be accessed byte-wise (8-bit access): in this case only one data-byte is written by single access.

- halfword-wise (16 bit access) in this case 2 data-bytes or 1 halfword-data can be written by single access.
- word-wise (32 bit access). In this case 4 data-bytes or 2 halfword-data or word-data can be written by single access.

Write access of this register less than the configured data size is forbidden.

**CRCPOLY[15:0]**
Bits 31:0 **CRCPOLY[31:0]:** CRC polynomial register

This register contains the polynomial for the CRC calculation.

The default 9-bit polynomial setting 0x107 corresponds to default 8-bit setting of DSIZE. It is compatible with setting 0x07 used in other ST products with fixed length of the polynomial string, where the most significant bit of the string is always kept hidden.

Length of the polynomial is given by the most significant bit of the value stored in this register. It must be set greater than DSIZE. CRC33_17 bit must be set additionally with CRCPOLY register when DSIZE is configured to maximum 32-bit or 16-bit size and CRC is enabled (to keep polynomial length greater than data size).

*Note:* CRCPOLY[31:16] bits are reserved at instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

**TXCRC[15:0]**

Bits 31:0 **TXCRC[31:0]:** CRC register for transmitter

When CRC calculation is enabled, the TXCRC[31:0] bits contain the computed CRC value of the subsequently transmitted bytes. CRC calculation is initialized when the CRCEN bit of SPI_CR1 is set or when a data block is transacted completely. The CRC is calculated serially using the polynomial programmed in the SPI_CRCPOLY register.

The number of bits considered at calculation depends on SPI_CRCPOLY register and CRCSIZE bits settings at SPI_CFG1 register.

*Note:* A read to this register when the communication is ongoing may return an incorrect value.

*Note:* This bitfield is not used in I2S mode.

*Note:* TXCRC[31-16] bits are reserved at instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

*Note:* The configuration of CRCSIZE bit field is not taken into account when the content of this register is read by software. No masking is applied for unused bits in this case.
52.11.12  SPI/I2S receiver CRC register (SPI_RXCRC)

Address offset: 0x48
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 31:0 RXCRC[31:0]: CRC register for receiver

When CRC calculation is enabled, the RXCRC[31:0] bits contain the computed CRC value of the subsequently received bytes. CRC calculation is initialized when the CRCEN bit of SPI_CR1 is set or when a data block is transacted completely. The CRC is calculated serially using the polynomial programmed in the SPI_CRCPOLY register.

The number of bits considered at calculation depends on SPI_CRCPOLY register and CRCSIZE bits settings at SPI_CFG1 register.

Note: A read to this register when the communication is ongoing may return an incorrect value.

This bitfield is not used in I2S mode.

RXCRC[31-16] bits are reserved at the peripheral instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses.

Reserved bits 31-16 are always read zero while any write to them is ignored.

Note: The configuration of CRCSIZE bit field is not taken into account when the content of this register is read by software. No masking is applied for unused bits in this case.

52.11.13  SPI/I2S underrun data register (SPI_UDRDR)

Address offset: 0x4C
Reset value: 0x0000 0000

The content of this register is write protected when SPI is enabled.

<table>
<thead>
<tr>
<th>Bits 31:16 UDRDR[31:16]</th>
<th>Bits 15:0 UDRDR[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>

</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
</tr>
</tbody>
</table>

Note: The configuration of CRCSIZE bit field is not taken into account when the content of this register is read by software. No masking is applied for unused bits in this case.
Bits 31:0 **UDRDR[31:0]**: data at slave underrun condition

The register is taken into account in Slave mode and at underrun condition only. The number of bits considered depends on DSIZE bit settings of the SPI_CFG1 register. Underrun condition handling depends on setting UDRCFG bit at SPI_CFG1 register.

Note: **UDRDR[31-16]** bits are reserved at the peripheral instances with data size limited to 16-bit. There is no constraint when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

### 52.11.14 SPI/I2S configuration register (SPI_I2SCFGR)

Address offset: 0x50

Reset value: 0x0000 0000

This register must be configured when the I2S is disabled (SPE = 0). The content of this register is not taken into account in SPI mode except for the I2SMOD bit which needs to be kept at 0.

This register is reserved at instances not supporting I2S mode.

| Bits 31:26 | Reserved, must be kept at reset value. |
| Bit 25 | **MCKOE**: master clock output enable |
| 0: Master clock output is disabled |
| 1: Master clock output is enabled |
| Bit 24 | **ODD**: odd factor for the prescaler |
| 0: Real divider value is = I2SDIV * 2 |
| 1: Real divider value is = (I2SDIV * 2) + 1 |
| Refer to **Section 52.9.9: Clock generator** for details |
| Bits 23:16 | **I2SDIV[7:0]**: I²S linear prescaler |
| I2SDIV can take any values except the value 1, when ODD is also equal to 1. |
| Refer to **Section 52.9.9: Clock generator** for details |
| Bit 15 | Reserved, must be kept at reset value. |
| Bit 14 | **DATFMT**: data format |
| 0: The data inside the SPI_RXDR or SPI_TXDR are right aligned |
| 1: The data inside the SPI_RXDR or SPI_TXDR are left aligned. |
Bit 13 **WSINV**: word select inversion
This bit is used to invert the default polarity of WS signal.
0: In I2S Philips standard, the left channel transfer starts one CK cycle after the WS falling edge, and the right channel one CK cycle after the WS rising edge.
In MSB or LSB justified mode, the left channel is transferred when WS is HIGH, and the right channel when WS is LOW.
In PCM short mode the data transfer starts at the falling edge of WS, while it starts at the rising edge of WS in PCM long mode.
1: In I2S Philips standard, the left channel transfer starts one CK cycle after the WS rising edge, and the right channel one CK cycle after the WS falling edge.
In MSB or LSB justified mode, the left channel is transferred when WS is LOW, and right channel when WS is HIGH.
In PCM short mode the data transfer starts at the rising edge of WS, while it starts at the falling edge of WS in PCM long mode.

Bit 12 **FIXCH**: fixed channel length in slave
0: the channel length in Slave mode is different from 16 or 32 bits (CHLEN must be set)
1: the channel length in Slave mode is supposed to be 16 or 32 bits (according to CHLEN)

Bit 11 **CKPOL**: serial audio clock polarity
0: the signals generated by the SPI/I2S (i.e. SDO and WS) are changed on the falling edge of CK and the signals received by the SPI/I2S (i.e. SDI and WS) are read of the rising edge of CK.
1: the signals generated by the SPI/I2S (i.e. SDO and WS) are changed on the rising edge of CK and the signals received by the SPI/I2S (i.e. SDI and WS) are read of the falling edge of CK.

Bit 10 **CHLEN**: channel length (number of bits per audio channel)
0: 16-bit wide
1: 32-bit wide

Bits 9:8 **DATLEN[1:0]**: data length to be transferred.
00: 16-bit data length
01: 24-bit data length
10: 32-bit data length
11: Not allowed

*Note: Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10), refer to Section 52.3: SPI implementation to check the supported data size.*

Bit 7 **PCMSYNC**: PCM frame synchronization
0: short frame synchronization
1: long frame synchronization

Bit 6 Reserved, must be kept at reset value.

Bits 5:4 **I2SSTD[1:0]**: I2S standard selection
00: I2S Philips standard.
01: MSB justified standard (left justified)
10: LSB justified standard (right justified)
11: PCM standard

For more details on I2S standards, refer to Section 52.9.5: Supported audio protocols.
### Bits 3:1 I2SCFG[2:0]: I2S configuration mode

- 000: slave - transmit
- 001: slave - receive
- 010: master - transmit
- 011: master - receive
- 100: slave - Full Duplex
- 101: master - Full Duplex
- Others, not used

Bit 0 I2SMOD: I2S mode selection
- 0: SPI mode is selected
- 1: I2S/PCM mode is selected

1. The bitfield is reserved for instances with limited set of features and it must be kept at reset value. For more details, refer to the concrete register description in Section 52.11: SPI/I2S registers.

2. The bits 31-16 are reserved for the peripheral instances with data size limited to 16-bit. There is no constrain when the 32-bit access is applied at these addresses. The bits 31-16, when reserved, are always read to zero while any write to them is ignored.

Refer to Section 2.3 for the register boundary addresses.
53  Serial audio interface (SAI)

53.1  Introduction

The SAI interface (serial audio interface) offers a wide set of audio protocols due to its flexibility and wide range of configurations. Many stereo or mono audio applications may be targeted. I2S standards, LSB or MSB-justified, PCM/DSP, TDM, and AC’97 protocols may be addressed for example. SPDIF output is offered when the audio block is configured as a transmitter.

To bring this level of flexibility and reconfigurability, the SAI contains two independent audio subblocks. Each block has its own clock generator and I/O line controller.

The SAI works in master or slave configuration. The audio subblocks are either receiver or transmitter and work synchronously or not (with respect to the other one).

The SAI can be connected with other SAIIs to work synchronously.

53.2  SAI main features

- Two independent audio subblocks which can be transmitters or receivers with their respective FIFO.
- 8-word integrated FIFOs for each audio subblock.
- Synchronous or asynchronous mode between the audio subblocks.
- Possible synchronization between multiple SAIIs.
- Master or slave configuration independent for both audio subblocks.
- Clock generator for each audio block to target independent audio frequency sampling when both audio subblocks are configured in master mode.
- Data size configurable: 8-, 10-, 16-, 20-, 24-, 32-bit.
- Audio protocol: I2S, LSB or MSB-justified, PCM/DSP, TDM, AC’97
- PDM interface, supporting up to 4 microphone pairs
- SPDIF output available if required.
- Up to 16 slots available with configurable size.
- Number of bits by frame can be configurable.
- Frame synchronization active level configurable (offset, bit length, level).
- First active bit position in the slot is configurable.
- LSB first or MSB first for data transfer.
- Mute mode.
- Stereo/Mono audio frame capability.
- Communication clock strobing edge configurable (SCK).
- Error flags with associated interrupts if enabled respectively.
  - Overrun and underrun detection,
  - Anticipated frame synchronization signal detection in slave mode,
  - Late frame synchronization signal detection in slave mode,
  - Codec not ready for the AC’97 mode in reception.
Interrupt sources when enabled:
- Errors,
- FIFO requests.
- 2-channel DMA interface.

53.4 SAI functional description

53.4.1 SAI block diagram

Figure 749 shows the SAI block diagram while Table 564 and Table 565 list SAI internal and external signals.
The SAI is mainly composed of two audio subblocks with their own clock generator. Each audio block integrates a 32-bit shift register controlled by their own functional state machine. Data are stored or read from the dedicated FIFO. FIFO may be accessed by the CPU, or by DMA in order to leave the CPU free during the communication. Each audio block is independent. They can be synchronous with each other.

An I/O line controller manages a set of 4 dedicated pins (SD, SCK, FS, MCLK) for a given audio block in the SAI. Some of these pins can be shared if the two subblocks are declared as synchronous to leave some free to be used as general purpose I/Os. The MCLK pin can be output, or not, depending on the application, the decoder requirement and whether the audio block is configured as the master.

If one SAI is configured to operate synchronously with another one, even more I/Os can be freed (except for pins SD_x).

The functional state machine can be configured to address a wide range of audio protocols. Some registers are present to set-up the desired protocols (audio frame waveform generator).

The audio subblock can be a transmitter or receiver, in master or slave mode. The master mode means the SCK_x bit clock and the frame synchronization signal are generated from the SAI, whereas in slave mode, they come from another external or internal master. There is a particular case for which the FS signal direction is not directly linked to the master or slave mode definition. In AC’97 protocol, it is an SAI output even if the SAI (link controller) is set-up to consume the SCK clock (and so to be in Slave mode).

1. These signals might not be available for all SAI instances. Refer to Section 53.3: SAI implementation for details.
Note: For ease of reading of this section, the notation SAI_x refers to SAI_A or SAI_B, where ‘x’ represents the SAI_A or B subblock.

1. These signals might not be available in all SAI instances. Refer to Section 53.3: SAI implementation for details.

53.4.3 Main SAI modes

Each audio subblock of the SAI can be configured to be master or slave via MODE bits in the SAI_xCR1 register of the selected audio block.

Master mode

In master mode, the SAI delivers the timing signals to the external connected device:

- The bit clock and the frame synchronization are output on pin SCK_x and FS_x, respectively.
- If needed, the SAI can also generate a master clock on MCLK_x pin.

Both SCK_x, FS_x and MCLK_x are configured as outputs.
Slave mode
The SAI expects to receive timing signals from an external device.
- If the SAI subblock is configured in asynchronous mode, then SCK_x and FS_x pins are configured as inputs.
- If the SAI subblock is configured to operate synchronously with another SAI interface or with the second audio subblock, the corresponding SCK_x and FS_x pins are left free to be used as general purpose I/Os.

In slave mode, MCLK_x pin is not used and can be assigned to another function.
It is recommended to enable the slave device before enabling the master.

Configuring and enabling SAI modes
Each audio subblock can be independently defined as a transmitter or receiver through the MODE bit in the SAI_xCR1 register of the corresponding audio block. As a result, SAI_SD_x pin is respectively configured as an output or an input.

Two master audio blocks in the same SAI can be configured with two different MCLK and SCK clock frequencies. In this case they have to be configured in asynchronous mode.

Each of the audio blocks in the SAI are enabled by SAIEN bit in the SAI_xCR1 register. As soon as this bit is active, the transmitter or the receiver is sensitive to the activity on the clock line, data line and synchronization line in slave mode.

In master TX mode, enabling the audio block immediately generates the bit clock for the external slaves even if there is no data in the FIFO. However FS signal generation is conditioned by the presence of data in the FIFO. After the FIFO receives the first data to transmit, this data is output to external slaves. If there is no data to transmit in the FIFO, 0 values are then sent in the audio frame with an underrun flag generation.

In slave mode, the audio frame starts when the audio block is enabled and when a start of frame is detected.

In Slave TX mode, no underrun event is possible on the first frame after the audio block is enabled, because the mandatory operating sequence in this case is:
1. Write into the SAI_xDR (by software or by DMA).
2. Wait until the FIFO threshold (FLH) flag is different from 0b000 (FIFO empty).
3. Enable the audio block in slave transmitter mode.

53.4.4 SAI synchronization mode
There are two levels of synchronization, either at audio subblock level or at SAI level.

Internal synchronization
An audio subblock can be configured to operate synchronously with the second audio subblock in the same SAI. In this case, the bit clock and the frame synchronization signals are shared to reduce the number of external pins used for the communication. The audio block configured in synchronous mode sees its own SCK_x, FS_x, and MCLK_x pins released back as GPIOs while the audio block configured in asynchronous mode is the one for which FS_x and SCK_x ad MCLK_x I/O pins are relevant (if the audio block is considered as master).
Typically, the audio block in synchronous mode can be used to configure the SAI in full duplex mode. One of the two audio blocks can be configured as a master and the other as slave, or both as slaves with one asynchronous block (corresponding SYNCE[N][1:0] bits set to 00 in SAI_xCR1) and one synchronous block (corresponding SYNCE[N][1:0] bits set to 01 in the SAI_xCR1).

**Note:** Due to internal resynchronization stages, PCLK APB frequency must be higher than twice the bit rate clock frequency.

**External synchronization**

The audio subblocks can also be configured to operate synchronously with another SAI. This can be done as follow:

1. The SAI, which is configured as the source from which the other SAI is synchronized, has to define which of its audio subblock is supposed to provide the FS and SCK signals to other SAI. This is done by programming SYNCOU[1:0] bits.
2. The SAI which receives the synchronization signals, has to select which SAI provides the synchronization by setting the proper value on SYNCEIN[1:0] bits. For each of the two SAI audio subblocks, the user must then specify if it operates synchronously with the other SAI via the SYNCE bit.

**Note:** SYNCEIN[1:0] and SYNCOU[1:0] bits are located into the SAI_GCR register, and SYNCE bits into SAI_xCR1 register.

If both audio subblocks in a given SAI need to be synchronized with another SAI, it is possible to choose one of the following configurations:

- Configure each audio block to be synchronous with another SAI block through the SYNCE[1:0] bits.
- Configure one audio block to be synchronous with another SAI through the SYNCE[1:0] bits. The other audio block is then configured as synchronous with the second SAI audio block through SYNCE[1:0] bits.

The following table shows how to select the proper synchronization signal depending on the SAI block used. For example SAI2 can select the synchronization from SAI1 by setting SAI2 SYNCEIN to 0. If SAI1 wants to select the synchronization coming from SAI2, SAI1 SYNCEIN must be set to 1. Positions noted as ‘Reserved’ must not be used.

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>SAI1</td>
<td>SAI2 sync.</td>
<td>Reserved</td>
</tr>
<tr>
<td>SAI2</td>
<td>Reserved</td>
<td>SAI1 sync.</td>
</tr>
</tbody>
</table>

**53.4.5 Audio data size**

The audio frame can target different data sizes by configuring bit DS[2:0] in the SAI_xCR1 register. The data sizes may be 8, 10, 16, 20, 24 or 32 bits. During the transfer, either the MSB or the LSB of the data are sent first, depending on the configuration of bit LSBFIRST in the SAI_xCR1 register.
53.4.6 Frame synchronization

The FS signal acts as the Frame synchronization signal in the audio frame (start of frame). The shape of this signal is completely configurable in order to target the different audio protocols with their own specificities concerning this Frame synchronization behavior. This reconfigurability is done using register SAI_xFRCR. Figure 750 illustrates this flexibility.

Figure 750. Audio frame

In AC’97 mode or in SPDIF mode (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01 in the SAI_xCR1 register), the frame synchronization shape is forced to match the AC’97 protocol. The SAI_xFRCR register value is ignored.

Each audio block is independent and consequently each one requires a specific configuration.

Frame length

- Master mode
  The audio frame length can be configured to up to 256 bit clock cycles, by setting FRL[7:0] field in the SAI_xFRCR register.

  If the frame length is greater than the number of declared slots for the frame, the remaining bits to transmit is extended to 0 or the SD line is released to HI-z depending the state of bit TRIS in the SAI_xCR2 register (refer to FS signal role). In reception mode, the remaining bit is ignored.

  If bit NODIV is cleared, (FRL+1) must be equal to a power of 2, from 8 to 256, to ensure that an audio frame contains an integer number of MCLK pulses per bit clock cycle.

  If bit NODIV is set, the (FRL+1) field can take any value from 8 to 256. Refer to Section 53.4.8: SAI clock generator.

- Slave mode
  The audio frame length is mainly used to specify to the slave the number of bit clock cycles per audio frame sent by the external master. It is used mainly to detect from the master any anticipated or late occurrence of the Frame synchronization signal during an ongoing audio frame. In this case an error is generated. For more details refer to Section 53.4.14: Error flags.

  In slave mode, there are no constraints on the FRL[7:0] configuration in the SAI_xFRCR register.

  The number of bits in the frame is equal to FRL[7:0] + 1.

  The minimum number of bits to transfer in an audio frame is 8.
Frame synchronization polarity

FSPOL bit in the SAI_xFRCR register sets the active polarity of the FS pin from which a frame is started. The start of frame is edge sensitive.

In slave mode, the audio block waits for a valid frame to start transmitting or receiving. Start of frame is synchronized to this signal. It is effective only if the start of frame is not detected during an ongoing communication and assimilated to an anticipated start of frame (refer to Section 53.4.14: Error flags).

In master mode, the frame synchronization is sent continuously each time an audio frame is complete until the SAIEN bit in the SAI_xCR1 register is cleared. If no data are present in the FIFO at the end of the previous audio frame, an underrun condition is managed as described in Section 53.4.14: Error flags), but the audio communication flow is not interrupted.

Frame synchronization active level length

The FSALL[6:0] bits of the SAI_xFRCR register enable the configuration of the length of the active level of the Frame synchronization signal. The length can be set from 1 to 128 bit clock cycles.

As an example, the active length can be half of the frame length in I2S, LSB or MSB-justified modes, or one-bit wide for PCM/DSP or TDM.

Frame synchronization offset

Depending on the audio protocol targeted in the application, the Frame synchronization signal can be asserted when transmitting the last bit or the first bit of the audio frame (this is the case in I2S standard protocol and in MSB-justified protocol, respectively). FSOFF bit in the SAI_xFRCR register enables to choose one of the two configurations.

FS signal role

The FS signal can have a different meaning depending on the FS function. FSDEF bit in the SAI_xFRCR register selects which meaning it has:

- 0: start of frame, like for instance the PCM/DSP, TDM, AC’97, audio protocols,
- 1: start of frame and channel side identification within the audio frame like for the I2S, the MSB or LSB-justified protocols.

When the FS signal is considered as a start of frame and channel side identification within the frame, the number of declared slots must be considered to be half the number for the left channel and half the number for the right channel. If the number of bit clock cycles on half audio frame is greater than the number of slots dedicated to a channel side, and TRIS = 0, 0 is sent for transmission for the remaining bit clock cycles in the SAI_xCR2 register. Otherwise if TRIS = 1, the SD line is released to HI-Z. In reception mode, the remaining bit clock cycles are not considered until the channel side changes.
1. The frame length must be even.

   If FSDEF bit in SAI_xFRCR is kept clear, so FS signal is equivalent to a start of frame, and if the number of slots defined in NBSLOT[3:0] in SAI_xSLOTR multiplied by the number of bits by slot configured in SLOTSZ[1:0] in SAI_xSLOTR is less than the frame size (bit FRL[7:0] in the SAI_xFRCR register), then:
   
   - if TRIS = 0 in the SAI_xCR2 register, the remaining bit after the last slot is forced to 0 until the end of frame in case of transmitter,
   - if TRIS = 1, the line is released to HI-Z during the transfer of these remaining bits. In reception mode, these bits are discarded.
Figure 752. FS role is start of frame (FSDEF = 0)

The FS signal is not used when the audio block in transmitter mode is configured to get the SPDIF output on the SD line. The corresponding FS I/O is released and left free for other purposes.

53.4.7 Slot configuration

The slot is the basic element in the audio frame. The number of slots in the audio frame is equal to NBSLOT[3:0] + 1.

The maximum number of slots per audio frame is fixed at 16.

For AC’97 protocol or SPDIF (when bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01), the number of slots is automatically set to target the protocol specification, and the value of NBSLOT[3:0] is ignored.

Each slot can be defined as a valid slot, or not, by setting SLOTEN[15:0] bits of the SAI_xSLOTR register.

When a invalid slot is transferred, the SD data line is either forced to 0 or released to HI-z depending on TRIS bit configuration (refer to Output data line management on an inactive slot) in transmitter mode. In receiver mode, the received value from the end of this slot is ignored. Consequently, there is no FIFO access and so no request to read or write the FIFO linked to this inactive slot status.

The slot size is also configurable as shown in Figure 753. The size of the slots is selected by setting SLOTSZ[1:0] bits in the SAI_xSLOTR register. The size is applied identically for each slot in an audio frame.
It is possible to choose the position of the first data bit to transfer within the slots. This offset is configured by FBOFF[4:0] bits in the SAI_xSLOTR register. 0 values are injected in transmitter mode from the beginning of the slot until this offset position is reached. In reception, the bit in the offset phase is ignored. This feature targets the LSB justified protocol (if the offset is equal to the slot size minus the data size).

It is mandatory to respect the following conditions to avoid bad SAI behavior:

\[ FBOFF \leq (\text{SLOTSZ} - \text{DS}), \]
\[ DS \leq \text{SLOTSZ}, \]
\[ \text{NBSLOT} \times \text{SLOTSZ} \leq \text{FRL} \text{ (frame length)}, \]

The number of slots must be even when bit FSDEF in the SAI_xFRCR register is set.

In AC’97 and SPDIF protocol (bit PRTC[1:0] = 10 or PRTC[1:0] = 01), the slot size is automatically set as defined in Section 53.4.11: AC’97 link controller.
53.4.8 SAI clock generator

Each audio block has its own clock generator. The clock generator builds the master clock (MCLK_x) and bit clock (SCK_x) signals from the sai_x_ker_ck. The sai_x_ker_ck clock is delivered by the clock controller of the product (RCC).

Generation of the master clock (MCLK_x)

The clock generator provides the master clock (MCLK_x) when the audio block is defined as Master or Slave. The master clock is generated as soon as the MCKEN bit is set to 1 even if the SAIEN bit for the corresponding block is set to 0. This feature can be useful if the MCLK_x clock is used as system clock for an external audio device, since it enables the generation of the MCLK_x before activating the audio stream.

To generate a master clock on MCLK_x output before transferring the audio samples, the user application has to follow the sequence below:

1. Check that SAIEN = 0.
2. Program the MCKDIV[5:0] divider to the required value.
3. Set the MCKEN bit to 1.
4. Later, the application can configure other parts of the SAI, and sets the SAIEN bit to 1 to start the transfer of audio samples.

To avoid disturbances on the clock generated on MCLK_x output, the following operations are not recommended:

- Changing MCKDIV when MCKEN = 1
- Setting MCKEN to 0 if the SAIEN = 1

The SAI guarantees that there is no spurs on MCLK_x output when the MCLK_x is switched ON and OFF via MCKEN bit (with SAIEN = 0).

Table 567 shows MCLK_x activation conditions.

<table>

</tr>
</tbody>
</table>

Note: MCLK_x can also be generated in AC’97 mode, when MCLKEN is set to 1.
Generation of the bit clock (SCK_x)

The clock generator provides the bit clock (SCK_x) when the audio block is defined as Master. The frame synchronization (FS_x) is also derived from the signals provided by the clock generator.

In Slave mode, the value of NODIV and OSR fields are ignored, and the SCK_x clock is not generated.

The bit clock strobing edge of SCK_x can be configured through the CKSTR fields, which is functional both in master and slave mode.

Figure 755 illustrates the architecture of the audio block clock generator.

![Figure 755. Audio block clock generator overview](image)

The NODIV bit must be used to force the ratio between the master clock (MCLK_x) and the frame synchronization (FS_x) frequency to 256 or 512.

- If NODIV is set to 0, the frequency ratio between the frame synchronization and the master clock is fixed to 512 or 256, according to OSR value, but the frame length must be a power of 2. More details are given hereafter.
- If NODIV is set to 1, the application can adjust the frequency of the bit clock (SCK_x) via MCKDIV. In addition there is no restriction on the frame length value as long as the frame length is bigger or equal to 8 (i.e. FRL[7:0] > 6). The frame synchronization frequency depends on MCKDIV and frame length (FRL[7:0]). In that case, the frequency of the MCLK_x is equal to the SCK_x.

The NODIV, MCKEN, SAIEN, OVR, CKSTR and MCKDIV[5:0] bits belong to the SAI_xCR1 register, while FRL[7:0] belongs to SAI_xFRCR.
Clock generator programming when NODIV = 0

In that case, MCLK_x frequency is:
- \( F_{MCLK_x} = 256 \times F_{FS_x} \) if OSR = 0
- \( F_{MCLK_x} = 512 \times F_{FS_x} \) if OSR = 1

When MCKDIV is different from 0, MCLK_x frequency is given by the formula below:

\[
F_{MCLK_x} = \frac{F_{sai_x \_ker \_ck}}{MCKDIV}
\]

The frame synchronization frequency is given by:

\[
F_{FS_x} = \frac{F_{sai_x \_ker \_ck}}{MCKDIV \times (OSR + 1) \times 256}
\]

The bit clock frequency (SCK_x) is given by the following formula:

\[
F_{SCK_x} = \frac{F_{sai_x \_ker \_ck} \times (FRL + 1)}{MCKDIV \times (OSR + 1) \times 256}
\]

**Note:** When NODIV is equal to 0, \((FRL + 1)\) must be a power of two. In addition \((FRL + 1)\) must range between 8 and 256. \((FRL + 1)\) represents the number of bit clock in the audio frame.

When MCKDIV division ratio is odd, the MCLK duty cycle is not 50%. The bit clock signal (SCK_x) can also have a duty cycle different from 50% if MCKDIV is odd, if OSR is equal to 0, and if \((FRL + 1) = 2^8\).

It is recommended, to program MCKDIV to an even value or to big values (higher than 10).

**Note that MCKDIV = 0 gives the same result as MCKDIV = 1.**

Clock generator programming when NODIV = 1

When MCKDIV is different from 0, the frequency of the bit clock (SCK_x) is given in the formula below:

\[
F_{SCK_x} = F_{MCLK_x} = \frac{F_{sai_x \_ker \_ck}}{MCKDIV}
\]

The frequency of the frame synchronization (FS_x) is given by the following formula:

\[
F_{FS_x} = \frac{F_{sai_x \_ker \_ck}}{(FRL + 1) \times MCKDIV}
\]

**Note:** When NODIV is set to 1, \((FRL + 1)\) can take any values from 8 to 256.

**Note that MCKDIV = 0 gives the same result as MCKDIV = 1.**

1. \(N\) is an integer value between 3 and 8.

53.4.9 Internal FIFOs

Each audio block in the SAI has its own FIFO. Depending if the block is defined to be a transmitter or a receiver, the FIFO can be written or read, respectively. There is therefore only one FIFO request linked to FREQ bit in the SAI_xSR register.

An interrupt is generated if FREQIE bit is enabled in the SAI_xIM register. This depends on:
- FIFO threshold setting (FLVL bits in SAI_xCR2)
- Communication direction (transmitter or receiver). Refer to Interrupt generation in transmitter mode and Interrupt generation in reception mode.

**Interrupt generation in transmitter mode**

The interrupt generation depends on the FIFO configuration in transmitter mode:
- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO empty (FTH[2:0] set to 0b000), an interrupt is generated (FREQ bit set by hardware to 1 in SAI_xSR register) if no data are available in SAI_xDR register (FLVL[2:0] bits in SAI_xSR is less than 001b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is no more empty (FLVL[2:0] bits in SAI_xSR are different from 0b000) i.e one or more data are stored in the FIFO.
- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO quarter full (FTH[2:0] set to 001b), an interrupt is generated (FREQ bit set by hardware to 1 in SAI_xSR register) if less than a quarter of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 0b010). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least a quarter of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher or equal to 0b010).
- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO half full (FTH[2:0] set to 0b010), an interrupt is generated (FREQ bit set by hardware to 1 in...
SAI_xSR register) if less than half of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 011b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least half of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher or equal to 011b).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 011b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if less than three quarters of the FIFO contain data (FLVL[2:0] bits in SAI_xSR are less than 011b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least three quarters of the FIFO contain data (FLVL[2:0] bits in SAI_xSR are higher or equal to 011b).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if the FIFO is not full (FLVL[2:0] bits in SAI_xSR is less than 0b101). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is full (FLVL[2:0] bits in SAI_xSR is equal to 101b value).

**Interrupt generation in reception mode**

The interrupt generation depends on the FIFO configuration in reception mode:

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO empty (FTH[2:0] set to 0b00), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least one data is available in SAI_xDR register (FLVL[2:0] bits in SAI_xSR is higher or equal to 001b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO becomes empty (FLVL[2:0] bits in SAI_xSR is equal to 0b00) i.e no data are stored in FIFO.

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO quarter fully (FTH[2:0] set to 001b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least one quarter of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 0b010). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when less than a quarter of the FIFO data locations become available (FLVL[2:0] bits in SAI_xSR is less than 0b001).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO half fully (FTH[2:0] set to 0b010 value), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least half of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 011b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when less than half of the FIFO data locations become available (FLVL[2:0] bits in SAI_xSR is less than 0b110).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 011b value), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least three quarters of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 0b100). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO has less than three quarters of the FIFO data locations available (FLVL[2:0] bits in SAI_xSR is less than 0b010).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if the FIFO is full (FLVL[2:0] bits in SAI_xSR is equal to 101b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is full (FLVL[2:0] bits in SAI_xSR is less than 101b).
Like interrupt generation, the SAI can use the DMA if DMAEN bit in the SAI_xCR1 register is set. The FREQ bit assertion mechanism is the same as the interrupt generation mechanism described above for FREQIE.

Each FIFO is an 8-word FIFO. Each read or write operation from/to the FIFO targets one word FIFO location whatever the access size. Each FIFO word contains one audio slot. FIFO pointers are incremented by one word after each access to the SAI_xDR register.

Data must be right aligned when it is written in the SAI_xDR.

Data received are right aligned in the SAI_xDR.

The FIFO pointers can be reinitialized when the SAI is disabled by setting bit FFLUSH in the SAI_xCR2 register. If FFLUSH is set when the SAI is enabled the data present in the FIFO are lost automatically.

### 53.4.10 PDM interface

The PDM (Pulse Density Modulation) interface is provided in order to support digital microphones. Up to 4 digital microphone pairs can be connected in parallel. Depending on product implementation, less microphones can be supported (refer to Section 53.3: SAI implementation).

*Figure 756 shows a typical connection of a digital microphone pair via a PDM interface. Both microphones share the same bitstream clock and data line. Thanks to a configuration pin (LR), a microphone can provide valid data on SAI_CK[m] rising edge while the other provides valid data on SAI_CK[m] falling edge (m being the number of clock lines).*

*Figure 756. PDM typical connection and timing*

1. \( n \) refers to the number of data lines and \( p \) to the number of microphone pairs.

The PDM function is intended to be used in conjunction with SAI_A subblock configured in TDM master mode. It cannot be used with SAI_B subblock. The PDM interface uses the timing signals provided by the TDM interface of SAI_A and adapts them to generate a bitstream clock (SAI_CK[m]).
The data processing sequence into the PDM is the following:

1. The PDM interface builds the bitstream clock from the bit clock received from the TDM interface of SAI_A.
2. The bitstream data received from the microphones (SAI_D[n]) are de-interleaved and go through a 7-bit delay line in order to fine-tune the delay of each microphone with the accuracy of the bitstream clock.
3. The shift registers translate each serial bitstream into bytes.
4. The last operation consists in shifting-out the resulting bytes to SAI_A via the serial data line of the TDM interface.

*Figure 757* hereafter shows the block diagram of PDM interface, with a detailed view of a de-interleaver.

*Note:* The PDM interface does not embed the decimation filter required to build-up the PCM audio samples from the bitstream. It is up to the application software to perform this operation.

*Figure 757. Detailed PDM interface block diagram*

1. \( n \) refers to the number of data lines and \( p \) to the number of microphone pairs.
2. These signals might not be available in all SAI instances. Refer to *Section 53.3: SAI implementation* for details.

The PDM interface can be enabled through the PDMEN bit in SAI_PDMCR register. However the PDM interface must be enabled prior to enabling SAI_A block.
To reduce the memory footprint, the user can select the amount of microphones the application needs. This can be done through MICNBR[1:0] bits. It is possible to select between 2, 4, 6 or 8 microphones. For example, if the application is using 3 microphones, the user has to select 4.

**Enabling the PDM interface**

To enable the PDM interface, follow the sequence below:

1. Configure SAI_A in TDM master mode (see Table 569).
2. Configure the PDM interface as follows:
   a) Define the number of digital microphones via MICNBR.
   b) Enable the bitstream clock needed in the application by setting the corresponding bits on CKEN to 1.
3. Enable the PDM interface, via PDMEN bit.
4. Enable the SAI_A.

**Note:** Once the PDM interface and SAI_A are enabled, the first 2 TDMA frames received on SAI_ADR are invalid and must be dropped.

**Start-up sequence**

*Figure 758* shows the start-up sequence: Once the PDM interface is enabled, it waits for the frame synchronization event prior to starting the acquisition of the microphone samples. After 8 SAI_CK clock periods, a data byte coming from each microphone is available, and transferred to the SAI, via the TDM interface.

*Figure 758. Start-up sequence*
SAI_ADR data format

The arrangement of the data coming from the microphone into the SAI_ADR register depends on the following parameters:

- The amount of microphones
- The slot width selected
- LSBFIRST bit.

The slot width defines the amount of significant bits into each word available into the SAI_ADR.

When a slot width of 32 bits is selected, each data available into the SAI_ADR contains 32 useful bits. This reduces the amount of words stored into the memory. However the counterpart is that the software has to perform some operations to de-interleave the data of each microphone.

In the other hand, when the slot width is set to 8 bits, each data available into the SAI_ADR contain 8 useful bits. This increases the amount of words stored into the memory. However, it offers the advantage to avoid extra processing since each word contains information from one microphone.

SAI_ADR data format example

- **32-bit slot width** (DS = 0b111 and SLOTSZ = 0). Refer to Figure 759.

  For an 8 microphone configuration, two consecutive words read from the SAI_ADR register contain a data byte from each microphone.

  For a 4 microphones configuration, each word read from the SAI_ADR register contains a data byte from each microphone.

**Figure 759. SAI_ADR format in TDM, 32-bit slot width**

- **16-bit slot width** (DS = 0b100 and SLOTSZ = 0). Refer to Figure 760.

  For an 8 microphone configuration, four consecutive words read from the SAI_ADR register contain a data byte from each microphone. Note that the 16-bit data of SAI_ADR are right aligned.

  For 4 or 2 microphone configuration, the SAI behavior is similar to 8-microphone configurations. Up to 2 words of 16 bits are required to acquire a byte from 4 microphones and a single word for 2 microphones.
Using a 8-bit slot width (DS = 0b010 and SLOTSZ = 0). Refer to Figure 761. For an 8 microphone configuration, 8 consecutive words read from the SAI_ADR register contain a byte of data from each microphone. Note that the 8-bit data of SAI_ADR are right aligned.

For 4 or 2 microphone configuration, the SAI behavior is similar to 8 microphone configurations. Up to 4 words of 8 bits are required to acquire a byte from 4 microphones and 2 words from 2 microphones.
TDM configuration for PDM interface

SAI_A TDM interface is internally connected to the PDM interface to get the microphone samples. The user application must configure the PDM interface as shown in Table 569 to ensure a good connection with the PDM interface.

Adjusting the bitstream clock rate

To properly program the SAI TDM interface, the user application must take into account the settings given in Table 569, and follow the below sequence:

1. Adjust the bit clock frequency \( F_{SCK_A} \) according to the required frequency for the PDM bitstream clock, using the following formula:

\[
F_{SCK_A} = F_{PDM\_CK} \times (MICNBR + 1) \times 2
\]

MICNBR can be 0, 1, 2 or 3 (0 = 2 microphones., see Section 53.6.18)

2. Set the frame length (FRL) using the following formula

\[
FRL = (16 \times (MICNBR + 1)) - 1
\]

3. Configure the slot size (DS) to a multiple of (FRL+1).

Adjusting the delay lines

When the PDM interface is enabled, the application can adjust on-the-fly the delay cells of each microphone input via SAI_PDMDLY register.

The new delays values become effective after two TDM frames.
53.4.11 AC’97 link controller

The SAI is able to work as an AC’97 link controller. In this protocol:

- The slot number and the slot size are fixed.
- The frame synchronization signal is perfectly defined and has a fixed shape.

To select this protocol, set PRTCFG[1:0] bits in the SAI_xCR1 register to 10. When AC’97 mode is selected, only data sizes of 16 or 20 bits can be used, otherwise the SAI behavior is not guaranteed.

- NBSLOT[3:0] and SLOTSZ[1:0] bits are consequently ignored.
- The number of slots is fixed to 13 slots. The first one is 16-bit wide and all the others are 20-bit wide (data slots).
- FBOFF[4:0] bits in the SAI_xSLOTR register are ignored.
- The SAI_xFRCR register is ignored.
- The MCLK is not used.

The FS signal from the block defined as asynchronous is configured automatically as an output, since the AC’97 controller link drives the FS signal whatever the master or slave configuration.

*Figure 762 shows an AC’97 audio frame structure.*

**Figure 762. AC’97 audio frame**

**Note:** In AC’97 protocol, bit 2 of the tag is reserved (always 0), so bit 2 of the TAG is forced to 0 level whatever the value written in the SAI FIFO.

For more details about tag representation, refer to the AC’97 protocol standard.

One SAI can be used to target an AC’97 point-to-point communication.

Using two SAIs (for devices featuring two embedded SAIs) enables the control of three external AC’97 decoders as illustrated in *Figure 763.*

In SAI1, the audio block A must be declared as asynchronous master transmitter whereas the audio block B is defined to be slave receiver and internally synchronous to the audio block A.

The SAI2 is configured for audio block A and B both synchronous with the external SAI1 in slave receiver mode.
In receiver mode, the SAI acting as an AC’97 link controller requires no FIFO request and so no data storage in the FIFO when the Codec ready bit in the slot 0 is decoded low. If bit CNRDYIE is enabled in the SAI_xIM register, flag CNRDY is set in the SAI_xSR register and an interrupt is generated. This flag is dedicated to the AC’97 protocol.

**Clock generator programming in AC’97 mode**

In AC’97 mode, the frame length is fixed at 256 bits, and its frequency must be set to 48 kHz. The formulas given in Section 53.4.8: SAI clock generator must be used with FRL = 255, in order to generate the proper frame rate (FFS_x).

---

Figure 763. Example of typical AC’97 configuration on devices featuring at least 2 embedded SAIs (three external AC’97 decoders)
53.4.12  SPDIF output

The SPDIF interface is available in transmitter mode only. It supports the audio IEC60958. To select SPDIF mode, set PRTCFG[1:0] bit to 01 in the SAI_xCR1 register.

For SPDIF protocol:

- Only SD data line is enabled.
- FS, SCK, MCLK I/Os pins are left free.
- MODE[1] bit is forced to 0 to select the master mode in order to enable the clock generator of the SAI and manage the data rate on the SD line.
- The data size is forced to 24 bits. The value set in DS[2:0] bits in the SAI_xCR1 register is ignored.
- The clock generator must be configured to define the symbol-rate, knowing that the bit clock must be twice the symbol-rate. The data is coded in Manchester protocol.
- The SAI_xFRCR and SAI_xSLOTR registers are ignored. The SAI is configured internally to match the SPDIF protocol requirements as shown in Figure 764.

**Figure 764. SPDIF format**

A SPDIF block contains 192 frames. Each frame is composed of two 32-bit sub-frames, generally one for the left channel and one for the right channel. Each sub-frame is composed of a SOPD pattern (4-bit) to specify if the sub-frame is the start of a block (and so is identifying a channel A) or if it is identifying a channel A somewhere in the block, or if it is referring to channel B (see Table 571). The next 28 bits of channel information are composed of 24 bits data + 4 status bits.
The data stored in SAI_xDR has to be filled as follows:
- SAI_xDR[26:24] contain the Channel status, User and Validity bits.
- SAI_xDR[23:0] contain the 24-bit data for the considered channel.

If the data size is 20 bits, then data must be mapped on SAI_xDR[23:4].
If the data size is 16 bits, then data must be mapped on SAI_xDR[23:8].
SAI_xDR[23] always represents the MSB.

**Table 571. SOPD pattern**

<table>
<thead>
<tr>
<th>SOPD</th>
<th>Preamble coding</th>

</tr>
</tbody>
</table>

The data stored in SAI_xSR has to be filled as follows:

- SAI_xDR[26:24] contain the Channel status, User and Validity bits.
- SAI_xDR[23:0] contain the 24-bit data for the considered channel.

If the data size is 20 bits, then data must be mapped on SAI_xDR[23:4].
If the data size is 16 bits, then data must be mapped on SAI_xDR[23:8].
SAI_xDR[23] always represents the MSB.

**Figure 765. SAI_xDR register ordering**

Note: The transfer is performed always with LSB first.

The SAI first sends the adequate preamble for each sub-frame in a block. The SAI_xDR is then sent on the SD line (manchester coded). The SAI ends the sub-frame by transferring the Parity bit calculated as described in **Table 572**.

**Table 572. Parity bit calculation**

</tbody>
</table>

The underrun is the only error flag available in the SAI_xSR register for SPDIF mode since the SAI can only operate in transmitter mode. As a result, the following sequence must be...
executed to recover from an underrun error detected via the underrun interrupt or the underrun status bit:

1. Disable the DMA stream (via the DMA peripheral) if the DMA is used.
2. Disable the SAI and check that the peripheral is physically disabled by polling the SAIEN bit in SAI_xCR1 register.
3. Clear the COVRUNDR flag in the SAI_xCLRFR register.
4. Flush the FIFO by setting the FFLUSH bit in SAI_xCR2.
   The software needs to point to the address of the future data corresponding to a start of new block (data for preamble B). If the DMA is used, the DMA source base address pointer must be updated accordingly.
5. Enable again the DMA stream (DMA peripheral) if the DMA used to manage data transfers according to the new source base address.
6. Enable again the SAI by setting SAIEN bit in SAI_xCR1 register.

Clock generator programming in SPDIF generator mode

For the SPDIF generator, the SAI provides a bit clock twice faster as the symbol-rate. The table hereafter shows usual examples of symbol rates with respect to the audio sampling rate.

<table>
<thead>
<tr>
<th>Audio sampling frequencies ($F_S$)</th>
<th>Symbol-rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>44.1 kHz</td>
<td>2.8224 MHz</td>
</tr>
<tr>
<td>48 kHz</td>
<td>3.072 MHz</td>
</tr>
<tr>
<td>96 kHz</td>
<td>6.144 MHz</td>
</tr>
<tr>
<td>192 kHz</td>
<td>12.288 MHz</td>
</tr>
</tbody>
</table>

More generally, the relationship between the audio sampling frequency ($F_S$) and the bit clock rate ($F_{SCK_x}$) is given by the formula:

$$F_S = \frac{F_{SCK_x}}{128}$$

The bit clock rate is obtained as follows:

$$F_{SCK_x} = \frac{F_{sai_x \_ker \_ck}}{MCKDIV}$$

**Note:** The above formulas are valid only if NODIV is set to 1 in SAI_ACR1 register.
53.4.13 Specific features

The SAI interface embeds specific features which can be useful depending on the audio protocol selected. These functions are accessible through specific bits of the SAI_xCR2 register.

**Mute mode**

The mute mode can be used when the audio subblock is a transmitter or a receiver.

**Audio subblock in transmission mode**

In transmitter mode, the mute mode can be selected at anytime. The mute mode is active for entire audio frames. The MUTE bit in the SAI_xCR2 register enables the mute mode when it is set during an ongoing frame.

The mute mode bit is strobed only at the end of the frame. If it is set at this time, the mute mode is active at the beginning of the new audio frame and for a complete frame, until the next end of frame. The bit is then strobed to determine if the next frame is still a mute frame.

If the number of slots set through NBSLOT[3:0] bits in the SAI_xSLOTR register is lower than or equal to 2, it is possible to specify if the value sent in mute mode is 0 or if it is the last value of each slot. The selection is done via MUTEVAL bit in the SAI_xCR2 register.

If the number of slots set in NBSLOT[3:0] bits in the SAI_xSLOTR register is greater than 2, MUTEVAL bit in the SAI_xCR2 is meaningless as 0 values are sent on each bit on each slot.

The FIFO pointers are still incremented in mute mode. This means that data present in the FIFO and for which the mute mode is requested are discarded.

**Audio subblock in reception mode**

In reception mode, it is possible to detect a mute mode sent from the external transmitter when all the declared and valid slots of the audio frame receive 0 for a given consecutive number of audio frames (MUTECNT[5:0] bits in the SAI_xCR2 register).

When the number of MUTE frames is detected, the MUTEDET flag in the SAI_xSR register is set and an interrupt can be generated if MUTEDETIE bit is set in SAI_xCR2.

The mute frame counter is cleared when the audio subblock is disabled or when a valid slot receives at least one data in an audio frame. The interrupt is generated just once, when the counter reaches the value specified in MUTECNT[5:0] bits. The interrupt event is then reinitialized when the counter is cleared.

*Note:* The mute mode is not available for SPDIF audio blocks.

**Mono/stereo mode**

In transmitter mode, the mono mode can be addressed, without any data preprocessing in memory, assuming the number of slots is equal to 2 (NBSLOT[3:0] = 0001 in SAI_xSLOTR).

In this case, the access time to and from the FIFO is reduced by 2 since the data for slot 0 is duplicated into data slot 1.

To enable the mono mode,

1. Set MONO bit to 1 in the SAI_xCR1 register.
2. Set NBSLOT to 1 and SLOTEN to 3 in SAI_xSLOTR.
In reception mode, the MONO bit can be set and is meaningful only if the number of slots is equal to 2 as in transmitter mode. When it is set, only slot 0 data are stored in the FIFO. The data belonging to slot 1 are discarded since, in this case, it is supposed to be the same as the previous slot. If the data flow in reception mode is a real stereo audio flow with a distinct and different left and right data, the MONO bit is meaningless. The conversion from the output stereo file to the equivalent mono file is done by software.

**Companding mode**

Telecommunication applications can require to process the data to be transmitted or received using a data companding algorithm.

Depending on the COMP[1:0] bits in the SAI_xCR2 register (used only when Free protocol mode is selected), the application software can choose to process or not the data before sending it on SD serial output line (compression) or to expand the data after the reception on SD serial input line (expansion) as illustrated in Figure 766. The two companding modes supported are the µ-Law and the A-Law log which are a part of the CCITT G.711 recommendation.

The companding standard used in the United States and Japan is the µ-Law. It supports 14 bits of dynamic range (COMP[1:0] = 10 in the SAI_xCR2 register).

The European companding standard is A-Law and supports 13 bits of dynamic range (COMP[1:0] = 11 in the SAI_xCR2 register).

Both µ-Law or A-Law companding standard can be computed based on 1’s complement or 2’s complement representation depending on the CPL bit setting in the SAI_xCR2 register.

In µ-Law and A-Law standards, data are coded as 8 bits with MSB alignment. Companded data are always 8-bit wide. For this reason, DS[2:0] bits in the SAI_xCR1 register are forced to 010 when the SAI audio block is enabled (SAIEN bit = 1 in the SAI_xCR1 register) and when one of these two companding modes selected through the COMP[1:0] bits.

If no companding processing is required, COMP[1:0] bits must be kept clear.
Expansion and compression mode are automatically selected through the SAI_xCR2:

- If the SAI audio block is configured to be a transmitter, and if the COMP[1] bit is set in the SAI_xCR2 register, the compression mode is applied.
- If the SAI audio block is declared as a receiver, the expansion algorithm is applied.

**Output data line management on an inactive slot**

In transmitter mode, it is possible to choose the behavior of the SD line output when an inactive slot is sent on the data line (via TRIS bit).

- Either the SAI forces 0 on the SD output line when an inactive slot is transmitted, or
- The line is released in HI-z state at the end of the last bit of data transferred, to release the line for other transmitters connected to this node.

It is important to note that the two transmitters cannot attempt to drive the same SD output pin simultaneously, which may result in a short circuit. To ensure a gap between transmissions, if the data is lower than 32-bit, the data can be extended to 32-bit by setting bit SLOTSZ[1:0] = 10 in the SAI_xSLOTR register. The SD output pin is then tri-stated at the end of the LSB of the active slot (during the padding to 0 phase to extend the data to 32-bit) if the following slot is declared inactive.

In addition, if the number of slots multiplied by the slot size is lower than the frame length, the SD output line is tri-stated when the padding to 0 is done to complete the audio frame. *Figure 767* illustrates these behaviors.
When the selected audio protocol uses the FS signal as a start of frame and a channel side identification (bit FSDEF = 1 in the SAI_xFRCR register), the tristate mode is managed according to Figure 768 (where bit TRIS in the SAI_xCR1 register = 1, and FSDEF=1, and half frame length is higher than number of slots/2, and NBSLOT=6).
If the TRIS bit in the SAI_xCR2 register is cleared, all the High impedance states on the SD output line on Figure 767 and Figure 768 are replaced by a drive with a value of 0.

53.4.14 Error flags

The SAI implements the following error flags:

- FIFO overrun/underrun
- Anticipated frame synchronization detection
- Late frame synchronization detection
- Codec not ready (AC’97 exclusively)
- Wrong clock configuration in master mode.

FIFO overrun/underrun (OVRUDR)

The FIFO overrun/underrun bit is called OVRUDR in the SAI_xSR register.

The overrun or underrun errors share the same bit since an audio block can be either receiver or transmitter and each audio block in a given SAI has its own SAI_xSR register.

Overrun

When the audio block is configured as receiver, an overrun condition may appear if data are received in an audio frame when the FIFO is full and not able to store the received data. In this case, the received data are lost, the flag OVRUDR in the SAI_xSR register is set and an interrupt is generated if OVRUDRIE bit is set in the SAI_xIM register. The slot number, from which the overrun occurs, is stored internally. No more data are stored into the FIFO until it becomes free to store new data. When the FIFO has at least one data free, the SAI audio block receiver stores new data (from new audio frame) from the slot number which was stored internally when the overrun condition was detected. This avoids data slot de-alignment in the destination memory (refer to Figure 769).

The OVRUDR flag is cleared when COVRUDR bit is set in the SAI_xCLRFR register.
Underrun

An underrun may occur when the audio block in the SAI is a transmitter and the FIFO is empty when data need to be transmitted. If an underrun is detected, the slot number for which the event occurs is stored and MUTE value (00) is sent until the FIFO is ready to transmit the data corresponding to the slot for which the underrun was detected (refer to Figure 770). This avoids desynchronization between the memory pointer and the slot in the audio frame.

The underrun event sets the OVRUDR flag in the SAI_xSR register and an interrupt is generated if the OVRUDRIE bit is set in the SAI_xIM register. To clear this flag, set COVRUDR bit in the SAI_xCLRFR register.

The underrun event can occur when the audio subblock is configured as master or slave.
**Anticipated frame synchronization detection (AFSDET)**

The AFSDET flag is used only in slave mode. It is never asserted in master mode. It indicates that a frame synchronization (FS) has been detected earlier than expected since the frame length, the frame polarity, the frame offset are defined and known.

Anticipated frame detection sets the AFSDET flag in the SAI_xSR register.

This detection has no effect on the current audio frame which is not sensitive to the anticipated FS. This means that “parasitic” events on signal FS are flagged without any perturbation of the current audio frame.

An interrupt is generated if the AFSDETIE bit is set in the SAI_xIM register. To clear the AFSDET flag, CAFSDET bit must be set in the SAI_xCLRFR register.

To resynchronize with the master after an anticipated frame detection error, four steps are required:

1. Disable the SAI block by resetting SAIEN bit in SAI_xCR1 register. To make sure the SAI is disabled, read back the SAIEN bit and check it is set to 0.
2. Flush the FIFO via FFLUS bit in SAI_xCR2 register.
3. Enable again the SAI peripheral (SAIEN bit set to 1).
4. The SAI block waits for the assertion on FS to restart the synchronization with master.

*Note:* The AFSDET flag is not asserted in AC’97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the FS signal is not used.

**Late frame synchronization detection**

The LFSDET flag in the SAI_xSR register can be set only when the SAI audio block operates as a slave. The frame length, the frame polarity and the frame offset configuration are known in register SAI_xFRCR.

If the external master does not send the FS signal at the expecting time thus generating the signal too late, the LFSDET flag is set and an interrupt is generated if LFSDETIE bit is set in the SAI_xIM register.

The LFSDET flag is cleared when CLFSDET bit is set in the SAI_xCLRFR register.

The late frame synchronization detection flag is set when the corresponding error is detected. The SAI needs to be resynchronized with the master (see sequence described in Anticipated frame synchronization detection (AFSDET)).

In a noisy environment, glitches on the SCK clock may be wrongly detected by the audio block state machine and shift the SAI data at a wrong frame position. This event can be detected by the SAI and reported as a late frame synchronization detection error.

There is no corruption if the external master is not managing the audio data frame transfer in continuous mode, which must not be the case in most applications. In this case, the LFSDET flag is set.

*Note:* The LFSDET flag is not asserted in AC’97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the signal FS is not used by the protocol.
Codec not ready (CNRDY AC'97)

The CNRDY flag in the SAI_xSR register is relevant only if the SAI audio block is configured to operate in AC'97 mode (PRTCFG[1:0] = 10 in the SAI_xCR1 register). If CNRDYIE bit is set in the SAI_xIM register, an interrupt is generated when the CNRDY flag is set.

CNRDY is asserted when the Codec is not ready to communicate during the reception of the TAG 0 (slot0) of the AC'97 audio frame. In this case, no data are automatically stored into the FIFO since the Codec is not ready, until the TAG 0 indicates that the Codec is ready. All the active slots defined in the SAI_xSLOTR register are captured when the Codec is ready.

To clear CNRDY flag, CCNRDY bit must be set in the SAI_xCLRFR register.

Wrong clock configuration in master mode (with NODIV = 0)

When the audio block operates as a master (MODE[1] = 0) and NODIV bit is equal to 0, the WCKCFG flag is set as soon as the SAI is enabled if the following conditions are met:

- \((FRL+1)\) is not a power of 2, and
- \((FRL+1)\) is not between 8 and 256.

MODE, NODIV, and SAIEN bits belong to SAI_xCR1 register and FRL to SAI_xFRCR register.

If WCKCFGIE bit is set, an interrupt is generated when WCKCFG flag is set in the SAI_xSR register. To clear this flag, set CWCKCFG bit in the SAI_xCLRFR register.

When WCKCFG bit is set, the audio block is automatically disabled, thus performing a hardware clear of SAIEN bit.

53.4.15 Disabling the SAI

The SAI audio block can be disabled at any moment by clearing SAIEN bit in the SAI_xCR1 register. All the already started frames are automatically completed before the SAI stops working. SAIEN bit remains High until the SAI is completely switched-off at the end of the current audio frame transfer.

If an audio block in the SAI operates synchronously with the other one, the one which is the master must be disabled first.

53.4.16 SAI DMA interface

To free the CPU and to optimize bus bandwidth, each SAI audio block has an independent DMA interface to read/write from/to the SAI_xDR register (to access the internal FIFO). There is one DMA channel per audio subblock supporting basic DMA request/acknowledge protocol.

To configure the audio subblock for DMA transfer, set DMAEN bit in the SAI_xCR1 register. The DMA request is managed directly by the FIFO controller depending on the FIFO threshold level (for more details refer to Section 53.4.9: Internal FIFOs). DMA transfer direction is linked to the SAI audio subblock configuration:

- If the audio block operates as a transmitter, the audio block FIFO controller outputs a DMA request to load the FIFO with data written in the SAI_xDR register.
- If the audio block is operated as a receiver, the DMA request is related to read operations from the SAI_xDR register.
Follow the sequence below to configure the SAI interface in DMA mode:
1. Configure SAI and FIFO threshold levels to specify when the DMA request is launched.
2. Configure SAI DMA channel.
3. Enable the DMA.
4. Enable the SAI interface.

*Note:* Before configuring the SAI block, the SAI DMA channel must be disabled.

### 53.5 SAI interrupts

The SAI supports 7 interrupt sources as shown in *Table 574*.

Bits 5:4 SYNOUT[1:0]: Synchronization outputs

These bits are set and cleared by software.
00: No synchronization output signals. SYNOUT[1:0] must be configured as “No synchronization output signals” when audio block is configured as SPDIF
01: Block A used for further synchronization for others SAI
10: Block B used for further synchronization for others SAI
11: Reserved. These bits must be set when both audio blocks (A and B) are disabled.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 SYNadin[1:0]: Synchronization inputs

These bits are set and cleared by software.
Refer to Table 566: External synchronization selection for information on how to program this field.
These bits must be set when both audio blocks (A and B) are disabled.
They are meaningful if one of the two audio blocks is defined to operate in synchronous mode with an external SAI (SYNcen[1:0] = 10 in SAI_ACR1 or in SAI_BCR1 registers).

Bits 31:28: Reserved, must be kept at reset value.

Bit 27 **MCK EN**: Master clock generation enable
- 0: The master clock is not generated
- 1: The master clock is generated independently of SAIEN bit

Bit 26 **OSR**: Oversampling ratio for master clock
- This bit is meaningful only when NODIV bit is set to 0.
- 0: Master clock frequency = $F_{FS} \times 256$
- 1: Master clock frequency = $F_{FS} \times 512$

Bits 25:20 **MCKDIV[5:0]**: Master clock divider
- These bits are set and cleared by software.
- 000000: Divides by 1 the kernel clock input (sai_x_ker_ck).
- Otherwise, the master clock frequency is calculated according to the formula given in Section 53.4.8: SAI clock generator.
- These bits have no meaning when the audio block is slave.
- They have to be configured when the audio block is disabled.

Bit 19 **NODIV**: No divider
- This bit is set and cleared by software.
- 0: the ratio between the Master clock generator and frame synchronization is fixed to 256 or 512
- 1: the ratio between the Master clock generator and frame synchronization depends on FRL[7:0]

Bit 18: Reserved, must be kept at reset value.

Bit 17 **DMAEN**: DMA enable
- This bit is set and cleared by software.
- 0: DMA disabled
- 1: DMA enabled

*Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must be configured before setting DMAEN to avoid a DMA request in receiver mode.*
Bit 16  **SAIEN**: Audio block enable  
This bit is set by software.  
To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command is not taken into account.  
This bit enables to control the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.  
0: SAI audio block disabled  
1: SAI audio block enabled.  
*Note*:  When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting SAIEN bit.

Bits 15:14  Reserved, must be kept at reset value.

Bit 13  **OUTDRIV**: Output drive  
This bit is set and cleared by software.  
0: Audio block output driven when SAIEN is set  
1: Audio block output driven immediately after the setting of this bit.  
*Note*:  This bit has to be set before enabling the audio block and after the audio block configuration.

Bit 12  **MONO**: Mono mode  
This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2.  
When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are stored. Refer to [Section : Mono/stereo mode](#) for more details.  
0: Stereo mode  
1: Mono mode.

Bits 11:10  **SYNCEN[1:0]**: Synchronization enable  
These bits are set and cleared by software. They must be configured when the audio subblock is disabled.  
00: audio subblock in asynchronous mode.  
01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio subblock must be configured in slave mode  
10: audio subblock is synchronous with an external SAI embedded peripheral. In this case the audio subblock must be configured in Slave mode.  
11: Reserved  
*Note*:  The audio subblock must be configured as asynchronous when SPDIF mode is enabled.

Bit 9  **CKSTR**: Clock strobing edge  
This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.  
0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.  
1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

Bit 8  **LSBFIRST**: Least significant bit first  
This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC’97 audio protocol since AC’97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.  
0: Data are transferred with MSB first  
1: Data are transferred with LSB first.
Bits 7:5 **DS[2:0]: Data size**

These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.

These bits must be configured when the audio block is disabled.

- 000: Reserved
- 001: Reserved
- 010: 8 bits
- 011: 10 bits
- 100: 16 bits
- 101: 20 bits
- 110: 24 bits
- 111: 32 bits

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **PRTCFG[1:0]: Protocol configuration**

These bits are set and cleared by software. These bits have to be configured when the audio block is disabled.

- 00: Free protocol. Free protocol enables to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting most of the configuration register bits as well as frame configuration register.
- 01: SPDIF protocol
- 10: AC’97 protocol
- 11: Reserved

Bits 1:0 **MODE[1:0]: SAIx audio block mode**

These bits are set and cleared by software. They must be configured when SAIx audio block is disabled.

- 00: Master transmitter
- 01: Master receiver
- 10: Slave transmitter
- 11: Slave receiver

Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced (MODE[1:0] = 00).

Serial audio interface (SAI) RM0481

Bits 31:28  Reserved, must be kept at reset value.

Bit 27 **MCKEN**: Master clock generation enable
0: The master clock is not generated
1: The master clock is generated independently of SAIEN bit

Bit 26 **OSR**: Oversampling ratio for master clock
This bit is meaningful only when NODIV bit is set to 0.
0: Master clock frequency = \( F_{\text{FS}} \times 256 \)
1: Master clock frequency = \( F_{\text{FS}} \times 512 \)

Bits 25:20 **MCKDIV[5:0]**: Master clock divider
These bits are set and cleared by software.
000000: Divides by 1 the kernel clock input (sai_x_ker_ck).
Otherwise, The master clock frequency is calculated according to the formula given in Section 53.4.8: SAI clock generator.
These bits have no meaning when the audio block is slave.
They have to be configured when the audio block is disabled.

Bit 19 **NODIV**: No divider
This bit is set and cleared by software.
0: the ratio between the Master clock generator and frame synchronization is fixed to 256 or 512
1: the ratio between the Master clock generator and frame synchronization depends on FRL[7:0]

Bit 18 Reserved, must be kept at reset value.

Bit 17 **DMAEN**: DMA enable
This bit is set and cleared by software.
0: DMA disabled
1: DMA enabled

*Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must be configured before setting DMAEN to avoid a DMA request in receiver mode.*

Bit 16 **SAIEN**: Audio block enable
This bit is set by software.
To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command is not taken into account.
This bit enables to control the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.
0: SAI audio block disabled
1: SAI audio block enabled.

*Note: When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting SAIEN bit.*

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OUTDRIV**: Output drive
This bit is set and cleared by software.
0: Audio block output driven when SAIEN is set
1: Audio block output driven immediately after the setting of this bit.

*Note: This bit has to be set before enabling the audio block and after the audio block configuration.*
Bit 12 **MONO**: Mono mode

This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2. When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are stored. Refer to Section : Mono/stereo mode for more details.

0: Stereo mode
1: Mono mode.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable

These bits are set and cleared by software. They must be configured when the audio subblock is disabled.

00: audio subblock in asynchronous mode.
01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio subblock must be configured in slave mode.
10: audio subblock is synchronous with an external SAI embedded peripheral. In this case the audio subblock must be configured in Slave mode.
11: Reserved

*Note: The audio subblock must be configured as asynchronous when SPDIF mode is enabled.*

Bit 9 **CKSTR**: Clock strobing edge

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.

0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.
1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

Bit 8 **LSBFIRST**: Least significant bit first

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC’97 audio protocol since AC’97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.

0: Data are transferred with MSB first
1: Data are transferred with LSB first

Bits 7:5 **DS[2:0]**: Data size

These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.

Bits 31-16: Reserved, must be kept at reset value.

Bits 15:14: **COMP[1:0]:** Compressing mode.
   
   These bits are set and cleared by software. The μ-Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on CPL bit.
   
   The data expansion or data compression are determined by the state of bit MODE[0].
   
   The data compression is applied if the audio block is configured as a transmitter.
   
   The data expansion is automatically applied when the audio block is configured as a receiver.
   
   Refer to Section: Compressing mode for more details.
   
   00: No compressing algorithm
   
   01: Reserved.
   
   10: μ-Law algorithm
   
   11: A-Law algorithm

   Note: Compressing mode is applicable only when Free protocol mode is selected.

Bit 13: **CPL**: Complement bit.
   
   This bit is set and cleared by software.
   
   It defines the type of complement to be used for compressing mode
   
   0: 1’s complement representation.
   
   1: 2’s complement representation.

   Note: This bit has effect only when the compressing mode is μ-Law algorithm or A-Law algorithm.

Bits 12:7: **MUTE[5:0]**: Mute counter.
   
   These bits are set and cleared by software. They are used only in reception mode.
   
   The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET is set and an interrupt is generated if bit MUTEDETIE is set.
   
   Refer to Section: Mute mode for more details.

Bit 6: **MUTEVAL**: Mute value.
   
   This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.
   
   This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the MUTE bit is set.
   
   If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.
   
   If the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.
   
   Refer to Section: Mute mode for more details.
   
   0: Bit value 0 is sent during the mute mode.
   
   1: Last values are sent during the mute mode.

   Note: This bit is meaningless and must not be used for SPDIF audio blocks.

Bit 5: **MUTE**: Mute.
   
   This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.
   
   Refer to Section: Mute mode for more details.
   
   0: No mute mode.
   
   1: Mute mode enabled.

   Note: This bit is meaningless and must not be used for SPDIF audio blocks.
Bit 4 TRIS: Tristate management on data line.
This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It must be configured when SAI is disabled. Refer to Section: Output data line management on an inactive slot for more details.
0: SD output line is still driven by the SAI when a slot is inactive.
1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

Bit 3 FFLUSH: FIFO flush.
This bit is set by software. It is always read as 0. This bit must be configured when the SAI is disabled.
0: No FIFO flush.
1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interrupt must be disabled.

Bits 2:0 FTH[2:0]: FIFO threshold.
This bit is set and cleared by software.
000: FIFO empty
001: ¼ FIFO
010: ½ FIFO
011: ¾ FIFO
100: FIFO full
101: Reserved
110: Reserved
111: Reserved

2494/3119 RM0481 Rev 1
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:14  **COMP[1:0]**: Comping mode.
These bits are set and cleared by software. The µ-Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on **CPL bit**.
The data expansion or data compression are determined by the state of bit **MODE[0]**.
The data compression is applied if the audio block is configured as a transmitter.
The data expansion is automatically applied when the audio block is configured as a receiver.
Refer to **Section : Comping mode** for more details.
00: No companding algorithm
01: Reserved.
10: µ-Law algorithm
11: A-Law algorithm

*Note:* **Comping mode is applicable only when Free protocol mode is selected.**

Bit 13  **CPL**: Complement bit.
This bit is set and cleared by software.
It defines the type of complement to be used for companding mode
0: 1’s complement representation.
1: 2’s complement representation.

*Note:* **This bit has effect only when the companding mode is µ-Law algorithm or A-Law algorithm.**

Bits 12:7  **MUTECNT[5:0]**: Mute counter.
These bits are set and cleared by software. They are used only in reception mode.
The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET is set and an interrupt is generated if bit MUTEDETIE is set.
Refer to **Section : Mute mode** for more details.

Bit 6  **MUTEVAL**: Mute value.
This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.
This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the MUTE bit is set.
If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.
if the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.
Refer to **Section : Mute mode** for more details.
0: Bit value 0 is sent during the mute mode.
1: Last values are sent during the mute mode.

*Note:* **This bit is meaningless and must not be used for SPDIF audio blocks.**

Bit 5  **MUTE**: Mute.
This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.
Refer to **Section : Mute mode** for more details.
0: No mute mode.
1: Mute mode enabled.

*Note:* **This bit is meaningless and must not be used for SPDIF audio blocks.**
53.6.6 SAI frame configuration register (SAI_AFRCR)

Address offset: 0x00C
Reset value: 0x0000 0007

Bit 4 TRIS: Tristate management on data line.
This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It must be configured when SAI is disabled.
Refer to Section: Output data line management on an inactive slot for more details.
0: SD output line is still driven by the SAI when a slot is inactive.
1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

Bit 3 FFLUSH: FIFO flush.
This bit is set by software. It is always read as 0. This bit must be configured when the SAI is disabled.
0: No FIFO flush.
1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interrupt must be disabled.

Bits 2:0 FTH[2:0]: FIFO threshold.
This bit is set and cleared by software.
000: FIFO empty
001: ¼ FIFO
010: ½ FIFO
011: ¾ FIFO
100: FIFO full
101: Reserved
110: Reserved
111: Reserved
Bits 31:19  Reserved, must be kept at reset value.

Bit 18  **FSOFF**: Frame synchronization offset.
   This bit is set and cleared by software. It is meaningless and is not used in AC’97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.
   0: FS is asserted on the first bit of the slot 0.
   1: FS is asserted one bit before the first bit of the slot 0.

Bit 17  **FSPOL**: Frame synchronization polarity.
   This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC’97 or SPDIF audio block configuration.
   This bit must be configured when the audio block is disabled.
   0: FS is active low (falling edge)
   1: FS is active high (rising edge)

Bit 16  **FSDEF**: Frame synchronization definition.
   This bit is set and cleared by software.
   0: FS signal is a start frame signal
   1: FS signal is a start of frame signal + channel side identification
   When the bit is set, the number of slots defined in the SAI_xSLOTR register has to be even. It means that half of this number of slots are dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols...).
   This bit is meaningless and is not used in AC’97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.

Bit 15  Reserved, must be kept at reset value.

Bits 14:8  **FSALL[6:0]**: Frame synchronization active level length.
   These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame.
   These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.
   They must be configured when the audio block is disabled.

Bits 7:0  **FRL[7:0]**: Frame length.
   These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.
   The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI_xSLOTR register (NBSLOT[3:0] = 0000).
   In master mode, if the master clock (available on MCLK_x pin) is used, the frame length must be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256.
   These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration. They must be configured when the audio block is disabled.
53.6.7 **SAI frame configuration register (SAI_BFRCR)**

Address offset: 0x02C  
Reset value: 0x0000 0007

**Note:** This register has no meaning in AC’97 and SPDIF audio protocol

Bits 31:19 Reserved, must be kept at reset value.

**Bit 18 FSOFF:** Frame synchronization offset.  
This bit is set and cleared by software. It is meaningless and is not used in AC’97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.  
0: FS is asserted on the first bit of the slot 0.  
1: FS is asserted one bit before the first bit of the slot 0.

**Bit 17 FSPOL:** Frame synchronization polarity.  
This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC’97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.  
0: FS is active low (falling edge)  
1: FS is active high (rising edge)

**Bit 16 FSDEF:** Frame synchronization definition.  
This bit is set and cleared by software.  
0: FS signal is a start frame signal  
1: FS signal is a start of frame signal + channel side identification

When the bit is set, the number of slots defined in the SAI_xSLOTR register has to be even. It means that half of this number of slots is dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols…).  
This bit is meaningless and is not used in AC’97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.
Bit 15  Reserved, must be kept at reset value.

Bits 14:8  **FSALL[6:0]**: Frame synchronization active level length.
These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame.
These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration.
They must be configured when the audio block is disabled.

Bits 7:0  **FRL[7:0]**: Frame length.
These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.
The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI_xSLOTR register (NBSLOT[3:0] = 0000).
In master mode, if the master clock (available on MCLK_x pin) is used, the frame length must be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256.
These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration.

### 53.6.8  SAI slot register (SAI_ASLOTR)

Address offset: 0x010
Reset value: 0x0000 0000

**Note:** This register has no meaning in AC'97 and SPDIF audio protocol.

Bits 31:16  **SLOTEN[15:0]**: Slot enable.
These bits are set and cleared by software.
Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).
0: Inactive slot.
1: Active slot.
The slot must be enabled when the audio block is disabled.
They are ignored in AC'97 or SPDIF mode.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:8  **NBSLOT[3:0]**: Number of slots in an audio frame.
These bits are set and cleared by software.
The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.
The number of slots must be even if FSDEF bit in the SAI_xFRCR register is set.
The number of slots must be configured when the audio block is disabled.
They are ignored in AC'97 or SPDIF mode.
Bits 7:6 **SLOTSZ[1:0]:** Slot size

This bits is set and cleared by software.
The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI is undetermined.
Refer to *Output data line management on an inactive slot* for information on how to drive SD line.
These bits must be set when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.
00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI_xCR1 register).
01: 16-bit
10: 32-bit
11: Reserved

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]:** First bit offset

These bits are set and cleared by software.
The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.
These bits must be set when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.

### 53.6.9 SAI slot register (SAI_BSLOTR)

Address offset: 0x030
Reset value: 0x0000 0000

*Note:* This register has no meaning in AC’97 and SPDIF audio protocol.

Bits 31:16 **SLOTEN[15:0]**: Slot enable.

These bits are set and cleared by software.

Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).

- 0: Inactive slot.
- 1: Active slot.

The slot must be enabled when the audio block is disabled.

They are ignored in AC’97 or SPDIF mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame.

These bits are set and cleared by software.

The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.

The number of slots must be even if FSDEF bit in the SAI_xFRCR register is set.

The number of slots must be configured when the audio block is disabled.

They are ignored in AC’97 or SPDIF mode.

Bits 7:6 **SLOTSZ[1:0]**: Slot size

This bits is set and cleared by software.

The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI is undetermined.

Refer to *Output data line management on an inactive slot* for information on how to drive SD line.

These bits must be set when the audio block is disabled.

They are ignored in AC’97 or SPDIF mode.

- 00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI_xCR1 register).
- 01: 16-bit
- 10: 32-bit
- 11: Reserved

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]**: First bit offset

These bits are set and cleared by software.

The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.

These bits must be set when the audio block is disabled.

They are ignored in AC’97 or SPDIF mode.

### 53.6.10 SAI interrupt mask register (SAI_AIM)

Address offset: 0x014

Reset value: 0x0000 0000
Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **LFSDETIE**: Late frame synchronization detection interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When this bit is set, an interrupt is generated if the LFSDET bit is set in the SAI_xSR register.
   This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit 5  **AFSDDETIE**: Anticipated frame synchronization detection interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When this bit is set, an interrupt is generated if the AFSDDET bit in the SAI_xSR register is set.
   This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit 4  **CNRDYIE**: Codec not ready interrupt enable (AC’97).
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC’97 frame if the
   Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI_xSR
   register is set and an interrupt is generated.
   This bit has a meaning only if the AC’97 mode is selected through PRTCFG[1:0] bits and the audio
   block is operates as a receiver.

Bit 3  **FREQIE**: FIFO request interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When this bit is set, an interrupt is generated if the FREQ bit in the SAI_xSR register is set.
   Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be
   configured before setting FREQIE to avoid a parasitic interrupt in receiver mode.

Bit 2  **WCKCFGIE**: Wrong clock configuration interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and
   NODIV = 0.
   It generates an interrupt if the WCKCFG flag in the SAI_xSR register is set.
   *Note*: This bit is used only in Free protocol mode and is meaningless in other modes.

Bit 1  **MUTEDETIE**: Mute detection interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI_xSR register is set.
   This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0  **OVRUDRIE**: Overrun/underrun interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI_xSR register is set.
53.6.11 SAI interrupt mask register (SAI_BIM)

Bits 31:7 Reserved, must be kept at reset value.

- **Bit 6 LFSDETIE**: Late frame synchronization detection interrupt enable.
  - This bit is set and cleared by software.
  - 0: Interrupt is disabled
  - 1: Interrupt is enabled
  - When this bit is set, an interrupt is generated if the LFSDET bit is set in the SAI_xSR register.
  - This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

- **Bit 5 AFSDETIE**: Anticipated frame synchronization detection interrupt enable.
  - This bit is set and cleared by software.
  - 0: Interrupt is disabled
  - 1: Interrupt is enabled
  - When this bit is set, an interrupt is generated if the AFSDET bit in the SAI_xSR register is set.
  - This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

- **Bit 4 CNRDYIE**: Codec not ready interrupt enable (AC'97).
  - This bit is set and cleared by software.
  - 0: Interrupt is disabled
  - 1: Interrupt is enabled
  - When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC’97 frame if the Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI_xSR register is set and an interrupt is generated.
  - This bit has a meaning only if the AC’97 mode is selected through PRTCFG[1:0] bits and the audio block operates as a receiver.

- **Bit 3 FREQIE**: FIFO request interrupt enable.
  - This bit is set and cleared by software.
  - 0: Interrupt is disabled
  - 1: Interrupt is enabled
  - When this bit is set, an interrupt is generated if the FREQ bit in the SAI_xSR register is set.
  - Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be configured before setting FREQIE to avoid a parasitic interrupt in receiver mode,
Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable.
- This bit is set and cleared by software.
- 0: Interrupt is disabled
- 1: Interrupt is enabled
This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and NODIV = 0.
It generates an interrupt if the WCKCFG flag in the SAI_xSR register is set.
*Note: This bit is used only in Free protocol mode and is meaningless in other modes.*

Bit 1 **MUTEDETIE**: Mute detection interrupt enable.
- This bit is set and cleared by software.
- 0: Interrupt is disabled
- 1: Interrupt is enabled
When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI_xSR register is set.
This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDRIE**: Overrun/underrun interrupt enable.
- This bit is set and cleared by software.
- 0: Interrupt is disabled
- 1: Interrupt is enabled
When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI_xSR register is set.

### 53.6.12 SAI status register (SAI_ASR)

Address offset: 0x018
Reset value: 0x0000 0008

| Bit 31:19 | Reserved, must be kept at reset value. |
| Bit 18:16 | **FLVL[2:0]**: FIFO level threshold. |
|           | This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode). |
|           | 000: FIFO empty (transmitter and receiver modes) |
|           | 001: FIFO ≤ ¼ but not empty (transmitter mode), FIFO < ¼ but not empty (receiver mode) |
|           | 010: ¼ < FIFO ≤ ½ (transmitter mode), ¼ ≤ FIFO < ½ (receiver mode) |
|           | 011: ½ < FIFO ≤ ¾ (transmitter mode), ½ ≤ FIFO < ¾ (receiver mode) |
|           | 100: ¾ < FIFO but not full (transmitter mode), ¾ ≤ FIFO but not full (receiver mode) |
|           | 101: FIFO full (transmitter and receiver modes) |
|           | Others: Reserved |
| Bit 15:7  | Reserved, must be kept at reset value. |
Bit 6 **LFSDET**: Late frame synchronization detection.
   This bit is read only.
   0: No error.
   1: Frame synchronization signal is not present at the right time.
   This flag can be set only if the audio block is configured in slave mode.
   It is not used in AC’97 or SPDIF mode.
   It can generate an interrupt if LFSDETIE bit is set in the SAI_xIM register.
   This flag is cleared when the software sets bit CLFSDET in SAI_xCLRFR register.

Bit 5 **AFSDET**: Anticipated frame synchronization detection.
   This bit is read only.
   0: No error.
   1: Frame synchronization signal is detected earlier than expected.
   This flag can be set only if the audio block is configured in slave mode.
   It is not used in AC’97 or SPDIF mode.
   It can generate an interrupt if AFSDETIE bit is set in SAI_xIM register.
   This flag is cleared when the software sets CAFSDET bit in SAI_xCLRFR register.

Bit 4 **CNRDY**: Codec not ready.
   This bit is read only.
   0: External AC’97 Codec is ready
   1: External AC’97 Codec is not ready
   This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register and
   configured in receiver mode.
   It can generate an interrupt if CNRDYIE bit is set in SAI_xIM register.
   This flag is cleared when the software sets CCNRDY bit in SAI_xCLRFR register.

Bit 3 **FREQ**: FIFO request.
   This bit is read only.
   0: No FIFO request.
   1: FIFO request to read or to write the SAI_xDR.
   The request depends on the audio block configuration:
   – If the block is configured in transmission mode, the FIFO request is related to a write request
     operation in the SAI_xDR.
   – If the block configured in reception, the FIFO request related to a read request operation from the
     SAI_xDR.
   This flag can generate an interrupt if FREQIE bit is set in SAI_xIM register.
Bit 2 **WCKCFG**: Wrong clock configuration flag.
   This bit is read only.
   0: Clock configuration is correct
   1: Clock configuration does not respect the rule concerning the frame length specification defined in
   Section 53.4.6: Frame synchronization (configuration of FRL[7:0] bit in the SAI_xFRCR register)
   This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0.
   It can generate an interrupt if WCKCFGIE bit is set in SAI_xIM register.
   This flag is cleared when the software sets CWCKCFG bit in SAI_xCLRFR register.

Bit 1 **MUTEDET**: Mute detection.
   This bit is read only.
   0: No MUTE detection on the SD input line
   1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio
   frame
   This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a
   consecutive number of audio frames (set in the MUTECNT bit in the SAI_xCR2 register).
   It can generate an interrupt if MUTEDETIE bit is set in SAI_xIM register.
   This flag is cleared when the software sets CMUTEDET in the SAI_xCLRFR register.

Bit 0 **OVRUDR**: Overrun / underrun.
   This bit is read only.
   0: No overrun/underrun error.
   1: Overrun/underrun error detection.
   The overrun and underrun conditions can occur only when the audio block is configured as a
   receiver and a transmitter, respectively.
   It can generate an interrupt if OVRUDRIE bit is set in SAI_xIM register.
   This flag is cleared when the software sets COVRUDR bit in SAI_xCLRFR register.

</table>
Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **FLVL[2:0]**: FIFO level threshold.
This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).
000: FIFO empty (transmitter and receiver modes)
001: FIFO ≤ ¼ but not empty (transmitter mode), FIFO < ¼ but not empty (receiver mode)
010: ¼ < FIFO ≤ ½ (transmitter mode), ¼ ≤ FIFO < ½ (receiver mode)
011: ½ < FIFO ≤ ¾ (transmitter mode), ½ ≤ FIFO < ¾ (receiver mode)
100: ¾ < FIFO but not full (transmitter mode), ¾ ≤ FIFO but not full (receiver mode)
101: FIFO full (transmitter and receiver modes)
Others: Reserved

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **LFSDET**: Late frame synchronization detection.
This bit is read only.
0: No error.
1: Frame synchronization signal is not present at the right time.
This flag can be set only if the audio block is configured in slave mode.
It is not used in AC’97 or SPDIF mode.
It can generate an interrupt if LFSDETIE bit is set in the SAI_xIM register.
This flag is cleared when the software sets bit CLFSDET in SAI_xCLRFR register.

Bit 5 **AFSDET**: Anticipated frame synchronization detection.
This bit is read only.
0: No error.
1: Frame synchronization signal is detected earlier than expected.
This flag can be set only if the audio block is configured in slave mode.
It is not used in AC’97 or SPDIF mode.
It can generate an interrupt if AFSDETIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CAFSDET bit in SAI_xCLRFR register.

Bit 4 **CNRDY**: Codec not ready.
This bit is read only.
0: External AC’97 Codec is ready
1: External AC’97 Codec is not ready
This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register and configured in receiver mode.
It can generate an interrupt if CNRDYIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CCNRDY bit in SAI_xCLRFR register.

Bit 3 **FREQ**: FIFO request.
This bit is read only.
0: No FIFO request.
1: FIFO request to read or to write the SAI_xDR.
The request depends on the audio block configuration:
– If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI_xDR.
– If the block configured in reception, the FIFO request related to a read request operation from the SAI_xDR.
This flag can generate an interrupt if FREQIE bit is set in SAI_xIM register.
Bit 2 **WCKCFG**: Wrong clock configuration flag.
This bit is read only.
0: Clock configuration is correct
1: Clock configuration does not respect the rule concerning the frame length specification defined in Section 53.4.6: Frame synchronization (configuration of FRL[7:0] bit in the SAI_xFRCR register)
This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0.
It can generate an interrupt if WCKCFGIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CWCKCFG bit in SAI_xCLRFR register.

Bit 1 **MUTEDET**: Mute detection.
This bit is read only.
0: No MUTE detection on the SD input line
1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frames
This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTECNT bit in the SAI_xCR2 register).
It can generate an interrupt if MUTEDETIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CMUTEDET in the SAI_xCLRFR register.

Bit 0 **OVRUDR**: Overrun / underrun.
This bit is read only.
0: No overrun/underrun error.
1: Overrun/underrun error detection.
The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.
It can generate an interrupt if OVRUDRIE bit is set in SAI_xIM register.
This flag is cleared when the software sets COVRUDR bit in SAI_xCLRFR register.

### 53.6.14 SAI clear flag register (SAI_ACLRFR)
Address offset: 0x01C
Reset value: 0x0000 0000
Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CLFSDET**: Clear late frame synchronization detection flag.
This bit is write only.
Programming this bit to 1 clears the LFSDET flag in the SAI_xSR register.
This bit is not used in AC’97 or SPDIF mode.
Reading this bit always returns the value 0.

Bit 5 **CAFSDET**: Clear anticipated frame synchronization detection flag.
This bit is write only.
Programming this bit to 1 clears the AFSDET flag in the SAI_xSR register.
It is not used in AC’97 or SPDIF mode.
Reading this bit always returns the value 0.

Bit 4 **CCNRDY**: Clear Codec not ready flag.
This bit is write only.
Programming this bit to 1 clears the CNRDY flag in the SAI_xSR register.
This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register.
Reading this bit always returns the value 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CWCKCFG**: Clear wrong clock configuration flag.
This bit is write only.
Programming this bit to 1 clears the WCKCFG flag in the SAI_xSR register.
This bit is used only when the audio block is set as master (MODE[1] = 0) and NODIV = 0 in the SAI_xCR1 register.
Reading this bit always returns the value 0.

Bit 1 **CMUTEDET**: Mute detection flag.
This bit is write only.
Programming this bit to 1 clears the MUTEDET flag in the SAI_xSR register.
Reading this bit always returns the value 0.

Bit 0 **COVRUDR**: Clear overrun / underrun.
This bit is write only.
Programming this bit to 1 clears the OVRUDR flag in the SAI_xSR register.
Reading this bit always returns the value 0.

### 53.6.15 SAI clear flag register (SAI_BCLRFR)

RM0481 Rev 1 2509/3119
Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **CLFSDET**: Clear late frame synchronization detection flag.
This bit is write only.
Programming this bit to 1 clears the LFSDET flag in the SAI_xSR register.
This bit is not used in AC’97 or SPDIF mode.
Reading this bit always returns the value 0.

Bit 5  **CAFSDET**: Clear anticipated frame synchronization detection flag.
This bit is write only.
Programming this bit to 1 clears the AFSDET flag in the SAI_xSR register.
It is not used in AC’97 or SPDIF mode.
Reading this bit always returns the value 0.

Bit 4  **CCNRDY**: Clear Codec not ready flag.
This bit is write only.
Programming this bit to 1 clears the CNRDY flag in the SAI_xSR register.
This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register.
Reading this bit always returns the value 0.

Bit 3  Reserved, must be kept at reset value.

Bit 2  **CWCKCFG**: Clear wrong clock configuration flag.
This bit is write only.
Programming this bit to 1 clears the WCKCFG flag in the SAI_xSR register.
This bit is used only when the audio block is set as master (MODE[1] = 0) and NODIV = 0 in the SAI_xCR1 register.
Reading this bit always returns the value 0.

Bit 1  **CMUTEDET**: Mute detection flag.
This bit is write only.
Programming this bit to 1 clears the MUTEDET flag in the SAI_xSR register.
Reading this bit always returns the value 0.

Bit 0  **COVRUDR**: Clear overrun / underrun.
This bit is write only.
Programming this bit to 1 clears the OVRUDR flag in the SAI_xSR register.
Reading this bit always returns the value 0.

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CKEN2:** Clock enable of bitstream clock number 2
- This bit is set and cleared by software.
- 0: SAI_CK2 clock disabled
- 1: SAI_CK2 clock enabled

Note: **It is not recommended to configure this bit when PDMEN = 1.**
- **SAI_CK2 might not be available for all SAI instances. Refer to Section 53.3: SAI implementation for details.**
Bit 8 **CKEN1**: Clock enable of bitstream clock number 1
This bit is set and cleared by software.
0: SAI_CK1 clock disabled
1: SAI_CK1 clock enabled

*Note*: It is not recommended to configure this bit when PDMEN = 1.
SAI_CK1 might not be available for all SAI instances. Refer to Section 53.3: SAI implementation for details.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **MICNBR[1:0]**: Number of microphones
This bit is set and cleared by software.
00: Configuration with 2 microphones
01: Configuration with 4 microphones
10: Configuration with 6 microphones
11: Configuration with 8 microphones

*Note*: It is not recommended to configure this field when PDMEN = 1.*
The complete set of data lines might not be available for all SAI instances. Refer to Section 53.3: SAI implementation for details.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **PDMEN**: PDM enable
This bit is set and cleared by software. This bit enables to control the state of the PDM interface block.
Make sure that the SAI in already operating in TDM master mode before enabling the PDM interface.
0: PDM interface disabled
1: PDM interface enabled

### 53.6.19 SAI PDM delay register (SAI_PDMDLY)

Address offset: 0x0048
Reset value: 0x0000 0000
Bit 31  Reserved, must be kept at reset value.

Bits 30:28  **DLYM4R[2:0]**: Delay line for second microphone of **pair 4**

  This bit is set and cleared by software.
  000: No delay
  001: Delay of 1 $T_{SAI\_CK}$ period
  010: Delay of 2 $T_{SAI\_CK}$ periods
  ...
  111: Delay of 7 $T_{SAI\_CK}$ periods

  This field can be changed on-the-fly.
  Note:  **This field can be used only if D4 line is available.** Refer to Section 53.3: SAI implementation to check if it is available.

Bit 27  Reserved, must be kept at reset value.

Bits 26:24  **DLYM4L[2:0]**: Delay line for first microphone of pair 4

  This bit is set and cleared by software.
  000: No delay
  001: Delay of 1 $T_{SAI\_CK}$ period
  010: Delay of 2 $T_{SAI\_CK}$ periods
  ...
  111: Delay of 7 of $T_{SAI\_CK}$ periods

  This field can be changed on-the-fly.
  Note:  **This field can be used only if D4 line is available.** Refer to Section 53.3: SAI implementation to check if it is available.

Bit 23  Reserved, must be kept at reset value.

Bits 22:20  **DLYM3R[2:0]**: Delay line for second microphone of pair 3

  This bit is set and cleared by software.
  000: No delay
  001: Delay of 1 $T_{SAI\_CK}$ period
  010: Delay of 2 $T_{SAI\_CK}$ periods
  ...
  111: Delay of 7 $T_{SAI\_CK}$ periods

  This field can be changed on-the-fly.
  Note:  **This field can be used only if D3 line is available.** Refer to Section 53.3: SAI implementation to check if it is available.

Bit 19  Reserved, must be kept at reset value.

Bits 18:16  **DLYM3L[2:0]**: Delay line for first microphone of pair 3

  This bit is set and cleared by software.
  000: No delay
  001: Delay of 1 $T_{SAI\_CK}$ period
  010: Delay of 2 $T_{SAI\_CK}$ periods
  ...
  111: Delay of 7 $T_{SAI\_CK}$ periods

  This field can be changed on-the-fly.
  Note:  **This field can be used only if D3 line is available.** Refer to Section 53.3: SAI implementation to check if it is available.
Serial audio interface (SAI)

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **DLYM2R[2:0]**: Delay line for second microphone of pair 2
   This bit is set and cleared by software.
   000: No delay
   001: Delay of 1 $T_{SAI\_CK}$ period
   010: Delay of 2 $T_{SAI\_CK}$ periods
   ...  
   111: Delay of 7 $T_{SAI\_CK}$ periods

   This field can be changed on-the-fly.
   *Note: This field can be used only if D2 line is available. Refer to Section 53.3: SAI implementation to check if it is available.*

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **DLYM2L[2:0]**: Delay line for first microphone of pair 2
   This bit is set and cleared by software.
   000: No delay
   001: Delay of 1 $T_{SAI\_CK}$ period
   010: Delay of 2 $T_{SAI\_CK}$ periods
   ...  
   111: Delay of 7 $T_{SAI\_CK}$ periods

   This field can be changed on-the-fly.
   *Note: This field can be used only if D2 line is available. Refer to Section 53.3: SAI implementation to check if it is available.*

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **DLYM1R[2:0]**: Delay line adjust for second microphone of pair 1
   This bit is set and cleared by software.
   000: No delay
   001: Delay of 1 $T_{SAI\_CK}$ period
   010: Delay of 2 $T_{SAI\_CK}$ periods
   ...  
   111: Delay of 7 $T_{SAI\_CK}$ periods

   This field can be changed on-the-fly.
   *Note: This field can be used only if D1 line is available. Refer to Section 53.3: SAI implementation to check if it is available.*

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **DLYM1L[2:0]**: Delay line adjust for first microphone of pair 1
   This bit is set and cleared by software.
   000: No delay
   001: Delay of 1 $T_{SAI\_CK}$ period
   010: Delay of 2 $T_{SAI\_CK}$ periods
   ...  
   111: Delay of 7 $T_{SAI\_CK}$ periods

   This field can be changed on-the-fly.
   *Note: This field can be used only if D1 line is available. Refer to Section 53.3: SAI implementation to check if it is available.*

Refer to Section 2.3 for the register boundary addresses.
54 FD controller area network (FDCAN)

54.1 Introduction

The controller area network (CAN) subsystem (see Figure 771) consists of one CAN module, a shared message RAM and a configuration block. Refer to the memory map for the base address of each of these parts.

The modules (FDCAN) are compliant with ISO 11898-1: 2015 (CAN protocol specification version 2.0 part A, B) and CAN FD protocol specification version 1.0.

A 0.8-Kbyte message RAM per FDCAN instance implements filters, receive FIFOs, transmit event FIFOs and transmit FIFOs.

The CAN subsystem I/O signals and pins are detailed, respectively, in Table 576 and Figure 771.

54.2 FDCAN main features

- Conform with CAN protocol version 2.0 part A, B and ISO 11898-1: 2015, -4
- CAN FD with maximum 64 Data bytes supported
- CAN error logging
- AUTOSAR and J1939 support
- Improved acceptance filtering
- Two receive FIFOs of three payloads each (up to 64 bytes per payload)
- Separate signaling on reception of high priority messages
- Configurable Transmit FIFO / queue of three payload (up to 64 bytes per payload)
- Transmit event FIFO
- Programmable loop-back test mode
- Maskable module interrupts
- Two clock domains: APB bus interface and CAN core kernel clock
- Power down support
54.3 FDCAN functional description

The FDCAN peripheral provides two interrupt lines, `fdcan_intr0_it` and `fdcan_intr1_it`.

By programming EINT0 and EINT1 bits in FDCAN_IIE register, the interrupt lines can be separately enabled or disabled.

**CAN core**

The CAN core contains the protocol controller and receive / transmit shift registers. It handles all ISO 11898-1: 2015 protocol functions and supports both 11-bit and 29-bit identifiers.

**Sync**

The Sync block synchronizes signals from the APB clock domain to the CAN kernel clock domain and vice versa.
**Tx handler**

Controls the message transfer from the Message RAM to the CAN core. A maximum of three Tx buffers is available for transmission. Tx buffer can be used as Tx FIFO or a Tx queue. Tx event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.

**Rx handler**

Controls the transfer of received messages from the CAN core to the external Message RAM. The Rx handler supports two receive FIFOs, for storage of all messages that have passed acceptance filtering. An Rx timestamp is stored together with each message. Up to 28 filters can be defined for 11-bit IDs, up to 8 filters for 29-bit IDs.

**APB interface**

Connects the FDCAN to the APB bus for configuration registers, controller configuration and RAM access.

**Message RAM interface**

Connects the FDCAN access to an external 1-Kbyte Message RAM through a RAM controller / arbiter.

### 54.3.1 Bit timing

The bit timing logic monitors the serial bus-line and performs sampling and adjustment of the sample point by synchronizing on the start-bit edge and resynchronizing on the following edges.

As shown in Figure 773, its operation may be explained simply by splitting the bit time in three segments, as follows:

- **Synchronization segment (SYNC_SEG):** a bit change is expected to occur within this time segment, having a fixed length of one time quantum (1 x tq).
- **Bit segment 1 (BS1):** defines the location of the sample point. It includes the PROP_SEG and PHASE_SEG1 of the CAN standard. Its duration is programmable between 1 and 16 time quanta, but may be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of various nodes of the network.
- **Bit segment 2 (BS2):** defines the location of the transmit point. It represents the PHASE_SEG2 of the CAN standard, its duration is programmable between one and eight time quanta, but may also be automatically shortened to compensate for negative phase drifts.
The baud rate is the inverse of bit time (baud rate = 1 / bit time), which, in turn, is the sum of three components. **Figure 773** indicates that bit time = \( t_{\text{SyncSeg}} + t_{\text{BS1}} + t_{\text{BS2}} \), where:

- for the nominal bit time
  - \( t_q = (\text{FDCAN\_NBTP\_NBRP}[8:0] + 1) \times t_{\text{fc}} \)
  - \( t_{\text{SyncSeg}} = t_q \)
  - \( t_{\text{BS1}} = t_q \times (\text{FDCAN\_NBTP\_NTSEG1}[7:0] + 1) \)
  - \( t_{\text{BS2}} = t_q \times (\text{FDCAN\_NBTP\_NTSEG2}[6:0] + 1) \)

- for the data bit time
  - \( t_q = (\text{FDCAN\_DBTP\_DBRP}[4:0] + 1) \times t_{\text{fc}} \)
  - \( t_{\text{SyncSeg}} = t_q \)
  - \( t_{\text{BS1}} = t_q \times (\text{FDCAN\_DBTP\_DTSEG1}[4:0] + 1) \)
  - \( t_{\text{BS2}} = t_q \times (\text{FDCAN\_DBTP\_DTSEG2}[3:0] + 1) \)

The (Re)Synchronization jump width (SJW) defines an upper bound for the amount of lengthening or shortening of the bit segments. It is programmable between one and four time quanta.

A valid edge is defined as the first transition in a bit time from dominant to recessive bus level, provided the controller itself does not send a recessive bit.

If a valid edge is detected in BS1 instead of SYNC_SEG, BS1 is extended by up to SJW so that the sample point is delayed.

Conversely, if a valid edge is detected in BS2 instead of SYNC_SEG, BS2 is shortened by up to SJW so that the transmit point is moved earlier.

As a safeguard against programming errors, the configuration of the Bit timing register is only possible while the device is in Standby mode. Registers FDCAN\_DBTP and FDCAN\_NBTP (dedicated, respectively, to data and nominal bit timing) are only accessible when CCCR.CCE and CCCR.INIT are set.

**Note:** For a detailed description of the CAN bit timing and resynchronization mechanism refer to the ISO 11898-1 standard.

### 54.3.2 Operating modes

#### Configuration

Access to IP version, hardware and input clock divider configuration. When the clock divider is set to 0, the primary input clock is used as it is.
Software initialization

Software initialization is started by setting INIT bit in FDCAN_CCCR register, either by software or by a hardware reset, or by going Bus_Off. While INIT bit in FDCAN_CCCR register is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output FDCAN_TX is recessive (high). The EML (error management logic) counters are unchanged. Setting INIT bit in FDCAN_CCCR does not change any configuration register. Clearing INIT bit in FDCAN_CCCR finishes the software initialization. Afterwards the bit stream processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the FDCAN configuration registers is only enabled when both INIT bit in FDCAN_CCCR register and CCE bit in FDCAN_CCCR register are set.

CCE bit in FDCAN_CCCR register can only be set/cleared while INIT bit in FDCAN_CCCR is set. CCE bit in FDCAN_CCCR register is automatically cleared when INIT bit in FDCAN_CCCR is cleared.

The following registers are reset when CCE bit in FDCAN_CCCR register is set:

- FDCAN_HPMS - High priority message status
- FDCAN_RXF0S - Rx FIFO 0 status
- FDCAN_RXF1S - Rx FIFO 1 status
- FDCAN_TXFQS - Tx FIFO/Queue status
- FDCAN_TXBRP - Tx buffer request pending
- FDCAN_TXBTO - Tx buffer transmission occurred
- FDCAN_TXBCF - Tx buffer cancellation finished
- FDCAN_TXEFS - Tx event FIFO status

The timeout counter value TOC bit in FDCAN_TOCV register is preset to the value configured by TOP bit in FDCAN_TOCC register when CCE bit in FDCAN_CCCR is set.

In addition the state machines of the Tx Handler and Rx handler are held in idle state while CCE bit in FDCAN_CCCR is set.

The following registers can be written only when CCE bit in FDCAN_CCCR register is cleared:

- TXBAR - Tx buffer add request
- TXBCR - Tx buffer cancellation request

TEST bit in FDCAN_CCCR and MON bit in FDCAN_CCCR can only be set by software while both INIT bit in CCCR and CCE bit in CCCR register are set. Both bits may be reset at any time. DAR bit in FDCAN_CCCR can only be set/cleared while both INIT bit in FDCAN_CCCR and CCE bit in FDCAN_CCCR are set.

Normal operation

The FDCAN default operating mode after hardware reset is event-driven CAN communication. TT Operation Mode is not supported.

Once the FDCAN is initialized and INIT bit in FDCAN_CCCR register is cleared, the FDCAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into the Rx FIFO 0 or Rx FIFO 1.
For messages to be transmitted, Tx FIFO or Tx queue can be initialized or updated. Automated transmission on reception of remote frames is not supported.

**CAN FD operation**

There are two variants in the FDCAN protocol:

1. **Long frame mode (LFM)**, where the data field of a CAN frame may be longer than eight bytes
2. **Fast frame mode (FFM)**, where control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate compared to the beginning and to the end of the frame

Fast Frame Mode can be used in combination with Long Frame Mode.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers are decoded as FDF bit: FDF recessive signifies a CAN FD frame, while FDF dominant signifies a classic CAN frame.

In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside this CAN FD frame is switched. A CAN FD bit rate switch is signified by res dominant and BRS recessive. The coding of res recessive is reserved for future expansion of the protocol. In case the FDCAN receives a frame with FDF recessive and res recessive, it signals a Protocol exception event by setting bit PSR.PXE. When Protocol exception handling is enabled (CCCR.PXHD = 0), this causes the operation state to change from Receiver (PSR.ACT = 10) to Integrating (PSR.ACT = 00) at the next sample point. In case Protocol exception Handling is disabled (CCCR.PXHD = 1), the FDCAN treats a recessive res bit as a form error and responds with an error frame.

CAN FD operation is enabled by programming CCCR.FDOE. In case CCCR.FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a classic CAN frame is transmitted can be configured via bit FDF in the respective Tx buffer element. With CCCR.FDOE = 0, received frames are interpreted as classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx buffer element is set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set.

With CCCR.FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format. With CCCR.FDOE = 1 and CCCR.BRSE = 0, only bit FDF of a Tx buffer element is evaluated. With CCCR.FDOE = 1 and CCCR.BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.
A mode change during CAN operation is recommended only under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case, disable the CAN FD bit rate switching option for transmissions.
- During system startup, all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN partial networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming is completed. Then all nodes switch back to Classic CAN communication.

In the FDCAN format, the coding of the DLC differs from the one of the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15 (that in standard CAN all code a data field of 8 bytes) are coded according to Table 577.

In CAN FD Fast frames, the bit timing is switched inside the frame, after the BRS (bit rate switch) bit, if this bit is recessive. Before the BRS bit, in the FDCAN arbitration phase, the standard CAN bit timing is used as defined by the Bit timing and prescaler register BTP. In the following FDCAN data phase, the fast CAN bit timing is used as defined by the Fast bit timing and prescaler register FBTP. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the FDCAN kernel clock frequency. For example, with a FDCAN kernel clock frequency of 20 MHz and the shortest configurable bit time of four time quanta (tq), the bit rate in the data phase is 5 Mbit/s.

In both data frame formats (CAN FD long frames and CAN FD fast frames), the value of bit ESI (error status indicator) is determined by the transmitter error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant. In CAN FD remote frames the ESI bit is always transmitted dominant, independent of the transmitter error state. The data length code of CAN FD remote frames is transmitted as 0.

In case a FDCAN Tx buffer is configured for FDCAN transmission with DLC > 8, the first eight bytes are transmitted as configured in the Tx buffer while the remaining part of the data field is padded with 0xCC. When the FDCAN receives a FDCAN frame with DLC > 8, the first eight bytes of that frame are stored into the matching Rx FIFO. The remaining bytes are discarded.

**Transceiver delay compensation**

During the data phase of a FDCAN transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin FDCAN_TX the protocol controller receives the transmitted data from its local CAN transceiver via pin FDCAN_RX. The received data is delayed by the CAN transceiver loop delay. If this delay is

<table>

</tr>
</tbody>
</table>
greater than TSEG1 (time segment before sample point), a bit error is detected. Without transceiver delay compensation, the bit rate in the data phase of a FDCAN frame is limited by the transceivers loop delay.

The FDCAN implements a delay compensation mechanism to compensate the CAN transceiver loop delay, thereby enabling transmission with higher bit rates during the FDCAN data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the secondary sample point (SSP). If a bit error is detected, the transmitter reacts on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit DBTP.TDC.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the FDCAN transmit output pin FDCAN_TX through the transceiver to the receive input pin FDCAN_RX plus the transmitter delay compensation offset as configured by TDCR.TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq (minimum time quantum, that is one period of fdcan_tq_ck clock).

PSR.TDCV shows the actual transmitter delay compensation value. PSR.TDCV is cleared when CCCR.INIT is set and is updated at each transmission of an FD frame while DBTP.TDC is set.

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the FDCAN:

- The sum of the measured delay from FDCAN_Tx to FDCAN_Rx and the configured transmitter delay compensation offset TDCR.TDCO has to be lower than 6 bit times in the data phase.
- The sum of the measured delay from FDCAN_TX to FDCAN_RX and the configured transmitter delay compensation offset TDCR.TDCO has to be lower than or equal to 127 mtq. If the sum exceeds this value, the maximum value (127 mtq) is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, which stops checking received bits at the SSPs.

If transmitter delay compensation is enabled by programming DBTP.TDC = 1, the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input pin FDCAN_TX of the transmitter. The resolution of this measurement is one mtq.
To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit (resulting in a too early SSP position), the use of a transmitter delay compensation filter window can be enabled by programming TDCR.TDCF. This defines a minimum value for the SSP position. Dominant edges on FDCAN_RX, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least TDCR.TDCF and FDCAN_RX is low.

**Restricted operation mode**

In Restricted operation mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters (ECR.REC, ECR.TEC) are frozen while error logging (ECR.CEL) is active. The software can set the FDCAN into Restricted operation mode by setting bit CCCR.ASM. The bit can only be set by software when both CCCR.CCE and CCCR.INIT are set to 1. The bit can be cleared by software at any time.

Restricted operation mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted operation mode the software has to reset CCCR.ASM.

The Restricted operation mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted operation mode after it has received a valid frame.

**Note:** The Restricted operation mode must not be combined with the Loop back mode (internal or external).
Bus monitoring mode

The FDCAN is set in Bus monitoring mode by setting CCCR.MON bit. In Bus monitoring mode (for more details refer to ISO11898-1, 10.12 Bus monitoring), the FDCAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the FDCAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the FDCAN can monitor it, even if the CAN bus remains in recessive state. In Bus monitoring mode the TXBRP register is held in reset state.

The Bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. **Figure 775** shows the connection of FDCAN_TX and FDCAN_RX signals to the FDCAN in Bus monitoring mode.

**Figure 775. Pin control in Bus monitoring mode**

Disabled automatic retransmission (DAR) mode

According to the CAN specification (see ISO11898-1, 6.3.3 Recovery Management), the FDCAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled.

Frame transmission in DAR mode

In DAR mode all transmissions are automatically canceled after they have been started on the CAN bus. A Tx buffer Tx Request Pending bit TXBRP.TRPx is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, or has been aborted due to lost arbitration, or when an error has occurred during frame transmission.
• Successful transmission
  – Corresponding Tx buffer transmission occurred bit TXBTO[TOx] set
  – Corresponding Tx buffer cancellation finished bit TXBCF[CFx] not set
• Successful transmission in spite of cancellation
  – Corresponding Tx buffer transmission occurred bit TXBTO[TOx] set
  – Corresponding Tx buffer cancellation finished bit TXBCF[CFx] set
• Arbitration loss or frame transmission disturbed
  – Corresponding Tx buffer transmission occurred bit TXBTO[TOx] not set
  – Corresponding Tx buffer cancellation finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

Power down (Sleep mode)

The FDCAN can be set into power down mode controlled by clock stop request input via CC control register CCCR[CSR]. As long as the clock stop request is active, bit CCCR[CSR] is read as 1.

When all pending transmission requests have completed, the FDCAN waits until bus idle state is detected. Then the FDCAN sets then CCCR[INIT] to 1 to prevent any further CAN transfers. Now the FDCAN acknowledges that it is ready for power down by setting CCCR[CSA] to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] has no effect. Now the module clock inputs may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting CC control register flag CCCR.CSR. The FDCAN acknowledges this by resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

Test modes

To enable write access to FDCAN test register (FDCAN_TEST), bit CCCR.TEST must be set to 1, thus enabling the configuration of test modes and functions.

Four output functions are available for the CAN transmit pin FDCAN_TX by programming TEST.TX. In addition to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the FDCAN bit timing and it can drive constant dominant or recessive values. The actual value at pin FDCAN_RX can be read from TEST.RX. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN kernel clock and APB clock domain, there may be a delay of several APB clock periods between writing to TEST.TX until the new configuration is visible at FDCAN_TX output pin. This applies also when reading FDCAN_RX input pin via TEST.RX.

Note: Test modes must be used for production tests or self test only. The software control for FDCAN_TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.
External loop back mode

The FDCAN can be set in External loop back mode by programming TEST.LBCK to 1. In Loop Back mode, the FDCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. Figure 776 shows the connection of transmit and receive signals FDCAN_TX and FDCAN_RX to the FDCAN in External loop back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the FDCAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data / remote frame) in Loop back mode. In this mode the FDCAN performs an internal feedback from its transmit output to its receive input. The actual value of the FDCAN_RX input pin is disregarded by the FDCAN. The transmitted messages can be monitored at the FDCAN_TX transmit pin.

Internal loop back mode

Internal loop back mode is entered by programming bits TEST.LBCK and CCCR.MON to 1. This mode can be used for a “Hot selftest”, meaning the FDCAN can be tested without affecting a running CAN system connected to the FDCAN_TX and FDCAN_RX pins. In this mode, FDCAN_RX pin is disconnected from the FDCAN and FDCAN_TX pin is held recessive. Figure 776 shows the connection of FDCAN_TX and FDCAN_RX pins to the FDCAN in case of Internal loop back mode.

Figure 776. Pin control in Loop back mode

Timestamp generation

For timestamp generation the FDCAN supplies a 16-bit wrap-around counter. A prescaler TSCC.TCP can be configured to clock the counter in multiples of CAN bit times (1 ... 16). The counter is readable via TSCV[TCV]. A write access to register TSCV resets the counter to 0. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception/transmission the counter value is captured and stored into the timestamp section of a Rx FIFO (RXTS[15:0]) or Tx event FIFO (TXTS[15:0]) element.

By programming bit TSCC.TSS, a 16-bit timestamp can be used.
**Debug mode behavior**

In debug mode the set / reset on read feature is automatically disabled during the debugger register access, and enabled during normal MCU operation.

**Timeout counter**

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx event FIFO the FDCAN supplies a 16-bit timeout counter. It operates as downcounter and uses the same prescaler controlled by TSCC[TCP] as the Timestamp Counter. The timeout counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC]. The timeout counter can only be started while CCCR[INIT] = 0. It is stopped when CCCR[INIT] = 1, e.g. when the FDCAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC[TOP] and continues downcounting.

When the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Downcounting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches 0, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

*Note:* The clock signal for the timeout counter is derived from the CAN core sample point signal. Therefore the point in time where the timeout counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN core. If the baud rate switch feature in FDCAN is used, the timeout counter is clocked differently in arbitration and data fields.

**54.3.3 Message RAM**

The Message RAM has a 32-bit width, and the FDCAN module is configured to allocate up to 212 words in it. It is not necessary to configure each of the sections shown in Figure 777.

![Figure 777. Message RAM configuration](attachment:image.png)
When the FDCAN addresses the Message RAM, it addresses 32-bit words (aligned), not a single byte. The RAM addresses are 32-bit words, i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored.

In case of multiple instances the RAM start address for the FDCANn is computed by end address + 4 of FDCANn-1, and the FDCANn end address is computed by FDCANn start address + 0x0350 - 4.

As an example, for two instances:
- FDCAN1:
  - start address: 0x0000
  - end address: 0x034C (as in Figure 777)
- FDCAN2:
  - start address = 0x034C (FDCAN1 end address) + 4 = 0x0350
  - end address = 0x0350 (FDCAN2 start address) + 0x0350 - 4 = 0x069C.

**Rx handling**

The Rx handler controls the acceptance filtering, the transfer of received messages to Rx to one of the two Rx FIFOs, as well as the Rx FIFO Put and Get Indexes.

**Acceptance filter**

The FDCAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and another for extended identifiers. These filters can be assigned to Rx FIFO 0 or Rx FIFO 1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element.

Following filter elements are not evaluated for this message.

The main features are:
- Each filter element can be configured as
  - range filter (from - to)
  - filter for one or two dedicated IDs
  - classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled/disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:
- Global Filter Configuration (RXGFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:
- Store received frame in FIFO 0 or FIFO 1
- Reject received frame
- Set High priority message interrupt flag IR[HPM]
- Set High priority message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1.
Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx FIFO has been found, the Message Handler starts writing the received message data in 32-bit portions to the matching Rx FIFO. If the CAN protocol controller has detected an error condition (e.g. CRC error), this message is discarded with the following impact:

- **Rx FIFO**
  Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see PSR.LEC and PSR.DLEC. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in *Rx FIFO overwrite mode* have to be considered.

*Note:* When an accepted message is written to one of the two Rx FIFOs, the unmodified received identifier is stored independently from the used filter(s). The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

**Range filter**

The filter matches for all received frames with Message IDs in the range defined by SF1ID/SF2ID and EF1ID/EF2ID.

There are two possibilities when range filtering is used together with extended frames:

- **EFT = 00:** The Message ID of received frames is AND-ed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- **EFT = 11:** The Extended ID AND Mask (XIDAM) is not used for range filtering

**Filter for dedicated IDs**

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SF1ID = SF2ID and EF1ID = EF2ID.

**Classic bit mask filter**

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SF1ID/EF1ID is used as Message ID filter, while SF2ID/EF2ID is used as filter mask.

A 0 bit at the filter mask masks out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are 0, all Message IDs match.

**Standard message ID filtering**

*Figure 778* shows the flow for standard message ID (11-bit Identifier) filtering. The standard message ID filter element is described in *Section 54.3.8*.

Controlled by the Global filter configuration (RXGFC) message ID, Remote transmission request bit (RTR), and the Identifier extension bit (IDE) of received frames are compared against the list of configured filter elements.
Figure 778. Standard Message ID filter path

- **Valid frame received**
- **Bit identifier**: 11-bit, 29-bit
- **Remote frame**: Yes, No
- **Receive filter list enabled**: Yes, No
- **RXGFC[RRFS]**: 0, 1
- **RXGFC[LSS[7:0]]**: > 0, = 0
- **Match filter element #0**: Yes, No
- **RXGFC[ANFS[1]]**: = 1, = 0
- **Target FIFO full**: Yes, No
- **Append to target FIFO**: Yes
- **Accept non-matching frames**: Yes, No
- **Acceptance or Rejection**: Reject, Accept
- **Discard frame**: Yes

- RXGFC[LSS[7:0]] > 0
- RXGFC[RRFS] = 0
- RXGFC[ANFS[1]] = 1
- RXGFC[ANFS[1]] = 0
Extended message ID filtering

Figure 779 shows the flow for extended message ID (29-bit identifier) filtering. The Extended Message ID filter element is described in Section 54.3.9.

Controlled by the Global filter configuration RXGFC and the Extended ID filter Configuration RXGFC message ID, Remote transmission request bit (RTR), and the Identifier extension bit (IDE) of received frames are compared against the list of configured filter elements.

Figure 779. Extended Message ID filter path

The Extended ID AND Mask (XIDAM) is AND-ed with the received identifier before the filter list is executed.
**Rx FIFOs**

Rx FIFO 0 and Rx FIFO 1 can hold up to three elements each.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1, see *Acceptance filter*. The Rx FIFO element is described in *Section 54.3.5*.

When an Rx FIFO full condition is signaled by IR[RFnF], no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. In case a message is received while the corresponding Rx FIFO is full, this message is discarded and interrupt flag IR[RFnL] is set.

When reading from an Rx FIFO, Rx FIFO Get Index RXFnS[FnGI] + FIFO Element Size has to be added to the corresponding Rx FIFO start address [FnSA].

**Rx FIFO blocking mode**

The Rx FIFO blocking mode is configured by RXGFC.FnOM = 0. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS.FnPI = RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signaled by RXFnS.FnF = 1. In addition interrupt flag IR.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signaled by RXFnS.RFnL = 1. In addition interrupt flag IR.RFnL is set.

**Rx FIFO overwrite mode**

The Rx FIFO overwrite mode is configured by RXGFC.FnOM = 1.

When an Rx FIFO full condition (RXFnS.FnPI = RXFnS.FnGI) is signaled by RXFnS.FnF = 1, the next message accepted for the FIFO overwrites the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signaled, reading of the Rx FIFO elements must start at least at get index + 1. This is because it can happen that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO.

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS.FnF = 0).

**Tx handling**

The Tx Handler handles transmission requests for the Tx FIFO, and the Tx queue. It controls the transfer of transmit messages to the CAN core, the Put and Get Indices, and the Tx event FIFO. Up to three Tx buffers can be set up for message transmission. The CAN
message data field is configured to 64 bytes, Tx FIFO allocates eighteen 32-bit words for storage of a Tx element.

Note: AUTOSAR requires at least three Tx queue buffers and support of transmit cancellation.

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx buffer with lowest Message ID) when the Tx buffer Request Pending register TXBRP is updated, or when a transmission has been started.

Transmit pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority must be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If, as an example, CAN ECU-1 has the feature enabled and is requested by its application software to transmit four messages, it waits, after the first successful message transmission, for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The feature is controlled by TXP bit in CCCR register. If the bit is set, the FDCAN, each time it has successfully transmitted a message, pauses for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is disabled (CCCR.TXP = 0).

This feature looses up burst transmissions coming from a single node and it protects against "babbling idiot" scenarios where the application program erroneously requests too many transmissions.

Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to 0. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx
FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx buffers in the order these messages have been written to the Tx FIFO. The FDCAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF]= 1) is signaled. In this case no further messages must be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing 1 to the TXBAR bit related to the Tx buffer referenced by the Tx FIFO Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers must not exceed the number of free Tx buffers as indicated by the Tx FIFO Free Level.

When a transmission request for the Tx buffer referenced by the Get Index is canceled, the Get Index is incremented to the next Tx buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates eighteen 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx FIFO buffer is calculated by adding four times the Put Index TXFQS[TFQPI] (0 ... 2) to the Tx buffer Start Address TBSA.

**Tx queue**

Tx queue operation is configured by programming TXBC[TFQM] to 1. Messages stored in the Tx queue are transmitted starting with the message with the lowest Message ID (highest priority).

In case of mixing of standard and extended Message IDs, the standard Message IDs are compared to bits [28:18] of extended Message IDs.

In case that multiple queue buffers are configured with the same Message ID, the queue buffer with the lowest buffer number is transmitted first.

New messages have to be written to the Tx buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx buffer. In case that the Tx queue is full (TXFQS[TFQF] = 1), the Put Index is not valid and no further message must be written to the Tx queue until at least one of the requested messages has been sent out or a pending transmission request has been canceled.

The application may use register TXBRP instead of the Put Index and may place messages to any Tx buffer without pending transmission request.

A Tx queue buffer allocates eighteen 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx queue buffer is calculated by adding four times the Tx queue Put Index TXFQS[TFQPI] (0 ... 2) to the Tx buffer Start Address TBSA.
Transmit cancellation

The FDCAN supports transmit cancellation. To cancel a requested transmission from a Tx queue buffer the Host has to write a 1 to the corresponding bit position (= number of Tx buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of register TXBCF to 1.

In case a transmit cancellation is requested while a transmission from a Tx buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note: In case a pending transmission is canceled immediately before it has been started, there is a short time window where no transmission is started even if another message is pending in the node. This may enable another node to transmit a message that may have a priority lower than that of the second message in the node.

Tx event handling

To support Tx event handling the FDCAN has implemented a Tx event FIFO. After the FDCAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx event FIFO element. To link a Tx event to a Tx event FIFO element, the Message Marker from the transmitted Tx buffer is copied into the Tx event FIFO element.

The Tx event FIFO is configured to three elements. The Tx event FIFO element is described in Tx FIFO.

The purpose of the Tx event FIFO is to decouple handling transmit status information from transmit message handling i.e. a Tx buffer holds only the message to be transmitted, while the transmit status is stored separately in the Tx event FIFO. This has the advantage, especially when operating a dynamically managed transmit queue, that a Tx buffer can be used for a new message immediately after successful transmission. There is no need to save transmit status information from a Tx buffer before overwriting that Tx buffer.

When a Tx event FIFO full condition is signaled by IR[TEFF], no further elements are written to the Tx event FIFO until at least one element has been read out and the Tx event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx event FIFO is full, this event is discarded and interrupt flag IR[TEFL] is set.

When reading from the Tx event FIFO, two times the Tx event FIFO Get Index TXEFS[EFGI] has to be added to the Tx event FIFO start address EFSA.

54.3.4 FIFO acknowledge handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index, see Section 54.4.23 and Section 54.4.25. Writing to the FIFO acknowledge index sets the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

1. When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.
2. When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO Get Index.
Due to the fact that the CPU has free access to the FDCAN Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High priority message from one of the two Rx FIFOs. In this case the FIFO Acknowledge Index must not be written because this would set the Get Index to a wrong position and also alters the FIFO Fill Level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The FDCAN does not check for erroneous values.

54.3.5 FDCAN Rx FIFO element

Two Rx FIFOs are configured in the Message RAM. Each Rx FIFO section can be configured to store up to three received messages. The structure of an Rx FIFO element is described in Table 579, the description is provided in Table 580.

</table>

1. The ESI bit of the transmit buffer is OR-ed with the error passive flag to decide the value of the ESI bit in the transmitted FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node always transmits the ESI bit recessive.
2. When RTR = 1, the FDCAN transmits a remote frame according to ISO11898-1, even if CCCR.FDOE enables the transmission in CAN FD format.

3. Bits ESI, FDF, and BRS are only evaluated when CAN FD operation is enabled CCCR.FDOE = 1. Bit BRS is only evaluated when in addition CCCR.BRSE = 1.

### 54.3.7 FDCAN Tx event FIFO element

Each element stores information about transmitted messages. By reading the Tx event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx event FIFO can be obtained from register TXEFS.

| T1 Bits 19:16 DLC[3:0] | Data length code  
0 - 8: Frame with 0-8 Data bytes transmitted  
9 - 15: Frame with 8 Data bytes transmitted |
| E1 Bits 15:0 TXTS[15:0] | Tx Timestamp  
Timestamp counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP]. |
1. With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behavior as with SFEC = 000).

Note: In case a reserved value is configured, the filter element is considered disabled.

**54.3.9 FDCAN Extended message ID filter element**

Up to 8 filters element can be configured for 29-bit extended IDs. When accessing an Extended message ID filter element, its address is the Filter list extended start address FLESA plus two times the index of the filter element (0 … 7).

**Table 587. Extended message ID filter element**

</thead>
</table>
| F0 Bits 31:29 EFEC[2:0] | Extended filter element configuration  
All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101 or 110 a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match.  
– 000: Disable filter element  
– 001: Store in Rx FIFO 0 if filter matches  
– 010: Store in Rx FIFO 1 if filter matches  
– 011: Reject ID if filter matches  
– 100: Set priority if filter matches  
– 101: Set priority and store in FIFO 0 if filter matches  
– 110: Set priority and store in FIFO 1 if filter matches  
– 111: Not used |
| F0 Bits 28:0 EFID1[28:0] | Extended filter ID 1  
First ID of extended ID filter element. When filtering for Rx FIFO, this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism. |
| F1 Bits 31:30 EFTI[1:0] | Extended filter type  
– 00: Range filter from EF1ID to EF2ID (EF2ID >= EF1ID)  
– 01: Dual ID filter for EF1ID or EF2ID  
– 10: Classic filter: EF1ID = filter, EF2ID = mask  
– 11: Range filter from EF1ID to EF2ID (EF2ID >= EF1ID), XIDAM mask not applied |
| F1 Bit 29 | Not used |
| F1 Bits 28:0 EFID2[28:0] | Extended filter ID 2  
Second ID of extended ID filter element. |
# FDCAN registers

## 54.4.1 FDCAN core release register (FDCAN_CREL)

<tr>
<td>15</td>
<td>14</td>
</tr>
</tbody>
</table>

**Bits 31:0**  ETV[31:0]: Endianness test value  
The endianness test value is 0x8765 4321.

**Note:** The register read must give the reset value to ensure no endianness issue.
54.4.3  FDCAN data bit timing and prescaler register (FDCAN_DBTP)

Address offset: 0x000C
Reset value: 0x0000 0A33

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN time quantum may be programmed in the range of 1 to 32 FDCAN clock periods. tq = (DBRP + 1) FDCAN clock period.

DTSEG1 is the sum of Prop_Seg and Phase_Seg1. DTSEG2 is Phase_Seg2. Therefore the length of the bit time is (programmed values) [DTSEG1 + DTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is 0, meaning the data for the next bit is available at the first clock edge after the sample point.

| Bit 31:24 | Reserved, must be kept at reset value. |
| Bit 23 | **TDC**: Transceiver delay compensation |
| 0: Transceiver delay compensation disabled |
| 1: Transceiver delay compensation enabled |
| Bit 20:16 | **DBRP[4:0]**: Data bit rate prescaler |
| The value by which the oscillator frequency is divided to generate the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 31. The hardware interpreters this value as the value programmed plus 1. |
| Bit 15:13 | Reserved, must be kept at reset value. |
| Bit 12:8 | **DTSEG1[4:0]**: Data time segment before sample point |
| Valid values are 0 to 31. The value used by the hardware is the one programmed, incremented by 1, i.e. tBS1 = (DTSEG1 + 1) x tq. |
| Bit 7:4 | **DTSEG2[3:0]**: Data time segment after sample point |
| Valid values are 0 to 15. The value used by the hardware is the one programmed, incremented by 1, i.e. tBS2 = (DTSEG2 + 1) x tq. |
| Bit 3:0 | **DSJW[3:0]**: Synchronization jump width |
| Valid values are 0 to 15. The value used by the hardware is the one programmed, incremented by 1: tSJW = (DSJW + 1) x tq. |

**Note:**  With an FDCAN clock of 8 MHz, the reset value 0x00000A33 configures the FDCAN for a fast bitrate of 500 kbit/s.

**Note:**  The data phase bit rate must be higher to or equal to the nominal bit rate.
54.4.4 FDCAN test register (FDCAN_TEST)

Write access to the this register is enabled by setting bit CCCR[TEST] to 1. All register functions are set to their reset values when bit CCCR[TEST] is reset.

Loop Back mode and software control of Tx pin FDCANx_TX are hardware test modes. Programming TX differently from 00 may disturb the message transfer on the CAN bus.

Address offset: 0x0010
Reset value: 0x0000 0000

Bits 31:8  Reserved, must be kept at reset value.

Bit 7  RX: Receive pin
  Monitors the actual value of pin FDCANx_RX
  0: The CAN bus is dominant (FDCANx_RX = 0)
  1: The CAN bus is recessive (FDCANx_RX = 1)

Bits 6:5  TX[1:0]: Control of transmit pin
  00: Reset value, FDCANx_TX TX is controlled by the CAN core, updated at the end of the CAN bit time
  01: Sample point can be monitored at pin FDCANx_TX
  10: Dominant (0) level at pin FDCANx_TX
  11: Recessive (1) at pin FDCANx_TX

Bit 4  LBCK: Loop back mode
  0: Reset value, Loop Back mode is disabled
  1: Loop Back mode is enabled (see Power down (Sleep mode))

Bits 3:0  Reserved, must be kept at reset value.
**54.4.5 FDCAN RAM watchdog register (FDCAN_RWD)**

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access starts the Message RAM Watchdog Counter with the value configured by the RWD[WDC] bits.

The counter is reloaded with RWD[WDC] bits when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to 0, the counter stops and interrupt flag IR[WDI] bit is set. The RAM Watchdog Counter is clocked by the fdcan_pclk clock.

Address offset: 0x0014

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **WDV[7:0]**: Watchdog value

Actual message RAM watchdog counter value.

Bits 7:0 **WDC[7:0]**: Watchdog configuration

Start value of the message RAM watchdog counter. With the reset value of 00, the counter is disabled.

These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of FDCAN_CCCR register are set to 1.

**54.4.6 FDCAN CC control register (FDCAN_CCCR)**

Address offset: 0x0018

Reset value: 0x0000 0001

For details about setting and resetting of single bits, see *Software initialization*.

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **NISO**: Non ISO operation

If this bit is set, the FDCAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0.

0: CAN FD frame format according to ISO11898-1

1: CAN FD frame format according to Bosch CAN FD Specification V1.0
Bit 14 **TXP:**
If this bit is set, the FDCAN pauses for two CAN bit times before starting the next transmission after successfully transmitting a frame.
0: disabled
1: enabled

Bit 13 **EFBI:** Edge filtering during bus integration
0: Edge filtering disabled
1: Two consecutive dominant tq required to detect an edge for hard synchronization

Bit 12 **PXHD:** Protocol exception handling disable
0: Protocol exception handling enabled
1: Protocol exception handling disabled

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **BRSE:** FDCAN bit rate switching
0: Bit rate switching for transmissions disabled
1: Bit rate switching for transmissions enabled

Bit 8 **FDOE:** FD operation enable
0: FD operation disabled
1: FD operation enabled

Bit 7 **TEST:** Test mode enable
0: Normal operation, register TEST holds reset values
1: Test Mode, write access to register TEST enabled

Bit 6 **DAR:** Disable automatic retransmission
0: Automatic retransmission of messages not transmitted successfully enabled
1: Automatic retransmission disabled

Bit 5 **MON:** Bus monitoring mode
Bit MON can only be set by software when both CCE and INIT are set to 1. The bit can be reset by the Host at any time.
0: Bus monitoring mode disabled
1: Bus monitoring mode enabled

Bit 4 **CSR:** Clock stop request
0: No clock stop requested
1: Clock stop requested. When clock stop is requested, first INIT and then CSA is set after all pending transfer requests have been completed and the CAN bus reached idle.

Bit 3 **CSA:** Clock stop acknowledge
0: No clock stop acknowledged
1: FDCAN may be set in power down by stopping APB clock and kernel clock.
Bit 2 **ASM**: ASM restricted operation mode

The restricted operation mode is intended for applications that adapt themselves to different CAN bit rates. The application tests different bit rates and leaves the Restricted operation Mode after it has received a valid frame. In the optional Restricted operation Mode the node is able to transmit and receive data and remote frames and it gives acknowledge to valid frames, but it does not send active error frames or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. Bit ASM can only be set by software when both CCE and INIT are set to 1. The bit can be reset by the software at any time.

0: Normal CAN operation
1: Restricted operation Mode active

Bit 1 **CCE**: Configuration change enable

0: The CPU has no write access to the protected configuration registers.
1: The CPU has write access to the protected configuration registers (while CCCR.INIT = 1).

Bit 0 **INIT**: Initialization

0: Normal operation
1: Initialization started

**Note**: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

### 54.4.7 FDCAN nominal bit timing and prescaler register (FDCAN_NBTP)

Address offset: 0x001C

Reset value: 0x0600 0A03

This register is only writable if bits CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programed in the range of 4 to 81 tq. The CAN time quantum may be programmed in the range of \([1 \ldots 1024]\) FDCAN kernel clock periods.

\[tq = (BRP + 1) \text{ FDCAN clock period fdcan clk}\]

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2. Therefore the length of the bit time is (programmed values) \([\text{NTSEG1} + \text{NTSEG2} + 3]\) tq or (functional values) \([\text{Sync_Seg} + \text{Prop_Seg} + \text{Phase_Seg1} + \text{Phase_Seg2}]\) tq.

The Information Processing Time (IPT) is 0, meaning the data for the next bit is available at the first clock edge after the sample point.
Note: With a CAN kernel clock of 48 MHz, the reset value of 0x06000A03 configures the FDCAN for a bit rate of 3 Mbit/s.

54.4.8 FDCAN timestamp counter configuration register (FDCAN_TSCC)

Address offset: 0x0020
Reset value: 0x0000 0000

| Bit 31:20 | Reserved, must be kept at reset value. |
| Bit 19:16 | TCP[3:0]: Timestamp counter prescaler |
| Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1 … 16]. |
| The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. |
| In CAN FD mode the internal timestamp counter TCP does not provide a constant time base due to the different CAN bit times between arbitration phase and data phase. Thus CAN FD requires an external counter for timestamp generation (TSS = 10). |
| These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1. |

| Bit 15:2 | Reserved, must be kept at reset value. |
| Bit 7 | Reserved, must be kept at reset value. |
| Bit 6:0 | TSS[1:0]: |
| rw rw |

Bits 31:25 NSJW[6:0]: Nominal (re)synchronization jump width
Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that the used value is the one programmed incremented by one.
These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bits 24:16 NBRP[8:0]: Bit rate prescaler
Value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values are 0 to 511. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bits 15:8 NTSEG1[7:0]: Nominal time segment before sample point
Valid values are 0 to 255. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
These are protected write (P) bits, write access is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 NTSEG2[6:0]: Nominal time segment after sample point
Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
54.4.9 **FDCAN timestamp counter value register (FDCAN_TSCV)**

Address offset: 0x0024

Reset value: 0x0000 0000

<table>
<thead>
<tr>

<th>Bit 16</th>
</tr>
</thead>
</table>

TSC[15:0] = 0x00

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TSC[15:0]: Timestamp counter**

The internal/external timestamp counter value is captured on start of frame (both Rx and Tx). When TSCC[TSS] = 01, the timestamp counter is incremented in multiples of CAN bit times [1 … 16] depending on the configuration of TSCC[TCP]. A wrap around sets interrupt flag IR[TSW]. Write access resets the counter to 0.

When TSCC.TSS = 10, TSC reflects the external timestamp counter value. A write access has no impact.

**Note:** A “wrap around” is a change of the Timestamp Counter value from non-0 to 0 that is not caused by write access to TSCV.

54.4.10 **FDCAN timeout counter configuration register (FDCAN_TOCC)**

Address offset: 0x0028

Reset value: 0xFFFF 0000

Bits 31:23 Reserved

Bits 22:20 **REC[8:0]:** Error counter

Bits 19:17 **TEC[7:0]:** Time error counter
Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **CEL[7:0]: CAN error logging**

The counter is incremented each time when a CAN protocol error causes the transmit error counter or the receive error counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag IR[EL0].

Access type is RX: reset on read.

Bit 15 **RP**: Receive error passive

0: The receive error counter is below the error passive level of 128.
1: The receive error counter has reached the error passive level of 128.

Bits 14:8 **REC[6:0]: Receive error counter**

Actual state of the receive error counter, values between 0 and 127.

Bits 7:0 **TEC[7:0]: Transmit error counter**

Actual state of the transmit error counter, values between 0 and 255.

When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.

### 54.4.13 FDCAN protocol status register (FDCAN_PSR)

Address offset: 0x0044

Reset value: 0x0000 0707

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **TDCV[6:0]: Transmitter delay compensation value**

Position of the secondary sample point, defined by the sum of the measured delay from FDCAN_TX to FDCAN_RX and TDCR.TDCO. The SSP position is, in the data phase, the number of minimum time quanta (mtq) between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **PXE**: Protocol exception event

0: No protocol exception event occurred since last read access
1: Protocol exception event occurred

Bit 13 **REDL**: Received FDCAN message

This bit is set independent of acceptance filtering.
0: Since this bit was reset by the CPU, no FDCAN message has been received.
1: Message in FDCAN format with EDL flag set has been received.

Access type is RX: reset on read.
Bit 12 **RBRS**: BRS flag of last received FDCAN message
   This bit is set together with REDL, independent of acceptance filtering.
   0: Last received FDCAN message did not have its BRS flag set.
   1: Last received FDCAN message had its BRS flag set.
   Access type is RX: reset on read.

Bit 11 **RESI**: ESI flag of last received FDCAN message
   This bit is set together with REDL, independent of acceptance filtering.
   0: Last received FDCAN message did not have its ESI flag set.
   1: Last received FDCAN message had its ESI flag set.
   Access type is RX: reset on read.

Bits 10:8 **DLEC[2:0]**: Data last error code
   Type of last error that occurred in the data phase of a FDCAN format frame with its BRS flag set. Coding is the same as for LEC. This field is cleared to 0 when a FDCAN format frame with its BRS flag set has been transferred (reception or transmission) without error.
   Access type is RS: set on read.

Bit 7 **BO**: Bus_Off status
   0: The FDCAN is not Bus_Off.
   1: The FDCAN is in Bus_Off state.

Bit 6 **EW**: Warning Status
   0: Both error counters are below the Error_Warning limit of 96.
   1: At least one of error counter has reached the Error_Warning limit of 96.

Bit 5 **EP**: Error passive
   0: The FDCAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected.
   1: The FDCAN is in the Error_Passive state.

Bits 4:3 **ACT[1:0]**: Activity
   Monitors the module’s CAN communication state.
   00: Synchronizing: node is synchronizing on CAN communication.
   01: Idle: node is neither receiver nor transmitter.
   10: Receiver: node is operating as receiver.
   11: Transmitter: node is operating as transmitter.
Bits 2:0 **LEC[2:0]**: Last error code

The LEC indicates the type of the last error to occur on the CAN bus. This field is cleared to 0 when a message has been transferred (reception or transmission) without error.

- **000**: No Error: No error occurred since LEC has been reset by successful reception or transmission.
- **001**: Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.
- **010**: Form Error: A fixed format part of a received frame has the wrong format.
- **011**: AckError: The message transmitted by the FDCAN was not acknowledged by another node.
- **100**: Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant.
- **101**: Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value 0), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).
- **110**: CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.
- **111**: NoChange: Any read access to the Protocol status register re-initializes the LEC to ‘7’. When the LEC shows the value ‘7’, no CAN bus event was detected since the last CPU read access to the Protocol status register.

Access type is RS: set on read.

Note: When a frame in FDCAN format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) is shown in FLEC instead of LEC. An error in a fixed stuff bit of a FDCAN CRC sequence is shown as a Form Error, not Stuff Error.

Note: The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT]. If the device goes Bus_Off, it sets CCCR.INIT of its own, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device then waits for 129 occurrences of Bus_Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters are reset. During the waiting time after the reset of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

### 54.4.14 FDCAN transmitter delay compensation register (FDCAN_TDCR)

Address offset: 0x0048

Reset value: 0x0000 0000

</table>
The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position.

Writing a 0 has no effect. A hard reset clears the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

Address offset: 0x0050
Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 ARA: Access to reserved address
0: No access to reserved address occurred
1: Access to reserved address occurred

Bit 22 PED: Protocol error in data phase (data bit time is used)
0: No protocol error in data phase
1: Protocol error in data phase detected (PSR.DLEC different from 0,7)

Bit 21 PEA: Protocol error in arbitration phase (nominal bit time is used)
0: No protocol error in arbitration phase
1: Protocol error in arbitration phase detected (PSR.LEC different from 0,7)

Bit 20 WDI: Watchdog interrupt
0: No message RAM watchdog event occurred
1: Message RAM watchdog event due to missing READY
Bit 19  **BO**: Bus_Off status  
0: Bus_Off status unchanged  
1: Bus_Off status changed  

Bit 18  **EW**: Warning status  
0: Error_Warning status unchanged  
1: Error_Warning status changed  

Bit 17  **EP**: Error passive  
0: Error_Passive status unchanged  
1: Error_Passive status changed  

Bit 16  **ELO**: Error logging overflow  
0: CAN error logging counter did not overflow.  
1: Overflow of CAN error logging counter occurred.  

Bit 15  **TOO**: Timeout occurred  
0: No timeout  
1: Timeout reached  

Bit 14  **MRAF**: Message RAM access failure  
The flag is set when the Rx handler:  
1. has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx handler starts processing of the following message.  
2. was unable to write a message to the message RAM. In this case message storage is aborted.  
In both cases the FIFO put index is not updated. The partly stored message is overwritten when the next message is stored to this location.  
The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the FDCAN is switched into Restricted operation Mode (see Restricted operation mode). To leave Restricted operation Mode, the Host CPU has to reset CCCR.ASM.  
0: No Message RAM access failure occurred  
1: Message RAM access failure occurred  

Bit 13  **TSW**: Timestamp wraparound  
0: No timestamp counter wrap-around  
1: Timestamp counter wrapped around  

Bit 12  **TEFL**: Tx event FIFO element lost  
0: No Tx event FIFO element lost  
1: Tx event FIFO element lost  

Bit 11  **TEFF**: Tx event FIFO full  
0: Tx event FIFO Not full  
1: Tx event FIFO full  

Bit 10  **TEFN**: Tx event FIFO New Entry  
0: Tx event FIFO unchanged  
1: Tx handler wrote Tx event FIFO element.  

Bit 9  **TFE**: Tx FIFO empty  
0: Tx FIFO non-empty  
1: Tx FIFO empty
Bit 8  **TCF**: Transmission cancellation finished
   0: No transmission cancellation finished
   1: Transmission cancellation finished

Bit 7  **TC**: Transmission completed
   0: No transmission completed
   1: Transmission completed

Bit 6  **HPM**: High-priority message
   0: No high-priority message received
   1: High-priority message received

Bit 5  **RF1L**: Rx FIFO 1 message lost
   0: No Rx FIFO 1 message lost
   1: Rx FIFO 1 message lost

Bit 4  **RF1F**: Rx FIFO 1 full
   0: Rx FIFO 1 not full
   1: Rx FIFO 1 full

Bit 3  **RF1N**: Rx FIFO 1 new message
   0: No new message written to Rx FIFO 1
   1: New message written to Rx FIFO 1

Bit 2  **RF0L**: Rx FIFO 0 message lost
   0: No Rx FIFO 0 message lost
   1: Rx FIFO 0 message lost

Bit 1  **RF0F**: Rx FIFO 0 full
   0: Rx FIFO 0 not full
   1: Rx FIFO 0 full

Bit 0  **RF0N**: Rx FIFO 0 new message
   0: No new message written to Rx FIFO 0
   1: New message written to Rx FIFO 0

54.4.16  **FDCAN interrupt enable register (FDCAN_IE)**

The settings in the interrupt enable register determine which status changes in the interrupt
register are signaled on an interrupt line.

Address offset: 0x00054

Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **LSE[3:0]:** List size extended
- 0: No extended message ID filter
- 1 to 8: Number of extended message ID filter elements
- >8: Values greater than 8 are interpreted as 8.
  These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **LSS[4:0]:** List size standard
- 0: No standard message ID filter
- 1 to 28: Number of standard message ID filter elements
- >28: Values greater than 28 are interpreted as 28.
  These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **F0OM:** FIFO 0 operation mode (overwrite or blocking)
- This is a protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bit 8 **F1OM:** FIFO 1 operation mode (overwrite or blocking)
- This is a protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ANFS[1:0]:** Accept Non-matching frames standard
- Defines how received messages with 11-bit IDs that do not match any element of the filter list are treated.
  - 00: Accept in Rx FIFO 0
  - 01: Accept in Rx FIFO 1
  - 10: Reject
  - 11: Reject
  These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.
Bits 3:2 **ANFE[1:0]**: Accept non-matching frames extended

Defines how received messages with 29-bit IDs that do not match any element of the filter list are treated.

- 00: Accept in Rx FIFO 0
- 01: Accept in Rx FIFO 1
- 10: Reject
- 11: Reject

These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bit 1 **RRFS**: Reject remote frames standard

- 0: Filter remote frames with 11-bit standard IDs
- 1: Reject all remote frames with 11-bit standard IDs

These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

Bit 0 **RRFE**: Reject remote frames extended

- 0: Filter remote frames with 29-bit standard IDs
- 1: Reject all remote frames with 29-bit standard IDs

These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

### 54.4.20 FDCAN extended ID and mask register (FDCAN_XIDAM)

**Bits 31:29** Reserved, must be kept at reset value.

**Bits 28:0** **EIDM[28:0]**: Extended ID mask

For acceptance filtering of extended frames the Extended ID AND Mask is AND-ed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to 1 the mask is not active.

These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.
54.4.21 FDCAN high-priority message status register (FDCAN\_HPMS)

This register is updated every time a Message ID filter element configured to generate a priority event match. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Address offset: 0x0088

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **FLST**: Filter list

- Indicates the filter list of the matching filter element.
- 0: Standard filter list
- 1: Extended filter list

Bits 14:13 Reserved, must be kept at reset value.

Bits 12:8 **FIDX[4:0]**: Filter index

- Index of matching filter element. Range is 0 to RXGFC[LSS] - 1 or RXGFC[LSE] - 1.

Bits 7:6 **MSI[1:0]**: Message storage indicator

- 00: No FIFO selected
- 01: FIFO overrun
- 10: Message stored in FIFO 0
- 11: Message stored in FIFO 1

Bits 5:3 Reserved, must be kept at reset value.

Bits 2:0 **BIDX[2:0]**: Buffer index

- Index of Rx FIFO element to which the message was stored. Only valid when MSI[1] = 1.

54.4.22 FDCAN Rx FIFO 0 status register (FDCAN\_RXF0S)

Address offset: 0x0090

2568/3119   RM0481 Rev 1
54.4.25  FDCAN Rx FIFO 1 acknowledge register (FDCAN_RXF1A)

Address offset: 0x009C

Reset value: 0x0000 0000

Bits 31:3  Reserved, must be kept at reset value.

Bits 2:0  F1AI[2:0]: Rx FIFO 1 acknowledge index
After the Host has read a message or a sequence of messages from Rx FIFO 1 it has to write the buffer index of the last element read from Rx FIFO 1 to F1AI. This sets the Rx FIFO 1 get index RXF1S[F1GI] to F1AI + 1 and update the FIFO 1 Fill Level RXF1S[F1FL].
54.4.26  FDCAN Tx buffer configuration register (FDCAN_TXBC)

Address offset: 0x00C0
Reset value: 0x0000 0000

| Bit 31:25  | Reserved, must be kept at reset value. |
| Bit 24    | **TFQM**: Tx FIFO/queue mode |
| 0: Tx FIFO operation |
| 1: Tx queue operation. |
| This is a protected write (P) bit, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1. |

| Bit 21    | **TFQF**: Tx FIFO/queue full |
| 0: Tx FIFO/queue not full |
| 1: Tx FIFO/queue full |

| Bit 19:18 | Reserved, must be kept at reset value. |
| Bit 17:16 | **TFQPI[1:0]**: Tx FIFO/queue put index |
| Tx FIFO/queue write index pointer, range 0 to 3 |

| Bit 15:10 | Reserved, must be kept at reset value. |
| Bit 9:8   | **TFGI[1:0]**: Tx FIFO get index |
| Tx FIFO read index pointer, range 0 to 3. Read as 0 when Tx queue operation is configured (TXBC.TFQM = 1) |

54.4.27  FDCAN Tx FIFO/queue status register (FDCAN_TXFQS)

The Tx FIFO/Queue status is related to the pending Tx requests listed in register TXBRP. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (TXBRP not yet updated).

Address offset: 0x00C4
Reset value: 0x0000 0003

| Bit 31:22 | Reserved, must be kept at reset value. |

</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **TRP[2:0]: Transmission request pending**

Each Tx buffer has its own transmission request pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been canceled via register TXBCR.

After a TXBRP bit has been set, a Tx scan is started to check for the pending Tx request with the highest priority (Tx buffer with lowest Message ID).

A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset.

After a cancellation has been requested, a finished cancellation is signaled via TXBCF after successful transmission together with the corresponding TXBTO bit when the transmission has not yet been started at the point of cancellation when the transmission has been aborted due to lost arbitration when an error occurred during frame transmission

In DAR mode all transmissions are automatically canceled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions.

0: No transmission request pending
1: Transmission request pending

**Note:** *TXBRP bits set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx buffer, this Add Request is canceled immediately, the corresponding TXBRP bit is reset.*
54.4.29  FDCAN Tx buffer add request register (FDCAN_TXBAR)

</tbody>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bits 2:0  **AR[2:0]: Add request**

Each Tx buffer has its own add request bit. Writing a 1 sets the corresponding add request bit; writing a 0 has no impact. This enables the Host to set transmission requests for multiple Tx buffers with one write to TXBAR. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed.

0: No transmission request added
1: Transmission requested added.

**Note:** If an add request is applied for a Tx buffer with pending transmission request (corresponding TXBRP bit already set), the request is ignored.

54.4.30  FDCAN Tx buffer cancellation request register (FDCAN_TXBCR)

**Bits 3:0 PDIV[3:0]**: input clock divider
The APB clock can be divided prior to be used by the CAN sub system. The rate must be computed using the divider output clock.

- 0000: Divide by 1
- 0001: Divide by 2
- 0010: Divide by 4
- 0011: Divide by 6
- 0100: Divide by 8
- 0101: Divide by 10
- 0110: Divide by 12
- 0111: Divide by 14
- 1000: Divide by 16
- 1001: Divide by 18
- 1010: Divide by 20
- 1011: Divide by 22
- 1100: Divide by 24
- 1101: Divide by 26
- 1110: Divide by 28
- 1111: Divide by 30

These are protected write (P) bits, which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to 1.

### 54.4.38 FDCAN register map

**Table 589. FDCAN register map and reset values**

| Offset | Register | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

| Reset value | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 1 | 0 |

55 Universal serial bus full-speed host/device interface (USB)

55.1 Introduction
The USB peripheral implements an interface between a full-speed USB 2.0 bus and the APB2 bus.

USB suspend/resume are supported, which permits to stop the device clocks for low-power consumption.

55.2 USB main features
- USB specification version 2.0 full-speed compliant
- Supports both Host and Device modes
- Configurable number of endpoints from 1 to 8
- Dedicated packet buffer memory (SRAM) of 2048 bytes
- Cyclic redundancy check (CRC) generation/checking, Non-return-to-zero Inverted (NRZI) encoding/decoding and bit-stuffing
- Isochronous transfers support
- Double-buffered bulk/isochronous endpoint/channel support
- USB Suspend/Resume operations
- Frame locked clock pulse generation
- USB 2.0 Link Power Management support (Device mode only)
- Battery Charging Specification Revision 1.2 support (Device mode only)
- USB connect / disconnect capability (controllable embedded pull-up resistor on USB_DP line)

55.3 USB implementation
Table 590 describes the USB implementation in the devices.

55.4 USB functional description

Figure 780 shows the block diagram of the USB peripheral.

Figure 780. USB peripheral block diagram

General description and Device mode functionality

The USB peripheral provides a USB-compliant connection between the function implemented by the microcontroller and an external USB function which can be a host PC but also a USB Device. Data transfer between the external USB host or device and the system memory occurs through a dedicated packet buffer memory accessed directly by the USB peripheral. This dedicated memory size is 2048 bytes, and up to 16 mono-directional or 8 bidirectional endpoints can be used. The USB peripheral interfaces with the external USB Host or Device, detecting token packets, handling data transmission/reception, and processing handshake packets as required by the USB standard. Transaction formatting is performed by the hardware, including CRC generation and checking.
Each endpoint/channel is associated with a buffer description block indicating where the endpoint/channel-related memory area is located, how large it is or how many bytes must be transmitted. When a token for a valid function/endpoint pair is recognized by the USB peripheral, the related data transfer (if required and if the endpoint/channel is configured) takes place. The data buffered by the USB peripheral are loaded in an internal 16-bit register and memory access to the dedicated buffer is performed. When all the data have been transferred, if needed, the proper handshake packet over the USB is generated or expected according to the direction of the transfer.

At the end of the transaction, an endpoint/channel-specific interrupt is generated, reading status registers and/or using different interrupt response routines. The microcontroller can determine:

- which endpoint/channel has to be served,
- which type of transaction took place, if errors occurred (bit stuffing, format, CRC, protocol, missing ACK, over/underrun, etc.).

Special support is offered to isochronous transfers and high throughput bulk transfers, implementing a double buffer usage, which permits to always have an available buffer for the USB peripheral while the microcontroller uses the other one.

A special bit THR512 in register USB_ISTR allows notification of 512 bytes being received in (or transmitted from) the buffer. This bit must be used for long ISO packets (from 512 to 1023 bytes) as it facilitates early start or read/write of data. In this way, the first 512 bytes can be handled by software while avoiding use of double buffer mode. This bit works when only one ISO endpoint is configured.

The unit can be placed in low-power mode (SUSPEND mode), by writing in the control register, whenever required. At this time, all static power dissipation is avoided, and the USB clock can be slowed down or stopped. The detection of activity at the USB inputs, while in low-power mode, wakes the device up asynchronously. A special interrupt source can be connected directly to a wake-up line to permit the system to immediately restart the normal clock generation and/or support direct clock start/stop.

**Host mode and specific functionality**

A single bit, HOST, in register USB_CNTR permits Host mode to be activated. Host mode functionality permits the USB to talk to a remote peripheral. Supported functionality is aligned to Device mode and uses the same register structures to manage the buffers. The same number of endpoints can be supported in Host mode, however in Host mode the terminology “channel” is preferred, as each channel is in reality a combination of the connected device and the endpoint on that device. The basic mechanisms for packet transmission and reception are the same as those supported in Device mode.

When operating in Host mode, the USB is in charge of the bus and in order to do this must issue transaction requests corresponding to active periodic and non-periodic endpoints. A host frame scheduler assures efficient use of the frame. Connection to hubs is supported. Connection to low speed devices is supported, both with a direct connection and through a hub.

Double-buffered mode, as previously described in Device mode, is also supported in Host mode, in both bulk and isochronous channels. The THR512 functionality is also supported (but as in Device mode) only for ISO traffic.

**Note:** Unlike in Device mode, where there is a detection of battery charging capability (in order to facilitate fast charging), there is no integrated support in Host mode to present battery.
charging capability (CDP or DCP cases in the standard), the host port is always presented as a default standard data port (SDP).

**Note:** For LPM (link power management) this feature is not supported in Host mode.

### 55.4.1 Description of USB blocks used in both Device and Host modes

The USB peripheral implements all the features related to USB interfacing, which include the following blocks:

- USB physical interface (USB PHY): this block is maintaining the electrical interface to an external USB host. It contains the differential analog transceiver itself, controllable embedded pull-up resistor (connected to USB_DP line) and support for battery charging detection (BCD), multiplexed on same USB_DP and USB_DM lines. The output enable control signal of the analog transceiver (active low) is provided externally on USB_NOE. It can be used to drive some activity LED or to provide information about the actual communication direction to some other circuitry.

- Serial interface engine (SIE): the functions of this block include: synchronization pattern recognition, bit-stuffing, CRC generation and checking, PID verification/generation, and handshake evaluation. It must interface with the USB transceivers and uses the virtual buffers provided by the packet buffer interface for local data storage. This unit also generates signals according to USB peripheral events, such as start of frame (SOF), USB_Reset, data errors etc. and to endpoint related events like end of transmission or correct reception of a packet; these signals are then used to generate interrupts.

- Timer: this block generates a start-of-frame locked clock pulse and detects a global suspend (from the host) when no traffic has been received for 3 ms.

- Packet buffer interface: this block manages the local memory implementing a set of buffers in a flexible way, both for transmission and reception. It can choose the proper buffer according to requests coming from the SIE and locate them in the memory addresses pointed by the endpoint/channel registers. It increments the address after each exchanged byte until the end of packet, keeping track of the number of exchanged bytes and preventing the buffer to overrun the maximum capacity.

- Endpoint/channel-related registers: each endpoint/channel has an associated register containing the endpoint/channel type and its current status. For monodirectional/single-buffer endpoints, a single register can be used to implement two distinct endpoints. The number of registers is 8, allowing up to 16 monodirectional/single-buffer or up to 7 double-buffer endpoints in any combination. For example the USB peripheral can be programmed to have 4 double buffer endpoints and 8 single-buffer/mono-directional endpoints.

- Control registers: these are the registers containing information about the status of the whole USB peripheral and used to force some USB events, such as resume and power-down.

- Interrupt registers: these contain the interrupt masks and a record of the events. They can be used to inquire an interrupt reason, the interrupt status or to clear the status of a pending interrupt.

**Note:** * Endpoint/channel 0 is always used for control transfer in single-buffer mode.

The USB peripheral is connected to the APB2 bus through an APB2 interface, containing the following blocks:

- Packet memory: this is the local memory that physically contains the packet buffers. It can be used by the packet buffer interface, which creates the data structure and can be
accessed directly by the application software. The size of the packet memory is 2048 bytes, structured as 512 words of 32 bits.

- Arbiter: this block accepts memory requests coming from the APB2 bus and from the USB interface. It resolves the conflicts by giving priority to APB2 accesses, while always reserving half of the memory bandwidth to complete all USB transfers. This time-duplex scheme implements a virtual dual-port SRAM that allows memory access, while an USB transaction is happening. Multiword APB2 transfers of any length are also allowed by this scheme.

- Register mapper: this block collects the various byte-wide and bit-wide registers of the USB peripheral in a structured 32-bit wide word set addressed by the APB2.

- APB2 wrapper: this provides an interface to the APB2 for the memory and register. It also maps the whole USB peripheral in the APB2 address space.

- Interrupt mapper: this block is used to select how the possible USB events can generate interrupts and map them to the NVIC.

55.4.2 Description of host frame scheduler (HFS) specific to Host mode

The host frame scheduler is the hardware machine in charge to submit host channel requests on the bus according to the USB priority order and bandwidth access rules.

Host channels are divided in two categories:
- Periodic channels: isochronous and interrupt traffic types. With guaranteed bandwith access.
- Non-periodic channels: bulk and control traffic types. With best effort service.

The host frame scheduler organizes the full-speed frame in 3 sequential windows
- Periodic service window
- Non-periodic service window
- Black security window

At the start of a new frame the host scheduler:
1. First considers all periodic channels which were active (STAT bits VALID) at the start of frame
2. Executes single round of service of periodic channels, the periodic service window, in hardware priority order from CH#1 to CH#8. For bidirectional channels it executes the OUT direction first
3. When the periodic round is finished, HFS closes the periodic service window and stops servicing periodic traffic even if some periodic channel was re-enabled or some new channel was enabled after the SOF.
4. Starts servicing all non-periodic channels which are currently active (STAT bits VALID) in hardware priority order from CH#1 to CH#8. For bidirectional channels it executes the OUT direction first.
5. Executes multiple round-robin service cycles of non-periodic channels until almost the end of frame
6. Non periodic traffic can be requested at any time and is serviced by HFS with best effort latency, with the exception of a black security window at the end of the frame where new injected requests are directly postponed to the next frame to avoid babbles. This is also true for pending transactions which have not been serviced ahead of the security window.
55.5 Programming considerations for Device and Host modes

In the following sections, the expected interactions between the USB peripheral and the application program are described, in order to ease application software development.

55.5.1 Generic USB Device programming

This part describes the main tasks required of the application software in order to obtain USB compliant behavior. The actions related to the most general USB events are taken into account and paragraphs are dedicated to the special cases of double-buffered endpoints and isochronous transfers. Apart from system reset, an action is always initiated by the USB peripheral, driven by one of the USB events described below.

55.5.2 System and power-on reset

Upon system and power-on reset, the first operation the application software must perform is to provide all required clock signals to the USB peripheral and subsequently de-assert its reset signal so to be able to access its registers. The whole initialization sequence is hereafter described.

As a first step application software needs to activate register macrocell clock and de-assert macrocell specific reset signal using related control bits provided by device clock management logic.

After that, the analog part of the device related to the USB transceiver must be switched on using the PDWN bit in CNTR register, which requires a special handling. This bit is intended to switch on the internal voltage references that supply the port transceiver. This circuit has a defined startup time (t\text{STARTUP} specified in the datasheet) during which the behavior of the USB transceiver is not defined. It is thus necessary to wait this time, after setting the PDWN bit in the CNTR register, before removing the reset condition on the USB part (by clearing the USBRST bit in the CNTR register). Clearing the ISTR register removes any spurious pending interrupt before any other macrocell operation is enabled.

At system reset, the microcontroller must initialize all required registers and the packet buffer description table, to make the USB peripheral able to properly generate interrupts and data transfers. All registers not specific to any endpoint/channel must be initialized according to the needs of application software (choice of enabled interrupts, chosen address of packet buffers, etc.). Then the process continues as for the USB reset case (see further paragraph).

USB bus reset (RST_DCON interrupt) in Device mode

When this event occurs, the USB peripheral is put in the same conditions it is left by the system reset after the initialization described in the previous paragraph: communication is disabled in all endpoint registers (the USB peripheral does not respond to any packet). As a response to the USB reset event, the USB function must be enabled, having as USB address 0, implementing only the default control endpoint (endpoint address is 0 too). This is accomplished by setting the enable function (EF) bit of the USB_DADDR register and initializing the CHEP0R register and its related packet buffers accordingly. During USB enumeration process, the host assigns a unique address to this device, which must be written in the ADD[6:0] bits of the USB_DADDR register, and configures any other necessary endpoint.
When a RST_DCON interrupt is received, the application software is responsible to enable again the default endpoint of USB function 0 within 10 ms from the end of the reset sequence which triggered the interrupt.

**USB bus reset in Host mode**

In Host mode a bus reset is activated by setting the USBRST bit of the USB_CNTR register. It must subsequently be cleared by software once the minimum active reset time from the standard has been respected.

**Structure and usage of packet buffers**

Each bidirectional endpoint may receive or transmit data over the bus. The received data is stored in a dedicated memory buffer reserved for that endpoint, while another memory buffer contains the data to be transmitted by the endpoint. Access to this memory is performed by the packet buffer interface block, which delivers a memory access request and waits for its acknowledgment. Since the packet buffer memory has also to be accessed by the microcontroller, an arbitration logic takes care of the access conflicts, using half APB2 cycle for microcontroller access and the remaining half for the USB peripheral access. In this way, both agents can operate as if the packet memory would be a dual-port SRAM, without being aware of any conflict even when the microcontroller is performing back-to-back accesses. The USB peripheral logic uses a dedicated clock. The frequency of this dedicated clock is fixed by the requirements of the USB standard at 48 MHz, and this can be different from the clock used for the interface to the APB2 bus. Different clock configurations are possible where the APB2 clock frequency can be higher or lower than the USB peripheral one.

*Note:* Due to USB data rate and packet memory interface requirements, the APB2 clock must have a minimum frequency of 12 MHz to avoid data overrun/underrun problems.

Each endpoint is associated with two packet buffers (usually one for transmission and the other one for reception). Buffers can be placed anywhere inside the packet memory because their location and size is specified in a buffer description table, which is also located in the packet memory. Each table entry is associated to an endpoint register and it is composed of two 32-bit words so that table start address must always be aligned to an 8-byte boundary. Buffer descriptor table entries are described in Section 55.6.2: Buffer descriptor table. If an endpoint is unidirectional and it is neither an isochronous nor a double-buffered bulk, only one packet buffer is required (the one related to the supported transfer direction). Other table locations related to unsupported transfer directions or unused endpoints, are available to the user. Isochronous and double-buffered bulk endpoints have special handling of packet buffers (Refer to Section 55.5.5: Isochronous transfers in Device mode and Section 55.5.3: Double-buffered endpoints and usage in Device mode respectively). The relationship between buffer description table entries and packet buffer areas is depicted in Figure 781.

For Host mode different sections explain the buffer usage model, notably Section 55.5.6: Isochronous transfers in Host mode and Section 55.5.4: Double buffered channels: usage in Host mode.
Each packet buffer is used either during reception or transmission starting from the bottom. The USB peripheral never changes the contents of memory locations adjacent to the allocated memory buffers; if a packet bigger than the allocated buffer length is received (buffer overrun condition) the data is copied to the memory only up to the last available location.

**Endpoint initialization**

The first step to initialize an endpoint is to write appropriate values to the ADDRn_TX/ADDRn_RX fields in the CHEP_TXBD_n and CHEP_RXBD_n registers (in SRAM) so that the USB peripheral finds the data to be transmitted already available and the data to be received can be buffered. The UTYPE bits in the USB_CHEPnR register must be set according to the endpoint type, eventually using the EPKIND bit to enable any special required feature. On the transmit side, the endpoint must be enabled using the STATTX bits in the USB_CHEPnR register and COUNTn_TX must be initialized. For reception, STATRX bits must be set to enable reception and COUNTn_RX must be written with the allocated buffer size using the BLSIZE and NUM_BLOCK fields. Unidirectional endpoints, except isochronous and double-buffered bulk endpoints, need to initialize only bits and registers related to the supported direction. Once the transmission and/or reception are enabled, register USB_CHEPnR and locations ADDRn_TX/ADDRn_RX, COUNTn_TX/COUNTn_RX (respectively), must not be modified by the application software, as the hardware can...
change their value on the fly. When the data transfer operation is completed, notified by a CTR interrupt event, they can be accessed again to re-enable a new operation.

Data transmission in Device mode (IN packets)

When receiving an IN token packet, if the received address matches a configured and valid endpoint, the USB peripheral accesses the contents of CHEP_TXBD_n (fields ADDRn_TX and COUNTn_TX) inside the buffer descriptor table entry related to the addressed endpoint. The content of these locations is stored in its internal 16-bit registers ADDR and COUNT (not accessible by software). The packet memory is accessed again to read the first byte to be transmitted (refer to Structure and usage of packet buffers on page 2586) and the USB peripheral starts sending a DATA0 or DATA1 PID according to USB_CHEPnR bit DTOGTX. When the PID is completed, the first byte, read from buffer memory, is loaded into the output shift register to be transmitted on the USB bus. After the last data byte is transmitted, the computed CRC is sent. If the addressed endpoint is not valid, a NAK or STALL handshake packet is sent instead of the data packet, according to STATTX bits in the USB_CHEPnR register.

The ADDRn_TX field in the internal register CHEP_TXBD_n is used as a pointer to the current buffer memory location while COUNT is used to count the number of remaining bytes to be transmitted. Each half-word read from the packet buffer memory is transmitted over the USB bus starting from the least significant byte. Transmission buffer memory is read starting from the address pointed by ADDRn_TX for COUNTn_TX/4 words. If a transmitted packet is composed of an odd number of bytes, only the lower half of the last half-word accessed is used.

On receiving the ACK receipt by the host, the USB_CHEPnR register is updated in the following way: DTOGTX bit is toggled, the endpoint is made invalid by setting STATTX = 10 (NAK) and bit VTTX is set. The application software must first identify the endpoint, which is requesting microcontroller attention by examining the IDN and DIR bits in the USB_ISTR register. Servicing of the VTTX event starts, clearing the interrupt bit; the application software then prepares another buffer full of data to be sent, updates the COUNTn_TX table location with the number of byte to be transmitted during the next transfer, and finally sets STATTX to 11 (VALID) to re-enable transmission. While the STATTX bits are equal to 10 (NAK), any IN request addressed to that endpoint is NAKed, indicating a flow control condition: the USB host retries the transaction until it succeeds. It is mandatory to execute the sequence of operations in the above mentioned order to avoid losing the notification of a second IN transaction addressed to the same endpoint immediately following the one which triggered the CTR interrupt.

Data transmission in Host mode (OUT packets)

Data transmission in Host mode follows the same general principles as Device mode. The main differences are due to the protocol. For example the host initiates the transmission whereas the device responds to the incoming token.

ADDRn_TX must be set to the location in the packet memory reserved for the packet for transmission. The contents of an OUT packet are then written to that address in the packet memory and COUNTn_TX must be updated (when necessary) to indicate the number of bytes in the packet.

DEVADDR must be written for the correct endpoint and then STATTX must be set to 11 (VALID) in order to trigger the transmit. The transmission is then scheduled by the HFS.

After a successful transmission the CTR interrupt (correct transfer) is triggered. By examining IDN and DIR bits, the corresponding channel and direction is understood. On the
indicated channel, the STATTX field now has transitioned to DISABLE. In the case of a NAK being received (when the peripheral is not ready) STATTX is now in NAK. In the case of a STALL response, STATTX is in STALL. In this last case, the bus must be reset.

On receiving the ACK receipt by the device, the USB_CHEPnR register is updated in the following way: DTOGTX bit is toggled.

An error condition is signaled via the bits VTTX and ERR_TX in the case of:
- No handshake being received in time
- False EOP
- Bit stuffing error
- Invalid handshake PID

**Data reception in Device mode (OUT and SETUP packets)**

These two tokens are handled by the USB peripheral more or less in the same way; the differences in the handling of SETUP packets are detailed in the following paragraph about control transfers. When receiving an OUT/SETUP PID, if the address matches a valid endpoint, the USB peripheral accesses the contents of the ADDRn_RX and COUNTn_RX fields inside the buffer descriptor table entry related to the addressed endpoint. The content of the ADDRn_RX field is stored directly in its internal register ADDR. Internal register COUNT is now reset and the values of BLSIZE and NUM_BLOCK bit fields, which are read within USB_CHEP_RXBD_n content, are used to initialize BUF_COUNT, an internal 16-bit counter, which is used to check the buffer overrun condition (all these internal registers are not accessible by software). Data bytes subsequently received by the USB peripheral are packed in half-words (the first byte received is stored as least significant byte) and then transferred to the packet buffer starting from the address contained in the internal ADDR register while BUF_COUNT is decremented and COUNT is incremented at each byte transfer. When the end of DATA packet is detected, the correctness of the received CRC is tested and only if no errors occurred during the reception, an ACK handshake packet is sent back to the transmitting host.

In case of wrong CRC or other kinds of errors (bit-stuff violations, frame errors, etc.), data bytes are still copied in the packet memory buffer, at least until the error detection point, but the ACK packet is not sent and the ERR bit in USB_ISTR register is set. However, there is usually no software action required in this case: the USB peripheral recovers from reception errors and remains ready for the next transaction to come. If the addressed endpoint is not valid, a NAK or STALL handshake packet is sent instead of the ACK, according to bits STATRX in the USB_CHEPnR register, and no data is written in the reception memory buffers.

Reception memory buffer locations are written starting from the address contained in the ADDRn_RX for a number of bytes corresponding to the received data packet length, or up to the last allocated memory location, as defined by BLSIZE and NUM_BLOCK, whichever comes first. In this way, the USB peripheral never writes beyond the end of the allocated reception memory buffer area. If the length of the data packet payload (actual number of bytes used by the application) is greater than the allocated buffer, the USB peripheral detects a buffer overrun condition. In this case, a STALL handshake is sent instead of the usual ACK to notify the problem to the host, no interrupt is generated and the transaction is considered failed.

When the transaction is completed correctly, by sending the ACK handshake packet, the internal COUNT register is copied back in the COUNTn_RX location inside the buffer description table entry, leaving unaffected BLSIZE and NUM_BLOCK fields, which normally
do not require to be re-written, and the USB_CHEPnR register is updated in the following way: DTOGRX bit is toggled, the endpoint is made invalid by setting STATRX = 10 (NAK) and bit VTRX is set. If the transaction has failed due to errors or buffer overrun condition, none of the previously listed actions take place. The application software must first identify the endpoint, which is requesting microcontroller attention by examining the IDN and DIR bits in the USBISTR register. The VTRX event is serviced by first determining the transaction type (SETUP bit in the USB_CHEPnR register); the application software must clear the interrupt flag bit and get the number of received bytes reading the COUNTn_RX location inside the buffer description table entry related to the endpoint being processed.

After the received data is processed, the application software must set the STATRX bits to 11 (VALID) in the USB_CHEPnR, enabling further transactions. While the STATRX bits are equal to 10 (NAK), any OUT request addressed to that endpoint is NAKed, indicating a flow control condition: the USB host retries the transaction until it succeeds. It is mandatory to execute the sequence of operations in the above mentioned order to avoid losing the notification of a second OUT transaction addressed to the same endpoint following immediately the one which triggered the CTR interrupt.

Data reception in Host mode (IN packets)

Data reception in Host mode follows the same general principles as Device mode. The main differences are again due to the protocol. In the device, data can be received or not, depending on readiness after previous operations, whereas the host only requests receive data when it is ready and able to store them.

ADDRn_TX must be set to the location in the packet memory reserved for the packet for transmission. The contents received in the data phase response to the IN token packet are then written to that address in the packet memory and COUNTn_TX gets updated by hardware during this process to indicate the number of bytes in the packet.

DEVADDR must be written for the correct endpoint and then STATRX must be set to VALID in order to trigger the reception. The reception is then scheduled by the HFS.

After a successful reception the interrupt CTR (correct transfer) is triggered. By examining IDN and DIR bits, the corresponding channel and direction is understood. On the indicated channel, the STATRX field now has transitioned to DISABLE. In the case of a NAK being received (when the peripheral is not ready) STATRX now is in NAK. In the case of a STALL response, STATRX is in STALL. In this last case, the bus must be reset. During an IN packet an error condition is signaled via the bits VTRX and ERR_RX in case of:

- False EOP
- Bit stuffing error
- Wrong CRC

Control transfers in Device mode

Control transfers are made of a SETUP transaction, followed by zero or more data stages, all of the same direction, followed by a status stage (a zero-byte transfer in the opposite direction). SETUP transactions are handled by control endpoints only and are very similar to OUT ones (data reception) except that the values of DTOGTX and DTOGRX bits of the addressed endpoint registers are set to 1 and 0 respectively, to initialize the control transfer, and both STATTX and STATRX are set to 10 (NAK) to let software decide if subsequent transactions must be IN or OUT depending on the SETUP contents. A control endpoint must check SETUP bit in the USB_CHEPnR register at each VTRX event to distinguish normal OUT transactions from SETUP ones. A USB Device can determine the number and direction of data stages by interpreting the data transferred in the SETUP stage, and is
required to STALL the transaction in the case of errors. To do so, at all data stages before the last, the unused direction must be set to STALL, so that, if the host reverses the transfer direction too soon, it gets a STALL as a status stage.

While enabling the last data stage, the opposite direction must be set to NAK, so that, if the host reverses the transfer direction (to perform the status stage) immediately, it is kept waiting for the completion of the control operation. If the control operation completes successfully, the software changes NAK to VALID, otherwise to STALL. At the same time, if the status stage is an OUT, the STATUS_OUT (EPKIND in the USB_CHEPnR register) bit must be set, so that an error is generated if a status transaction is performed with non-zero data. When the status transaction is serviced, the application clears the STATUS_OUT bit and sets STATRX to VALID (to accept a new command) and STATTX to NAK (to delay a possible status stage immediately following the next setup).

Since the USB specification states that a SETUP packet cannot be answered with a handshake different from ACK, eventually aborting a previously issued command to start the new one, the USB logic does not permit a control endpoint to answer with a NAK or STALL packet to a SETUP token received from the host.

When the STATRX bits are set to 01 (STALL) or 10 (NAK) and a SETUP token is received, the USB accepts the data, performing the required data transfers and sends back an ACK handshake. If that endpoint has a previously issued VTRX request not yet acknowledged by the application (for example VTRX bit is still set from a previously completed reception), the USB discards the SETUP transaction and does not answer with any handshake packet regardless of its state, simulating a reception error and forcing the host to send the SETUP token again. This is done to avoid losing the notification of a SETUP transaction addressed to the same endpoint immediately following the transaction, which triggered the VTRX interrupt.

Control transfers in Host mode

Control transfers are made of a SETUP transaction, followed by zero or more data stages, all of the same direction, followed by a status stage (a zero-byte transfer in the opposite direction). SETUP transactions are handled by control endpoints only. A control endpoint must set the SETUP bit in the USB_CHEPnR register. The values of DTOGTX and DTOGRX bits of the addressed endpoint registers are set to 0. Depending on whether it is a control write or control read then STATTX or STATRX are set to 11 (ACTIVE) in order to trigger the control transfer via the host frame scheduler.

On receiving a CTR interrupt the channel (device address and endpoint) can be determined by examining IDN and DIR bits. Devices are expected to NAK every control unless the packet is corrupted in which case they do not acknowledge. The situation is reflected in the value of STATTX.

In the case of an error condition the ERR bit gets set. One possible case is where a CRC error is seen at the device, in this case no ACK is returned to the host. The host sees no ACK and after an appropriate delay this generates a timeout error with ERR_TX set (which can generate an interrupt).
55.5.3 Double-buffered endpoints and usage in Device mode

All different endpoint types defined by the USB standard represent different traffic models, and describe the typical requirements of different kind of data transfer operations. When large portions of data are to be transferred between the host PC and the USB function, the bulk endpoint type is the most suited model. This is because the host schedules bulk transactions so as to fill all the available bandwidth in the frame, maximizing the actual transfer rate as long as the USB function is ready to handle a bulk transaction addressed to it. If the USB function is still busy with the previous transaction when the next one arrives, it answers with a NAK handshake and the host PC issues the same transaction again until the USB function is ready to handle it, reducing the actual transfer rate due to the bandwidth occupied by re-transmissions. For this reason, a dedicated feature called ‘double-buffering’ can be used with bulk endpoints.

When ‘double-buffering’ is activated, data toggle sequencing is used to select, which buffer is to be used by the USB peripheral to perform the required data transfers, using both ‘transmission’ and ‘reception’ packet memory areas to manage buffer swapping on each successful transaction in order to always have a complete buffer to be used by the application, while the USB peripheral fills the other one. For example, during an OUT transaction directed to a ‘reception’ double-buffered bulk endpoint, while one buffer is being filled with new data coming from the USB host, the other one is available for the microcontroller software usage (the same would happen with a ‘transmission’ double-buffered bulk endpoint and an IN transaction).

Since the swapped buffer management requires the usage of all 4 buffer description table locations hosting the address pointer and the length of the allocated memory buffers, the USB_CHEPnR registers used to implement double-buffered bulk endpoints are forced to be used as unidirectional ones. Therefore, only one STAT bit pair must be set at a value different from 00 (DISABLED): STATRX if the double-buffered bulk endpoint is enabled for reception, STATTX if the double-buffered bulk endpoint is enabled for transmission. In case it is required to have double-buffered bulk endpoints enabled both for reception and transmission, two USB_CHEPnR registers must be used.

To exploit the double-buffering feature and reach the highest possible transfer rate, the endpoint flow control structure, described in previous chapters, has to be modified, in order to switch the endpoint status to NAK only when a buffer conflict occurs between the USB peripheral and application software, instead of doing it at the end of each successful transaction. The memory buffer which is currently being used by the USB peripheral is defined by the DTOG bit related to the endpoint direction: DTOGRX (bit 14 of USB_CHEPnR register) for ‘reception’ double-buffered bulk endpoints or DTOGTX (bit 6 of USB_CHEPnR register) for ‘transmission’ double-buffered bulk endpoints. To implement the new flow control scheme, the USB peripheral must know which packet buffer is currently in use by the application software, so to be aware of any conflict. Since in the USB_CHEPnR register, there are two DTOG bits but only one is used by USB peripheral for data and buffer sequencing (due to the unidirectional constraint required by double-buffering feature) the other one can be used by the application software to show which buffer it is currently using. This new buffer flag is called SW_BUF. In the following table the correspondence between USB_CHEPnR register bits and DTOG/SW_BUF definition is explained, for the cases of ‘transmission’ and ‘reception’ double-buffered bulk endpoints.
The memory buffer which is currently being used by the USB peripheral is defined by DTOG buffer flag, while the buffer currently in use by application software is identified by SW_BUF buffer flag. The relationship between the buffer flag value and the used packet buffer is the same in both cases, and it is listed in the following table.

Table 591. Double-buffering buffer flag definition

<table>
<thead>
<tr>
<th>Buffer flag</th>
<th>‘Transmission’ endpoint</th>
<th>‘Reception’ endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>DTOG</td>
<td>DTOGTX (USB_CHEPnR bit 6)</td>
<td>DTOGRX (USB_CHEPnR bit 14)</td>
</tr>
<tr>
<td>SW_BUF</td>
<td>USB_CHEPnR bit 14</td>
<td>USB_CHEPnR bit 6</td>
</tr>
</tbody>
</table>

Double-buffering feature for a bulk endpoint is activated by:
- Writing UTYPE bit field at 00 in its USB_CHEPnR register, to define the endpoint as a bulk, and
- Setting EPKIND bit at 1 (DBL_BUF), in the same register.

1. Endpoint in NAK Status.
The application software is responsible for DTOG and SW_BUF bits initialization according to the first buffer to be used; this has to be done considering the special toggle-only property that these two bits have. The end of the first transaction occurring after having set DBL_BUF, triggers the special flow control of double-buffered bulk endpoints, which is used for all other transactions addressed to this endpoint until DBL_BUF remain set. At the end of each transaction the VTRX or VTTX bit of the addressed endpoint USB_CHEPnR register is set, depending on the enabled direction. At the same time, the affected DTOG bit in the USB_CHEPnR register is hardware toggled making the USB peripheral buffer swapping completely software independent. Unlike common transactions, and the first one after DBL_BUF setting, STAT bit pair is not affected by the transaction termination and its value remains 11 (VALID). However, as the token packet of a new transaction is received, the actual endpoint status is masked as 10 (NAK) when a buffer conflict between the USB peripheral and the application software is detected (this condition is identified by DTOG and SW_BUF having the same value, see Table 592 on page 2593). The application software responds to the CTR event notification by clearing the interrupt flag and starting any required handling of the completed transaction. When the application packet buffer usage is over, the software toggles the SW_BUF bit, writing 1 to it, to notify the USB peripheral about the availability of that buffer. In this way, the number of NAKed transactions is limited only by the application elaboration time of a transaction data: if the elaboration time is shorter than the time required to complete a transaction on the USB bus, no re-transmissions due to flow control takes place and the actual transfer rate is limited only by the host PC.

The application software can always override the special flow control implemented for double-buffered bulk endpoints, writing an explicit status different from 11 (VALID) into the STAT bit pair of the related USB_CHEPnR register. In this case, the USB peripheral always uses the programmed endpoint status, regardless of the buffer usage condition.

55.5.4 Double buffered channels: usage in Host mode

In Host mode the underlying transmit and receive methods for double buffered channels are the same as those described for Device mode.

Similar to the Device mode table, a new table below Table 593: Bulk double-buffering memory buffers usage (Host mode) shows the programming settings for OUT and IN tokens.
55.5.5 Isochronous transfers in Device mode

The USB standard supports full speed peripherals requiring a fixed and accurate data production/consume frequency, defining this kind of traffic as ‘isochronous’. Typical examples of this data are: audio samples, compressed video streams, and in general any sort of sampled data having strict requirements for the accuracy of delivered frequency. When an endpoint is defined to be ‘isochronous’ during the enumeration phase, the host allocates in the frame the required bandwidth and delivers exactly one IN or OUT packet each frame, depending on endpoint direction. To limit the bandwidth requirements, no retransmission of failed transactions is possible for isochronous traffic; this leads to the fact that an isochronous transaction does not have a handshake phase and no ACK packet is expected or sent after the data packet. For the same reason, isochronous transfers do not support data toggle sequencing and always use DATA0 PID to start any data packet.

The isochronous behavior for an endpoint is selected by setting the UTYPE bits at 10 in its USB_CHEPnR register; since there is no handshake phase the only legal values for the STATRX/STATTX bit pairs are 00 (DISABLED) and 11 (VALID), any other value produces results not compliant to USB standard. Isochronous endpoints implement double-buffering
to ease application software development, using both ‘transmission’ and ‘reception’ packet memory areas to manage buffer swapping on each successful transaction in order to have always a complete buffer to be used by the application, while the USB peripheral fills the other.

The memory buffer which is currently used by the USB peripheral is defined by the DTOG bit related to the endpoint direction (DTOGRX for ‘reception’ isochronous endpoints, DTOGTX for ‘transmission’ isochronous endpoints, both in the related USB_CHEPnR register) according to Table 594.

### Table 594. Isochronous memory buffers usage

<table>
<thead>
<tr>
<th>Endpoint Type</th>
<th>DTOG bit value</th>
<th>Packet buffer used by the USB peripheral</th>
<th>Packet buffer used by the application software</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transmit (IN)</td>
<td>0</td>
<td>USB_CHEP_TXRXBD_0 (ADDR_TX / COUNT_TX)</td>
<td>USB_CHEP_RXTXBD_0 (ADDR_TX / COUNT_TX)</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>USB_CHEP_RXTXBD_0 (ADDR_TX / COUNT_TX)</td>
<td>USB_CHEP_TXRXBD_0 (ADDR_TX / COUNT_TX)</td>
</tr>
<tr>
<td>Receive (OUT)</td>
<td>0</td>
<td>USB_CHEP_RXTXBD_0 (ADDR_RX / COUNT_RX)</td>
<td>USB_CHEP_TXRXBD_0 (ADDR_RX / COUNT_RX)</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>USB_CHEP_TXRXBD_0 (ADDR_RX / COUNT_RX)</td>
<td>USB_CHEP_RXTXBD_0 (ADDR_RX / COUNT_RX)</td>
</tr>
</tbody>
</table>

As it happens with double-buffered bulk endpoints, the USB_CHEPnR registers used to implement isochronous endpoints are forced to be used as unidirectional ones. In case it is required to have isochronous endpoints enabled both for reception and transmission, two USB_CHEPnR registers must be used.

The application software is responsible for the DTOG bit initialization according to the first buffer to be used; this has to be done considering the special toggle-only property that these two bits have. At the end of each transaction, the VTRX or VTTX bit of the addressed endpoint USB_CHEPnR register is set, depending on the enabled direction. At the same time, the affected DTOG bit in the USB_CHEPnR register is hardware toggled making buffer swapping completely software independent. STAT bit pair is not affected by transaction completion; since no flow control is possible for isochronous transfers due to the lack of handshake phase, the endpoint remains always 11 (VALID). CRC errors or buffer-overrun conditions occurring during isochronous OUT transfers are anyway considered as correct transactions and they always trigger a VTRX event. However, CRC errors set the ERR bit in the USB_ISTR register anyway, in order to notify the software of the possible data corruption.

### 55.5.6 Isochronous transfers in Host mode

From the host point of view isochronous packets are issued or requested one by frame by the host frame scheduler. There is no NAK/ACK protocol and no resend of data or token.
The mechanism is based on a table very similar to that for Device mode. See Table 595 below to understand the relationship between the DTOG bit buffers and the buffer usage.

### Table 595. Isochronous memory buffers usage

<table>
<thead>
<tr>
<th>Endpoint Type</th>
<th>DTOG bit value</th>
<th>Packet buffer used by the USB peripheral</th>
<th>Packet buffer used by the application software</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transmit (OUT) 0</td>

</tr>
<tr>
<td></td>
<td>Buffer description table locations.</td>
<td>Buffer description table locations.</td>
<td></td>
</tr>
<tr>
<td>Receive (IN) 1</td>
<td>USB_CHEP_TXRXBD_0 (ADDRn_RX / COUNTn_RX)</td>
<td>USB_CHEP_RXRXBD_0 (ADDRn_RX / COUNTn_RX)</td>
<td>Buffer description table locations.</td>
</tr>
<tr>
<td></td>
<td>Buffer description table locations.</td>
<td>Buffer description table locations.</td>
<td></td>
</tr>
</tbody>
</table>

The isochronous behavior for an endpoint is selected by setting the UTYPE bits at 10 in its USB_CHEPnR register; since there is no handshake phase the only legal values for the STATRX/STATTX bit pairs are 00 (DISABLED) and 11 (VALID).

Just as in Device mode, the mechanism allows automatic toggle of the DTOG bit. Note that in Host mode, at the same time as this toggle, the STATTX or STATRX of the completed buffer is automatically set to DISABLED, permitting the future buffer to be accessed before re-enabling it by setting it to 11 (VALID).

### 55.5.7 Suspend/resume events

The USB standard defines a special peripheral state, called SUSPEND, in which the average current drawn from the USB bus must not be greater than 2.5 mA. This requirement is of fundamental importance for bus-powered devices, while self-powered devices are not required to comply to this strict power consumption constraint. In suspend mode, the host PC sends the notification by not sending any traffic on the USB bus for more than 3 ms: since a SOF packet must be sent every 1 ms during normal operations, the USB peripheral detects the lack of 3 consecutive SOF packets as a suspend request from the host PC and set the SUSP bit to 1 in USB_ISTR register, causing an interrupt if enabled.

Once the device is suspended, its normal operation can be restored by a so called RESUME sequence, which can be started from the host PC or directly from the peripheral itself, but it is always terminated by the host PC. The suspended USB peripheral must be anyway able to detect a RESET sequence, reacting to this event as a normal USB reset event.

The actual procedure used to suspend the USB peripheral is device dependent since according to the device composition, different actions may be required to reduce the total consumption.
A brief description of a typical suspend procedure is provided below, focused on the USB-related aspects of the application software routine responding to the SUSP notification of the USB peripheral:

1. Set the SUSPEN bit in the USB_CNTR register to 1. This action activates the suspend mode within the USB peripheral. As soon as the suspend mode is activated, the check on SOF reception is disabled to avoid any further SUSP interrupts being issued while the USB is suspended.

2. Remove or reduce any static power consumption in blocks different from the USB peripheral.

3. Set SUSPRDY bit in USB_CNTR register to 1 to remove static power consumption in the analog USB transceivers but keeping them able to detect resume activity.

4. Optionally turn off external oscillator and device PLL to stop any activity inside the device.

When an USB event occurs while the device is in SUSPEND mode, the RESUME procedure must be invoked to restore nominal clocks and regain normal USB behavior. Particular care must be taken to insure that this process does not take more than 10 ms when the wakening event is an USB reset sequence (see “Universal Serial Bus Specification” for more details). The start of a resume or reset sequence, while the USB peripheral is suspended, clears the SUSPRDY bit in USB_CNTR register asynchronously. Even if this event can trigger a WKUP interrupt if enabled, the use of an interrupt response routine must be carefully evaluated because of the long latency due to system clock restart; to have the shorter latency before re-activating the nominal clock it is suggested to put the resume procedure just after the end of the suspend one, so its code is immediately executed as soon as the system clock restarts. To prevent ESD discharges or any other kind of noise from waking-up the system (the exit from suspend mode is an asynchronous event), a suitable analog filter on data line status is activated during suspend; the filter width is about 70 ns.

The following is a list of actions a resume procedure must address:

1. Optionally turn on external oscillator and/or device PLL.

2. Clear SUSPEN bit of USB_CNTR register.

3. If the resume triggering event has to be identified, bits RXDP and RXDM in the USB_FNR register can be used according to Table 596, which also lists the intended software action in all the cases. If required, the end of resume or reset sequence can be detected monitoring the status of the above mentioned bits by checking when they reach the “10” configuration, which represent the idle bus state; moreover at the end of a reset sequence the RST_DCON bit in USB_ISTR register is set to 1, issuing an interrupt if enabled, which must be handled as usual.
A device may require to exit from suspend mode as an answer to particular events not directly related to the USB protocol (for example a mouse movement wakes up the whole system). In this case, the resume sequence can be started by setting the L2RES bit in the USB_CNTR register to 1 and resetting it to 0 after an interval between 1 ms and 15 ms (this interval can be timed using ESOF interrupts, occurring with a 1 ms period when the system clock is running at nominal frequency). Once the L2RES bit is clear, the resume sequence is completed by the host PC and its end can be monitored again using the RXDP and RXDM bits in the USB_FNR register.

*Note:* The L2RES bit must be anyway used only after the USB peripheral has been put in suspend mode, setting the SUSPEN bit in USB_CNTR register to 1.

**Suspend and resume in Host mode**

The basics of the suspend and resume mechanism has been described in the previous section.

From the host stand-point, suspend is entered by writing the SUSPEN bit in USB_CNTR. When suspend entry is confirmed, SUSPRDY (also in USB_CNTR) is set.

Once in suspend, and when the application want to resume the bus, this can be done by setting the L2RES bit in USB_CNTR to 1.

Below in Table 597, the different actions recommended after a wake-up event are indicated. According to the different line states after a wake-up event, the interpretation of the event and the suggested behavior are shown. Note that, this table here is somewhat expanded when compared to the previously shown device table, as the host may encounter both full speed and low speed devices which use different line states for both suspend and resume.

55.6 USB and USB SRAM registers

The USB peripheral registers can be divided into the following groups:
- Common registers: interrupt and control registers
- Endpoint/channel registers: endpoint/channel configuration and status

The USB SRAM registers cover:
- Buffer descriptor table: location of packet memory used to locate data buffers (see Section 2.3: Memory organization to find USB SRAM base address).

All register addresses are expressed as offsets with respect to the USB peripheral registers base address, except the buffer descriptor table locations, which starts at the USB SRAM base address.

Refer to Section 1.2 on page 101 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

55.6.1 Common registers

These registers affect the general behavior of the USB peripheral defining operating mode, interrupt handling, device address and giving access to the current frame number updated by the host PC.

Bit 31 HOST: HOST mode
HOST bit selects between host or device USB mode of operation. It must be set before enabling the USB peripheral by the function enable bit.
0: USB Device function
1: USB host function

Bits 30:18 Reserved, must be kept at reset value.

Bit 17 DDISCM: Device disconnection mask
- Host mode
  0: Device disconnection interrupt disabled
  1: Device disconnection interrupt enabled

Bit 16 THR512M: 512 byte threshold interrupt mask
  0: 512 byte threshold interrupt disabled
  1: 512 byte threshold interrupt enabled
Bit 15 CTRM: Correct transfer interrupt mask
  0: Correct transfer (CTR) interrupt disabled.
  1: CTR interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 14 PMAOVRM: Packet memory area over / underrun interrupt mask
  0: PMAOVR interrupt disabled.
  1: PMAOVR interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 13 ERRM: Error interrupt mask
  0: ERR interrupt disabled.
  1: ERR interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 12 WKUPM: Wake-up interrupt mask
  0: WKUP interrupt disabled.
  1: WKUP interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 11 SUSPM: Suspend mode interrupt mask
  0: Suspend mode request (SUSP) interrupt disabled.
  1: SUSP interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 10 RST_DCONM: USB reset request (Device mode) or device connect/disconnect (Host mode) interrupt mask
  0: RESET interrupt disabled.
  1: RESET interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 9 SOFM: Start of frame interrupt mask
  0: SOF interrupt disabled.
  1: SOF interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 8 ESOFM: Expected start of frame interrupt mask
  0: Expected start of frame (ESOF) interrupt disabled.
  1: ESOF interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 7 L1REQM: LPM L1 state request interrupt mask
  0: LPM L1 state request (L1REQ) interrupt disabled.
  1: L1REQ interrupt enabled, an interrupt request is generated when the corresponding bit in the USB_ISTR register is set.

Bit 6 Reserved, must be kept at reset value.

Bit 5 L1RES: L1 remote wake-up / resume driver
  – Device mode
    Software sets this bit to send a LPM L1 50 μs remote wake-up signaling to the host. After the signaling ends, this bit is cleared by hardware.
    0: No effect
    1: Send 50 μs remote-wake-up signaling to host
Bit 4 **L2RES**: L2 remote wake-up / resume driver

- **Device mode**
  
  The microcontroller can set this bit to send remote wake-up signaling to the host. It must be activated, according to USB specifications, for no less than 1 ms and no more than 15 ms after which the host PC is ready to drive the resume sequence up to its end.

- **Host mode**
  
  Software sets this bit to send resume signaling to the device.
  
  Software clears this bit to send end of resume to device and restart SOF generation.
  
  In the context of remote wake up, this bit is to be set following the WAKEUP interrupt.
  
  0: No effect
  
  1: Send L2 resume signaling to device

Bit 3 **SUSPEN**: Suspend state enable

- **Condition: Device mode**
  
  Software can set this bit when the SUSP interrupt is received, which is issued when no traffic is received by the USB peripheral for 3 ms. Software can also set this bit when the L1REQ interrupt is received with positive acknowledge sent.
  
  As soon as the suspend state is propagated internally all device activity is stopped, USB clock is gated, USB transceiver is set into low power mode and the SUSPRDY bit is set by hardware. In the case that device application wants to pursue more aggressive power saving by stopping the USB clock source and by moving the microcontroller to stop mode, as in the case of bus powered device application, it must first wait few cycles to see the SUSPRDY = 1 acknowledge the suspend request.
  
  This bit is cleared by hardware simultaneous with the WAKEUP flag set.
  
  0: No effect
  
  1: Enter L1/L2 suspend

- **Condition: Host mode**
  
  Software can set this bit when host application has nothing scheduled for the next frames and wants to enter long term power saving. When set, it stops immediately SOF generation and any other host activity, gates the USB clock and sets the transceiver in low power mode. If any USB transaction is on-going at the time SUSPEN is set, suspend is entered at the end of the current transaction.
  
  As soon as suspend state is propagated internally and gets effective the SUSPRDY bit is set. In the case that host application wants to pursue more aggressive power saving by stopping the USB clock source and by moving the micro-controller to STOP mode, it must first wait few cycles to see SUSPRDY=1 acknowledge to the suspend request.
  
  This bit is cleared by hardware simultaneous with the WAKEUP flag set.
  
  0: No effect
  
  1: Enter L1/L2 suspend

Bit 2 **SUSPRDY**: Suspend state effective

This bit is set by hardware as soon as the suspend state entered through the SUSPEN control gets internally effective. In this state USB activity is suspended, USB clock is gated, transceiver is set in low power mode by disabling the differential receiver. Only asynchronous wake-up logic and single ended receiver is kept alive to detect remote wake-up or resume events.

Software must poll this bit to confirm it to be set before any STOP mode entry.

This bit is cleared by hardware simultaneously to the WAKEUP flag being set.

  0: Normal operation
  
  1: Suspend state
Bit 1  **PDWN**: Power down

This bit is used to completely switch off all USB-related analog parts if it is required to completely disable the USB peripheral for any reason. When this bit is set, the USB peripheral is disconnected from the transceivers and it cannot be used.

0: Exit power down
1: Enter power down mode

Bit 0  **USBRST**: USB Reset

- Condition: Device mode

Software can set this bit to reset the USB core, exactly as it happens when receiving a RESET signaling on the USB. The USB peripheral, in response to a RESET, resets its internal protocol state machine. Reception and transmission are disabled until the RST_DCON bit is cleared. All configuration registers do not reset: the microcontroller must explicitly clear these registers (this is to ensure that the RST_DCON interrupt can be safely delivered, and any transaction immediately followed by a RESET can be completed). The function address and endpoint registers are reset by an USB reset event.

0: No effect
1: USB core is under reset

- Condition: Host mode

Software sets this bit to drive USB reset state on the bus and initialize the device. USB reset terminates as soon as this bit is cleared by software.

0: No effect
1: USB reset driven

**USB interrupt status register (USB_ISTR)**

Address offset: 0x44
Reset value: 0x0000 0000

This register contains the status of all the interrupt sources permitting application software to determine which events caused an interrupt request.

The upper part of this register contains single bits, each of them representing a specific event. These bits are set by the hardware when the related event occurs; if the corresponding bit in the USB_CNTR register is set, a generic interrupt request is generated. The interrupt routine, examining each bit, performs all necessary actions, and finally it clears the serviced bits. If any of them is not cleared, the interrupt is considered to be still pending, and the interrupt line is kept high again. If several bits are set simultaneously, only a single interrupt is generated.

Endpoint/channel transaction completion can be handled in a different way to reduce interrupt response latency. The CTR bit is set by the hardware as soon as an endpoint/channel successfully completes a transaction, generating a generic interrupt request if the corresponding bit in USB_CNTR is set. An endpoint/channel dedicated interrupt condition is activated independently from the CTRM bit in the USB_CNTR register. Both interrupt conditions remain active until software clears the pending bit in the corresponding USB_CHEPnR register (the CTR bit is actually a read only bit). For endpoint-/channel-related interrupts, the software can use the direction of transaction (DIR) and IDN read-only bits to identify which endpoint/channel made the last interrupt request and called the corresponding interrupt service routine.

The user can choose the relative priority of simultaneously pending USB_ISTR events by specifying the order in which software checks USB_ISTR bits in an interrupt service routine. Only the bits related to events, which are serviced, are cleared. At the end of the service routine, another interrupt is requested, to service the remaining conditions.
To avoid spurious clearing of some bits, it is recommended to clear them with a load instruction where all bits which must not be altered are written with 1, and all bits to be cleared are written with 0 (these bits can only be cleared by software). Read-modify-write cycles must be avoided because between the read and the write operations another bit can be set by the hardware and the next write clears it before the device has the time to service the event.

| Bit 31 | Reserved, must be kept at reset value. |
| Bit 30 | **LS_DCON**: Low speed device connected |
| - Host mode: |
|          | This bit is set by hardware when an LS device connection is detected. Device connection is signaled after LS J-state is sampled for 22 consecutive cycles of the USB clock (48 MHz) from the unconnected state. |
| Bit 29 | **DCON_STAT**: Device connection status |
| - Host mode: |
|          | This bit contains information about device connection status. It is set by hardware when a LS/FS device is attached to the host while it is reset when the device is disconnected. |
|          | 0: No device connected |
|          | 1: FS or LS device connected to the host |
| Bit 28:18 | Reserved, must be kept at reset value. |
| Bit 17 | **DDISC**: Device connection |
| - Host mode: |
|          | This bit is set when a device connection is detected. This bit is read/write but only 0 can be written and writing 1 has no effect. |
| Bit 16 | **THR512**: 512 byte threshold interrupt |
|          | This bit is set to 1 by the hardware when 512 bytes have been transmitted or received during isochronous transfers. This bit is read/write but only 0 can be written and writing 1 has no effect. Note that no information is available to indicate the associated channel/endpoint, however in practice only one ISO endpoint/channel with such large packets can be supported, so that channel. |
| Bit 15 | **CTR**: Completed transfer in host mode |
|          | This bit is set by the hardware to indicate that an endpoint/channel has successfully completed a transaction; using DIR and IDN bits software can determine which endpoint/channel requested the interrupt. This bit is read-only. |
Bit 14 **PMAOV**: Packet memory area over / underrun
This bit is set if the microcontroller has not been able to respond in time to an USB memory request. The USB peripheral handles this event in the following way: During reception an ACK handshake packet is not sent, during transmission a bit-stuff error is forced on the transmitted stream; in both cases the host retries the transaction. The PMAOV interrupt must never occur during normal operations. Since the failed transaction is retried by the host, the application software has the chance to speed-up device operations during this interrupt handling, to be ready for the next transaction retry; however this does not happen during isochronous transfers (no isochronous transaction is anyway retried) leading to a loss of data in this case. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 13 **ERR**: Error
This flag is set whenever one of the errors listed below has occurred:
- **NANS**: No ANSWer. The timeout for a host response has expired.
- **CRC**: Cyclic redundancy check error. One of the received CRCs, either in the token or in the data, was wrong.
- **BST**: Bit stuffing error. A bit stuffing error was detected anywhere in the PID, data, and/or CRC.
- **FVIO**: Framing format violation. A non-standard frame was received (EOP not in the right place, wrong token sequence, etc.).

The USB software can usually ignore errors, since the USB peripheral and the PC host manage retransmission in case of errors in a fully transparent way. This interrupt can be useful during the software development phase, or to monitor the quality of transmission over the USB bus, to flag possible problems to the user (for example loose connector, too noisy environment, broken conductor in the USB cable and so on). This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 12 **WKUP**: Wake-up
This bit is set to 1 by the hardware when, during suspend mode, activity is detected that wakes up the USB peripheral. This event asynchronously clears the SUSPRDY bit in the CTRLR register and activates the USB_WAKEUP line, which can be used to notify the rest of the device (for example wake-up unit) about the start of the resume process. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 11 **SUSP**: Suspend mode request
- **Device mode**
  This bit is set by the hardware when no traffic has been received for 3 ms, indicating a suspend mode request from the USB bus. The suspend condition check is enabled immediately after any USB reset and it is disabled by the hardware when the suspend mode is active (SUSPEN=1) until the end of resume sequence. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 10 **RST_DCON**: USB reset request (Device mode) or device connect/disconnect (Host mode)
- **Device mode**
  This bit is set by hardware when an USB reset is released by the host and the bus returns to idle. USB reset state is internally detected after the sampling of 60 consecutive SE0 cycles.
- **Host mode**
  This bit is set by hardware when device connection or device disconnection is detected. Device connection is signaled after J state is sampled for 22 cycles consecutively from unconnected state. Device disconnection is signaled after SE0 state is seen for 22 bit times consecutively from connected state.
Bit 9 **SOF:** Start of frame
This bit signals the beginning of a new USB frame and it is set when a SOF packet arrives through the USB bus. The interrupt service routine may monitor the SOF events to have a 1 ms synchronization event to the USB host and to safely read the USB_FNR register which is updated at the SOF packet reception (this can be useful for isochronous applications). This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 8 **ESOF:** Expected start of frame
- **Device mode**
  This bit is set by the hardware when an SOF packet is expected but not received. The host sends an SOF packet each 1 ms, but if the device does not receive it properly, the suspend timer issues this interrupt. If three consecutive ESOF interrupts are generated (for example three SOF packets are lost) without any traffic occurring in between, a SUSP interrupt is generated. This bit is set even when the missing SOF packets occur while the suspend timer is not yet locked. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bit 7 **L1REQ:** LPM L1 state request
- **Device mode**
  This bit is set by the hardware when LPM command to enter the L1 state is successfully received and acknowledged. This bit is read/write but only 0 can be written and writing 1 has no effect.

Bits 6:5 **Reserved,** must be kept at reset value.

Bit 4 **DIR:** Direction of transaction
This bit is written by the hardware according to the direction of the successful transaction, which generated the interrupt request.
- If DIR bit = 0, VTTX bit is set in the USB_CHEPnR register related to the interrupting endpoint. The interrupting transaction is of IN type (data transmitted by the USB peripheral to the host PC).
- If DIR bit = 1, VTRX bit or both VTTX/VTRX are set in the USB_CHEPnR register related to the interrupting endpoint. The interrupting transaction is of OUT type (data received by the USB peripheral from the host PC) or two pending transactions are waiting to be processed.
  This information can be used by the application software to access the USB_CHEPnR bits related to the triggering transaction since it represents the direction having the interrupt pending. This bit is read-only.

Bits 3:0 **IDN[3:0]:** Device Endpoint / host channel identification number
These bits are written by the hardware according to the host channel or device endpoint number, which generated the interrupt request. If several endpoint/channel transactions are pending, the hardware writes the identification number related to the endpoint/channel having the highest priority defined in the following way: two levels are defined, in order of priority: isochronous and double-buffered bulk channels/endpoints are considered first and then the others are examined. If more than one endpoint/channel from the same set is requesting an interrupt, the IDN bits in USB_ISTR register are assigned according to the lowest requesting register, CHEP0R having the highest priority followed by CHEP1R and so on. The application software can assign a register to each endpoint/channel according to this priority scheme, so as to order the concurring endpoint/channel requests in a suitable way. These bits are read only.
USB frame number register (USB_FNR)

Address offset: 0x48
Reset value: 0x0000 0XXX (where X is undefined)

### Bit Definitions

#### Bit 31:16
Reserved, must be kept at reset value.

- **Bit 15**: RXDP: Receive data + line status
  
  This bit can be used to observe the status of received data plus upstream port data line. It can be used during end-of-suspend routines to help determining the wake-up event.

- **Bit 14**: RXDM: Receive data - line status
  
  This bit can be used to observe the status of received data minus upstream port data line. It can be used during end-of-suspend routines to help determining the wake-up event.

- **Bit 13**: LCK: Locked
  
  - **Device mode**
    
    This bit is set by the hardware when at least two consecutive SOF packets have been received after the end of an USB reset condition or after the end of an USB resume sequence. Once locked, the frame timer remains in this state until an USB reset or USB suspend event occurs.

- **Bits 12:11**: LSOF[1:0]: Lost SOF
  
  - **Device mode**
    
    These bits are written by the hardware when an ESOF interrupt is generated, counting the number of consecutive SOF packets lost. At the reception of an SOF packet, these bits are cleared.

- **Bits 10:0**: FN[10:0]: Frame number
  
  This bit field contains the 11-bits frame number contained in the last received SOF packet. The frame number is incremented for every frame sent by the host and it is useful for isochronous transfers. This bit field is updated on the generation of an SOF interrupt.

USB Device address (USB_DADDR)

Address offset: 0x4C
Reset value: 0x0000 0000
Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **EF**: Enable function

This bit is set by the software to enable the USB Device. The address of this device is contained in the following ADD[6:0] bits. If this bit is at 0 no transactions are handled, irrespective of the settings of USB_CHEPnR registers.

Bits 6:0 **ADD[6:0]**: Device address

- **Device mode**
  These bits contain the USB function address assigned by the host PC during the enumeration process. Both this field and the endpoint/channel address (EA) field in the associated USB_CHEPnR register must match with the information contained in a USB token in order to handle a transaction to the required endpoint.

- **Host mode**
  These bits contain the address transmitted with the LPM transaction

### LPM control and status register (USB_LPMCSR)

Address offset: 0x54

Reset value: 0x0000 0000

</table>

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **BESL[3:0]**: BESL value

- **Device mode**
  These bits contain the BESL value received with last ACKed LPM Token

Bit 3 **REMWAKE**: bRemoteWake value

- **Device mode**
  This bit contains the bRemoteWake value received with last ACKed LPM Token

Bit 2 Reserved, must be kept at reset value.

Bit 1 **LPMACK**: LPM token acknowledge enable

- **Device mode**:
  0: the valid LPM token is NYET.
  1: the valid LPM token is ACK.

  The NYET/ACK is returned only on a successful LPM transaction:
  - No errors in both the EXT token and the LPM token (else ERROR)
  - A valid bLinkState = 0001B (L1) is received (else STALL)

Bit 0 **LPMEN**: LPM support enable

- **Device mode**
  This bit is set by the software to enable the LPM support within the USB Device. If this bit is at 0 no LPM transactions are handled.
Battery charging detector (USB_BCDR)

Address offset: 0x58
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **DPPU_DPD**: DP pull-up / DPDM pull-down
- **Device mode**
  This bit is set by software to enable the embedded pull-up on DP line. Clearing it to 0 can be used to signal disconnect to the host when needed by the user software.
- **Host mode**
  This bit is set by software to enable the embedded pull-down on DP and DM lines.

Bits 14:8 Reserved, must be kept at reset value.

Bit 7 **PS2DET**: DM pull-up detection status
- **Device mode**
  This bit is active only during PD and gives the result of comparison between DM voltage level and $V_{LGC}$ threshold. In normal situation, the DM level must be below this threshold. If it is above, it means that the DM is externally pulled high. This can be caused by connection to a PS2 port (which pulls-up both DP and DM lines) or to some proprietary charger not following the BCD specification.
  0: Normal port detected (connected to SDP, ACA, CDP or DCP).
  1: PS2 port or proprietary charger detected.

Bit 6 **SDET**: Secondary detection (SD) status
- **Device mode**
  This bit gives the result of SD.
  0: CDP detected.
  1: DCP detected.

Bit 5 **PDET**: Primary detection (PD) status
- **Device mode**
  This bit gives the result of PD.
  0: no BCD support detected (connected to SDP or proprietary device).
  1: BCD support detected (connected to ACA, CDP or DCP).

Bit 4 **DCDET**: Data contact detection (DCD) status
- **Device mode**
  This bit gives the result of DCD.
  0: data lines contact not detected.
  1: data lines contact detected.
Host channel-specific/device endpoint-specific registers

The number of these registers varies according to the number of endpoints or host channels that the USB peripheral is designed to handle. The USB peripheral supports up to 8 bidirectional endpoints or host channels. Each USB Device must support a control endpoint/channel whose address (EA bits) must be set to 0. The USB peripheral behaves in an undefined way if multiple endpoints are enabled having the same endpoint/channel number value. For each endpoint, an USB_CHEPnR register is available to store the endpoint/channel specific information.

USB endpoint/channel n register (USB_CHEPnR)

Address offset: 0x00 + 0x4 * n, (n = 0 to 7)

Reset value: 0x0000 0000

They are also reset when an USB reset is received from the USB bus or forced through bit USBRST in the CTLR register, except the VTRX and VTTX bits, which are kept unchanged to avoid missing a correct packet notification immediately followed by an USB reset event. Each endpoint/channel has its USB_CHEPnR register where n is the endpoint/channel identifier.

Read-modify-write cycles on these registers must be avoided because between the read and the write operations some bits can be set by the hardware and the next write would modify them before the CPU has the time to detect the change. For this purpose, all bits affected by this problem have an ‘invariant’ value that must be used whenever their modification is not required. It is recommended to modify these registers with a load instruction where all the bits, which can be modified only by the hardware, are written with their ‘invariant’ value.

</tr>
</tbody>
</table>
Bit 24 **LS_EP**: Low speed endpoint – host with HUB only
- Host mode
  This bit is set by the software to send an LS transaction to the corresponding endpoint.
  0: Full speed endpoint
  1: Low speed endpoint

Bit 23 **NAK**:  
- Host mode
  This bit is set by the hardware when a device responds with a NAK. Software can use this bit to monitor the number of NAKs received from a device.

Bits 22:16 **DEVADDR[6:0]**:  
- Host mode
  Device address assigned to the endpoint during the enumeration process.

Bit 15 **VTRX**: USB valid transaction received  
- Device mode  
  This bit is set by the hardware when an OUT/SETUP transaction is successfully completed on this endpoint; the software can only clear this bit. If the CTRM bit in USB_CNTR register is set accordingly, a generic interrupt condition is generated together with the endpoint related interrupt condition, which is always activated. The type of occurred transaction, OUT or SETUP, can be determined from the SETUP bit described below.  
  A transaction ended with a NAK or STALL handshake does not set this bit, since no data is actually transferred, as in the case of protocol errors or data toggle mismatches.
  This bit is read/write but only 0 can be written, writing 1 has no effect.  
- Host mode
  This bit is set by the hardware when an IN transaction is successfully completed on this channel. The software can only clear this bit. If the CTRM bit in USB_CNTR register is set a generic interrupt condition is generated together with the channel related flag, which is always activated.

- A transaction ended with a NAK sets this bit and NAK answer is reported to application reading the NAK state from the STATRX field of this register. One NAKed transaction keeps pending and is automatically retried by the host at the next frame, or the host can immediately retry by resetting STATRX state to VALID.

- A transaction ended by STALL handshake sets this bit and the STALL answer is reported to application reading the STALL state from the STATRX field of this register. Host application must consequently disable the channel and re-enumerate.

- A transaction ended with ACK handshake sets this bit
  If double buffering is disabled, ACK answer is reported by application reading the DISABLE state from the STATRX field of this register. Host application must read received data from USBRAM and re-arm the channel by writing VALID to the STATRX field of this register.
  If double buffering is enabled, ACK answer is reported by application reading VALID state from the STATRX field of this register. Host application must read received data from USBRAM and toggle the DTOGTX bit of this register.

- A transaction ended with error sets this bit.
  Errors can be seen via the bits ERR_RX (host mode only).

This bit is read/write but only 0 can be written, writing 1 has no effect.
Bit 14 **DTOGRX**: Data Toggle, for reception transfers

If the endpoint/channel is not isochronous, this bit contains the expected value of the data toggle bit (0 = DATA0, 1 = DATA1) for the next data packet to be received. Hardware toggles this bit, when the ACK handshake is sent following a data packet reception having a matching data PID value; if the endpoint is defined as a control one, hardware clears this bit at the reception of a SETUP PID received from host (in device mode), while it sets this bit to 1 when SETUP transaction is acknowledged by device (in host mode).

If the endpoint/channel is using the double-buffering feature this bit is used to support packet buffer swapping too (Refer to Section 55.5.3: Double-buffered endpoints and usage in Device mode).

If the endpoint/channel is isochronous, this bit is used only to support packet buffer swapping for data transmission since no data toggling is used for this kind of channels/endpoints and only DATA0 packet are transmitted (Refer to Section 55.5.5: Isochronous transfers in Device mode). Hardware toggles this bit just after the end of data packet reception, since no handshake is used for isochronous transfers.

This bit can also be toggled by the software to initialize its value (mandatory when the endpoint is not a control one) or to force specific data toggle/packet buffer usage. When the application software writes 0, the value of DTOGRX remains unchanged, while writing 1 makes the bit value toggle. This bit is read/write but it can be only toggled by writing 1.
Bits 13:12 **STATRX[1:0]:** Status bits, for reception transfers

- **Device mode**
  
  These bits contain information about the endpoint status, which are listed in **Table 598: Reception status encoding on page 2618**. These bits can be toggled by software to initialize their value. When the application software writes 0, the value remains unchanged, while writing 1 makes the bit value to toggle. Hardware sets the STATRX bits to NAK when a correct transfer has occurred (VTRX = 1) corresponding to a OUT or SETUP (control only) transaction addressed to this endpoint, so the software has the time to elaborate the received data before it acknowledges a new transaction.

  Double-buffered bulk endpoints implement a special transaction flow control, which control the status based upon buffer availability condition (Refer to **Section 55.5.3: Double-buffered endpoints and usage in Device mode**).

  If the endpoint is defined as isochronous, its status can be only "VALID" or "DISABLED", so that the hardware cannot change the status of the endpoint after a successful transaction. If the software sets the STATRX bits to ‘STALL’ or ‘NAK’ for an isochronous endpoint, the USB peripheral behavior is not defined. These bits are read/write but they can be only toggled by writing 1.

- **Host mode**
  
  These bits are the host application controls to start, retry, or abort host transactions driven by the channel.

  These bits also contain information about the device answer to the last IN channel transaction and report the current status of the channel according to the following STATRX table of states:

  - **DISABLE**
    
    DISABLE value is reported in case of ACK acknowledge is received on a single-buffer channel. When in DISABLE state the channel is unused or not active waiting for application to restart it by writing VALID. Application can reset a VALID channel to DISABLE to abort a transaction. In this case the transaction is immediately removed from the host execution list. If the aborted transaction was already under execution it is regularly terminated on the USB but the relative VTRX interrupt is not generated.

  - **VALID**
    
    A host channel is actively trying to submit USB transaction to device only when in VALID state. VALID state can be set by software or automatically by hardware on a NAKED channel at the start of a new frame. When set to VALID, an host channel enters the host execution queue and waits permission from the host frame scheduler to submit its configured transaction.

    VALID value is also reported in case of ACK acknowledge is received on a double-buffered channel. In this case the channel remains active on the alternate buffer while application needs to read the current buffer and toggle DTOGTX. In case software is late in reading and the alternate buffer is not ready, the host channel is automatically suspended transparently to the application. The suspended double buffered channel is re-activated as soon as delay is recovered and DTOGTX is toggled.

  - **NAK**
    
    NAK value is reported in case of NAK acknowledge received. When in NAK state the channel is suspended and does not try to transmit. NAK state is moved to VALID by hardware at the start of the next frame, or software can change it to immediately retry transmission by writing it to VALID, or can disable it and abort the transaction by writing DISABLE.

  - **STALL**
    
    STALL value is reported in case of STALL acknowledge received. When in STALL state the channel behaves as disabled. Application must not retry transmission but reset the USB and re-enumerate.
Bit 11 **SETUP**: Setup transaction completed
  
  **– Device mode**
  
  This bit is read-only and it is set by the hardware when the last completed transaction is a SETUP. This bit changes its value only for control endpoints. It must be examined, in the case of a successful receive transaction (VTRX event), to determine the type of transaction occurred. To protect the interrupt service routine from the changes in SETUP bits due to next incoming tokens, this bit is kept frozen while VTRX bit is at 1; its state changes when VTRX is at 0. This bit is read-only.
  
  **– Host mode**
  
  This bit is set by the software to send a SETUP transaction on a control endpoint. This bit changes its value only for control endpoints. It is cleared by hardware when the SETUP transaction is acknowledged and VTTX interrupt generated.

Bits 10:9 **UTYPE[1:0]**: USB type of transaction

These bits configure the behavior of this endpoint/channel as described in *Table 599: Endpoint/channel type encoding*. Channel0/Endpoint0 must always be a control endpoint/channel and each USB function must have at least one control endpoint/channel which has address 0, but there may be other control channels/endpoints if required. Only control channels/endpoints handle SETUP transactions, which are ignored by endpoints of other kinds. SETUP transactions cannot be answered with NAK or STALL. If a control endpoint/channel is defined as NAK, the USB peripheral does not answer, simulating a receive error, in the receive direction when a SETUP transaction is received. If the control endpoint/channel is defined as STALL in the receive direction, then the SETUP packet is accepted anyway, transferring data and issuing the CTR interrupt. The reception of OUT transactions is handled in the normal way, even if the endpoint/channel is a control one. Bulk and interrupt endpoints have very similar behavior and they differ only in the special feature available using the EPKIND configuration bit.

The usage of isochronous channels/endpoints is explained in *Section 55.5.5: Isochronous transfers in Device mode*

Bit 8 **EPKIND**: endpoint/channel kind

The meaning of this bit depends on the endpoint/channel type configured by the UTYPE bits. *Table 600* summarizes the different meanings.

**DBL_BUF**: This bit is set by the software to enable the double-buffering feature for this bulk endpoint. The usage of double-buffered bulk endpoints is explained in *Section 55.5.3: Double-buffered endpoints and usage in Device mode*.

**STATUS_OUT**: This bit is set by the software to indicate that a status out transaction is expected: in this case all OUT transactions containing more than zero data bytes are answered ‘STALL’ instead of ‘ACK’. This bit may be used to improve the robustness of the application to protocol errors during control transfers and its usage is intended for control endpoints only. When STATUS_OUT is reset, OUT transactions can have any number of bytes, as required.

Bit 7 **VTTX**: Valid USB transaction transmitted

  **– Device mode**
  
  This bit is set by the hardware when an IN transaction is successfully completed on this endpoint; the software can only clear this bit. If the CTRM bit in the USB_CNTR register is set accordingly, a generic interrupt condition is generated together with the endpoint related interrupt condition, which is always activated.

  A transaction ended with a NAK or STALL handshake does not set this bit, since no data is actually transferred, as in the case of protocol errors or data toggle mismatches.

  This bit is read/write but only 0 can be written.
  
  **– Host mode**
  
  Same as VTRX behavior but for USB OUT and SETUP transactions.
Bit 6 **DTOGTX**: Data toggle, for transmission transfers

If the endpoint/channel is non-isochronous, this bit contains the required value of the data toggle bit \((0 = \text{DATA0}, 1 = \text{DATA1})\) for the next data packet to be transmitted. Hardware toggles this bit when the ACK handshake is received from the USB host, following a data packet transmission. If the endpoint/channel is defined as a control one, hardware sets this bit to 1 at the reception of a SETUP PID addressed to this endpoint (in device mode) or when a SETUP transaction is acknowledged by the device (in host mode).

If the endpoint/channel is using the double buffer feature, this bit is used to support packet buffer swapping too (Refer to Section 55.5.3: Double-buffered endpoints and usage in Device mode).

If the endpoint/channel is isochronous, this bit is used to support packet buffer swapping since no data toggling is used for this sort of endpoints and only DATA0 packet are transmitted (refer to Section 55.5.5: Isochronous transfers in Device mode). Hardware toggles this bit just after the end of data packet transmission, since no handshake is used for isochronous transfers.

This bit can also be toggled by the software to initialize its value (mandatory when the endpoint/channel is not a control one) or to force a specific data toggle/packet buffer usage. When the application software writes 0, the value of DTOGTX remains unchanged, while writing 1 makes the bit value to toggle. This bit is read/write but it can only be toggled by writing 1.

Bits 5:4 **STATTX\[1:0\]**: Status bits, for transmission transfers

- **Device mode**
  
  These bits contain the information about the endpoint status, listed in Table 601. These bits can be toggled by the software to initialize their value. When the application software writes 0, the value remains unchanged, while writing 1 makes the bit value to toggle. Hardware sets the STATTX bits to NAK, when a correct transfer has occurred \((VTTX = 1)\) corresponding to a IN or SETUP (control only) transaction addressed to this channel/endpoint. It then waits for the software to prepare the next set of data to be transmitted.

  Double-buffered bulk endpoints implement a special transaction flow control, which controls the status based on buffer availability condition (Refer to Section 55.5.3: Double-buffered endpoints and usage in Device mode).

  If the endpoint is defined as isochronous, its status can only be "VALID" or "DISABLED". Therefore, the hardware cannot change the status of the channel/endpoint/channel after a successful transaction. If the software sets the STATTX bits to 'STALL' or 'NAK' for an isochronous channel/endpoint, the USB peripheral behavior is not defined. These bits are read/write but they can only be toggled by writing 1.

- **Host mode**

  The STATTX bits contain the information about the channel status. Refer to Table 601 for the full descriptions ("Host mode" descriptions). Whereas in Device mode, these bits contain the status that are given out on the following transaction, in Host mode they capture the status last received from the device. If a NAK is received, STATTX contains the value indicating NAK.

Bits 3:0 **EA\[3:0\]**: endpoint/channel address

- **Device mode**

  Software must write in this field the 4-bit address used to identify the transactions directed to this endpoint. A value must be written before enabling the corresponding endpoint.

- **Host mode**

  Software must write in this field the 4-bit address used to identify the channel addressed by the host transaction.

55.6.2 Buffer descriptor table

**Note:** The buffer descriptor table is located inside the packet buffer memory in the separate "USB SRAM" address space.

Although the buffer descriptor table is located inside the packet buffer memory ("USB SRAM" area), its entries can be considered as additional registers used to configure the location and size of the packet buffers used to exchange data between the USB macro cell and the device.

The first packet memory location is located at USB SRAM base address. The buffer descriptor table entry associated with the USB_CHEPnR registers is described below. The memory must be addressed using Word (32-bit) accesses.

A thorough explanation of packet buffers and the buffer descriptor table usage can be found in *Structure and usage of packet buffers on page 2586*.

**Channel/endpoint transmit buffer descriptor n (USB_CHEP_TXRXBD_n)**

Address offset: n*8

This register description applies when corresponding CHEPnR register does not program the use of double buffering working in receive mode (otherwise refer to following register description)

| Bits 31:26 Reserved, must be kept at reset value. |
| Bits 25:16 **COUNT_TX[9:0]**: Transmission byte count |
| These bits contain the number of bytes to be transmitted by the endpoint/channel associated with the USB_CHEPnR register at the next IN token addressed to it. |
| Bits 15:0 **ADDR_TX[15:0]**: Transmission buffer address |
| These bits point to the starting address of the packet buffer containing data to be transmitted by the endpoint/channel associated with the USB_CHEPnR register at the next IN token addressed to it. Bits 1 and 0 must always be written as "00" since packet memory is word wide and all packet buffers must be word aligned. |

**Channel/endpoint receive buffer descriptor n [alternate] (USB_CHEP_TXRXBD_n)**

Address offset: n*8

This register description applies when corresponding CHEPnR register programs the use of double buffering and activates receive buffers (otherwise refer to previous register description).

This table location is used to store two different values, both required during packet reception. The most significant bits contains the definition of allocated buffer size, to allow buffer overflow detection, while the least significant part of this location is written back by the USB peripheral at the end of reception to give the actual number of received bytes. Due to
the restrictions on the number of available bits, buffer size is represented using the number of allocated memory blocks, where block size can be selected to choose the trade-off between fine-granularity/small-buffer and coarse-granularity/large-buffer. The size of allocated buffer is a part of the endpoint/channel descriptor and it is normally defined during the enumeration process according to its maxPacketSize parameter value (see “Universal Serial Bus Specification”).

</table>

Bit 31  **BLSIZE**: Block size

This bit selects the size of memory block used to define the allocated buffer area.

- If BLSIZE = 0, the memory block is 2-byte large, which is the minimum block allowed in a half-word wide memory. With this block size the allocated buffer size ranges from 2 to 62 bytes.
- If BLSIZE = 1, the memory block is 32-byte large, which permits to reach the maximum packet length defined by USB specifications. With this block size the allocated buffer size theoretically ranges from 32 to 1024 bytes, which is the longest packet size allowed by USB standard specifications. However, the applicable size is limited by the available buffer memory.

Bits 30:26  **NUM_BLOCK[4:0]**: Number of blocks

These bits define the number of memory blocks allocated to this packet buffer. The actual amount of allocated memory depends on the BLSIZE value as illustrated in Table 602.

Bits 25:16  **COUNT_RX[9:0]**: Reception byte count

These bits contain the number of bytes received by the endpoint/channel associated with the USB_CHEPnR register during the last OUT/SETUP transaction addressed to it.

Bits 15:0  **ADDR_RX[15:0]**: Reception buffer address

These bits point to the starting address of the packet buffer, which contains the data received by the endpoint/channel associated with the USB_CHEPnR register at the next OUT/SETUP token addressed to it. Bits 1 and 0 must always be written as “00” since packet memory is word wide and all packet buffers must be word aligned.

Channel/endpoint receive buffer descriptor n
(USB_CHEP_RTXXBD_n)

Address offset: n*8 + 4

This register description applies when corresponding CHEPnR register does not program use of double buffering in the transmit mode (otherwise refer to following register description).

This table location is used to store two different values, both required during packet reception. The most significant bits contains the definition of allocated buffer size, to allow buffer overflow detection, while the least significant part of this location is written back by the USB peripheral at the end of reception to give the actual number of received bytes. Due to the restrictions on the number of available bits, buffer size is represented using the number of allocated memory blocks, where block size can be selected to choose the trade-off between fine-granularity/small-buffer and coarse-granularity/large-buffer. The size of allocated buffer is a part of the endpoint/channel descriptor and it is normally defined during the enumeration process according to its maxPacketSize parameter value (see “Universal Serial Bus Specification”).
Bit 31  **BLSIZE**: Block size

This bit selects the size of memory block used to define the allocated buffer area.

- If BLSIZE = 0, the memory block is 2-byte large, which is the minimum block allowed in a half-word wide memory. With this block size the allocated buffer size ranges from 2 to 62 bytes.
- If BLSIZE = 1, the memory block is 32-byte large, which permits to reach the maximum packet length defined by USB specifications. With this block size the allocated buffer size theoretically ranges from 32 to 1024 bytes, which is the longest packet size allowed by USB standard specifications. However, the applicable size is limited by the available buffer memory.

Bits 30:26 **NUM_BLOCK[4:0]**: Number of blocks

These bits define the number of memory blocks allocated to this packet buffer. The actual amount of allocated memory depends on the BLSIZE value as illustrated in Table 602.

Bits 25:16 **COUNT_RX[9:0]**: Reception byte count

These bits contain the number of bytes received by the endpoint/channel associated with the USB_CHEPnR register during the last OUT/SETUP transaction addressed to it.

Bits 15:0 **ADDR_RX[15:0]**: Reception buffer address

These bits point to the starting address of the packet buffer, which contains the data received by the endpoint/channel associated with the USB_CHEPnR register at the next OUT/SETUP token addressed to it. Bits 1 and 0 must always be written as "00" since packet memory is word wide and all packet buffers must be word aligned.

**Channel/endpoint transmit buffer descriptor n [alternate]**

(USB_CHEP_RXTXBD_n)

Address offset: n*8 + 4

This register description applies when corresponding CHEPnR register programs use of double buffering and activates transmit buffers (otherwise refer to previous register description).

Refer to Section 2.3 on page 111 for the register boundary addresses.
56 USB Type-C®/USB Power Delivery interface (UCPD)

56.1 Introduction

The USB Type-C/USB Power Delivery interface complies with:
- Universal Serial Bus Type-C Cable and Connector Specification: release 2.2, Oct 2022
- Universal Serial Bus Power Delivery specifications:
  - revision 2.0, version 1.3, January 12, 2017
  - revision 3.1, version 1.6, October 2022

It integrates the physical layer of the Power Delivery (PD) specification, with CC signaling method (no VBUS), for operation with Type-C cables.

56.2 UCPD main features

- Compliance with USB Type-C specification release 2.2
- Compliance with USB Power Delivery specifications revision 2.0 and 3.1
  - Enabling advanced applications such as PPS (programmable power supply)
- Stop mode low-power operation support
- Built-in analog PHY
  - USB Type-C pull-up (Rp, all values) and pull-down (Rd) resistors
  - “Dead battery” Rd support
  - USB Power Delivery message transmission and reception
  - FRS (fast role swap) Rx support
- Digital controller
  - BMC (bi-phase mark coding) encode and decode
  - 4b5b encode and decode
  - USB Type-C level detection with de-bounce, generating interrupts
  - FRS signaling
  - FRS detection, generating an interrupt
  - DMA-compatible byte-level interface for USB Power Delivery payload, generating interrupts
  - USB Power Delivery clock pre-scaler / dividers
  - CRC generation/checking
  - Support of ordered sets, with a programmable ordered set mask at receive
  - Clock recovery from incoming Rx stream

56.3 UCPD implementation

The devices have one UCPD controller to support one USB Type-C port.
The following table gives the memory locations of trim data stored in the non-volatile memory, to use in the software trimming procedure described in Section 56.5.5: UCPD software trimming.

Table 605. UCPD software trim data

56.4 UCPD functional description

The UCPD peripheral provides hardware support for the USB Power Delivery control interface specification, using I/Os specifically designed for that purpose.

The built-in PHY directly detects Type-C voltage levels, supports Power Delivery BIST carrier mode 2 (Tx only), BIST test data (Tx and Rx), and Power Delivery Rx FRS signaling.

For Power Delivery FRS Tx signaling, the device can be configured to control, through UCPD_FRSTX pin (alternate function), external NMOS transistors that ensure low-resistance pull-down on CC lines.

The UCPD transmitter BMC (bi-phase mark) encodes and transmits data: preamble, SOP, payload data from protocol layer (after 4b5b-encoding), CRC, and EOP on the Type-C connector CC lines. It automatically inserts inter-frame gap and executes “Hard Reset”.

The UCPD receiver detects SOP, BMC-decodes the incoming stream, recovers the preamble, 4b5b-decodes payload data, detects EOP, and checks CRC. It automatically detects five K-code SOP and two Reset ordered sets, plus two software-defined patterns (allows for only three out of four K-codes being correctly received, as defined by the standard).
In Stop mode, the peripheral maintains the ability to detect incoming USB Power Delivery messages and FRS signaling, which allows low-power operation.

### 56.4.1 UCPD block diagram

#### Figure 782. UCPD block diagram

The following table lists external signals (alternate or additional I/O functions).

#### Table 606. UCPD signals on pins

<table>
<thead>
<tr>
<th>Pin name</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UCPDx_FRSTX</td>
<td>Output</td>
<td>USB Type-C fast role swap (FRS) signaling control, applicable to DRPs only. The signal (active high) drives an external NMOS transistor that pulls down the active CC line. A typical application has two such transistors (one per CC line) and reserves a separate I/O to drive either NMOS. Initially, the I/Os are configured as low-driving GPIOs. Upon detecting, through the Type-C state machine, the orientation of the cable attached, which determines the active CC line, the I/O of the active CC line must be set to its UCPDx_FRSTX alternate function and the I/O of the inactive CC line as low-driving GPIO.</td>
</tr>

### 56.4.2 UCPD reset and clocks

The peripheral has a single reset signal (APB bus reset).

The register section is clocked with the APB clock (ucpd_pclk).

The main functional part of the transmitter is clocked with ucpd_clk clock, pre-scaled from the ucpd_ker_ck (HSI16) clock according to the PSC_USBPDCLK[2:0] bitfield of the UCPD_CFGR1 register. The main functional part of the receiver is clocked with the ucpd_rx_clk recovered from the incoming bitstream.

The receiver is designed to work in the clock frequency range from 6 to 18 MHz. However, the optimum performance is ensured in the range from 9 to 18 MHz.

The following diagram shows the clocking and timing elements of the UCPD peripheral.
Refer to the USB PD specification in order to set appropriate delays. For \( t_{\text{TransitionWindow}} \) and especially for \( t_{\text{InterFrameGap}} \), the clock frequency uncertainty must be taken into account so as to respect specified timings in all cases.

### 56.4.3 Physical layer protocol

The physical layer covers the signaling underlying the USB Power Delivery specification.

On the transmitter side its main function is to form packets according to the defined packet format including generally:
- preamble
- start of packet (SOP, ordered set)
- payload header
- payload data
- cyclic redundancy check (CRC) information
- end of packet (EOP)

Before going on the CC line, the data stream is BMC-encoded, respecting specified timing restrictions.

On the receive side, the principle task is to:
- extract start of packet (SOP, ordered set) information
- extract payload header
- extract payload data
- receive and check CRC
- receive end of packet (EOP)

The receive is basically a reverse of the transmit process, thus starting with BMC data stream decoding.

**Symbol encoding**

Apart from the preamble all symbols are encoded with a 4b5b scheme according to the specification shown in the following table.
## Table 608. 4b5b symbol encoding table

Ordered sets

An ordered set consists of four K-codes as shown in the following figure.

Figure 784. K-code transmission

The following table lists the defined ordered sets, including all possible SOP* sequences. At the physical layer, the Hard Reset has higher priority than the other ordered sets so it can interrupt an ongoing Tx message.

Table 609. Ordered sets

**Hard Reset**

The physical layer handles the Hard Reset signaling differently than the other types of message as it has higher priority to be able to interrupt an ongoing transfer.

The physical layer specification implies the following sequence in the case of an ongoing Tx message:

1. Terminate the message by sending an EOP K-code and discard the rest of the message.
2. Wait for $t_{InterFrameGap}$ time.
3. If the CC line is not idle, wait until it goes idle.
4. Send the preamble followed by the four K-codes of Hard Reset signaling.
5. Disable the CC channel (stop sending and receiving), reset the physical layer and inform the protocol layer that the physical layer is reset.
6. Re-enable the channel when requested by the protocol layer.

**Figure 787. Line format of Hard Reset**

Collision avoidance

The physical layer respects the $t_{InterFrameGap}$ delay between end of last-transmitted bit of a Tx message, and the first bit of a following message.

It also checks the idle state of the CC line before starting transmission. The CC line is considered idle if it shows less than three ($n_{TransitionCount}$) transitions within $t_{TransitionWindow}$ (12 to 20 μs). The Power Delivery specification revision 3.1 also requires to manage the $R_p$ value (source) and monitor Type-C voltage level for these $R_p$ modifications (at the sink).

Physical layer signaling schemes

The bit are signaled with bi-phase mark coding (BMC).

BIST

Depending on the BIST action required by the protocol layer, either of the following can be run:
- a Tx BIST pattern test, achieved by writing TXMODE and TXSEND
- an Rx BIST pattern test, achieved by writing RXMODE to the correct value for RXBIST.

The two possible patterns supported in UCPD (corresponding to "BMC" mode) are:
- BIST Test Data (192 bit pattern), applies to Tx and Rx. In the case of Rx, the message is received (but discarded rather than passing to the protocol layer, which must nevertheless still generate a GoodCRC Tx message in acknowledgment).
- BIST Carrier Mode 2 (single pattern, infinite length message), applies to Tx only. As opposed to Tx, the receiver in this mode simply ignores the CC line during this state.

BIST test data pattern

The test data pattern is not viewed as a special case in UCPD.
The BIST test data packet frame format is shown in the following figure.

**Figure 789. BIST test data frame**

![BIST test data frame diagram](image)

This is a fixed length test data pattern. In reality the only aspect that marks its difference from the general packet format already shown in *Figure 786: Packet format* is the contents of the Header. As UCPD receives the Tx Header contents via programming (it is simply viewed as part of the payload), it is only this programming (and not the block’s behavior) that differentiates the general packet from the BIST Test Data packet.

**BIST Carrier Mode 2**

When required, this BIST test mode sends an alternating pattern of 1010 that is continually repeated. As this mode is intended for signal analysis it is stable condition with (in V1.0 of the USB PD specification) no defined length. Starting from V1.1 of the USB PD specification, the protocol layer defines a counter that indicates when to exit this mode.

The way to quit the infinite 1010 sequence (according to requirements of the USB PD specification) is to disable the UCPD peripheral via the UCPDEN bit.

**Figure 790. BIST Carrier Mode 2 frame**

![BIST Carrier Mode 2 frame diagram](image)

### 56.4.4 UCPD BMC transmitter

The BMC transmitter comprises 4b5b encoding, CRC generation, and BMC encode, as shown in the following figure. Its output goes to the analog PHY through a channel switch.
BMC encoder

The half-bit clock hbit_clk is derived from ucpd_clk through a simple divider controlled by the HBITCLKDIV[5:0] bitfield of the UCPD_CFGR1 register. This ensures the same duration of high and low half-bit periods (if neglecting a small difference due to different rising and falling edge duration and due to jitter), and the same bit duration (if neglecting jitter).

Transmitter timing and collision avoidance

Hardware support of collision avoidance is made as a function of the half bit time for the transmitter. Two counters are implemented:

- $t_{\text{InterFrameGap}}$: via IFRGAP (pre-defined value, can be altered)
- $t_{\text{TransitionWindow}}$: via TRANSWIN (pre-defined value, can be altered)

These two counters once set correctly generates the interframe gap.

Hard Reset in transmitter

In order to facilitate generation of a Hard Reset, a special code of TXMODE field is used. No other fields need to be written.

On writing the correct code, the hardware forces Hard Reset Tx under the correct (optimal) timings with respect to an ongoing Tx message, which (if still in progress) is cleanly terminated by truncating the current Tx message and directly appending an EOP K-code sequence. No specific interrupt is generated relating to this truncation event.

Transmitter behavior in the case of errors

The under-run condition (TXUND interrupt) may happen by accident and in this case, the UCPD is starved of (the correct) Tx payload and is not able to complete the Tx message correctly. This is a serious error (for this to happen the software fails to respond in time). As a result the hardware ensures the CRC is incorrect at the end of the message, thus guaranteeing the message to be discarded at the receiver.
56.4.5 **UCPD BMC receiver**

The UCPD BMC receiver performs:

- Clock recovery
- Preamble detection / timing derivation
- BMC decoding
- 4b5b decoding
- K-code ordered set recognition
- CRC checking
- SOP detection
- EOP detection

The receiver is activated as soon as the UCPD peripheral is enabled (via UCPDEN), but it waits for an idle CC line state before attempting to receive a message.

The following figure shows the UCPD BMC receiver high-level architecture.

![UCPD BMC receiver architecture](image)

**CRC checker**

The received bits are fed into a CRC checker which evolves a 32-bit state during the received the payload bitstream. At the end the 32 bits of the CRC also fed into the logic.

The EOP detection (5 bits) halts the process and a check is performed for the fixed residual state which confirms correct reception of the payload (in fact the residual is 0xC704DD78).

At this point the UCPD raises interrupt RXMSGEND. If the CRC was not correct then RXERR is set true and the receive data must be discarded.

Under normal operation, this interrupt would previously have been acknowledged and thus cleared. If this is not the case, a different interrupt RXOVR is generated in place of RXMSGEND.
Ordered set detection

This function detects the different ordered sets each consisting of four 5-bit K-codes. Once we are in the preamble we open a sliding window detection of the ordered set (4 words of 5 bits).

The ordered sets detected include all SOP* codes (SOP, SOP', and SOP''), but also Hard Reset, Cable Reset, SOP'_Debug, SOP''_Debug, and two extensions defined by registers UCPD_RX_ORDEXT1 and UCPD_RX_ORDEXT2.

EOP detection and Hard Reset exception handling

EOP is a fixed 5-bit K-code marking the end of a message.

The way in which a transmitter is required to send a Hard Reset (if a previous message transmit is still in progress) is that this previous message is truncated early with an EOP.

If Hard Reset were ignored, then the EOP detection can be done only at the expected time. However, due to the Hard Reset issue, the EOP detector must be active while an Rx message is arriving. When an “early EOP” is detected, the truncated Rx message is immediately discarded.

Truncated or corrupted message exception

Once the ordered set has been detected, depending on the message, there may be data bytes to be received which is completed with a CRC and EOP. If at any point during these phases an error condition happens:

• the line becomes static for a time significantly longer than one “UI” period (the exact threshold for this condition is not critical but the exception must occur before three UIs), or
• the message goes to the end but it is not recognized (for example EOP is corrupted).

In both cases, the receiver quits the current message, raising RXMSGEND and RXERR flags.

Short preamble or incomplete ordered set exception

In the exceptional case of the receiver seeing less that half of the expected preamble, the frequency estimation allowing correct BMC-decode becomes impossible. Even if the full preamble is seen, allowing frequency estimation, but the ordered set is not fully received before the line becomes static, the receiver state machine does not start.

In both of these cases, the clock-recovery/BMC decoder re-starts, checking initially for an IDLE condition, followed by a preamble, and then estimating frequency.

56.4.6 UCPD Type-C pull-ups (Rp) and pull-downs (Rd)

UCPD offers simple control of these resistors via ANAMODE and ANASUBMODE[1:0]. In case only one of the CC lines is to be used, it is possible to optimize power consumption by disabling control on the other line, through the CCENABLE[1:0] bitfield.

When the MCU is unpowered, it still presents the “dead battery” Rd, provided that UCPDx_DBCC1 and UCPDx_DBCC2 pins are each connected to UCPDx_CC1 and UCPDx_CC2 pins, respectively.

If dead battery behavior is not required (for example for source only products), then UCPDx_DBCC1 and UCPDx_DBCC2 pins must both be tied to ground.
After power arrives and the MCU boots, the desired behavior (for example source) must be programmed into ANAMODE and ANASUBMODE[1:0] before setting the UCPD_DBDIS bit of the PWR_CR3 register to remove dead battery pull-down resistor and allow the values just programmed to take effect.

Use of Standby low-power mode is possible for sinks in the unattached state.

56.4.7 UCPD Type-C voltage monitoring and de-bouncing

For correct operation of the Type-C state machine and for detecting the cable orientation, the CC1/2 lines must be monitored for voltage level, while ignoring fast events such as peaks.

Thresholds between voltage levels on the CC1/2 lines are determined through PHY threshold detector settings.

The TYPEC_VSTATE_CC1/2[1:0] bitfields reflect the CC1/2 line levels processed with a hardware de-bouncing filter that suppresses high-speed line events such as peaks. The PHYCCSEL bit selects the line, CC1 or CC2, to be used for Power Delivery signaling.

For minimizing the power consumption, it is recommended to use the polling method, with the Type-C detectors only turned on for the instant of polling, rather than keeping the Type-C detectors permanently on and wake the device up from Stop mode upon CC1/2 line events.

56.4.8 UCPD fast role swap (FRS)

FRS signaling

The FRS condition (a pulse of a specific length), is generated upon setting the FRSTX bit.

For the duration of FRS condition, the I/O configured as UCPD_FRSTX (alternate function) controls, with high level, the gate of an external NMOS transistor that pulls the active CC line down.

FRS detection

FRS monitoring is enabled by setting the bit FRSRXEN, after writing PHYCCSEL that selects the active CC line depending on the cable orientation detected.

56.4.9 UCPD DMA Interface

DMA is implemented in the UCPD and when it is enabled the byte-level interrupts to handle UCPD1_TXDR and UCPD1_RXDR registers (Tx and Rx data register, each one byte) are no longer needed.

By enabling bits TXDMAEN and/or RXDMAEN, DMA can be activated independently for Tx and/or Rx functionality.

56.4.10 Wake-up from Stop mode

For power consumption optimization, it is useful to use Stop mode and wait for events on CC lines to wake the MCU up.

In order for this to work, it must be first enabled by writing a 1 to WUPEN.
The events causing the wake-up can be:

- Events on the BMC receiver (RXORDDET, RXHRSTDET), hardware enable PHYRXEN
- Event on the FRS detector (FRSEVT), hardware enable FRSRXEN
- Events on the Type-C detectors (TYPECEVT1, TYPECEVT2), hardware enables CC1TCDIS, CC2TCDIS

56.5 UCPD programming sequences

The normal sequence of use of the UCPD unit is:
1. Configure UCPD.
2. Enable UCPD.
3. Concurrently:
   - On demand from protocol layer, send Tx message
   - Intercept (poll or wait for interrupt) relevant Rx messages and recover detail to hand off to protocol layer

Repeat the last point infinitely.

56.5.1 Initialization phase

Use the following sequence for a clean startup:
1. Prepare all initial clock divider values, by writing the UCPD_CFG register.
2. Enable the unit, by setting the UCPDEN bit.
3. Enable the analog Rx filter of either CC line, via the RXAFILTEN bit of the UCPD_CFG2 register.

56.5.2 Type-C state machine handling

For the general application cases of source, sink, or dual-role port (the last alternating the source and the sink), the software must implement a corresponding USB Type-C state machine. The basic coding is in the following table.

<table>
<thead>
<tr>
<th>ANAMODE</th>
<th>ANASUBMODE[1:0]</th>
<th>Notes</th>
<th>TYPEC_VSTATE_CCx[1:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0: Source</td>
<td>00: Disabled</td>
<td></td>
<td>00</td>
</tr>
<tr>
<td></td>
<td>01: Default USB Rp</td>
<td>-</td>
<td>vRa[Def] vRd[Def] vOPEN[Def]</td>
</tr>
<tr>
<td></td>
<td>10: 1.5A Rp</td>
<td>-</td>
<td>vRa[1.5] vRd[1.5] vOPEN[1.5]</td>
</tr>
<tr>
<td>1: Sink</td>
<td>xx</td>
<td>-</td>
<td>vRa vRd-USB vRd-1.5 vRd-3.0</td>
</tr>
</tbody>
</table>

The CCENABLE[1:0] bitfield can disable pull-up/pull-downs on one of the CC lines.

Note: The Type-C state machine depends not only on CC line levels, but also on VBUS presence detection (sink mode) and, when in source mode, determines VCONN generation and
VBUS state (ON/OFF/+voltage level); discharge). UCPD does not directly control VBUS generation circuitry nor VCONN load switch (enabling VCONN supply generator to be connected to the CC line), but the application needs these inputs and controls, to function correctly.

General programming sequence (with UCPD configured then enabled)

1. Set ANAMODE and ANASUBMODE[1:0] based on the current position in USB Type-C state machine (and also the current advertisement in the case of a source). This turns on the appropriate pull-ups/pull-downs on the CC lines, and defines the voltage levels that the TYPEC_VSTATE fields represent. Note that before programming, the PHY is effectively off.

2. Read TYPEC_VSTATE_CC1/2 to determine the initial Type-C state (for example whether the local source is connected to a remote sink).

3. In the case of no connection, wait for a connection event.

4. Assuming a connection is detected and assuming a local Power Delivery functionality is implemented, start sending/receiving Power Delivery messages.

5. When a new interrupt/event occurs on PHYEV1/2 indicating a change in stable voltage, re-evaluate the implications and give this input to the Type-C state machine.

Case of a source that needs to change between one of the three possible Rp values (Default-USB / 1.5A / 3.0A) and the sink connected to it:

- [Source] Simply reprogram ANASUBMODE[1:0]
- [Sink behavior from that time] PHYEV1/2 occurs and the TYPEC_VSTATE1/2 changes accordingly

Programming for a dual-role port (DRP) toggling from source to sink:

- Simply re-program ANAMODE and ANASUBMODE[1:0] to start the new behavior

Detailed programming sequence (example):
### 56.5.3 USB PD transmit

On reception of a message from the protocol layer (that is, to be sent), prepare Tx message contents by writing the UCPD_TX_ORDSET and UCPD_TX_PAYSZ registers.

The message transmission is triggered by setting the TXSEND bit, with an appropriate value of the TXMODE bitfield.

When the data byte is transmitted, the TXIS flag is raised to request a new data write to the UCPD_TXDR register.

This re-iterates until the entire payload of data is transmitted.

---

<td></td>
</tr>
</tbody>
</table>

1. Two GPIOs to enable VCONN through external load switch components
Upon sending the CRC packet, the TXMSGSENT flag is set to indicate the completion of the message transmission.

**Hard Reset transmission**

As soon as it is known that a Hard Reset needs to be transmitted, setting the TXHRST bit of the UCPD_CR register forces the internal state machine to generate the correct sequence. The value of UCPD_TX_ORDSET does not require update in this precise case (the correct code for Hard Reset is sent by UCPD).

The USB Power Delivery specification requires that in the case of an ongoing message transmission, the Hard Reset takes precedence. In this case, for example, UCPD truncates the payload of the current message, appending EOP to the end. No notification is available via the registers (for example through the TXMSGSEND flag). This is justified by the fact that the Hard Reset takes precedence over any previous activity (for which it is therefore no longer important to know if it is completed).

**Use of DMA for transmission**

DMA (Direct Memory Access) can be enabled for transmission by setting the TXDMAEN bit in the UCPD_CR register.

For each message:

- Prepare the whole message in memory (starting with two header bytes)
- Program the DMA operation with a length corresponding to the two header bytes plus a number of data bytes corresponding to the number of data words multiplied by four
- Write TXSEND to initiate the message transfer
- If TXMSGDISC then go back to previous line (TXSEND)
- Wait for DMA transfer complete interrupt (that is, when last Tx byte written to UCPD)
- Double-check subsequent TXMSGSENT interrupt appears

### 56.5.4 USB PD receive

Notification of start of the receive message sequence is triggered by an interrupt on UCPD_SR (bit RXORDDET).

The information is recovered by reading:

- UCPD_RX_SOP (on interrupt RXORDDET)
- UCPD_RXDR (on interrupt RXNE, repeats for each byte)
- UCPD_RXPAYSZ (on interrupt RXMSGEND)

The data previously read from UCPD_RXDR above must be discarded at this point if the RXERR flag is set.

If the CRC is valid, the received data is transferred to the protocol layer.

For debug purposes, it may be desirable to track statistics of the number of incorrect K-codes received (this is done only when 3/4 K-codes were valid as defined in the specification). This is facilitated through:

- RXSOP3OF4 bit indicating the presence of at least one invalid K-code
- RXSOPKINVALID bitfield identifying the order of invalid K-code in the ordered set
Use of DMA for reception

DMA (Direct Memory Access) can be enabled for reception by setting the RXDMAEN bit in the UCPD_CR register.

Whenever a Rx message is expected:
- Program a DMA receive operation (and spare buffer) a little longer than the maximum possible message (length depends on extended message support).
- After receiving RXORDDET, DMA operation starts working in the background.
- On reception of RXMSGEND interrupt, read RXPAYSZ.
- Double-check RXPAYSZ vs. the number of DMA Rx bytes (must correspond but DMA read of RXDR is slightly after RXDR gets last byte).
- Process the DMA Rx buffer.
- Prepare next Rx DMA buffer as soon as possible in order to be ready.

56.5.5 UCPD software trimming

The CC pull-up (Rp) and pull-down (Rd) devices must be trimmed on each part, to meet the required accuracy. The trimming values are saved in the non-volatile memory.

To trim the CC pull-up and pull-down devices by software, apply the following procedure:
1. Retrieve the trim values from the non-volatile memory (refer to Table 605: UCPD software trim data)
2. At initialization, write the trim values to the UCPD_CFGR3 register bitfields as follows:
   - 3A0_CC1[3:0] to TRIM_CC1_RP[3:0]
   - 3A0_CC2[3:0] to TRIM_CC2_RP[3:0]
   - Rd_CC1[3:0] to TRIM_CC1_RD[3:0]
   - Rd_CC2[3:0] to TRIM_CC2_RD[3:0]
3. At each setting of ANASUBMODE to 1A5 or 3A0, respectively, write the trimming values to the UCPD_CFGR3 register bitfields as follows:
   - 1A5_CC1[3:0] or 3A0_CC1[3:0], respectively, to TRIM_CC1_RP[3:0]
   - 1A5_CC2[3:0] or 3A0_CC2[3:0], respectively, to TRIM_CC2_RP[3:0]

56.6 UCPD low-power modes

A summary of low-power modes is shown below in Table 614: Effect of low power modes on the UCPD.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect</td>
</tr>
<tr>
<td>Stop</td>
<td>Detection of events (Type-C, BMC Rx, FRS detection) remains operational and can wake up the MCU.</td>
</tr>
<tr>
<td>Standby</td>
<td>UCPD is not operating, and cannot wake up the MCU. Pull-downs remain active if configured.</td>
</tr>
<tr>
<td>Unpowered</td>
<td>Dead battery pull-downs remain active.</td>
</tr>
</tbody>
</table>
The UCPD is able to wake up the MCU from Stop mode when it recognizes a relevant event, either:

- Type-C event relating to a change in the voltage range seen on either of the CC lines, visible in TYPEC_VSTATE_CCx
- Power delivery receive message with an ordered set matching those filtered according to RXORDSETEN[8:0], visible by reading RXORDSET

Wake-up from Stop mode is enabled by setting the WUPEN bit in the UCPD_CFG2 register.

At UCPD level three types of event requiring kernel clock activity may occur during Stop mode:

- Activity on the analog PHY voltage threshold detectors which can later be confirmed to be a stable change between voltage ranges defined in the Type-C specification
- Activity on Power Delivery BMC receiver (coming from the selected CC line) which can potentially generate an Rx message event (that is, RXORDSET) later
- Activity on Power Delivery FRS detector which can potentially generate an FRS signaling detection event (that is, FRSEVT) later

It order to function correctly with the RCC, the clock request signal is activated (conditional on WUPEN) when there is asynchronous activity on:

- Type-C voltage threshold detectors (coming from either CC line)
- Power Delivery receiver signal (from the selected CC line)
- FRS detection signal (from the selected CC line)

### 56.7 UCPD interrupts

The table below lists the UCPD event flags, with the associated flag clear bits and interrupt enable bits.

<table>

</tbody>
</table>
When an interrupt from the UCPD is received, then the software has to check what is the source of the interrupt by reading the UCPD_SR register. Depending on which bit is at 1, the ISR must handle that condition and clear the bit by a write to the appropriate bit of the UCPD_ICR register.

### 56.8 UCPD registers

#### 56.8.1 UCPD configuration register 1 (UCPD_CFGR1)

**Address offset:** 0x000  
**Reset value:** 0x0000 0000  

General configuration of the peripheral. Writing to this register is only effective when UCPD is disabled (UCPDEN = 0).

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

**Bit 31** **UCPDEN**: UCPD peripheral enable  
General enable of the UCPD peripheral.  
0: Disable  
1: Enable  
Upon disabling, the peripheral instantly quits any ongoing activity and all control bits and bitfields default to their reset values. They must be set to their desired values each time the peripheral transits from disabled to enabled state.

**Bit 30** **RXDMAEN**: Reception DMA mode enable  
When set, the bit enables DMA mode for reception.  
0: Disable  
1: Enable
Bit 29 TXDMAEN: Transmission DMA mode enable
 When set, the bit enables DMA mode for transmission.
 0: Disable
 1: Enable

Bits 28:20 RXORDSETEN[8:0]: Receiver ordered set enable
 The bitfield determines the types of ordered sets that the receiver must detect. When
 set/cleared, each bit enables/disables a specific function:
 0bXXXXXXXX1: SOP detect enabled
 0bXXXXXXXX1X: SOP’ detect enabled
 0bXXXXXXXX1XX: SOP” detect enabled
 0bXXXXXX1XXXX: Hard Reset detect enabled
 0bXXXXX1XXXX: Cable Detect reset enabled
 0bXXXX1XXXXX: SOP_Debug enabled
 0bXX1XXXXXX: SOP”_Debug enabled
 0bX1XXXXXXX: SOP extension#1 enabled
 0b1XXXXXXXX: SOP extension#2 enabled

Bits 19:17 PSC_USBPDCLK[2:0]: Pre-scaler division ratio for generating ucpd_clk
 The bitfield determines the division ratio of a kernel clock pre-scaler producing UCPD
 peripheral clock (ucpd_clk).
 0x0: 1 (bypass)
 0x1: 2
 0x2: 4
 0x3: 8
 0x4: 16
 It is recommended to use the pre-scaler so as to set the ucpd_clk frequency in the range
 from 6 to 9 MHz.

Bit 16 Reserved, must be kept at reset value.

Bits 15:11 TRANSWIN[4:0]: Transition window duration
 The bitfield determines the division ratio (the bitfield value minus one) of a hbit_clk divider
 producing tTransitionWindow interval.
 0x0: Not supported
 0x01: 2
 0x09: 10 (recommended)
 0x1F: 32
 Set a value that produces an interval of 12 to 20 us, taking into account the ucpd_clk
 frequency and the HBITCLKDIV[5:0] bitfield setting.

Bits 10:6 IFRGAP[4:0]: Division ratio for producing inter-frame gap timer clock
 The bitfield determines the division ratio (the bitfield value minus one) of a ucpd_clk divider
 producing inter-frame gap timer clock (tInterFrameGap).
 0x0: Not supported
 0x01: 2
 0x0D: 14
 0x0E: 15
 0x0F: 16
 0x1F: 32
 The division ratio 15 is to apply for Tx clock at the USB PD 2.0 specification nominal value.
 The division ratios below 15 are to apply for Tx clock below nominal, and the division ratios
 above 15 for Tx clock above nominal.
### UCPD configuration register 2 (UCPD_CFGR2)

Address offset: 0x004  
Reset value: 0x0000 0000

Configuration of the UCPD Rx signal filtering. Writing to this register is only effective when UCPD is disabled (UCPDEN = 0).

</tr>
</tbody>
</table>

**Bits 31:9** Reserved, must be kept at reset value.

**Bit 8** RXAFILTEN: Rx analog filter enable  
Setting the bit enables the Rx analog filter required for optimum Power Delivery reception.  
0: Disable  
1: Enable

**Bits 7:4** Reserved, must be kept at reset value.

**Bit 3** WUPEN: Wake-up from Stop mode enable  
Setting the bit enables the UCPD_ASYNC_INT signal.  
0: Disable  
1: Enable

**Bit 2** FORCECLK: Force ClkReq clock request  
0: Do not force clock request  
1: Force clock request

**Bit 1** RXFILT2N3: BMC decoder Rx pre-filter sampling method  
Number of consistent consecutive samples before confirming a new value.  
0: 3 samples  
1: 2 samples

**Bit 0** RXFILTDIS: BMC decoder Rx pre-filter enable  
0: Enable  
1: Disable

The sampling clock is that of the receiver (that is, after pre-scaler).
56.8.3 UCPD configuration register 3 (UCPD_CFGR3)

Address offset: 0x008
Reset value: 0x0000 0000

Configuration of UCPD trimming of the CC pull-up and pull-down devices. The trimming is managed by hardware until the first software write into this register.

The register is reserved (must not be written) for devices that support the fully automatic trimming. Refer to Table 604: UCPD implementation.

</table>

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:25 TRIM_CC2_RP[3:0]: SW trim value for Rp current sources on the CC2 line

Bits 24:20 Reserved, must be kept at reset value.

Bits 19:16 TRIM_CC2_RD[3:0]: SW trim value for Rd resistor on the CC2 line

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:9 TRIM_CC1_RP[3:0]: SW trim value for Rp current sources on the CC1 line

Bits 8:4 Reserved, must be kept at reset value.

Bits 3:0 TRIM_CC1_RD[3:0]: SW trim value for Rd resistor on the CC1 line

56.8.4 UCPD control register (UCPD_CR)

Address offset: 0x00C
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **CC2TCDIS**: CC2 Type-C detector disable
   The bit disables the Type-C detector on the CC2 line.
   0: Enable
   1: Disable
   When enabled, the Type-C detector for CC2 is configured through ANAMODE and
   ANASUBMODE[1:0].

Bit 20  **CC1TCDIS**: CC1 Type-C detector disable
   The bit disables the Type-C detector on the CC1 line.
   0: Enable
   1: Disable
   When enabled, the Type-C detector for CC1 is configured through ANAMODE and
   ANASUBMODE[1:0].

Bit 19  Reserved, must be kept at reset value.

Bit 18  **RDCH**: Rdch condition drive
   The bit drives Rdch condition on the CC line selected through the PHYCCSEL bit (thus
   associated with VCONN), by remaining set during the source-only UnattachedWait.SRC
   state, to respect the Type-C state. Refer to "USB Type-C ECN for Source VCONN
   Discharge". The CCENABLE[1:0] bitfield must be set accordingly, too.
   0: No effect
   1: Rdch condition drive

Bit 17  **FRSTX**: FRS Tx signaling enable.
   Setting the bit enables FRS Tx signaling.
   0: No effect
   1: Enable
   The bit is cleared by hardware after a delay respecting the USB Power Delivery specification
   Revision 3.1.

Bit 16  **FRSRXEN**: FRS event detection enable
   Setting the bit enables FRS Rx event (FRSEVT) detection on the CC line selected through
   the PHYCCSEL bit. 0: Disable
   1: Enable
   Clear the bit when the device is attached to an FRS-incapable source/sink.

Bit 15  Reserved, must be kept at reset value.

Bit 14  Reserved, must be kept at reset value.

Bit 13  Reserved, must be kept at reset value.

Bit 12  Reserved, must be kept at reset value.

Bits 11:10  **CCENABLE[1:0]**: CC line enable
   This bitfield enables CC1 and CC2 line analog PHYs (pull-ups and pull-downs) according to
   ANAMODE and ANASUBMODE[1:0] setting.
   0x0: Disable both PHYs
   0x1: Enable CC1 PHY
   0x2: Enable CC2 PHY
   0x3: Enable CC1 and CC2 PHY
   A single line PHY can be enabled when, for example, the other line is driven by VCONN via
   an external VCONN switch. Enabling both PHYs is the normal usage for sink/source.
Bit 9 **ANAMODE**: Analog PHY operating mode
0: Source
1: Sink
The use of CC1 and CC2 depends on CCENABLE. Refer to Table 612: Coding for ANAMODE, ANASUBMODE and link with TYPEC_VSTATE_CCx for the effect of this bitfield in conjunction with ANASUBMODE[1:0].

Bits 8:7 **ANASUBMODE[1:0]**: Analog PHY sub-mode
Refer to Table 612: Coding for ANAMODE, ANASUBMODE and link with TYPEC_VSTATE_CCx for the effect of this bitfield.

Bit 6 **PHYCCSEL**: CC1/CC2 line selector for USB Power Delivery signaling
0: Use CC1 IO for Power Delivery communication
1: Use CC2 IO for Power Delivery communication
The selection depends on the cable orientation as discovered at attach.

Bit 5 **PHYRXEN**: USB Power Delivery receiver enable
0: Disable
1: Enable
Both CC1 and CC2 receivers are disabled when the bit is cleared. Only the CC receiver selected via the PHYCCSEL bit is enabled when the bit is set.

Bit 4 **RXMODE**: Receiver mode
Determines the mode of the receiver.
0: Normal receive mode
1: BIST receive mode (BIST test data mode)
When the bit is set, RXORDSET behaves normally, RXDR no longer receives bytes yet the CRC checking still proceeds as for a normal message. As this mode prevents reception of the header (containing MessageID), software has to auto-increment a received MessageID counter for inclusion in the GoodCRC acknowledge that must still be transmitted during this test.

Bit 3 **TXHRST**: Command to send a Tx Hard Reset
0: No effect
1: Start Tx Hard Reset message
The bit is cleared by hardware as soon as the message transmission begins or is discarded.

Bit 2 **TXSEND**: Command to send a Tx packet
0: No effect
1: Start Tx packet transmission
The bit is cleared by hardware as soon as the packet transmission begins or is discarded.

Bits 1:0 **TXMODE[1:0]**: Type of Tx packet
Writing the bitfield triggers the action as follows, depending on the value:
0x0: Transmission of Tx packet previously defined in other registers
0x1: Cable Reset sequence
0x2: BIST test sequence (BIST Carrier Mode 2)
Others: invalid
From V1.1 of the USB PD specification, there is a counter defined for the duration of the BIST Carrier Mode 2. To quit this mode correctly (after the "tBISTContMode" delay), disable the peripheral (UCPDEN = 0).
56.8.5 UCPD interrupt mask register (UCPD_IMR)

Address offset: 0x010
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

1: Enable

### 56.8.6 UCPD status register (UCPD_SR)

Address offset: 0x014  
Reset value: 0x0000 0000

The flags (single-bit status bitfields) are associated with interrupt request. Interrupt is generated if enabled by the corresponding bit of the UCPD_IMR register.

<table>
<thead>
<tr>
<th>Bit 31:21 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 31:21 Reserved, must be kept at reset value.</td>

</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit 31:21 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 31:21 Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bit 20 **FRSEVT**: FRS detection event

The flag is cleared by setting the FRSEVTCF bit.
0: No new event
1: New FRS receive event occurred

Bits 19:18 **TYPEC_VSTATE_CC2[1:0]**: CC2 line voltage level

The status bitfield indicates the voltage level on the CC2 line in its steady state.
0x0: Lowest
0x1: Low
0x2: High
0x3: Highest

The voltage variation on the CC2 line during USB PD messages due to the BMC PHY modulation does not impact the bitfield value.

Bits 17:16 **TYPEC_VSTATE_CC1[1:0]**:

The status bitfield indicates the voltage level on the CC1 line in its steady state.
0x0: Lowest
0x1: Low
0x2: High
0x3: Highest

The voltage variation on the CC1 line during USB PD messages due to the BMC PHY modulation does not impact the bitfield value.

Bit 15 **TYPECEVT2**: Type-C voltage level event on CC2 line

The flag indicates a change of the TYPEC_VSTATE_CC2[1:0] bitfield value, which corresponds to a new Type-C event. It is cleared by setting the TYPECEVT2CF bit.
0: No new event
1: A new Type-C event

Bit 14 **TYPECEVT1**: Type-C voltage level event on CC1 line

The flag indicates a change of the TYPEC_VSTATE_CC1[1:0] bitfield value, which corresponds to a new Type-C event. It is cleared by setting the TYPECEVT2CF bit.
0: No new event
1: A new Type-C event

Bit 13 **RXERR**: Receive message error

The flag indicates errors of the last Rx message declared (via RXMSGEND), such as incorrect CRC or truncated message (a line becoming static before EOP is met). It is asserted whenever the RXMSGEND flag is set.
0: No error detected
1: Error(s) detected

Bit 12 **RXMSGEND**: Rx message received

The flag indicates whether a message (except Hard Reset message) has been received, regardless the CRC value. The flag is cleared by setting the RXMSGENDCF bit.
0: No new Rx message received
1: A new Rx message received

The RXERR flag set when the RXMSGEND flag goes high indicates errors in the last-received message.

Bit 11 **RXOVR**: Rx data overflow detection

The flag indicates Rx data buffer overflow. It is cleared by setting the RXOVRRCF bit.
0: No overflow
1: Overflow

The buffer overflow can occur if the received data are not read fast enough.
Bit 10  **RXHRSTDET**: Rx Hard Reset receipt detection
   The flag indicates the receipt of valid Hard Reset message. It is cleared by setting the RXHRSTDETCF bit.
   0: Hard Reset not received
   1: Hard Reset received

Bit 9  **RXORDDET**: Rx ordered set (4 K-codes) detection
   The flag indicates the detection of an ordered set. The relevant information is stored in the RXORDSET[2:0] bitfield of the UCPD_RX_ORDSET register. It is cleared by setting the RXORDDETCF bit.
   0: No ordered set detected
   1: A new ordered set detected

Bit 8  **RXNE**: Receive data register not empty detection
   The flag indicates that the UCPD_RXDR register is not empty. It is automatically cleared upon reading UCPD_RXDR.
   0: Rx data register empty
   1: Rx data register not empty

Bit 7  Reserved, must be kept at reset value.

Bit 6  **TXUND**: Tx data underrun detection
   The flag indicates that the Tx data register (UCPD_TXDR) was not written in time for a transmit message to execute normally. It is cleared by setting the TXUNDCF bit.
   0: No Tx data underrun detected
   1: Tx data underrun detected

Bit 5  **HRSTSENT**: Hard Reset message sent
   The flag indicates that the Hard Reset message is sent. The flag is cleared by setting the HRSTSENCF bit.
   0: No Hard Reset message sent
   1: Hard Reset message sent

Bit 4  **HRSTDISC**: Hard Reset discarded
   The flag indicates that the Hard Reset message is discarded. The flag is cleared by setting the HRSTDISCCF bit.
   0: No Hard Reset discarded
   1: Hard Reset discarded

Bit 3  **TXMSGABT**: Transmit message abort
   The flag indicates that a Tx message is aborted due to a subsequent Hard Reset message send request taking priority during transmit. It is cleared by setting the TXMSGABTCF bit.
   0: No transmit message abort
   1: Transmit message abort

Bit 2  **TXMSGSENT**: Message transmission completed
   The flag indicates the completion of packet transmission. It is cleared by setting the TXMSGSENCF bit.
   0: No Tx message completed
   1: Tx message completed

In the event of a message transmission interrupted by a Hard Reset, the flag is not raised.
56.8.7 UCPD interrupt clear register (UCPD_ICR)

Address offset: 0x018

Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

| Bit 31:21 Reserved, must be kept at reset value. |
| Bit 20 | FRSEVTCF: FRS event flag (FRSEVT) clear |
| Setting the bit clears the FRSEVT flag in the UCPD_SR register. |
| Bit 19:16 Reserved, must be kept at reset value. |
| Bit 15 | TYPECEVT2CF: Type-C CC2 line event flag (TYPECEVT2) clear |
| Setting the bit clears the TYPECEVT2 flag in the UCPD_SR register. |
| Bit 14 | TYPECEVT1CF: Type-C CC1 event flag (TYPECEVT1) clear |
| Setting the bit clears the TYPECEVT1 flag in the UCPD_SR register. |
| Bit 13 Reserved, must be kept at reset value. |
| Bit 12 | RXMSGENDCF: Rx message received flag (RXMSGEND) clear |
| Setting the bit clears the RXMSGEND flag in the UCPD_SR register. |
Bit 11 **RXOVRCF**: Rx overflow flag (RXOVR) clear
Setting the bit clears the RXOVR flag in the UCPD_SR register.

Bit 10 **RXHRSTDETFC**: Rx Hard Reset detect flag (RXHRSTDET) clear
Setting the bit clears the RXHRSTDET flag in the UCPD_SR register.

Bit 9 **RXORDDETCF**: Rx ordered set detect flag (RXORDDET) clear
Setting the bit clears the RXORDDET flag in the UCPD_SR register.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TXUNDCF**: Tx underflow flag (TXUND) clear
Setting the bit clears the TXUND flag in the UCPD_SR register.

Bit 5 **HRSTSENDCF**: Hard reset send flag (HRSTSENT) clear
Setting the bit clears the HRSTSENT flag in the UCPD_SR register.

Bit 4 **HRSTDISCCF**: Hard reset discard flag (HRSTDISC) clear
Setting the bit clears the HRSTDISC flag in the UCPD_SR register.

Bit 3 **TXMSGABTCF**: Tx message abort flag (TXMSGABT) clear
Setting the bit clears the TXMSGABT flag in the UCPD_SR register.

Bit 2 **TXMSGSENCF**: Tx message send flag (TXMSGSENT) clear
Setting the bit clears the TXMSGSENT flag in the UCPD_SR register.

Bit 1 **TXMSGDSCCF**: Tx message discard flag (TXMSGDSC) clear
Setting the bit clears the TXMSGDSC flag in the UCPD_SR register.

Bit 0 Reserved, must be kept at reset value.

### 56.8.8 UCPD Tx ordered set type register (UCPD_TX_ORDSETR)

Address offset: 0x01C
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1) and no packet transmission is in progress (TXSEND and TXHRST bits are both low).

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **TXORDSET[19:0]**: Ordered set to transmit

The bitfield determines a full 20-bit sequence to transmit, consisting of four K-codes, each of five bits, defining the packet to transmit. The bit 0 (bit 0 of K-code1) is the first, the bit 19 (bit 4 of K-code4) the last.
56.8.9 UCPD Tx payload size register (UCPD_TX_PAYSZR)

Address offset: 0x020

Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TXPAYSZ[9:0]**: Payload size yet to transmit

The bitfield is modified by software and by hardware. It contains the number of bytes of a payload (including header but excluding CRC) yet to transmit: each time a data byte is written into the UCPD_TXDR register, the bitfield value decrements and the TXIS bit is set, except when the bitfield value reaches zero. The enumerated values are standard payload sizes before the start of transmission.

- 0x2: 2 bytes - the size of Control message from the protocol layer
- 0x6: 6 bytes - the shortest Data message allowed from the protocol layer
- 0x1E: 30 bytes - the longest non-extended Data message allowed from the protocol layer
- 0x106: 262 bytes - the longest possible extended message
- 0x3FF: 1024 bytes - the longest possible payload (for future expansion)

56.8.10 UCPD Tx data register (UCPD_TXDR)

Address offset: 0x024

Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

</tbody>
</table>

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 RXPAYSZ[9:0]: Rx payload size received

This bitfield contains the number of bytes of a payload (including header but excluding CRC) received: each time a new data byte is received in the UCPD_RXDR register, the bitfield value increments and the RXMSGEND flag is set (and an interrupt generated if enabled).

0x2: 2 bytes - the size of Control message from the protocol layer
0x6: 6 bytes - the shortest Data message allowed from the protocol layer
0x1E: 30 bytes - the longest non-extended Data message allowed from the protocol layer
0x106: 262 bytes - the longest possible extended message
0x3FF: 1024 bytes - the longest possible payload (for future expansion)

The bitfield may return a spurious value when a byte reception is ongoing (the RXMSGEND flag is low).

Refer to Section 2.3 on page 111 for the register boundary addresses.
57 Ethernet (ETH): media access control (MAC) with DMA controller

57.1 Ethernet introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

The Ethernet peripheral enables to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2008 standard.

The peripheral is configurable to meet the needs of a large variety of consumer and industrial applications.

57.2 Ethernet main features

The Ethernet peripheral embeds a dedicated DMA for direct memory interface, a media access controller (MAC) and a PHY interface block supporting several formats.

57.2.1 Standard compliance

The Ethernet peripheral is compliant with the following standards:
- IEEE 802.3-2008 for Ethernet MAC and media independent interface (MII)
- IEEE 1588-2008 for precision networked clock synchronization (PTP)
- IEEE 802.3az-2010 for Energy Efficient Ethernet (EEE)
- AMBA 2.0 for AHB master and AHB slave ports
- RMII specification version 1.2 from RMII consortium

57.2.2 MAC features

MAC Tx and Rx common features
- Separate transmission, reception, and control interfaces to the application
- 10, 100 Mbps data transfer rates with the following PHY interfaces:
  - IEEE 802.3-compliant MII interface to communicate with an external Fast Ethernet PHY
  - RMII interface to communicate with an external Fast Ethernet PHY
- Half-duplex operation:
  - CSMA/CD protocol support
  - Flow control using backpressure (based on implementation-specific white papers and UNH Ethernet Clause 4 MAC Test Suite - Annex D)
- Standard IEEE 802.3az-2010 for Energy Efficient Ethernet in MII PHYs
• 32-bit data transfer interface on the application side
• Full-duplex flow control operations (IEEE 802.3x Pause packets and Priority flow control)
• Network statistics with RMON or MIB counters (partial support of RFC2819/RFC2665)
• Ethernet packet timestamping as described in IEEE 1588-2002 and IEEE 1588-2008 (64-bit timestamps given in the Tx or Rx status of PTP packet). Both one-step and two-step timestamping are supported in Tx direction.
• Flexibility to control pulse-per-second (PPS) output signal (eth_ptp_pps_out and ETH_PPS_OUT)
• MDIO (Clause 22 and Clause 45) master interface for PHY device configuration and management

**MAC Tx features**
• Preamble and start-of-frame data (SFD) insertion
• Separate 32-bit status for each packet transmitted from the application
• Automatic CRC and pad generation controllable on a per-frame basis
• Programmable packet length to support Standard or Jumbo Ethernet packets of up to 16 Kbytes
• Programmable Inter Packet Gap (40–96 bit times in steps of 8)
• IEEE 802.3x Flow Control automatic transmission of zero-quanta Pause packet when flow control input transitions from assertion to de-assertion (in Full-duplex mode)
• Source address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control
• Insertion, replacement, or deletion of up to two VLAN tags
• Option to transmit packets with reduced preamble size in Full-duplex mode
• Insert, replace, or delete queue/channel-based VLAN tags

**MAC Rx features**
• Automatic Pad and CRC stripping options
• Option to disable automatic CRC checking
• Preamble and SFD deletion
• Separate 112-bit or 128-bit status
• Programmable watchdog timeout limit
• Flexible address filtering modes:
  – Four 48-bit perfect (DA) address filters with masks for each byte
  – Four 48-bit SA address comparison check with masks for each byte
  – 64 bit Hash filter for multicast and unicast (DA) addresses
• Option to pass all multicast addressed packets
• Promiscuous mode to pass all packets without any filtering for network monitoring
• Pass all incoming packets (as per filter) with a status report
Additional packet filtering:
- VLAN tag-based: Perfect match and Hash-based filtering based either on the outer or inner VLAN tag
- Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6

IEEE 802.1Q VLAN tag detection and option to delete the VLAN tags in received packets

Detection of remote wake-up packets and AMD magic packets

Optional forwarding of received Pause packets to the application (in Full-duplex mode)

Layer 3/Layer 4 checksum offload for received packets

Stripping of up to two VLAN tags and providing the tags in the status

57.2.3 Transaction layer (MTL) features

MTL Tx and Rx Common Features
- 32-bit Transaction Layer block (bridges the application and the MAC)
- Optimization for packet-oriented transfers with packets delimiters
- Programmable burst length, up to half the size of the MTL Rx queue or Tx queue size, to support burst data transfer in the EQOS-MTL configuration
- Programmable threshold capability for each queue (default of 64 bytes)

MTL Tx features
- 2048-byte Transmit FIFO with programmable threshold capability
- Store-and-forward mechanism or threshold mode (cut-through) for transmission to the MAC
- Automatic retransmission of collision packets in Half-duplex mode
- Discard packets on late collision, excessive collisions, excessive deferral, and under-run conditions with appropriate status
- Module to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum on frames transmitted in Store-and-forward mode
- Statistics by generating pulses for packets dropped (because of underflow) in the Tx FIFO
- Packet-level control for
  - VLAN tag insertion or replacement
  - Ethernet source address insertion
  - Layer 3/Layer 4 checksum insertion control
  - One-step timestamp
  - Timestamp control
  - CRC and pad control
MTL Rx features

- 2048-byte Receive FIFO with configurable threshold
- Programmable Rx queue threshold (default fixed at 64 bytes) in Threshold (or cut-through) mode
- Option to filter all error packets on reception and not forward them to the application in the store-and-forward mode
- Option to forward the undersized good packets
- Statistics by generating pulses for packets dropped (because of overflow) in the Rx FIFO
- Automatic generation of Pause packet control or backpressure signal to the MAC based on the Rx Queue fill level

57.2.4 DMA block features

The DMA block exchanges data between the peripheral and the system memory. DMA transfers are driven by software descriptors structure. The application can use a set of registers (see Section 57.11.2: Ethernet DMA registers) to control the DMA operations. The DMA block supports the following features:

- 32-bit data transfers
- Separate DMA in Transmit path and receive paths
- Optimization for packet-oriented DMA transfers with packet delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) descriptor support
- Descriptor architecture allowing large blocks of data transfer with minimum CPU intervention (each descriptor can transfer up to 32 Kbytes of data)
- Comprehensive status reporting normal operation and transfer errors
- Individual programmable burst length for Tx DMA and Rx DMA engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-packet Transmit or Receive Complete Interrupt control
- Round-robin or fixed-priority arbitration between the Receive and Transmit engines
- Start and Stop modes
- Separate ports for host control (AHB) access and host data interface
- Tx DMA channel with TCP segmentation offload (TSO) feature enabled
- Programmable control for Transmit Descriptor posted writes to improve the throughput

57.2.5 Bus interface features

AHB master interface

The AHB master interface features are the following:

- Interfaces with the application through AHB
- 32-bit data on the AHB master port
- Split, Retry, and Error AHB responses
- AHB 1-Kbyte boundary burst splitting
- Software-selected type of AHB burst (fixed burst, indefinite burst, or mix of both)
The AHB master interface does not generate the following:
- Wrap burst
- Locked or protected transfers

**AHB slave interface**

The AHB slave interface supports the following features:
- Interfaces with the application through AHB
- AHB slave interface (32-bit) for CSR access
- All AHB burst types

The AHB slave interface does not generate the following responses:
- Split
- Retry
- Error

### 57.3 Ethernet pins and internal signals

*Table 617* lists the Ethernet inputs and output signals connected to package pins or balls. Active pins depend on the PHY type selected (MII or RMII) and on the device configuration. *Table 618* shows the internal Ethernet signals.

**Table 617. Ethernet peripheral pins**

The Ethernet peripheral is composed of 4 main functional modules:

- **The control and status register module (CSR)** that controls the registers access through AHB 32-bit slave interface
- The direct memory access interface (DMA)
  This is the logical DMA module with one physical channel for reception and 1 for transmission. It controls the data transfers between MAC and system memory through the AMBA AHB 32-bit master interface.
- **The media access control module (MAC)** in charge of implementing the Ethernet protocol
- **The MAC transaction layer (MTL)** in charge of controlling the data flow between application and MAC.

A protocol adaption module is added to support the RMII PHY Media Independent Interfaces.
57.4.1 DMA controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines. The Tx engine transfers data from the system memory to the MAC Transaction Layer (MTL), whereas the Rx engine transfers data from the device port (PHY) to the system memory.

The controller uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

DMA data structures

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA transfers the data packets received by the MAC to the Rx buffer in system memory and Tx data packets from the Tx buffer in the system memory. The descriptors that reside in the system memory contain the pointers to these buffers.

The base address of each list is written to the respective Tx and Rx registers: Channel Tx descriptor list address register (ETH_DMACTXDLAR) and Channel Rx descriptor list address register (ETH_DMACRXDLAR).

---

1. For a definition of the internal signals, refer to Table 618.
2. Refer to RCC chapter "Clock distribution for Ethernet" for a detailed description of the Ethernet clock architecture.
The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The number of descriptors in the list is programmed in the respective Tx/Rx, Channel Tx descriptor ring length register (ETH_DMACTXRLR) and Channel Rx descriptor ring length register (ETH_DMACRXRLR).

Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List address register to create a descriptor ring. The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used and physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet, but cannot exceed a single packet. Buffers contain only data. The buffer status is saved in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

Descriptors are specified in Section 57.10: Descriptors.

DMA arbitration

The DMA module incorporates an arbiter that performs the arbitration between the Tx and Rx channels accesses from the AHB master interface. The following two types of arbitrations are supported and can be selected through DMA mode register (ETH_DMAMR):

- Round-robin arbitration: the arbiter allocates the data bus between Rx and Tx in ratio set by Bits [14:12] of ETH_DMAMR.
- Fixed-priority arbitration: by default Rx DMA always gets priority over Tx DMA for data access. Setting bit 11 of ETH_DMAMR register gives priority to the Tx DMA.
DMA transmission in default mode

The Tx DMA engine in default mode proceeds as follows:

1. The application sets up the Transmit descriptor (TDES0–TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet Packet data.

2. The application shifts the Descriptor tail pointer offset value of the Transmit channel.

3. The DMA fetches the descriptor from the application memory.

4. If the DMA detects one of the following conditions, the transmission from that channel is suspended, bit 2 and 16 of the corresponding DMA channel Status register are set, and the Tx engine proceeds to step 11:
   - The descriptor is flagged as owned by the application (TDES3[31] = 0).
   - The descriptor tail pointer is equal to the current descriptor pointer in Ring Descriptor list mode.
   - An error condition occurs.

5. If the acquired descriptor is flagged as owned by the DMA (TDES3[31] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.

6. The DMA fetches the Transmit data from the system memory and transfers the data to the MTL for transmission.

7. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3 through 7 are repeated until the end-of-Ethernet-packet data is transferred to the MTL.

8. When packet transmission is complete, if IEEE 1588 timestamp feature was enabled for the packet (as indicated in the Tx status), the timestamp value obtained from MTL is written to the Tx descriptor (TDES0 and TDES1) that contains the EOP buffer. The status information is written to this Tx descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step. If the timestamp feature is disabled for this packet, the DMA does not alter TDES0 and TDES1 contents.

9. Bit 0 of Channel status register (ETH_DMACSR) is set after completing transmission of a packet that has Interrupt on Completion (TDES2[31]) set in its Last Descriptor. The DMA engine returns to step 3.

10. In the Suspend state, the DMA tries to acquire the descriptor again (and thereby return to step 3). A poll demand command is triggered by writing any value to the Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. If the application stopped the DMA by clearing Bit 0 of Transmit control register of corresponding DMA channel, the DMA enters the Stop state.
**DMA transmission in OSP (Operate on Second Packet) mode**

In Run state, if bit 4 is set in the Channel transmit control register (ETH_DMACTXCR), the Transmit process can simultaneously acquire two packets without closing the Status descriptor of the first packet. While the Transmit process completes the first packet transfer, it immediately polls the Transmit descriptor list for the second packet. If the second packet is valid, the Transmit process transfers this packet before writing the status information of the first packet.
In OSP mode, DMA transmission in the Run state operates as described in the following sequence:

1. The DMA executes steps 1 to 7 of the DMA transmission sequence in default mode (see Section: DMA transmission in default mode).
2. The DMA fetches the next descriptor without closing previous packet last descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and jumps to step 7.
4. The DMA fetches the Transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors.
5. The DMA waits for the packet transmission status and timestamp of previous packet. When the status is available, the DMA writes the timestamp to TDES0 and TDES1 if such timestamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES3, thus closing the descriptor. If Timestamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES2 and TDES3.
6. The Transmit interrupt is set (if enabled). The DMA fetches the next descriptor and proceeds to step 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (step 7).
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA performs the following operations:
   a) The DMA writes the timestamp (if enabled for the current packet) to TDES2 and TDES3.
   a) The DMA writes the status to the corresponding TDES3.
   a) The DMA sets the relevant interrupts and returns to Suspend mode.
   If no status is pending and the application stopped the DMA by clearing bit 0 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state.
8. The DMA can exit Suspend mode and enter the Run state (it goes either to step 1 or to step 2 depending on pending status) only after receiving a Transmit Poll demand in Transmit Descriptor Tail Pointer register of corresponding channel.

A description of the basic DMA transmission flow in OSP mode in given in Figure 796: Receive DMA flow.

**DMA reception**

In the Receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel.

The reception sequence for Rx DMA engine is as follows (see also Figure 796: Receive DMA flow):

1. The application sets up the Rx descriptors (RDES0-RDES3) and the Own bit (RDES3[31]). The application must set the correct value in the Receive descriptor tail pointer register of corresponding DMA channel.

2. When bit 0 of `Channel receive control register (ETH_DMACRXCR)` is set, the DMA enters the Run state. The DMA looks for free descriptors based on the Rx Current Descriptor and Descriptor tail pointer register values. If there are no free descriptors, the DMA channel enters the Suspend state and goes to step 11.

3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors.

4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of current descriptor and sets the CTXT field (RDES3[30]).

5. The DMA processes the incoming packets and stores them in the data buffers of acquired descriptor.

6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to step 10.

7. The DMA retrieves the status of the Receive frame from the MTL and writes the status word to current descriptor with the Own bit cleared and the Last descriptor bit set.

8. The DMA writes the Frame Length to RDES3 and the VLAN tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor.

9. The DMA stores the timestamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor).

10. If more descriptors are available in the Rx DMA descriptor ring, go to step 3, otherwise go to the Suspend state (step 11).

11. The Receive DMA exits the Suspend state when a Receive Poll demand is given and the application increments the channel Receive tail pointer register. The engine proceeds to step 2 and fetches again the next descriptor.

Priority scheme for Tx DMA and Rx DMA

The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channel 0 to access descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the DMA mode register (ETH_DMAMR) specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a given channel.

If the Tx DMA and Rx DMA of a given channel are enabled, the DMA which gets the bus when the channel gets control of the bus must be specified. The priority between the corresponding Tx DMA and Rx DMA can be configured through the TXPR field of the DMA mode register (ETH_DMAMR). For round-robin arbitration, the weighted priority between the Tx DMA and Rx DMA is configured through the PR field of the DMA mode register (ETH_DMAMR). Table 619 provides information about the priority scheme between Tx DMA and Rx DMA.

57.4.2 MTL

The MAC Transaction Layer (MTL) provides the FIFO memory interface to buffer and regulate the packets between the application system memory and the MAC. It also enables the data to be transferred between the application clock and MAC clock domains. The MTL layer features two 32-bit wide data paths: the Transmit path and the Receive Path.

- Transmit path
  The application or internal DMA pushes the Ethernet packets read from the application or system memory into the Tx FIFO. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the application or internal DMA. The Tx queue size is 2048 bytes.

- Receive path
  The MTL Rx module receives the packets from the MAC and pushes them into the Rx queue. The status (fill level) of the queue is indicated to the application or to DMA when it crosses the configured Receive threshold (RTC bits[1:0] defined in Rx queue operating mode register (ETH_MTLRXQOMR)), or when the complete packet was received. The MTL also indicates the queue fill level so that the DMA can initiate preconfigured burst transfers towards the master interface. The Rx queue size is 2048 bytes.

57.4.3 MAC

The MAC is responsible of the Ethernet protocol processing. In Transmission mode, it receives data from MTL before transferring it to the PHY interface. In Reception mode, the MAC receives data from the PHY interface before transferring them to the Rx FIFO of the MTL module.

This section briefly describes transmission and reception sequences.

MAC transmission

The transmission sequence is as follows:

1. Transmission is initiated when the MTL application pushes in data with the SOP (Start of packet) signal asserted.
2. When the SOP signal is detected, the MAC accepts the data and begins the transmission to the MII.
3. When the EOP (End of packet) is transferred to the MAC, the MAC does one of the following:
   - The MAC completes the normal transmission and provides the transmission status to the MTL.
   - If a normal collision (in Half-duplex mode) occurs during transmission, the MAC provides the Transmit status to the MTL, with the Retry bit set. The MAC provides the Retry request till one of the following is true:
     - the packet was successfully transmitted;
     - the maximum number of Retry requests expires. In this case, the MAC aborts the packet transmission with Excessive Collision Transmit status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP when a Retry request (in the Status) is observed from the MAC.
– If any one of the following event happens, the MAC aborts the packet transmission:
  no carrier (Half-duplex mode)
  loss of carrier (Half-duplex mode)
  excessive deferral (Half-duplex mode)
  late collisions (Half-duplex mode)
  jabber

the MAC accepts and drops all further data until the next SOP is received.

4. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.

5. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

*Figure 797: Overview of MAC transmission flow* illustrates the MAC transmission process flow.
Figure 797. Overview of MAC transmission flow

1. Start
2. Wait for data & SOP From MTL
3. SOP asserted by MTL? YES
4. Wait for IPG/any back-off delay (hal-duplex)
5. Transmit preamble+SFD+Data received from the MTL to the PHY
6. No carrier/Carrier loss/Excessive deferral/Late collisions/Jabber? YES
   - Drop all the data received from MTL and abort transmission
7. NO
   - Collision
     - A. EOP asserted by MTL?
     - B. Underflow asserted by MAC?
     - Condition A
     - Condition B
   - Normal transmission completed and Transmission status conveyed to MTL
8. Send status to MTL with Retry bit set
9. Condition D: Retry_count ≤ retry_limit
10. YES
    - Drop all the data received from MTL and abort transmission
11. NO
MAC reception

A receive operation is initiated when the MAC detects an SFD on MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

The reception sequence is as follows:

1. When the receive data valid signal (RxDV) of MII becomes active, the Receive State Machine (RSM) starts looking for the SFD field (0xD nibble).
   The state machine drops received packets until it detects SFD.

2. When SFD is detected, the state machine starts sending the data of Ethernet packet to the RPC module, beginning with the first byte following the SFD (destination address).

3. If IEEE 1588 timestamp feature is enabled, the MAC takes a snapshot of the system time at which SFD of any packet is detected on MII. If this packet is not dropped during MAC filtering, the timestamp is passed to the application. The MAC converts the received nibble data into bytes and forwards the valid packet data to the RFC module.

4. The Receive State Machine decodes the Length/Type field of the Ethernet packet being received.
   If the Length/Type field is less than 1,536 and if the MAC is programmed for the Auto CRC/Pad Stripping (bit 20 of the Operating mode configuration register (ETH_MACCR)), the state machine sends the packet data up to the count specified in the Length/Type field and starts dropping bytes (including the FCS field). The state machine decodes the Length/Type field and checks for the Length interpretation.

5. If the Length/Type field is greater than or equal to 1,536, the RPE module sends all received Ethernet packet data to the RFC module if you have not enabled the CRC stripping for Type packet in Bit 21 of the Operating mode configuration register (ETH_MACCR). However, if the CRC stripping has been enabled for Type packets and not enabled the Receive Checksum Offload Engine, the MAC strips and drops the last 4 bytes of all packets of ether type before forwarding the packets to the application.

6. By default, the MAC is programmed for watchdog timer to be enabled, that is, packets above 2,048 (10,240 if Jumbo Packet is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the RPE module. In addition, you can use a programmable watchdog timer (bit 16 of Watchdog timeout register (ETH_MACWTR)) to override the fixed timeout of 2,048 or 10,240 bytes. You can disable the watchdog timer by programming bit 19 of Operating mode configuration register (ETH_MACCR). However, even if the watchdog timer is disabled, a packet greater than 32 Kbytes is cut off and a watchdog timeout status is given.
Figure 798. MAC reception flow

1. Start
2. Wait for phy_rxRxdv_i from GMII/MII
3. Wait until SFD is detected
4. Start sending the received Ethernet packet to the application layer, starting from DA field
5. IEEE 1588 timestamp feature enabled?
   - YES: Store the snapshot of the system time when SFD detected
   - NO: Length/Type field < 1536 & Auto CRC/Pad stripping enabled?
      - NO: Length/Type field ≥ 1536
      - YES: CRC stripping for Type packets enabled?
         - YES: Receive checksum
         - NO: CRC error? OR Packet to be filtered?
            - NO: CRC error? OR Packet to be filtered?
            - YES: Drop the packet and send the Status to the Application layer
            - NO: Send the packet, timestamp and Status to the Application layer
   - NO: Send only the number of bytes (specified in the Length field) of the received Ethernet packet to RFC. Drop extra padding and FCS field
      - CRC error? OR Packet to be filtered?
        - NO: CRC error? OR Packet to be filtered?
        - YES: Drop the packet and send the Status to the Application layer
        - NO: Send all received Ethernet packet data to RFC
          - CRC error? OR Packet to be filtered?
            - NO: CRC error? OR Packet to be filtered?
            - YES: Drop the last 4 bytes of all Ether type packets and send the remaining bytes to RFC
            - NO: Drop the packet and send the Status to the Application layer

57.5 **Ethernet functional description: MAC**

57.5.1 **Double VLAN processing**

The Ethernet peripheral supports the double VLAN (Virtual LAN) tagging feature in which the MAC can process up to two VLAN tags (inner and outer).

The MAC supports the following:
- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status

**Transmit path**

*Table 620: Double VLAN processing features in Tx path* describes the features supported by the MAC on the Transmit side.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support for C-VLAN and S-VLAN Tag types</td>
<td>The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of VLAN inclusion register (ETH_MACVIR) and Inner VLAN inclusion register (ETH_MACIVIR), respectively. The Ethernet peripheral supports processing of any sequence of outer and inner VLAN tags. However, it does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: – The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. – The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. – The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. – The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.</td>
</tr>
<tr>
<td>VLAN Tag deletion</td>
<td>VLAN tag deletion can be enabled for outer or inner tag through VLC field in the VLAN inclusion register (ETH_MACVIR) or Inner VLAN inclusion register (ETH_MACIVIR), respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag.</td>
</tr>
<tr>
<td>VLAN Tag Insertion or Replacement</td>
<td>VLAN tag insertion or replacement can be enabled for outer or inner tag through VLC field in the VLAN inclusion register (ETH_MACVIR) or Inner VLAN inclusion register (ETH_MACIVIR), respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the previous register is used to determine whether the VLAN tag should be taken from the register or the control word.</td>

57.5.2 Source address and VLAN insertion, replacement, or deletion

Source address insertion or replacement

The software can use the SA (source address) insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address registers in the SA field
- Replace the content of the SA field with the content of the MAC Address registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

SA insertion or replacement feature can be enabled for all Transmit packets or selective packets:

- Enabling SA insertion or replacement for all packets
  To enable this feature for all packets, program the SARC field of the Operating mode configuration register (ETH_MACCR).
- Enabling SA insertion or replacement for selective packets
  To enable this feature for selective packets, use the following program the SA Insertion Control field (bits[25:23] of Transmit Descriptor Word 3/TDES3, refer to Section 57.10.3: Transmit descriptor) in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or
replacement by MAC Address1 registers. When bit 25 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.

If MAC Address1 registers are not enabled, the MAC Address0 registers are used for insertion or replacement whatever of the value of the most-significant bit of the SA Insertion Control field.

**VLAN insertion, replacement, or deletion**

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields
- Insert or replace the VLAN Type and VLAN Tag fields

Insertion or replacement is performed based on the setting of VLTI bit in the **VLAN inclusion register (ETH_MACVIR)** as described in **Table 622: VLAN insertion or replacement based on VLTI bit**.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLTI bit is set</td>
<td>The MAC inserts or replaces the following:</td>
</tr>
<tr>
<td></td>
<td>VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of VLAN inclusion register (ETH_MACVIR))</td>
</tr>
<tr>
<td></td>
<td>VLAN Tag field with VT field of Transmit context descriptor of the packet</td>
</tr>
<tr>
<td>VLTI bit is reset</td>
<td>The MAC inserts or replaces the following:</td>
</tr>
<tr>
<td></td>
<td>VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of VLAN inclusion register (ETH_MACVIR))</td>
</tr>
<tr>
<td></td>
<td>VLAN Tag field with the VLT field of VLAN inclusion register (ETH_MACVIR)</td>
</tr>
</tbody>
</table>

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88A8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- To enable this feature for all packets, program the VLC and VLP fields of **VLAN inclusion register (ETH_MACVIR)**.
- To enable this feature for selective packets, program the VTIR field of TDES2 Normal Descriptor (see **Table 655: TDES2 normal descriptor (read format)**).

In addition, the VLP (VLAN Priority control) bit must be reset in **VLAN inclusion register (ETH_MACVIR)** (for outer VLAN) and **Inner VLAN inclusion register (ETH_MACIVIR)** (in inner VLAN) for the MAC to take the control inputs from the host, depending on the configuration.
57.5.3 Packet filtering

The MAC supports the following types of filtering for Rx packets:

- **MAC source or destination address filtering**: the Address Filtering Module (AFM) checks the source address and destination address fields of each incoming packet.
- **VLAN filtering**: the MAC supports the VLAN tag-based and VLAN Hash filtering.
- **Layer 3 and Layer 4 filtering**: Layer 3 filtering refers to IP source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering.

The three filter types can be cascaded. *Figure 799* shows the filtering sequence for Rx packets.

*Figure 799. Packet filtering sequence*

The sequence shown in *Figure 799* is valid when all the filters (L2, VLAN, L3, L4) are active. If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters is discarded. However, the discarded packet can be forwarded to the host based on the register control.

For example, when RA bit of *Packet filtering control register (ETH_MACPFR)* is set to 1, all the discarded packets are forwarded to the host but with their packet status indicating the
specific filter failure. If RA bit is cleared to 0, VTFE and IPFE bits of Packet filtering control register (ETH_MACPFR) control if the packets that fail the VLAN filter and Layer 3-4 filter should be discarded or forwarded to the host.

**MAC source or destination address filtering**

The MAC address filtering module checks the source address (SA) and destination address (DA) fields of each incoming packet.

**Unicast destination address filtering**

The MAC supports 4 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of Packet filtering control register (ETH_MACPFR) is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default MacAddr0 is always enabled.

The MacAddr1 to MacAddr3 addresses are selected with an individual enable bit. You can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in MAC Address x high register (ETH_MACAxHR). This enables group address filtering for the DA.

In Hash filtering mode (when HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For Hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 00000 selects bit 0 of selected register, and a value of 11111 selects bit 63 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

**Multicast destination address filtering**

To program the MAC to pass all multicast packets, set the PM bit in Packet filtering control register (ETH_MACPFR). If the PM bit is reset, the MAC performs the filtering for multicast addresses based on the HMC bit of the Packet filtering control register (ETH_MACPFR).

In Perfect filtering mode, the multicast address is compared with the programmed MAC destination address registers. Group address filtering is also supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC of received multicast address to index the content of the Hash table. A value of 00000 selects bit 0 of selected register and a value of 11111 selects bit 63 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

**Hash or Perfect address filtering**

To configure the DA filter to pass a packet when its DA matches either the Hash filter or the Perfect filter, set the HPF bit and the corresponding HUC or HMC bits in Packet filtering control register (ETH_MACPFR). This is applicable to both unicast and multicast packets. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to receive packet.

**Broadcast address filtering**

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in Packet filtering control register (ETH_MACPFR).

**Unicast source address filtering**
The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. You can configure the MAC Address registers to use SA instead of DA for comparison by setting bit 30 of MAC Address x high register (ETH_MACAxHR).

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in Packet filtering control register (ETH_MACPFR). Otherwise, the result of the SA filter is given as a status bit in the Receive Status word (see Table 624). When the SAF bit is set, the SA filter and DA filter result is ANDed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

**Inverse filtering**

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of Packet filtering control register (ETH_MACPFR). The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 623 and Table 624 summarize the DA and SA filtering based on the type of packets received.

**Note:** When the RA bit of Packet filtering control register (ETH_MACPFR) is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx status.

</table>
VLAN filtering

The MAC supports Perfect and Hash VLAN filtering. Refer to Section 57.9.14: Programming guidelines to perform VLAN filtering on the receive for detailed programming steps.

VLAN tag Perfect filtering

In VLAN tag Perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag Perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of VLAN tag register (ETH_MACVTR). In addition, you can enable matching of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of VLAN tag register (ETH_MACVTR). The VLAN packet status bit (bit 10 of RDES0) indicates the VLAN tag match status for the matched packets.

Note: The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results.

VLAN tag Hash filtering

The 16-bit VLAN Hash Table is used for group address filtering based on the VLAN tag. The VLAN tag Hash filtering feature can be enabled using the VTHM (VLAN tag Hash Table match enable) bit of the VLAN tag register (ETH_MACVTR). If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

</tbody>
</table>
Note: The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in ETH_MACVTR register.

When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of VLAN Hash table register (ETH_MACVHTR).

When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of VLAN tag register (ETH_MACVTR).

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the Perfect or Hash filter, the packet should be dropped. If the VLAN perfect and VLAN Hash match are enabled, a packet is considered as matched if either the VLAN Hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and Hash filters indicate mismatch.

Table 625 shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of Packet filtering control register (ETH_MACPFR) is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 normal descriptor (write-back format). When the RA bit is not set and the VTFE bit is set in Packet filtering control register (ETH_MACPFR), the packet is dropped if the final VLAN match status is Fail. In Table 625, value X means that this column can have any value.

When VLAN VID is programmed to 0 in the VL field of VLAN tag register (ETH_MACVTR), all VLAN-tagged packets are considered as perfect matched but the status of the VLAN Hash match depends on the VTHM and VTIM bits in VLAN tag register (ETH_MACVTR).

1. In this table, 'X' represents any value.
Layer 3 and Layer 4 filtering

The MAC supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

The Layer 3 and Layer 4 packet filtering feature automatically enables the IPC Full Checksum Offload Engine on the Receive side. For Layer 3 or Layer 4 filtering operation, you must set the IPC bit of the Operating mode configuration register (ETH_MACCR) to enable the Rx Checksum Offload engine.

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- Matched packets
  The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of the Operating mode configuration register (ETH_MACCR) is set and one of the following conditions is true:
    - All enabled Layer 3 and Layer 4 fields match.
    - At least one of the enabled field matches and other fields are bypassed or disabled

  When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 3 is the highest filter. For example, if Filter 0 and Filter 1 match, the MAC gives the status corresponding to filter 0.

  **Note:** The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

- Unmatched packets
  The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets. The aborted or partial packets are dropped in the MTL Rx FIFO. If the Rx FIFO operates in the Threshold (cut-through) mode and the threshold is programmed to a small value. Such packet transfer to the application starts before the failed Layer 3 and Layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.

- Non-TCP or UDP IP Packets
  By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Layer 3 filtering

The MAC supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can enable the last four data registers of a register set to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programmed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.
For IPv4 packet filtering, you can enable the second and third data registers of a register set to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source Address or Destination Address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

**Layer 4 filtering**

The MAC supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number.

The TCP or UDP Source and Destination Port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received packet is in the higher byte of the register.

**Layer 3 and Layer 4 filters register set**

The MAC implements two sets of registers for Layer 3 and Layer 4 based packet filtering. In a register set, there is a control register, such as `L3 and L4 control 0 register (ETH_MACL3L4C0R)`, to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- **Layer4 Address filter 0 register (ETH_MACL4A0R)**
- **Layer3 Address 0 filter 0 register (ETH_MACL3A00R)**
- **Layer3 Address 1 filter 0 register (ETH_MACL3A10R)**
- **Layer3 Address 2 filter 0 register (ETH_MACL3A20R)**
- **Layer3 Address 3 filter 0 register (ETH_MACL3A30R)**

The second, and independent set of registers are: `L3 and L4 control 1 register (ETH_MACL3L4C1R)`, `Layer 4 address filter 1 register (ETH_MACL4A1R)`, `Layer3 address 0 filter 1 Register (ETH_MACL3A01R)`, `Layer3 address 1 filter 1 register (ETH_MACL3A11R)`, `Layer3 address 2 filter 1 Register (ETH_MACL3A21R)` and `Layer3 address 3 filter 1 register (ETH_MACL3A31R)`.

**57.5.4 IEEE 1588 timestamp support**

The IEEE 1588 standard defines a precision time protocol (PTP) which allows precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the submicrosecond range with minimal network and local clock computing resources.

This chapter contains the following sections:

- **IEEE 1588 timestamp support**
- **IEEE 1588 system time source**
- **IEEE 1588 auxiliary snapshots**
- **Flexible pulse-per-second output**
• **PTP timestamp offload function**
• **One-step timestamp**

### IEEE 1588 timestamp support

The Ethernet peripheral supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP. The IEEE 1588 2008 supports PTP transported over Ethernet. The peripheral provides programmable support for both standards. It supports the following features:

- Support of both timestamp formats
- Optional snapshot of all packets or only PTP type packets
- Optional snapshot of only event messages
- Optional snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Optional selection of the node to act as master or slave for ordinary and boundary clock
- Identification of the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Optional measurement subsecond time in digital or binary format

### Clock types

The MAC supports the following clock types defined in the IEEE 1588-2008 specifications:

- **Ordinary clock**

  The ordinary clock of a domain supports a single copy of the protocol. It has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.

  The ordinary clock can be a grandmaster or a slave clock. It supports the following features:
  
  - Transmission and reception of PTP messages. The timestamp snapshot can be controlled as described in *Timestamp control Register (ETH_MACTSCR)*.
  - Maintenance of the data sets such as timestamp values.

  The table below shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

  **Table 626. Ordinary clock: PTP messages for snapshot**

<table>
<thead>
<tr>
<th>Master</th>
<th>Slave</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delay_Req</td>
<td>SYNC</td>
</tr>
</tbody>
</table>

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in *Timestamp control Register (ETH_MACTSCR)*.

- **Boundary clock**

  The boundary clock typically has several physical ports which communicate with the network. The messages related to synchronization, master-slave hierarchy, and
signaling end in the protocol engine of the boundary clock. Such messages are not forwarded. The PTP message type status given by the MAC helps to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock.
- The local clock is common to all ports of the boundary clock.

• End-to-end transparent clock
The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in Table 627. You can take the snapshot by setting the SNAPTYPSEL bits to 10 in the Timestamp control Register (ETH_MACTSCR).

<table>
<thead>
<tr>
<th>PTP messages</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYNC</td>
</tr>
<tr>
<td>Delay_Req</td>
</tr>
</tbody>
</table>

• Peer-to-peer transparent clock
In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer.

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdelay_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as shown in Table 635.
You can take the snapshot by setting the SNAPTYPESEL bit to 11 in Timestamp control Register (ETH_MACTSCR).

**Delay request-response mechanism**

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Figure 800 shows the process that PTP uses for synchronizing a slave node with a master node by exchanging PTP messages.

**Figure 800. Networked time synchronization**

As shown in Figure 800, the PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at \( t_1 \). This time must be captured for Ethernet ports at MII.
2. The slave receives the SYNC message and also captures the exact time, \( t_2 \), using its timing reference.
3. The master sends a Follow_up message to the slave, which contains \( t_1 \) information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, \( t_3 \), at which this packet leaves the MII interface.

<table>
<thead>

<td>( t_3 )</td>
<td>( t_1, t_2, t_3, t_4 )</td>
</tr>
<tr>
<td></td>
<td>( t_4 )</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 628: Peer-to-peer transparent clock: PTP messages for snapshot
5. The master receives the message, capturing the exact time \( t_4 \), at which the message enters its system.
6. The master sends the \( t_4 \) information to the slave in the Delay Resp message.
7. The slave uses the four values of \( t_1, t_2, t_3, \) and \( t_4 \) to synchronize its local timing reference with the timing reference of the master.

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

**Peer-to-peer PTP transparent clock (P2P TC) message support**

The IEEE 1588-2008 standard supports peer-to-peer PTP (Pdelay) message in addition to the Sync, Delay Request, Follow-up, and Delay Response messages. *Figure 801* shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

*Figure 801. Propagation delay calculation in clocks supporting peer-to-peer path correction*

As shown in *Figure 801*, the propagation delay is calculated as follows:
1. Port 1 issues a Pdelay_Req message and generates a timestamp (\( t_1 \)) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (\( t_2 \)) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp ($t_3$) for this message.

To minimize errors caused by frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:

- Difference between the timestamps $t_2$ and $t_3$ in the Pdelay_Resp message
- Difference between the timestamps $t_2$ and $t_3$ in the Pdelay_Resp_Follow_Up message
- Timestamps $t_2$ and $t_3$ in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively

4. Port 1 generates a timestamp ($t_4$) on receiving the Pdelay_Resp message.

5. Port 1 uses all four timestamps to compute the mean link delay.

**Timestamp correction**

According to the IEEE 1588 specifications, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network.

As the MAC takes the timestamp at an internal point far from the actual boundary of the node and network, this captured timestamp is corrected/updated for the ingress/egress path latency (including the delay in the PHY layers). Further correction is done for the inaccuracies/errors introduced due to the clock (MII Tx, Rx clock) being different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that is used to generate the time. The resultant CDC (clock domain crossing) circuits add an error the depends on the clock period of the MII and PTP clocks.

**Ingress correction**

In the Receive side, the timestamp captured at the internal snapshot point is delayed (later in time) as compared to the time at which that packet SFD bit is received at the port boundary. Therefore, the captured timestamp must be reduced by the ingress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the Timestamp Ingress correction nanosecond register (ETH_MACTSICNR).

The correction value consists of the following three components:

1. External latency in the PHY layer between boundary point and the input of the core
   
   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has registers indicating the maximum and minimum ingress latency. The software can read these registers and determine the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), the ingress latency must be determined from the PHY datasheet or timing characteristics.

2. Internal latency from the input of the core to the internal capture point
   
   The latency differs based on the active PHY interface (such as MII or RMII) and the operating speed, as shown in Table 629.

3. CDC synchronization
   
   The CDC synchronization error is almost equal to twice the clock-period of the PTP clock (clk_ptp_ref_i).
The values determined from these three components should be added by the software and must be written into the TSIC field of the Timestamp Ingress correction nanosecond register (ETH_MACTSICNR).

Note: The value written to the register must be negative (two’s complement), because it has to be subtracted from the captured timestamp. The MAC receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is set, the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1 ns. So bit 31 of TSIC must be set to 1 (for negative value) and bits 30 to 0 must be programmed with \(10^{9} - \text{total ingress_correction_value[nanosecond part]}\) represented in binary. For example, if the required correction value is \(-5\) ns, then the value is 0xBB9A C9FB.

When TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is reset, the nanoseconds field of the captured timestamp is in binary format with a granularity of \(~0.466\) ns. Therefore, bits[30:0] must be written with \(2^{31} - \text{total ingress_correction_value}\) represented in binary with bit[31] = 1.

**Egress correction**

In the Transmit side, the timestamp captured at the internal snapshot point is earlier (advanced in time) as compared to the time at which that packet SFD bit is output at the port boundary. Therefore, the captured timestamp must be compensated by the egress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the Timestamp Egress correction nanosecond register (ETH_MACTSECNR).

The correction value consists of the following three components:

1. External latency in the PHY layer between the output of the core and the boundary of the port and the network
   
   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has registers indicating the maximum and minimum egress latency. The software can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), the egress latency must be determined from the PHY datasheet or timing characteristics.

2. Internal latency from the internal capture point and the output of the core
   
   The latency differs based on the active PHY interface (RMII, MII, etc.) and the operating speed as shown in Table 629.

3. CDC synchronization error
   
   The timestamp correction because of synchronization is compensated by adding
   
   \[
   \text{EGRESS_SYNC_CORR} = (1 \times \text{PTP_CLK_PER} + 4 \times \text{TX_CLK_PER})
   \]

*Table 629* lists the Egress and Ingress latency values for various PHY interfaces:

<table>

</tr>
</tbody>
</table>
Phy interface | Egress latency | Ingress latency
---|---|---
RMII 100 Mbps | 40 | 120
RMII 10 Mbps | 400 | 800

### Frequency range of reference timing clock

The timestamp information are transferred across asynchronous clock domains, from the MAC clock domain to the application clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is four clock cycles of MII and three clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

The PTP clock frequency limitations are the following:

- **Maximum PTP clock frequency**
  - The maximum PTP clock frequency is limited by the maximum resolution of the reference time (10 ns at 100 MHz). In addition, the resolution or granularity of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

- **Minimum PTP clock frequency**
  - The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes and the time taken for synchronizing the time with the MII clock domain. This relationship is given by the following equation:
    
    \[3 \times \text{PTP clock period} + 4 \times \text{MII clock period} \leq \text{Minimum gap between two SFDs}\]

  The MII clock frequency is fixed by IEEE specifications. Therefore, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC as shown in Table 630.

<table>

1. The controlField is used in version 1. In version 2, the messageType field is used for detecting different message types.

Some fields of the Ethernet payload can be used to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP packets over IPv4
- PTP frames over IPv6
- PTP packets over Ethernet

PTP packets over IPv4

Table 632 provides information about the fields that are matched to control the snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 631.

1. The Extension header is not defined for PTP packets.
Transmit path functions

The MAC captures a timestamp when the start packet delimiter (SFD) of a packet is sent on the MII interface. The packets, for which a timestamp has to be captured, can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. The packets for which a timestamp has to be captured must be specified. The packets can be defined by using the control bits in the Transmit Descriptor (see Section 57.10.3: Transmit descriptor). The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus automatically connecting the timestamp to the specific PTP packet.

The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

Receive path functions

The MAC can be programmed to capture the timestamp of all packets received on the MII interface or to process packets to identify the valid PTP messages. The snapshot of the time to be sent to the application can be controlled by using the following options of the Timestamp control Register (ETH_MACTSCR):

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp

<table>

</table>

1. The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of Timestamp control Register (ETH_MACTSCR) is set.
2. IEEE 1588-2008, Annex F
3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.
• Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
• Enable timestamp snapshot for the received packet for IPv4 or IPv6
• Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
• Enable the node to be a master or slave and select the snapshot type
  This feature controls the type of messages for which snapshots are taken.

Note: The peripheral also supports the PTP messages over VLAN packets.

Table 635 indicates the PTP messages for which a snapshot is taken depending on the SNAPTYPESEL field in Timestamp control Register (ETH_MACTSCR).

The DMA returns the timestamp to the software application inside the corresponding Receive descriptor. The extended status, containing the timestamp message status and the IPC status, is written in the RDES1 normal descriptor and the snapshot of the timestamp is written in RDES0 and RDES1 fields of the context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

Programming guidelines for IEEE 1588 timestamping (system time correction)

See Section : System time correction in Section 57.9.9: Programming guidelines for IEEE 1588 timestamping on page 2769.

IEEE 1588 system time source

To get a snapshot of the time, the MAC requires a reference time in 64-bit format as defined in the IEEE 1588-2002 (80-bit format as defined in the IEEE 1588-2008).

Description of IEEE 1588 system time source

The peripheral uses the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps.

The timestamp has the following fields:
• UInteger48 seconds field
The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bit wide. For example, 2.000000001 seconds are represented as seconds Field = 0x0000 0000 0002.

- **UInteger32 nanosecondsField**
  The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 seconds are represented as nanoSeconds = 0x0000 0001.
  The nanoseconds field supports the following two modes:
  - **Digital rollover mode**: In this mode, the maximum value in the nanoseconds field is 0x3B9A C9FF, that is, (10e9-1) nanoseconds.
  - **Binary rollover mode**: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF FFFF. Accuracy is ~0.466 ns per bit.
  These modes can be set through TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR).

### System time register module

The 64-bit PTP time is updated using the PTP input reference clock, clk_ptp_ref_i. This PTP time is used as a source to take snapshots (timestamps) of the Ethernet frames being transmitted or received at the MII.

The system time counter can be initialized or corrected using either the coarse or the fine correction method.

In the coarse correction method, the initial value or the offset value is written to the timestamp update register. For initialization, the system time counter is programmed with the value in the timestamp update registers, whereas for system time correction the offset value (timestamp update register) is added to or subtracted from the system time.

In the fine correction method, the slave clock (reference clock) frequency drift with respect to the master clock (as defined in IEEE 1588-2002 specifications) is corrected over a period of time, unlike in the coarse correction method where it is corrected in a single clock cycle. The longer correction time helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register as shown in Figure 802. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

This system time update algorithm is shown in Figure 802.
The system time update logic requires a 50 MHz clock frequency to achieve 20 ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (clk_ptp_ref_i) is 66 MHz, this ratio is calculated as 66 MHz/50 MHz = 1.32. Therefore, the default addend value to be set in the register is $2^{32} / 1.32$, or 0xC1F07C1F.

If the reference clock drifts lower, for example, to 65 MHz, the ratio is 65 / 50, that is 1.3 and the value to set in the addend register is $2^{32} / 1.30$, or 0xC4EC4EC4.

If the clock drifts higher, for example to 67 MHz, the addend register must be set to 0xBF0B7672. When there is not clock drift, the default addend value of 0xC1F07C1F ($2^{32} / 1.32$) must be programmed.

In Figure 802, the constant value used to accumulate the subsecond register is decimal 43, which achieves a system time accuracy of 20 ns (in other words, it is incremented in 20 ns steps).

The software must calculate the drift in frequency based on the SYNC messages and accordingly update the Addend register.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$$\text{FreqCompensationValue}_0 = \frac{2^{32}}{\text{FreqDivisionRatio}}$$
If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm given in this section must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and resynchronize with the master using the new value.

The algorithm is as follows:

1. At time MasterSyncTime\(_n\) the master sends the slave clock a SYNC message. The slave receives this message when its local clock is SlaveClockTime\(_n\) and computes MasterClockTime\(_n\) as follows:
   \[
   \text{MasterClockTime}_{n} = \text{MasterSyncTime}_{n} + \text{MasterToSlaveDelay}_{n}
   \]

2. The master clock counts for current Sync cycle, MasterClockCount\(_n\) is
   \[
   \text{MasterClockCount}_{n} = \text{MasterClockTime}_{n} - \text{MasterClockTime}_{n-1}
   \]
   (assuming that MasterToSlaveDelay is the same for Sync cycles \(n\) and \(n - 1\))

3. The slave clock count for current Sync cycle, SlaveClockCount\(_n\) is
   \[
   \text{SlaveClockCount}_{n} = \text{SlaveClockTime}_{n} - \text{SlaveClockTime}_{n-1}
   \]

4. The difference between master and slave clock counts for current Sync cycle, ClockDiffCount\(_n\) is
   \[
   \text{ClockDiffCount}_{n} = \text{MasterClockTime}_{n} - \text{SlaveClockTime}_{n}
   \]

5. The frequency-scaling factor for slave clock, FreqScaleFactor\(_n\) is
   \[
   \text{FreqScaleFactor}_{n} = (\text{MasterClockCount}_{n} + \text{ClockDiffCount}_{n})/ \text{SlaveClockCount}_{n}
   \]

6. The frequency compensation value for Addend register, FreqCompensationValue\(_n\) is
   \[
   \text{FreqCompensationValue}_{n} = \text{FreqScaleFactor}_{n} \times \text{FreqCompensationValue}_{n-1}
   \]

In theory, this algorithm achieves the lock in one Sync cycle. However, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting. If the slave clock is initially set to an incorrect value by the master, the algorithm corrects it at the cost of additional Sync cycles.

Refer to Section 57.9.9: Programming guidelines for IEEE 1588 timestamping for detailed programming steps.

**IEEE 1588 auxiliary snapshots**

The auxiliary snapshot feature enables to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the eth_ptp_trgx (where \(x = 1\) to 4) sideband signal.

Up to four auxiliary snapshot inputs can be configured and up to four snapshots can be stored. A FIFO is accessible through registers: Auxiliary timestamp seconds register (ETH_MACATSSR) and Auxiliary timestamp nanoseconds register (ETH_MACATSNR).

The snapshots taken for any input are stored in a common FIFO; only 64 bits are kept. The application can read the Timestamp status register (ETH_MACTSSR) to know the timestamp of which input is available for reading at the top of this FIFO.
When a snapshot is stored, the MAC indicates this to the application with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, a snapshot trigger-missed status (ATSSTM) is set in the Timestamp status register (ETH_MACTSSR). This indicates that the latest auxiliary snapshot of the timestamp is not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full.

When an application reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting the ATSFC bit in Auxiliary control register (ETH_MACACR). When multiple snapshots are present in the FIFO, the count is indicated in bits[27:25] of Timestamp status register (ETH_MACTSSR).

**Flexible pulse-per-second output**

The MAC supports either a fixed pulse-per-second output mode (also called fixed mode) or a flexible pulse-per-second output mode for the ETH_PPS_OUT and eth_ptp_pps_out outputs:

- **Fixed pulse-per-second output**
  
  In this mode, only the frequency of the PPS output can be changed by setting the PPSCTRL0 field in the PPS control register (ETH_MACPPSCR).

- **Flexible pulse-per-second output**
  
  In this mode, the software has the flexibility to program the start or stop time, width, and interval of the pulse generated on the eth_ptp_pps_out output:
  
  The start and stop times are programmed through PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR).
  
  The PPS width and interval are programmed in terms of granularity of system time (number of the units of subsecond increment value) through PPS width register (ETH_MACPPSWR) and PPS interval register (ETH_MACPPSIR), respectively.

*Note:* By default, the peripheral is in Fixed mode and indicates one second interval. When Fixed mode is selected by clearing PPSEN0 to 0 in the PPS control register (ETH_MACPPSCR):

- the output on all PPS outputs is controlled by the value programmed in the PPSCTRL_PPSCMD field. Independent control of individual PPS output is not supported in Fixed mode.

- PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR) are used only for generating target time reached interrupt; they are not used for PPS output generation.

- TRGTMODSEL0/1/2/3 must be programmed to 0.

- the frequency of the PPS output can be changed by setting the PPSCTRL0 field in the PPS control register (ETH_MACPPSCR).
Description of flexible pulse-per-second (PPS) output

The peripheral supports the following features with the flexible PPS outputs:

- Programming the start or stop time in terms of system time.
- Programming the start point of the single pulse and start and stop points of the pulse train in terms of 64-bit system time. The Target Time registers are used to program the start and stop time.
- Programming the stop time in advance, that is, the stop time can be programmed before the actual start time has elapsed.
- Programming the width between the rising edge and corresponding falling edge of PPS signal output in terms of number of units of subsecond increment value programmed in the Subsecond increment register (ETH_MACSSIR). The pulse width can be programmed from 1 to 2^{32}–1 units of subsecond increment value.
- Programming the interval, between the rising edges of PPS signal, in terms of number of units of subsecond increment value. You can program the interval between pulses from 1 to 2^{32}–1 units of subsecond increment value.
- Option to cancel the programmed PPS start or stop request.
- Error if the start or stop time being programmed has already elapsed.

Note: The PTP reference clock mentioned in the following sections is the clock at which the system time is updated. When the TSCFUPDT bit of Timestamp control Register (ETH_MACTSCR) is set to 0, this clock is similar to the clk_ptp_ref_i clock. In Fine correction mode, this is the clock tick at which the system time is updated (using Subsecond increment register (ETH_MACSSIR)) (as shown in Figure 802).

Refer to Section 57.9.12: Programming guidelines for flexible pulse-per-second (PPS) output for further details on how configuring flexible pulse output.

PPS start and stop times

The initial start time can be programmed in the Target Time registers.

If required, the start or stop time can be programmed again. However, this can be done only after the earlier programmed value is synchronized with the PTP clock domain. Bit 31 of PPS target time nanoseconds register (ETH_MACPPSTTNR) indicates that the synchronization is complete. This enables to program the start or stop time in advance even before the earlier stop or start time has elapsed.

To ensure proper PPS signal output, it is recommended to program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

PPS width and interval

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of subsecond increment value. For example, to obtain a PPS pulse width of 40 ns and an interval of 100 ns with a PTP reference clock of 50 MHz, program the width and interval to values 2 and 5, respectively. Smaller granularity can be achieved by using a faster PTP reference clock.

Before giving the command to trigger a pulse or pulse train on the PPS output, program or update the interval and width of the PPS signal output.
PTP timestamp offload function

This feature enables the automatic generation of specific PTP packets to be performed, when the MAC operates as a specific node in the PTP network.

These packets can be generated periodically or triggered by the host software. In other modes, this feature can parse the incoming PTP packets on the receiver, and automatically generate and respond to the required PTP packets. It helps to offload certain PTP node functions with better accuracy and lower response latency.

The PTP offload feature is selected through **PTP Offload control register (ETH_MACPOCR)**. 80-bit PTP node identity is configured through the following three registers: **PTP Source Port Identity 0 Register (ETH_MACSPI0R)**, **PTP Source port identity 1 register (ETH_MACSPI1R)** and **PTP Source port identity 2 register (ETH_MACSPI2R)**.

Description of PTP offload function

Depending on the programmed mode, the MAC generates PTP Ethernet messages periodically or from the application, or based on reception of a particular PTP message. **Table 636** indicates the PTP message generation criteria.

</tbody>
</table>
Note: Clocks supporting peer delay mechanism must not generate delay request/delay response messages, according to IEEE 1588-2008 specifications. However, the peripheral controller supports this for flexibility, with a programmable control bit (DRRDIS) in the PTP Offload control register (ETH_MACPOCR).

The DRRDIS bit can be used to control the response generation for delay request/delay response message. For example, in transparent slave mode, delay request is generated in response to received \texttt{SYNC} only when the bit is reset.

When the MAC is set as an Ordinary or Boundary Slave clock in the PTP network, it can respond to the reception of \texttt{SYNC} messages with an automatic generation and transmission of the corresponding Delay\_Req message. Similarly, various other modes of operation are explained in Table 636.

The MAC supports the multicast communication model for the generation of \texttt{SYNC} and Pdelay\_Req PTP messages. For instance, the Destination Address field of the generated PTP over Ethernet packet is the defined special multicast addresses (0x011B 1900 0000 for all except peer delay mechanism messages and 0x0180 C200 000E for peer delay mechanism messages).

When the MAC responds to received \texttt{SYNC}, Delay\_Req and Pdelay\_Req PTP messages with special multicast destination address, it also uses the corresponding special multicast address in the DA field of the automatically generated Delay\_Req, Delay\_Resp, and Pdelay\_Resp PTP messages, respectively.

When the MAC responds to received \texttt{SYNC}, Delay\_Req and Pdelay\_Req PTP messages with unicast destination address, it takes the SA field of the received packets and makes

</tbody>
</table>

All other programming combinations are invalid for PTP Offload feature.
them as the DA field of the automatically generated Delay_Req, Delay_Resp, and Pdelay_Resp PTP messages, respectively.

At the same time, all the received PTP messages are forwarded to the application along with Rx status, indicating whether the response was generated by the MAC, if it satisfies the packet filtering logic of the MAC receiver.

When the MAC automatically generates a PdelayReq or responds with a Delay_Req, the egress timestamp of these two PTP messages are provided in the Tx TS status (Tx Timestamp Status register and interrupt generated).

In addition to messageType and versionPTP fields match for basic PTP over Ethernet message detection, the following additional fields are matched to qualify the received PTP message type:

1. The domainNumber field is checked for a match against the value programmed in the CSR.
2. The twoStepFlag in flagField field is checked for one-step indication (0b0).
3. The transportSpecific field is checked for Default PTP over Ethernet (0b0000) or 802.1AS mode (0b1111) when enabled.

**PTP packet generation**

This section explains the format and content of the automatically generated PTP packets by the MAC when this mode is enabled. It provides the template of the common PTP message header, as well as the detailed description of the fields of the specific PTP packets generated.

Table 637. Common PTP message header fields
PTP message header fields

- **messageType**
  The following encoded values are used for PTP message types:
  - SYNC: 0000
  - Delay_Req: 0001
  - Pdelay_Req: 0010
  - Pdelay_Resp: 0011
  - Delay_Resp: 1001

- **transportSpecific**
  The following transport protocol encoding is used:
  - Default PTP over Ethernet: 0000
  - 802.1AS mode: 0001

- **versionPTP**
  It is always set to 2 because PTP version 2 is supported.

- **domainNumber**
  This field contains the value from the **PTP Offload control register (ETH_MACPOCR)**.

- **flagField**
  The following values are used:
  - alternateMasterFlag (Octet 0 bit 0): 0 for SYNC and Delay_Resp
  - twoStepFlag (Octet 0 bit 1): 0 for SYNC and Pdelay_Resp
  - unicastFlag (Octet 0 bit 2): 0 for Multicast Address, 1 for Unicast Address

- **correctionField**
  For more information, see **Table 638**.

- **sourcePortIdentity**
  This field takes the value programmed in the **PTP Source Port Identity 0 Register (ETH_MACSPI0R)**, **PTP Source port identity 1 register (ETH_MACSPI1R)** and **PTP Source port identity 2 register (ETH_MACSPI2R)**.

- **sequenceId**
  Pdelay_Resp and Delay_Resp use the same sequenceId field from received Pdelay_Req and Delay_Req PTP messages. For SYNC/Delay_Req, Pdelay_Req, a separate sequenceId counter is maintained. These sequenceId counters get incremented by 1 every time the corresponding message is generated and transmitted.

- **controlField**
  The following encoded values are used for controlField:
  - SYNC: 0000 0000
  - Delay_Req: 0000 0001
  - Pdelay_Req: 0000 0010
  - Pdelay_Resp: 0000 0101
  - Delay_Resp: 0000 0011

- **logMessageInterval**
  - SYNC:
    This field contains logSyncInterval from the corresponding MAC_Log_Message_Interval register.
DelayResp:  
This field contains the sum of DRSYNC and logSyncInterval value taken from  
the Log message interval register (ETH_MACLMIR) for a multicast PTP message  
and 0111 1111 for unicast PTP message.

DelayReq, PdelayReq and PdelayResp: 0111 1111  
where logSyncInterval = log2 (Mean Value of Interval in seconds)

The MAC supports values of –15 to 15 for logSyncInterval fields, which translates to a range  
from 32.768 micro second (2–15) to 215 second. For a given value of log sync interval (N),  
the time interval between two SYNC packets is given by the following:
- \[2^{(30+N)} \text{ ns}, \text{ when } N \text{ is negative } (-1 \text{ to } -15)\]
- \[2^N \text{ seconds}, \text{ when } N \text{ is positive } (0 \text{ to } 15)\]

For example:
- When logSyncInterval is programmed to 1, the interval is \(2^1\); therefore, the SYNC  
message is sent once every 2 seconds.
- When logSyncInterval is programmed to -1, the interval is \(2^{-1} = 0.536 \text{ seconds}\);  
therefore, the SYNC message is sent once every 536 milliseconds. The value is 0.536  
seconds, because \(2^{-30} = 1 \text{ ns}\).
- When logSyncInterval is programmed to –5, the interval is \(2^{-5} = 33.55 \text{ ms}\); therefore,  
the SYNC message is sent once every 33.55 ms.

Note: The MAC uses the PTP system time to generate the intervals for periodic packet  
transmission. For negative values of log message interval programmed, the generated  
period may deviate from the value given by the equation \(2^{(30+N)}\), because of the non-binary  
nature of the nanoseconds field of the system time.

PTP message-specific fields

The message-specific fields are the following:
- **messageLength**  
There is no suffix supported, so this field contains the length of the PTP message that  
includes 34-byte PTP common header and the body specific to the message type.  
For SYNC and Delay_Req packets, this field contains 44, whereas for Delay_Resp,  
Pdelay_Req and Pdelay_Resp, it contains 54.
- **originTimestamp**  
This field is the captured egress timestamp for SYNC, Delay_Req, and Pdelay_Req  
PTP messages.
- **receiveTimestamp**  
For Delay_Resp PTP message, this is the ingress timestamp of the corresponding  
received Delay_Req PTP message.
- **requestingPortIdentity**  
For Delay_Resp and Pdelay_Resp PTP messages, this is the sourcePortIdentity field  
taken from the corresponding received Delay_Req and Pdelay_Req PTP messages.
- **requestReceiptTimestamp**  
For the Pdelay_Resp PTP message, this field is set to 0.
One-step timestamp

The MAC supports the one-step timestamp feature that enables to identify the offset in the packet and inserts the timestamp received from the application at that offset.

MAC Transmit PTP mode for one-step timestamp

Depending upon the type of message and its mode, the MAC updates the following fields of Transmit PTP packets:

- correctionField in the PTP header of messages
- originTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

Table 638 shows how the PTP mode is selected based on the settings of SNAPTYPSel, TSMSTRENA, and TSEVNTENA bits of the Timestamp control Register (ETH_MACTSCR) and the fields that are updated for the incoming PTP packets based on the message type in that mode, during the one-step timestamping operation.

1. The per-packet control values provided here are the recommended settings used by devices in typical PTP operation and for the programmed mode.
2. TTSE represents TTSE bit of TDES2 transmit normal descriptor. The TTSE function is independent from the OST function and the programmed operation mode for OST. The MAC captures and returns the timestamp when the TTSE bit is set.
3. OSTC represents OSTC bit of TDES3 transmit context descriptor
4. TTS represents the timestamp value provided in the TTSH, TTSL fields of TDES0 and TDES1 transmit normal descriptor (write-back format).

**Note:** Residence time/turnaround time is calculated as the difference between the captured timestamp (egress timestamp) and the ingress timestamp. Clocks supporting peer delay mechanism do not use delay request or response, but it is included in OST for flexibility.

**Enabling one-step timestamp**

The one-step timestamp feature can be enabled for a given packet by setting bit 20 (OSTC) in TDES3 context descriptor. To update the correction field in certain PTP packets, the ingress timestamp must be given in the TSSL and TSSH fields.

The one-step timestamp feature is supported only for the PTP over Ethernet packets. It is not supported for PTP over IPv4/IPv6 packets.

**57.5.5 Checksum offload engine**

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, as well as error detection in the Receive path.

**Transmit checksum offload engine**

In the transmit path, the MAC calculates the checksum and inserts it in the Tx packet. This feature helps reducing the load on the software and can improve the overall system throughput.

The COE module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 bits[17:16]).
Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, the Tx FIFO automatically operates in the Store-and-forward mode even if the MAC is configured in Threshold (cut-through) mode.

Make sure that the Tx FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter, the reason being that when space is not available to accept the programmed burst length of data, then the MTL Tx FIFO starts reading to avoid deadlock. In such a case, the COE fails as the start of the packet header is read out before the payload checksum can be calculated and inserted. Therefore, the checksum insertion must be enabled only in the packets that are less than the number of bytes, given by the following equation:

\[
\text{Packet size} < \text{TxQSize} - (\text{PBL} + 7) \times 4
\]

where

- \(\text{TxQSize}\) corresponds to the TQS bitfield of `Tx queue operating mode Register (ETH_MTLTXQOMR)`
- \(\text{PBL}\) corresponds to the TxPBL bitfield of `Channel transmit control register (ETH_DMACTXCR)`

Refer to IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

**IP header checksum engine**

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

**Note:** IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status in the Transmit status (bit 0 in Table 660: TDES3 normal descriptor (write-back format)).

This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as
indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86DD but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

**TCP/UDP/ICMP checksum engine**

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

**Note:** For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 0x0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 0x0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (bit 12 in Table 660: TDES3 normal descriptor (write-back format)). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

*Table 639* describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

**Note:** Do not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in *Section: Transmit checksum offload engine* because it might result in incorrect checksum insertion or unexpected behavior.

Receive checksum offload engine

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

The Receive Checksum Offload Engine (Rx COE) can be enabled by setting the IPC bit of Operating mode configuration register (ETH_MACCR). When this bit is set, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the EDVLP bit of the VLAN tag register (ETH_MACVTR) is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

Packets with TCP/IP errors (header or payload) are dropped in MTL when DIS_TCP_EF bit of the Rx queue operating mode register (ETH_MTLRXQOMR) is reset and FEP bit is set.

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 640: Receive checksum offload engine functions for different packet types describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

Note: The MAC does not append any payload checksum bytes to the received Ethernet packets.

57.5.6 TCP segmentation offload

The MAC supports the TCP segmentation offload (TSO) feature in which the DMA splits a large TCP packet into multiple small packets and passes these packets to the MTL as shown in Figure 803.

This feature is enabled by programming the TSE bit of corresponding ETH_DMACCR register (see Channel transmit control register (ETH_DMACTXCR)). It is only supported when the MAC operates in Full-duplex mode.

For detailed programming steps, refer to Section 57.9.13: Programming guidelines for TSO.

Figure 803. TCP segmentation offload overview

![TCP segmentation offload overview diagram]
DMA operation with TSO feature

*Figure 804* shows the TSO flow.

*Figure 804. TCP segmentation offload flow*

![TCP segmentation offload flow diagram](image)

For the TSO feature, the Tx DMA operation is as follows:

1. The application sets up the Transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES3[31]) after setting up the corresponding data buffer(s) with Ethernet packet data.

2. The application increases the offset value of the Descriptor tail pointer of the DMA Tx channel.

3. While in the Run state, the DMA fetches the next available descriptor and performs one of the following actions:
   - If the descriptor is a context descriptor and the context is not between the first and last descriptors of a packet, the DMA stores the context values.
– If the descriptor is a context descriptor and the context is between the first and last descriptors of a packet, the DMA closes the context descriptor indicating a Context Descriptor Error (TDES3[23]) and fetches the next descriptor.

– If the descriptor is a normal descriptor, the DMA checks the TSE bit. If the TSE bit is not set, the DMA continues with the default mode of operation or OSF operation (if enabled).

4. The DMA calculates the number of segments from the TCP payload length (TDES3[17:0]) and the MSS value.

5. The DMA goes through channel arbitration to fetch the data buffers. The DMA fetches the header and payload separately.

6. For the first segment, the DMA fetches the header from the system memory and stores it in the TSO memory (if present and when the length of header is not greater than the TSO memory size). If the current segmented packet is not the first segment, it fetches again the header buffer in system memory, as done for the first segment. In such cases, the DMA does not close the first descriptor containing the header buffer until the header for last segment is fetched.

7. The required fields in the header bytes are modified/updated as per the segmentation requirements and written into the corresponding MTL Tx queue.

8. The DMA then takes the payload buffer pointer, fetches the MSS number of payload bytes from the system memory, and directly pushes it into the MTL Tx queue. If the buffer(s) in the descriptor do(es) not have enough data for the MSS payload (except for the last segment), the DMA closes this descriptor.

9. The DMA jumps to Step 3 and repeats the process until the last segment is written into the Tx queue.

10. The DMA closes the last descriptor and the first descriptor (containing the header buffer when it is not stored in TSO memory), and then moves on to the next packet transfer.

The DMA repeats all these steps if more descriptors are available. When no more descriptor are available, the DMA enters the suspend state.

Note: The TSO engine determines whether to perform TSO or USO operation based on the THL field (TCP Header Length) in TDES3 of first Normal Tx descriptor for the packet. The value of 2 indicates USO and any value greater than or equal to 5 indicates TSO.
TCP/IP header fields

While segmenting a TCP packet, the DMA automatically updates the TCP/IP header fields. *Table 641* describes how the TCP and IP headers are updated.

**Table 641. TSO: TCP and IP header fields**

<table>
<thead>
<tr>
<th>Packet sequence</th>
<th>TCP header</th>
<th>IP header</th>
</tr>
</thead>
</table>
| **First packet** | 1. The sequence number is not updated. The value provided in the header is used.  
2. If set, the FIN and PSH flags are cleared.  
3. The TCP checksum is calculated again. | IPv4 Header  
– Total Length = MSS + TCP Header Length + IP Header Length  
– Identification field is not modified. It is sent as per the header provided by the software.  
– IPv4 Header Checksum is recalculated.  
IPv6 Header  
– Payload Length = MSS + TCP Header Length + IP Extension Header Length |
| **Subsequent packets** | 1. The sequence number is updated. The MSS value is added to the sequence number value of previous segment.  
2. If set, the FIN and PSH flags are cleared.  
3. The TCP checksum is calculated again. | IPv4 Header  
– Total Length = MSS + TCP Header Length + IP Header Length  
– Identification field = Previous Identification Field + 1  
– IPv4 Header Checksum is recalculated  
IPv6 Header  
– Payload Length = MSS + TCP Header Length + IP Extension Header Length |
| **Last packet** | 1. The sequence number is updated. The MSS value is added to the sequence number value of previous segment.  
2. If FIN and PSH flags were set in original header, these flags are set.  
3. The TCP checksum is calculated again. | IPv4 Header  
– Total Length = Remaining Payload + TCP Header Length + IP Header Length  
– Identification Field = Previous Identification Field + 1  
– IPv4 header Checksum is recalculated  
IPv6 Header  
– Payload Length = Remaining Payload + TCP Header Length + IP Extension Header Length |
**Header and payload fields of segmented packets**

After segmentation, the split packets use the same header as the parent TCP packet for header fields other than the ones described in Table 641: TSO: TCP and IP header fields. Figure 805: Header and payload fields of segmented packets shows how same header is used for the header fields of segmented packets.

The application must create the header in Buffer 1 of the first descriptor of the packet to be segmented and provide the header length in TDES2 of the first descriptor (FD = 1). When the FD bit is set, the DMA reads the header from the header buffer to which the TDES0 is pointing. Buffer 2 of the first descriptor can be used for payload and TDES0 and TDES1 of subsequent descriptors. For subsequent descriptors (FD = 0), the address to which the TDES0 and TDES1 are pointing is treated as payload buffer address of the same packet.

**Context descriptor sequence**

The context descriptor can provide the maximum segment size (MSS) value for segmentation. The application must provide the context descriptor before the normal descriptor to be used for the corresponding TCP packet. If the application needs to provide a new MSS, it must create the context descriptor in the descriptor list before the first normal descriptor of the packet to be segmented with the new MSS value. The MSS value in the context descriptor is valid only if the TCMSSV bit of TDES3 in context descriptor is set and the OSTC bit is reset (refer to Section 57.10.3: Transmit descriptor).

When the application provides a context descriptor with a valid MSS value, the DMA internally stores the MSS value and uses this value for all subsequent packets for which the TSO is enabled through the TSE bit of TDES3 normal descriptor.
If the application places a context descriptor in the middle of a packet (between the first and last descriptors of a packet), the DMA does the following:

1. The DMA ignores the context and closes the descriptor.
2. The DMA indicates the error in descriptor status.
3. The DMA generates an interrupt if the CDEE bit is set in the Interrupt enable register corresponding to a DMA channel (see Channel interrupt enable register (ETH_DMACIER)).

The application can read the interrupt status through CDE bit of Status register corresponding to a DMA channel (see Channel status register (ETH_DMACSR)).

**Building the Descriptor and the packet for the TSO feature**

To enable segmentation for a packet, the application must set the TSE bit of TDES3 of first normal descriptor (see Section 57.10.3: Transmit descriptor). If the TSE bit is set in TDES3 for a non TCP/IP packet, the DMA behavior is unpredictable.

The application must program the length of the TCP packet payload in TDES3[17:0] and the TCP header in TDES3[22:19]. The maximum length of TCP packet payload that can be segmented is 256 Kbytes.

The header of the packet including Ethernet header, L3 header and L4 header should be provided in Buffer1 of the first normal descriptor of the TSO packet. Only buffer 1 of the first normal descriptor of a packet enabled for TSO is taken as the buffer containing the header.

The TCP payload can begin from buffer 2 of the first normal descriptor and continue to buffer 1 and buffer 2 of second normal descriptor and subsequent descriptors.

The TCP payload may span across multiple buffers and multiple descriptors. The size of buffers containing the TCP payload should add up to be equal to the TCP payload length provided in TDES3[17:0] of the first normal descriptor.

The MAC always calculates and appends CRC and inserts Padding (if required) for all packets segmented by the DMA. If the TSE bit of TDES3 is enabled, the CRC PAD Control (CPC) field of TDES3 is reserved. To determine the size of a TCP packet after segmentation, the DMA uses the Maximum Segment Size (MSS) provided by the application through context descriptor. The DMA segments only those packets which have payload size greater than MSS. The application must provide the MSS by either programming the MSS value in ETH_DMACCR (see Channel control register (ETH_DMACCR)) or by providing a context descriptor. The DMA uses the last programmed value of MSS or the last MSS value provided through context (whichever is provided later).

The header length plus the MSS size (which is equal to the size of each TCP segment) should not exceed 16383 bytes otherwise the MAC transmitter truncates the packet after 16383 bytes causing a CRC error.

The header length plus MSS size plus programmed PBL value in ETH_DMACTXCR register (see Channel transmit control register (ETH_DMACTXCR)) should be lesser than the Tx queue size programmed in TQS field of ETH_MTLTXQOMR register (see Tx queue operating mode Register (ETH_MTLTXQOMR)). A MSS plus header equal to half the programmed Tx queue size is recommended.

The DMA also supports segmentation of VLAN-tagged TCP/IP frames. If the TCP packet has a VLAN tag, then the same tag is used for all the segments irrespective of the VLAN tag type provided (C-VLAN or S-VLAN). The VLAN tag insert/replace control bits are used for all segments.
If the Double VLAN feature is selected, then the DMA passes both tags for all segments irrespective of the VLAN tag types provided (C-VLAN or S-VLAN). The VLAN tag Insert/Replace control bits for both tags is applicable to all segments. If the Double VLAN feature is not selected, then the application must not set the TSE bit in TDES3 for a TCP/IP packet with two tags. The DMA behavior in this scenario is unpredictable.

If the TSE bit is set in TDES3 for the packet and TCP header length provided is less than 5 (meaning this is an invalid TCP header because it is less than 20 bytes), the DMA does not perform segmentation, instead it transmits the entire packet as a single packet. In this scenario, the CRC pad control bits are forced by DMA to 00 (MAC does CRC and padding) and checksum insertion control bits are forced to 11 (hardware does the checksum calculation for both header and payload).

57.5.7 IPv4 ARP offload

The MAC supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. This feature allows to process the IPv4 ARP request packet in the receive path and to generate the corresponding ARP response packet in the transmit path.

The MAC generates the ARP reply packets for appropriate ARP request packets. ARP packets for IPv4 are L2 layer packets with Length/Type of 0x0806.

The ARP offloading sequence is as follows:
1. The MAC receiver gets an ARP request if the request Target Protocol Address matches the IPv4 address programmed in the MAC L3 register.
2. The MAC generates an ARP reply packet.
3. The MAC copies the Sender Hardware Address field in the ARP request to the following fields:
   - DA field of the Ethernet packet header
   - Target Hardware Address field of the ARP reply packet
4. The MAC copies the Sender Protocol Address field in the ARP request to the Target Protocol Address field in the ARP reply packet.
5. The MAC places its MAC address in the following fields:
   - SA field of the Ethernet packet header
   - Sender Hardware Address field of the ARP reply packet
6. The MAC copies the Target Protocol Address field in the ARP request to the Sender Protocol Address field in the ARP reply packet.
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply.
8. The MAC recalculates the CRC and performs padding for the generated ARP reply packet.
9. The MAC transmitter sends the ARP reply

The MAC processes only one ARP request at a time. It does not store the fields of multiple ARP requests. If the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC does not generate the ARP reply for new ARP request. The MAC forwards the new ARP request packet to the application with ARP Reply Not Generated status bit set (bit 34). However, in power-down mode, if the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC drops the new ARP request. If the Disable CRC check (DCRCC) bit of the Extended operating mode configuration register (ETH_MACECR) is set, then the MAC does not check for valid CRC of a ARP
request packet. It can generate an ARP response packet if the other conditions are valid. The ARP request packet must always have a valid CRC.

Note: When the received ARP request is less than the 64-byte packet length, the MAC does not send an ARP response. It is treated as a normal packet and forwarded to the application based on the MAC filter settings.

57.5.8 Loopback

The MAC supports loopback of transmitted packets to its receiver.

Guidelines for using Loopback mode

Below some guidelines for using the Loopback mode:

- Enable loopback only with the Full-duplex mode. In Half-duplex mode, the carrier sense signal or collision signal inputs get sampled which may result into issues such as packet dropping.
- If the Loopback mode is enabled without connecting a PHY chip, externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets since they may get corrupted in the loopback FIFO.

The Transmit and Receive clocks can have an asynchronous timing relationship. Therefore, an asynchronous FIFO is used to make the loopback path of the transmitted data to the Receive path. The FIFO is free-running to write on the write clock (eth_mii_tx_clk) and read on every read clock (eth_mii_rx_clk). At the start of each packet read from the FIFO, the write and read pointers are reinitialized to have an offset of four (in 10/100 Mbps mode). This avoids overflow or underflow during a packet transfer, and ensures that the overflow or underflow occurs only during the IPG period between the packets. The FIFO depth of five or nine is sufficient to prevent data corruption for packet sizes up to 9,022 bytes with a difference of 200 ppm between MII Transmit and Receive clock frequencies.

Therefore, bigger packets should not be looped back because they may get corrupted in this loopback FIFO.

At the end of every received packet, the Receive Protocol Engine module generates received packet status and sends it to the Receive Packet Controller module. The control, missed packet, and filter fail status are added to the Receive status in the Receive Packet Controller module. The MAC does not process ARP or PMT packets that are looped back.

Enabling Loopback mode

To enable this feature, program the LM bit of the Operating mode configuration register (ETH_MACCR). Loopback can be enabled for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive MII interface, irrespective of which PHY interface is selected.

The loopback data is also passed through the corresponding transmit PHY interface block, onto the Ethernet line.

Note: During loopback, the data/packet is reflected on mii_txd signal. Preemption is not supported in Loopback mode.
57.5.9 Flow control

The transmit flow control involves transmitting Pause packets in Full-duplex mode and back-pressure in Half-duplex mode to control the flow of packets from the remote end. This section describes the flow control for transmit and receive paths.

Flow control in Full-duplex mode

In Full-duplex mode, the MAC uses IEEE 802.3x Pause packets for flow control. Table 642 describes the fields of a Pause packet.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DA</td>
<td>Contains the special multicast address</td>
</tr>
<tr>
<td>SA</td>
<td>Contains the MAC address 0</td>
</tr>
<tr>
<td>Type</td>
<td>Contains 8008</td>
</tr>
<tr>
<td>MAC Control opcode</td>
<td>Contains 0001 for IEEE 802.3x Pause Control packets</td>
</tr>
<tr>
<td>PT</td>
<td>Contains Pause time specified in the PT field of the Tx Queue flow control register (ETH_MACQTXFCR)</td>
</tr>
</tbody>
</table>

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

Flow control in Half-duplex mode

In Half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Table 643 describes the flow control in the Tx path based on the setting of the following bits:
- TFE bit of Tx Queue flow control register (ETH_MACQTXFCR)
- DM bit of Operating mode configuration register (ETH_MACCR)

Flow control is similar for all queues.
Transmit flow control

The transmit flow control is enabled when TFE bit is set in Tx Queue flow control register (ETH_MACQTXFCR).

Flow control trigger

The application can request the MAC to send a Pause packet or initiate back-pressure by setting the FCB bit in the corresponding Tx Queue flow control register (ETH_MACQTXFCR).

Receive flow control

In the Receive path, the flow control is functional only in Full-duplex mode. If any Pause packet is received in Half-duplex mode, the packet is considered as a normal control packet.

Description of receive flow control

Table 644 describes the flow control in the Rx path based on the setting of the following bits:
- RFE bit of Rx flow control register (ETH_MACRXFCR)
- DM bit of Operating mode configuration register (ETH_MACCR)

### Table 643. Tx MAC flow control

<table>
<thead>
<tr>
<th>TFE</th>

</tr>
</tbody>
</table>

### Table 644. Rx MAC flow control

<table>
<thead>
<tr>
<th>RFE</th>
<th>DM</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>x</td>
<td>The MAC receiver does not detect the received Pause packets.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.</td>
</tr>
</tbody>
</table>

The following sequence describes the Rx flow control:

1. The MAC checks the destination address (DA) of the received Pause packet for either of the following:
   - Multicast destination address: the DA matches the unique multicast address specified for the control packet (0x0180 C200 0001).
   - Unicast destination address: the DA matches the content of the MAC Address 0 registers (MAC Address 0 high register (ETH_MACA0HR) and MAC Address x...

low register (ETH_MACAxLR)) and the UP bit of Rx flow control register (ETH_MACRXFCR) is set.

If the UP bit is set, the MAC processes Pause packets with unicast destination address in addition to the unique multicast address.

2. The MAC decodes the following fields of the received packet:
   – Type field: this field is checked for 0x8808.
   – Opcode field: this field is checked for 0x0001 (Pause packet).
   – Pause time: the Pause time (for Pause packet) is captured to determine the time for which the transmitter needs to be blocked.

3. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC transmitter pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times).

If subsequent Pause packets are received before the earlier Pause Time expires, the MAC updates the Pause Timer with new value.

**Enabling receive flow control**

Set the RFE bit in the Rx flow control register (ETH_MACRXFCR) to enable the Pause flow control.
57.5.10 MAC management counters

The peripheral supports storing the statistics about the received and transmitted packets in registers that are accessible through the application.

The counters in the MAC management counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the AHB slave interface in the same way the CSR registers are accessed. The organization of these registers is shown in Section 57.11.4: Ethernet MAC and MMC registers.

The MMC counters are free running. There is no separate enable for the counters to start. A particular MMC counter starts counting when corresponding packet is received or transmitted.

The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, set bit 0 in the Packet filtering control register (ETH_MACPFR). The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

In addition to control registers, two sets of registers are implemented:

- 6 registers used for collision, error and good packets counters:
  - Tx single collision good packets register (Tx single collision good packets register (ETH_TX_SINGLE_COLLISION_GOOD_PACKETS))
  - Tx multiple collision good packets register (Tx multiple collision good packets register (ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS))
  - Tx packet count good register (Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD))
  - Rx CRC error packets register (Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS))
  - Rx alignment error packets register (Rx alignment error packets register (ETH_RX_ALIGNMENT_ERROR_PACKETS))
  - Rx unicast packets good register (Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD))

- 4 registers to record LPI mode transition:
  - Tx LPI microsecond timer register (Tx LPI microsecond timer register (ETH_TX_LPI_USEC_CNTR))
  - Tx LPI transition counter register (Tx LPI transition counter register (ETH_TX_LPI_TRAN_CNTR))
  - Rx LPI microsecond counter register (Rx LPI microsecond counter register (ETH_RX_LPI_USEC_CNTR))
  - Rx LPI transition counter register (Rx LPI transition counter register (ETH_RX_LPI_TRAN_CNTR))
Definitions

The following terminology is used in MMC register descriptions:

- Transmitted packets are considered “good” if transmitted successfully. In other words, a transmitted packet is good if the packets transmission is not aborted because of any of the following errors:
  - Jabber timeout
  - No carrier or loss of carrier
  - Late collision
  - Packet underflow
  - Excessive deferral
  - Excessive collision

- Received packets are considered “good” if none of the following errors exists:
  - CRC error
  - Runt packet (shorter than 64 bytes)
  - Alignment error (in 10/100 Mbps only)
  - Length error (non-Type packet only)
  - Out of range (non-Type packet only, longer than 1518 bytes)

- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1,518
  - VLAN frame maxsize = 1,522
  - Jumbo frame maxsize = 9,018
  - JumboVLAN frame maxsize = 9,022

- The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in the Table 645.

<table>
<thead>
<tr>

57.5.11 Interrupts generated by the MAC

Interrupts can be generated from the MAC as a result of various events. These interrupt events are combined with the events in the DMA on the eth_sbd_intr_it signal. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The *Interrupt status register (ETH_MACISR)* describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt on the eth_sbd_intr_it signals by setting the corresponding mask bits in the *Interrupt enable register (ETH_MACIER)*.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

57.5.12 MAC and MMC register descriptions

Refer to *Section 57.11.4: Ethernet MAC and MMC registers.*
57.6 **Ethernet functional description: PHY interfaces**

The Ethernet peripheral support several PHY interfaces. The root interface is the MII one. All other interfaces are derived from it as shown in Figure 806.

![Supported PHY interfaces](image)

This section describes the SMA module used for PHY control and different PHY interfaces. It contains the following sections:

- **Station management agent (SMA)**
- **Media independent interface (MII)**
- **Reduced media independent interface (RMII)**

57.6.1 **Station management agent (SMA)**

The application can access the PHY registers through the station management agent (SMA) module. The SMA includes a two-wire station management interface (MIM).

The SMA module supports accessing up to 32 PHYs. The application can address one of the 32 registers from any 32 PHYs. Only one register in one PHY can be addressed at a time. The application sends the control data to the PHY and receives status information from the PHY through the SMA module, as shown in Figure 807.

![SMA Interface block](image)

### SMA functional overview

The MAC initiates the management write or read operation with respect to the MDC clock. The MDC clock is derived from the CSR clock (eth_hclk). The maximum operating frequency of the ETH_MDC pin is 2.5 MHz, as specified in IEEE 802.3 specifications. However, a different divider can be selected if the system supports higher clock frequencies. The division factor depends on the clock range setting through CR[3:0] in the MDIO address register (ETH_MACMDIOAR) register. The MDC clock is selected as follows:

### Table 646. MCD clock selection

</table>
The data exchange between the MAC and the PHY is performed through a three-state buffer and brought out as ETH_MDIO line connected to the PHY.

*Figure 808* shows the structure of a Clause 45 MDIO packet, while *Table 647* provides a detailed description of the packet fields.

</tbody>
</table>

In addition to normal read and write operations, the SMA also supports post-read increment address while operating in Clause 45 mode.

MII management write operations

After the station management agent receives the PHY address and the write data from the MAC CSR module, the SMA starts a write operation to the PHY registers.

Figure 810 illustrates the flow for a write operation from the SMA module to the PHY registers.
When bits[3:2] are set to 01 and bit 0 to 1 in the MDIO address register (ETH_MACMDIOAR), the MAC CSR module transfers the PHY address, the register address in PHY, and the write data (MDIO data register (ETH_MACMDIODR)) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the MII management interface using the management packet format specified in the MII specifications (as per IEEE 802.3-2002 specifications, Section 22.2.4.5).

When the SMA module starts a Write operation, the write data packet is transmitted on the MDIO line. The MAC drives the MDIO line for complete duration of the packet. The Busy bit is set high until the write operation is complete. The CSR ignores the Write operations performed to the MDIO address register (ETH_MACMDIOAR) or the MDIO data register.
(ETH_MACMDIODR) during this period (the Busy bit is high). When the Write operation is complete, the SMA module indicates this to the CSR, and the CSR resets the Busy bit. The packet format for the Write operation is as follows:

Figure 811. Write data packet

<table>
<thead>
<tr>

<td>RRRRR</td>
<td>10</td>
<td>00</td>
<td>Z</td>
</tr>
</tbody>
</table>

**MII management read operation**

When bits[3:2] are set to 11 and bit 0 to 1 in the MDIO address register (ETH_MACMDIOAR), the MAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers. At this point, the SMA module starts a Read operation on the MII management interface using the management packet format specified in the MII specifications (as per IEEE 802.3-2002 specifications, Section 22.2.4.5).

When the SMA module starts a Read operation on the MDIO, the CSR ignores the Write operations to the MDIO address register (ETH_MACMDIOAR) or MDIO data register (ETH_MACMDIODR) during this period (the Busy bit is high) and the transaction is completed without any error on the MCI interface. When the Read operation is complete, the SMA indicates this to the CSR. The CSR resets the Busy bit and updates the MDIO data register (ETH_MACMDIODR) with the data read from the PHY. The MAC drives the MDIO line for the complete duration of the frame except during the Data fields when the PHY is driving the MDIO line. For more information about the communication from the application to the PHYs, see the Reconciliation Sublayer and Media Independent Interface Specifications sections of the IEEE 802.3z, 1000BASE Ethernet.

The packet format for the Read operation is as follows:

Figure 812. Read data packet

</table>
**Preamble suppression**

The IEEE standard specifies 32-bit preamble (all-ones) for the MDIO frames. The peripheral provides controls to support preamble suppression. It transmits MDIO frames with only 1 preamble bit. The preamble suppression can be enabled by setting the PSE bit in *MDIO address register (ETH_MACMDIOAR)*.

**Trailing clocks and back-to-back transactions**

The peripheral drives the ETH_MDC clock for the duration of the MDIO frame. There is no clock driven during the idle period. The trailing clock feature can be used if the PHY needs the ETH_MDC clock to be active for some cycles after the MDIO frame. The NTC[2:0] bitfield in *MDIO address register (ETH_MACMDIOAR)* allows the programming of trailing clocks from 0 to 7.

The peripheral supports back-to-back transactions which allow starting the next MDIO frame even before the trailing clocks are complete for previous MDIO frame. This feature can be enabled by setting BTB bit in *MDIO address register (ETH_MACMDIOAR)* when the trailing clock feature is also enabled. When back-to-back transactions are enabled, the GMII busy bit (GB) is cleared immediately after MDIO frame completion. This allows the software to issue the next command, which is executed by the peripheral while trailing clocks are still on for the previous MDIO frame. When (GB) transactions are not enabled, the GMII busy bit is cleared after the trailing clocks are complete for the MDIO frame.

**Interrupt for MDIO transaction completion**

The peripheral can generate an interrupt on completion of MDIO read or write transactions. Therefore, the application need not poll the GMII busy bit of the *MDIO address register (ETH_MACMDIOAR)* to know the completion of MDIO commands.
57.6.2 **Media independent interface (MII)**

The media-independent interface (MII) defines the interconnection between the MAC sublayer and the PHY for data transfer at 10 Mbit/s and 100 Mbit/s.

MII signals are given in *Figure 813: Media independent interface (MII) signals*.

*Figure 813. Media independent interface (MII) signals*

- **TX_CLK**: continuous clock that provides the timing reference for Tx data transfers. The nominal frequency is 2.5 MHz at 10 Mbit/s and 25 MHz at 100 Mbit/s.
- **TXD[3:0]**: transmit data.
  TXD is a bundle of 4 data signals driven synchronously by the MAC sublayer and qualified (valid data) on the assertion of the TX_EN signal. TXD[0] is the least significant bit, TXD[3] is the most significant bit. While TX_EN is deasserted, the transmit data must have no effect upon the PHY.
- **TX_EN**: transmission enable signal indicating that the MAC is presenting nibbles on the MII for transmission. It must be asserted synchronously (TX_CLK) with the first nibble of the preamble and must remain asserted while all nibbles to be transmitted are presented to the MII.
- **TX_ER (optional)**: required only for Energy Efficient Ethernet (EEE). The transmit error is indicated by inverting the CRC. The remote station can detect the Transmit error through incorrect CRC.
- **RX_CLK**: continuous clock that provides the timing reference for Rx data transfers. The nominal frequency is 2.5 MHz at 10 Mbit/s, 25 MHz at 100 Mbit/s.
- **RXD[3:0]**: receive data
  RXD is a bundle of 4 data signals driven synchronously by the PHY and qualified (valid data) on the assertion of the RX_DV signal. RXD[0] is the least significant bit, RXD[3] is...
the most significant bit. While RX_EN is deasserted and RX_ER is asserted, a specific RXD[3:0] value is used to transfer specific information from the PHY.

- **RX_DV**: receive data valid
  This signal indicates that the PHY is presenting recovered and decoded nibbles on the MII for reception. It must be asserted synchronously (RX_CLK) with the first recovered nibble of the frame and must remain asserted through the final recovered nibble. It must be deasserted prior to the first clock cycle that follows the final nibble. In order to receive the frame correctly, the RX_DV signal must encompass the frame, starting no later than the SFD field.

- **RX_ER**: receive error
  This signal must be asserted for one or more clock periods (RX_CLK) to indicate to the MAC sublayer that an error was detected somewhere in the frame. This error condition must be qualified by RX_DV assertion.

- **CRS**: carrier sense.
  This signal is asserted by the PHY when either the transmit or receive medium is non idle. It is deasserted by the PHY when both transmit and receive media are idle. The PHY must ensure that the CS signal remains asserted throughout the duration of a collision condition. This signal is not required to transition synchronously with respect to the Tx and Rx clocks. In Full-duplex mode the state of this signal is don’t care for the MAC sublayer.

- **COL**: collision detection signal
  This signal must be asserted by the PHY upon detection of a collision on the medium and must remain asserted while the collision condition persists. This signal is not required to transition synchronously with respect to the Tx and Rx clocks. In Full-duplex mode, the state of this signal is don’t care for the MAC sublayer.

### 57.6.3 Reduced media independent interface (RMII)

The reduced media independent interface (RMII) specification reduces the pin count between Ethernet PHYs and STM32 MCU. According to the IEEE 802.3u, an MII contains 16 pins for data and control. RMII specification reduces the pin count to 7.

Part of the Ethernet peripheral, the RMII module is instantiated at the MAC output. This helps in translating the MII of the MAC into the RMII. The RMII block has the following characteristics:

- Supports 10 Mbps and 100 Mbps operating rates. It does not support the 1000 Mbps operation.
- Provides independent 2-bits wide Transmit and Receive paths by sourcing two clock references externally.
**RMII block diagram**

*Figure 814: RMII block diagram* shows the position of the RMII block relative to the MAC and RMII PHY. The RMII block is placed in front of the MAC to translate the MII signals to RMII signals.

**Figure 814. RMII block diagram**

- **RMII_REF_CLK**: continuous 50 MHz reference clock input
- **TXD[1:0]**: transmit data
- **TX_EN**: transmit data enable. When high, this bit indicates that valid data are being transmitted on TXD[1:0].
- **RXD[1:0]**: receive data
- **CRS_DV**: carrier Sense (CRS) and RX_Data Valid (RX_DV) multiplexed on alternate clock cycles. In 10 Mbit/s mode, it alternates every 10 clock cycles.
Transmit bit order

Each nibble from the MII interface must be transmitted on the RMII interface di-bit at a time with the order of di-bit transmission shown in *Figure 815: Transmission bit order*. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

*Figure 815. Transmission bit order*
Receive bit order

Each nibble is transmitted to the MII interface from the di-bit received from the RMII interface in the nibble transmission order shown in Figure 816: Receive bit order. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

Figure 816. Receive bit order
57.7 Ethernet low-power modes

57.7.1 Low-power management

The Ethernet peripheral supports the following techniques to save power:

- Magic packet
- Remote wake-up

The magic packet and remove wake-up techniques are used to save power in the host system when it is idle (Sleep mode) and has to be woken up only at the reception of specific packets from the Ethernet network. In Sleep mode, the power to the host logic along with the majority of the peripheral (except the MAC receiver logic), can be shut down. On receiving the specific packets from the network, the MAC provides the trigger to restore the power to the host system and come back to normal state.

The Energy Efficient Ethernet (EEE) mode is compliant with the IEEE 802.3az-2010 standard. It is primarily targeted to save power in the Ethernet port when there is no traffic on the line. In this mode, the host indicates to the far-end that it does not have any packets to transmit in the near future and puts the transmitter port (MAC controller, PCS and PHY layers) in low-power mode. Similarly, the receiver port can also be put in low-power mode when the far-end host indicates that it does not have any traffic to transfer. This allows significant saving of power in the Ethernet port (mainly in the PHY) with intermittent and bursty traffic profile. The triggering of entry and exit out of the EEE mode is controlled by the MAC and is supported within the peripheral.

Simultaneous operation of the EEE mode along with any or both the other power saving modes is also supported.

Description of magic packet mode

This section describes how to save power through magic packet detection.

Note: The magic packet feature is based on the magic packet technology white paper from Advanced Micro Device (AMD).

The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit in Operating mode configuration register (ETH_MACCR) and PWE bit in Watchdog timeout register (ETH_MACWTR).

In the magic-packet-based power saving mode, the reception of a valid magic packet by the MAC receiver triggers an exit from low-power mode. The MAC enters power saving mode when PWRDWN bit of PMT control status register (ETH_MACPCSR) is programmed to 1.

Exit from the magic-packet-based power saving mode is enabled by setting the MGKPKTEN bit of PMT control status register (ETH_MACPCSR) to 1.

The magic packet contains a unique pattern at any offset after the Destination address, Source address, and Length/Type fields. In addition to the unique pattern matching, the MAC receiver also checks for the following, to detect the received packet as a valid magic packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register (ETH_MACA0LR)) or with multicast/broadcast address.
- The packet must not have any length error, FCS error, dribble bit error, GMII error, and collision.
- The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes).

**Magic packet data format**

The content of the unique pattern in magic packets is described as follows:

- Six bytes of all-ones (0xFF FF FF FF FF FF) called synchronization stream. There can be more than six bytes of 0xFF, but only the last six are considered.
- The synchronization stream is immediately followed by 16 repetitions of the Destination address field of the packet (MAC Address 0 high register (ETH_MACA0HR) and the MAC Address 0 low register (ETH_MACA0LR)) or multicast/broadcast address.
- No break or interruption between synchronization stream and first repetition of Destination address field or within its 16 repetitions.

If the MAC address of a node is 0x00 11 22 33 44 55, the MAC scans for the following data sequence:

Destination Address Source Address Length/Type............... FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
...CRC

**Description of remote wake-up packet mode**

This section describes the power saving mode based on remote wake-up packet.

*Note:* The remote wake-up packet feature implementation is based on the Device Class Power Management Reference Specification and various implementation-specific white papers.

The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit in Operating mode configuration register (ETH_MACCR) and PWE bit in Watchdog timeout register (ETH_MACWTR).

In the remote-wake-up-magic-packet-based power saving mode, the reception of expected remote wake-up packet by the MAC receiver triggers the exit from low-power mode. The MAC enters power saving mode when PWRDWN bit in PMT control status register (ETH_MACPCSR) is programmed to 1. Exit from the remote-wake-up-magic-packet-based power saving mode is enabled by programming RWKPKTEN bit of PMT control status register (ETH_MACPCSR) to 1.

The MAC implements a filter lookup table (programmed through Remote wake-up packet filter register (ETH_MACRWKPFR) in which CRC, offset, and byte mask of the pattern embedded in remote wake-up packet and the filter operation commands are programmed.

The pattern embedded in the remote wake-up packet is located at any offset after the Destination address and Source address fields. In addition to the CRC match for the pattern, the MAC receiver also checks the following, to detect the received packet as a valid remote wake-up packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register (ETH_MACA0LR)) or with multicast/broadcast address.
- The packet must not have any length error, FCS error, dribble bit error, GMII error, and collision.
• The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes).

When a valid remote wake-up packet is received, the MAC receiver sets the RWKPRCVD bit in PMT control status register (ETH_MACPCSR) and triggers the interrupt on pmt_intr_o output port. The PMTIS bit in Interrupt status register (ETH_MACISR) is set when power-gating is not enabled in low-power mode. An interrupt is triggered to the application on the sbd_intr_o output port when interrupt is enabled (PMTIE bit in Interrupt enable register (ETH_MACIER) is set) and CSR clock is not gated off in low-power mode.

Remote wake-up packet filters

When the remote-wake-up-based power saving mode is enabled, four remote wake-up filters can be selected. The structure of the remote wake-up filters is shown in Table 649: Remote wake-up packet filter register.

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter i Byte mask</td>
<td>The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2 or 3) to determine whether or not a packet is a wake-up packet.</td>
</tr>
<tr>
<td></td>
<td>– The MSB (31st bit) must be zero.</td>
</tr>
<tr>
<td></td>
<td>– Bit j[30:0] is the byte mask.</td>
</tr>
<tr>
<td></td>
<td>– If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.</td>
</tr>
<tr>
<td>Filter i Command</td>
<td>The 4-bit filter i command controls the filter i operation.</td>
</tr>
<tr>
<td></td>
<td>– Bit 3 specifies the address type, defining the destination address type of the pattern.</td>
</tr>
<tr>
<td></td>
<td>– When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packets.</td>
</tr>
<tr>
<td></td>
<td>– Bit 2 (Inverse mode), when set, reverses the logic of the CRC16 Hash function signal, to reject a packet with matching CRC_16 value.</td>
</tr>
<tr>
<td></td>
<td>– Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2”.</td>
</tr>
<tr>
<td></td>
<td>– Bit 1 (And_Previous) implements the Boolean logic(1).</td>
</tr>
<tr>
<td></td>
<td>– When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set.</td>
</tr>
<tr>
<td></td>
<td>– Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.</td>
</tr>
<tr>
<td>Filter i Offset</td>
<td>This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.</td>
</tr>
<tr>
<td></td>
<td>– This 8-bit pattern-offset is the offset for the filter i first byte to be examined.</td>
</tr>
<tr>
<td></td>
<td>– The minimum allowed offset is 12, which refers to the 13th byte of the packet.</td>
</tr>
<tr>
<td></td>
<td>– The offset value 0 refers to the first byte of the packet.</td>
</tr>
<tr>
<td>Filter i CRC-16</td>
<td>This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programmed to the wake-up filter register block.</td>
</tr>
<tr>
<td></td>
<td>– The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1</td>
</tr>
<tr>
<td></td>
<td>– Each mask, used in the Hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:</td>
</tr>
<tr>
<td></td>
<td>– 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC16 calculation.</td>
</tr>
<tr>
<td></td>
<td>– 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations.</td>
</tr>
</tbody>
</table>

1. The And_Previous bit setting is applicable within a set of four filters.

Setting And_Previous bit of a filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of four filters has no effect. For example, setting And_Previous bit of Filter 0 has no effect.

If And_Previous bit is set for a given filter to form an AND chained filter, the AND chain breaks when it finds a disabled filter. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting Filter 2 And_Previous bit has no effect, only Filter 1 result ORed with Filter 3 result is considered.

If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, then a remote wake-up frame does not pass the AND chained filter as a remote wake-up frame cannot be of both unicast and multicast address types.
The remote wake-up filter registers are implemented as eight indirect access registers (wkuppktfilter_reg#i) for four remote wake-up filters, and accessed by the application through *Remote wake-up packet filter register (ETH_MACRWKPFR)*. The entire set of wkuppktfilter_reg registers must be written to program the remote wake-up filters. The wkuppktfilter_reg register is programmed by sequentially writing the eight register values in *Remote wake-up packet filter register (ETH_MACRWKPFR)* for wkuppktfilter_reg0 to wkuppktfilter_reg3, respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of *PMT control status register (ETH_MACPCSR)*.

**Note:** If the *Remote wake-up packet filter register (ETH_MACRWKPFR)* is accessed in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when the CPU accesses Lane 3.

*When* *Remote wake-up packet filter register (ETH_MACRWKPFR)* is written, the content is transferred from CSR clock domain to PHY receive clock domain after the write operation. There should not be any further write to the *Remote wake-up packet filter register (ETH_MACRWKPFR)* until the first write is updated in PHY receive clock domain. Otherwise, the second write operation does not get updated to the PHY receive clock domain. Therefore, the delay between two write operations to the *Remote wake-up packet filter register (ETH_MACRWKPFR)* should be at least 4 cycles of the PHY receive clock.

**PMT interrupt**

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. *Table 651* lists the remote wake-up scenarios in which PMT interrupt is generated.

1. In all other combinations, the Remote wake-up packet is not detected and PMT interrupt is not generated.

In addition to sbd_intr_o signal, the pmt_intr_o (synchronous to Rx clock) signal is asserted. The pmt_intr_o signal, synchronous to the Rx clock domain, is provided so that the application clock can be stopped by software when the MAC is in the power-down mode. It is ORed with lpi_intr_o signal (see *Section : LPI interrupt*) and tied to the EXTI peripheral (line 86).

As the pmt_intr_o signal is generated in the PHY Rx clock domain, it is not cleared immediately when the *PMT control status register (ETH_MACPCSR)* is read. This is
because the resultant clear signal has to cross to the PHY Rx clock domain, and then clear the interrupt source. This delay is at least 4 clock cycles of Rx clock and can be significant when the peripheral is operating in the 10 Mbps mode. When the application clears the PWRDWN bit in Remote wake-up packet filter register (ETH_MACRWKPFR), the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

Power-down sequence

The software must perform the following tasks to initiate the power-down sequence:

- Disable the Transmit DMA (if applicable) by clearing the ST bit of the Channel transmit control register (ETH_DMACTXCR).
- Wait for any previous frame transmissions to complete. You can check this by reading TFCSTS[1:0] and TPESTS bits in Debug register (ETH_MACDR) and TXQSTS bit in Tx queue debug register (ETH_MTLTXQDR) of all MTL Tx Queues.
- Disable the MAC transmitter and MAC receiver by clearing TE and RE bits in Operating mode configuration register (ETH_MACCR).
- Wait till the Receive DMA empties all frames from the Rx FIFO. You can check this by reading PRXQ[13:0] in Rx queue debug register (ETH_MTLRXQDR) of all Rx Queues. If these bits are zero, it indicates that the Rx FIFO is empty.
- Configure the magic packet (MGPKTEN) and/or remote wake-up (RWKPKTEN) detection in the PMT control status register (ETH_MACPCSR).
- Set bit 31 (ARPEN) in the Operating mode configuration register (ETH_MACCR).
- Enable the MAC Receiver by setting RE bit and then set PWRDWN bit in the PMT control status register (ETH_MACPCSR) to initiate the power-down sequence in MAC.

Note: If the feature is enabled and the MAC Transmitter is in the LPI mode when it is put into the power-down mode, then the MII interface gets clamped to assert the LPI pattern. If the MAC Transmitter is not in the LPI mode when it is put into the power-down mode, the GMII or MII interface gets clamped to all-zero.

Power-up sequence

The MAC wakes up on receiving the magic packet or remote wake-up frame. The power-up sequence is as follows:

- The MAC asserts pmt_intr_o. When only clock-gating is employed in low-power mode, the pmt_intr_o signal can be used to start the clocks that were gated-off after entering low-power mode.
- The software performs the following tasks:
  - De-assert the pmt_intr_o by reading the PMT control status register (ETH_MACPCSR).
  - Perform a write operation (with reset values) to the PMT control status register (ETH_MACPCSR) and the Remote wake-up packet filter register (ETH_MACRWKPFR) so that the corresponding values in the always-on block gets synchronized. Otherwise, the values of these registers are different.
  - Perform write operations to the Operating mode configuration register (ETH_MACCR), MAC Address 0 high register (ETH_MACROHR) and MAC Address 0 low register (ETH_MACA0LR) to synchronize the values in the CSR module and the respective bits in the always-on block. Otherwise, the MAC receiver is on even though the Receive Enable bit is set to 0.
After completing these steps, the software must initialize all registers, enable the transmitter, and program the DMA (in DMA configurations) to resume the normal operation.

### 57.7.2 Energy Efficient Ethernet (EEE)

EEE is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sublayer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The peripheral supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows saving power by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

#### Transmit path functions

The transmit path functions include tasks that the MAC must perform to make the PHY enter the LPI state.

In the transmit path, the software must set the LPIEN bit of the **LPI control and status register (ETH_MACLCSR)** to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER LST[9:0] bitfield of **LPI timers control register (ETH_MACLTCR)**. The PHY Link Status PLS bit of the **LPI control and status register (ETH_MACLCSR)** indicates the link status of the PHY.

**Note:** The EEE feature is not supported when the MAC is configured to use the RMII.

According to the standard (IEEE 802.3az-2010), the PHY must not stop the TxCLK clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN.
2. Asserts TX_ER.
3. Sets TXD[3:0] to 0x1 (for 100 Mbps)
4. Updates the status (TLPIEN bit of **LPI control and status register (ETH_MACLCSR)**) and generates an interrupt.

**Note:** The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.
To bring the PHY out of the LPI state, that is when the software resets the LPIEN bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern.
2. Starts the LPI TW TIMER:
   The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the LPI timers control register (ETH_MACLTCR).
3. Updates the LPI exit status (TLPIEX bit of the LPI control and status register (ETH_MACLCSR)) and generates an interrupt.

Figure 817 shows the behavior of TX_EN, TX_ER, and TXD[3:0] signals during the LPI mode transitions.

**Note:** The MAC does not stop the TX_CLK clock. The application can stop this clock (as shown in Figure 817) if the PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1. The sbd_tx_clk_gating_ctrl_o signal is asserted after nine Tx Clock Cycles, one Pulse Synchronizer delay, and one CSR clock cycle. The assertion of the sbd_tx_clk_gating_ctrl_o signal depends on the LPITCSE bit of the LPI control and status register (ETH_MACLCSR) and can be done automatically as shown on Figure 818.

If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern and so the Tx Clock cannot be gated.

If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.

If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

---

**Figure 817. LPI transitions (Transmit, 100 Mbds)**

---
Automated entry/exit from LPI mode in transmit path

The MAC transmitter can be programmed to enter and exit LPI Idle mode automatically based on whether it is Idle for a specific period of time or has a packet to transfer. These modes are enabled and controlled by the LPI control and status register (ETH_MACLCSR).

When LPITXA and LPIEN of LPI control and status register (ETH_MACLCSR) are set, the MAC transmitter enters LPI Idle state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI Idle state and clears the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition, when LPITE is also set, the MAC transmitter enters LPI Idle state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in LPI entry timer register (ETH_MACLETR). In this mode also, the MAC transmitter exits the LPI Idle state as soon as any of the functions becomes non-idle. However, the LPIEN bit is not cleared but remains active so that reentry to LPI Idle state is possible without any software intervention when the MAC becomes idle again.

When both LPITE and LPITXA bits are cleared, the application can directly control the entry and exit of LPI Idle state by programming the LPIEN bit.

Receive path Functions

The receive path functions include the tasks that the PHY and MAC must perform when the PHY receives signals from the link partner to exit the LPI state.

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER.
2. The PHY sets RXD[3:0] to 0x1 (for 100 Mbps).
3. The PHY de-asserts RX_DV.
4. The MAC updates the RLPIEN bit of the LPI control and status register (ETH_MACLCSR) and immediately generates an interrupt.
Note: The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

If the LPI pattern is detected for a very short duration (that is, less than two cycles of Rx clock), the MAC does not enter the Rx LPI mode.

If the duration between the end of the current Rx LPI pattern and the start of the next Rx LPI pattern is very short (that is, less than two Rx clock cycles), then the MAC exits and enters again the Rx LPI mode. The MAC does not trigger the Rx LPI Exit and Entry interrupts.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the LPI control and status register (ETH_MACLCSR) and generates an interrupt immediately. The sideband signal lpi_intr_o (synchronous to Rx clock) is also asserted.

Figure 819 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

Figure 819. LPI transitions (receive, 100 Mbps)

Note: If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than nine clock cycles after the start of the LPI state as shown in Figure 819.

If the MAC is in LPI mode and the application issues a soft reset or hard reset, the MAC receiver exits from LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver enters again the LPI state.

If the RX clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the RX clock domain.

When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.
LPI timers

The transmitter maintains the LPI LS TIMER, LPI TW TIMER, and LPI AUTO ENTRY TIMER timers.

The following LPI timers are loaded with the respective values from the LPI timers control register (ETH_MACLTCR) and LPI entry timer register (ETH_MACLETR):

- **LPI LS TIMER**
  The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in the LST[9:0] bitfield in the LPI timers control register (ETH_MACLTCR). The LPI LS TIMER is 10-bit wide. The software can program up to 1023 milliseconds.

- **LPI TW TIMER**
  The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in Bit[15:0] of LPI timers control register (ETH_MACLTCR). The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count.
  The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 micro seconds.

- **LPI AUTO ENTRY TIMER**
  This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPITE bit in LPI control and status register (ETH_MACLCSR) is set.

LPI interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt sbd_intr_o is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the LPI control and status register (ETH_MACLCSR).

When the MAC exits the Rx LPI state, then in addition to the sbd_intr_o, the sideband signal lpi_intr_o (synchronous to Rx clock) is asserted. The lpi_intr_o signal can be used to trigger the external clock-gating circuitry to restore the application clock to the MAC. The lpi_intr_o signal, synchronous to the Rx clock domain, is provided so that the application clock can be stopped by software when the MAC is in the LPI state. It is ORed with pmt_intr_o signal (see Section : PMT interrupt) and tied to the EXTI peripheral (line 86).

The lpi_intr_o signal is generated in the Rx clock domain. It may not be cleared immediately after the LPI control and status register (ETH_MACLCSR) is read. This is because the clear signal, generated in CSR clock domain, has to cross the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the peripheral is operating in the 10 Mbps mode.

**Programming guidelines for Energy Efficient Ethernet**

For detailed guidelines on the programming guidelines, see Section 57.9.11: Programming guidelines for Energy Efficient Ethernet (EEE) on page 2774.
57.8 Ethernet interrupts

The Ethernet peripheral generates a single interrupt signal (eth_sbd_intr_it). This signal can be raised as a result of various events. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in a hierarchical manner so that it is easier for software to traverse and identify the source of interrupt event quickly. When interrupt is asserted, the Interrupt status register (ETH_DMAISR) register is first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX & RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- ETH_DMACSR: Channel Status (see Channel status register (ETH_DMACSR))
- ETH_MTLISR: Interrupt Status (see Interrupt status Register (ETH_MTLISR))
- ETH_MACISR: Interrupt Status (see Interrupt status register (ETH_MACISR))

57.8.1 DMA interrupts

Interrupt registers description

The ETH_DMACSR: Channel Status register (see Channel status register (ETH_DMACSR)) captures all the interrupt events of that TxDMA and RxDMA channel. The ETH_DMACIER: Channel Interrupt Enable register (see Channel interrupt enable register (ETH_DMACIER)) contains the corresponding enable bits for each of the interrupt event.

There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by Bits[15:14] of ETH_DMACSR register respectively. The normal group is for events that happen during the normal transfer of packets (TI: transmit interrupt, RI: receive interrupt, TBU: Transmit buffer unavailable) while the abnormal interrupt events are for error events.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. An interrupt is generated only once for multiple events. The driver must scan the Interrupt status register (ETH_DMAISR) for the cause of the interrupt and clear the source in the respective Status register. The interrupt is cleared only when all the bits of Interrupt status register (ETH_DMAISR) are cleared.

Periodic scheduling of Transmit and Receive Interrupt

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The Ethernet peripheral gives the flexibility to schedule the interrupt at regular intervals using two methods:

1. Set Interrupt on Completion bit in Transmit descriptor (TDES2[31] in Table 655: TDES2 normal descriptor (read format)) once for every “required” number of packets to be transmitted.
2. Similarly, set the IOC (RDES3[30] in Table 668: RDES3 normal descriptor (read format)) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated.
In addition to above, an interrupt timer (ETH_DMACRXIWTR: Channel Rx Interrupt Watchdog Timer) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programmed with a nonzero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[30] in Table 668: RDES3 normal descriptor (read format)) is not set. When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in ETH_DMACIER register (see Channel interrupt enable register (ETH_DMACIER)). The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor’s IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

Channel transfer complete interrupt

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in the Channel Status register (Channel status register (ETH_DMACSR)). The TI bit is set whenever the Tx DMA channel closes the descriptor in which the IOC bit is set (Interrupt On Completion - TDES2[31]). Similarly, the RI bit is set whenever the Rx DMA channel closes the descriptor with the LD bit set and, in any of the descriptors used for transferring that packet, IOC bit is set (Interrupt Enable on completion - RDES3[30]).

The interrupt signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in the channel interrupt enable register (Channel interrupt enable register (ETH_DMACIER)).

The behavior of the RI/TI interrupts changes depending on the settings of INTM field (bits[17:16]) in the ETH_DMAMR register (DMA mode register (ETH_DMAMR)). Table 652 explains the behavior of the Transfer Complete interrupt.

<table>
<thead>
<tr>
<th>Interrupt Mode</th>
<th>Behavior of TI/RI and interrupt signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTM=0</td>
<td>The TI/RI status signals are set whenever the Transfer complete event is detected. These bits are cleared whenever the software driver writes 1 to these bits. The interrupt signal is asserted whenever the corresponding interrupts are also enabled in ETH_DMACIER register.</td>
</tr>
<tr>
<td>INTM=1</td>
<td>The TI/RI is set as explained above. However, the interrupt is not asserted for any RI/TI event.</td>
</tr>
<tr>
<td>INTM=2</td>
<td>The RI/TI status bits are set whenever the Transfer Complete event is detected and are reset whenever software driver clears them by writing 1. However, if another Transfer complete event is detected before it is cleared (serviced) by the software, then these status bits are automatically set again. However, the interrupt is not generated based on TI/RI.</td>
</tr>
</tbody>
</table>

57.8.2 MTL interrupts

MTL interrupt events are combined with the events in the DMA to generate the interrupt signal.

*Interrupt status Register (ETH_MTLISR)* reports the queue number responsible for the event. ETH_MTLQICSR: Queue Interrupt Control Status must be read for event description.
The MTL interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the Interrupt status Register (ETH_MTLISR) register.

MTL interrupt signal is driven by one of these events:
- Receive Queue Overflow Interrupt
- Transmit Queue Underflow

### 57.8.3 MAC Interrupts

MAC interrupt events are combined with the events in the DMA to generate the interrupt signal.

The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The Interrupt status register (ETH_MACISR) describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the Interrupt status register (ETH_MACISR).

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

MAC interrupt signal is driven by one of these events:
- Receive Status Interrupt
- Transmit Status Interrupt
- Timestamp Interrupt Status
- MMC Interrupt Status
  - MMC Receive Checksum Offload Interrupt Status
  - MMC Transmit Interrupt Status
  - MMC Receive Interrupt Status
- LPI Interrupt Status
- PMT Interrupt Status
- PHY Interrupt

*Note:* Two sidebands signals are generated together with LPI and PMT interrupts: lpi_intr_o and pmt_intr_o. They are used for wake-up event detection at EXTI level.
57.9 Ethernet programming model

This chapter provides the instructions for initializing the DMA or MAC registers in the proper sequence. It contains the following sections:

- DMA initialization (see Section 57.9.1)
- MTL initialization (see Section 57.9.2)
- MAC initialization (see Section 57.9.3)
- Performing Normal Receive and Transmit Operation (see Section 57.9.4)
- Stopping and Starting Transmission (see Section 57.9.5)
- Programming Guidelines for MII Link State Transitions (see Section 57.9.8)
- Programming Guidelines for IEEE 1588 Timestamping (see Section 57.9.9)
- Programming Guidelines for Energy Efficient Ethernet (see Section 57.9.11)
- Programming Guidelines for flexible pulse-per-second (PPS) output (see Section 57.9.12)
- Programming Guidelines for TSO (see Section 57.9.13)
- Programming Guidelines for VLAN filtering on Receive (see Section 57.9.14)

57.9.1 DMA initialization

Complete the following steps to initialize the DMA:

1. Provide a software reset to reset all MAC internal registers and logic (bit 0 of DMA mode register (ETH_DMAMR)).
2. Wait for the completion of the reset process (poll bit 0 of the DMA mode register (ETH_DMAMR), which is cleared when the reset operation is completed).
3. Program the following fields to initialize the System bus mode register (ETH_DMASBMR):
   a) AAL
   b) Fixed burst or undefined burst
   c) Burst mode values in case of AHB bus interface.
4. Create a transmit and a receive descriptor list. In addition, ensure that the receive descriptors are owned by the DMA (set bit 31 of TDES3/RDES3 descriptor). For more information on descriptors, refer to Section 57.10: Descriptors.

Note: Descriptor address from start to end of the ring should not cross the 4GB boundary.

5. Program ETH_DMACTXRLR and ETH_DMACRXRLR registers (see Channel Tx descriptor ring length register (ETH_DMACTXRLR) and Channel Rx descriptor ring length register (ETH_DMACRXRLR)). The programmed ring length must be at least 4.

6. Initialize receive and transmit descriptor list address with the base address of transmit and receive descriptor (Channel Tx descriptor list address register (ETH_DMACTXDLAR), Channel Rx descriptor list address register (ETH_DMACRXDLAR)). In addition, program the transmit and receive tail pointer registers that inform the DMA about the available descriptors (see Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) and Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR)).

7. Program ETH_DMACCR, ETH_DMACTXCR and ETH_DMACRXCR registers (see Channel control register (ETH_DMACCR), Channel transmit control register (ETH_DMACTXCR) and Channel receive control register (ETH_DMACRXCR)) to
configure the parameters such as the maximum burst-length (PBL) initiated by the DMA, descriptor skip lengths, OSP for TxDMA, RBSZ[13:0] for RxDMA, and so on.

8. Enable the interrupts by programming the ETH_DMACIER register (see Channel interrupt enable register (ETH_DMACIER)).

9. Start the Receive and Transmit DMAs by setting SR (bit 0) of Channel receive control register (ETH_DMAMCRXCR) and ST (bit 0) of the ETH_DMAMCTR (see Channel transmit control register (ETH_DMAMCTXCR)).

57.9.2 MTL initialization

Complete the following steps to initialize the MTL registers:

1. Program the following fields to initialize the operating mode in Tx queue operating mode Register (ETH_MTLTXQOMR).
   a) Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) if the Threshold mode is used.
   b) Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue 0.
   c) Transmit Queue Size (TQS).

2. Program the following fields to initialize the operating mode in the ETH_MTLRXQOMR register (see Rx queue operating mode register (ETH_MTLRXQOMR)):
   a) Receive Store and Forward (RSF) or RTC if Threshold mode is used.
   b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD).
   c) Error Packet and undersized good Packet forwarding enable (FEP and FUP).
   d) Receive Queue Size (RQS).

57.9.3 MAC initialization

The MAC configuration registers establish the operating mode of the MAC. If possible, these registers must be initialized before initializing the DMA. The following MAC Initialization operations can also be performed after DMA initialization. If the MAC initialization is complete before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC Address x low register (ETH_MACAxLR), MAC Address 0 high register (ETH_MACA0HR) and MAC Address x high register (ETH_MACAxHR).

2. Program the following fields to set the appropriate filters for the incoming frames in the Packet filtering control register (ETH_MACPFR):
   a) Receive All.
   b) Promiscuous mode.
   c) Hash or Perfect Filter.
   d) Unicast, multicast, broadcast, and control frames filter settings.

3. Program the following fields for proper flow control in the Tx Queue flow control register (ETH_MACQTXFCR):
   a) Pause time and other Pause frame control bits.
   b) Transmit Flow control bits.
   c) Flow Control Busy.
4. Program the Interrupt enable register (ETH_MACIER) as required, if it is applicable for your configuration.

5. Program the appropriate fields in the Operating mode configuration register (ETH_MACCR) register. For example, Inter-packet gap while transmission and jabber disable.

6. Set bit 0 and 1 in Operating mode configuration register (ETH_MACCR) register to start the MAC transmitter and receiver.

To support Jumbo Transmit/Receive packets, follow these steps:
   • In the Operating mode configuration register (ETH_MACCR)
     a) Set JE bit to 1.
     b) Set JD and WD bits to 0 to avoid giant packet error reporting.
     c) Set GPSLCE bit to 1
     d) Set GPSL bitfield of the Extended operating mode configuration register (ETH_MACECR) to a value > 9026

To support Transmit/Receive packets, up to 16K, follow these steps:
   • In the Operating mode configuration register (ETH_MACCR)
     a) Set JD and WD bits to 1 to avoid giant packet error reporting.
     b) Set GPSLCE bit to 1.
     c) Set GPSL bitfield of the Extended operating mode configuration register (ETH_MACECR) to 16383.

57.9.4 Performing normal receive and transmit operation

For normal operation, complete the following steps:
1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptor by reading the status of the descriptor owned by the Host (either transmit or receive).

2. Set the descriptors to appropriate values. Make sure that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.

3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into Suspend state. The transmission or reception can be resumed by freeing the descriptors and writing the ETH_DMACTXDTPR (see Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR)) and ETH_DMACRXDTPR (see Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR)).

4. In debug mode, the values of the current host transmitter or receiver descriptor address pointer can be read in ETH_DMACCATXDR and ETH_DMACCARXDR registers (see Channel current application transmit descriptor register (ETH_DMACCATXDR) and Channel current application receive descriptor register (ETH_DMACCARXDR)).

5. In debug mode, the values of the current host transmit buffer address pointer and receive buffer address pointer can be read in ETH_DMACCATXDR and ETH_DMACCARXDR registers (see Channel current application transmit descriptor register (ETH_DMACCATXDR) and Channel current application receive descriptor register (ETH_DMACCARXDR)).
57.9.5 Stopping and starting transmission

Complete the following steps to pause the transmission for some time:

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of ETH_DMACTXCR register (see Channel transmit control register (ETH_DMACTXCR)).
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Tx queue debug register (ETH_MTLTXQDR) (TRCSTS[1:0] is not 01 and TXQSTS = 0).
3. Disable the MAC transmitter and MAC receiver by clearing RE and TE bits of the Operating mode configuration register (ETH_MACCR) Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of Tx queue debug register (ETH_MTLTXQDR), PRXQ=0 and RXQSTS[1:0] = 00).
5. Make sure that both Tx queue and Rx queue are empty (TXQSTS is 0 in Tx queue debug register (ETH_MTLTXQDR) and RXQSTS[1:0] is set to 00).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

**Note:** Do not change the configuration (such as duplex mode, speed, port, or loopback) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active. Similarly, do not change the DMA-related configuration when Transmit and Receive DMA are active.

57.9.6 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in Suspend state, as explained below:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to Suspend state due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames are lost because of an Rx FIFO overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into Stop state.

57.9.7 Programming guidelines for switching the AHB clock frequency

To dynamically change the AHB clock frequency (without applying soft reset or hard reset), follow these steps:

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. When the frame transmissions is complete, the Tx FIFO becomes empty and the Tx DMA enters Stop state. The Tx FIFO status is given in the Tx queue debug
register (ETH_MTLTXQDR) and the status of DMA is given in Debug status register (ETH_DMADSR).

2. Disable the MAC transmitter and the MAC receiver by clearing the appropriate bits in Operating mode configuration register (ETH_MACCR).

3. Disable the Receive DMA (if applicable) after making sure that the data in the Rx FIFO is transferred to the system memory. The Rx FIFO empty status is given in Rx queue debug register (ETH_MTLRXQDR).

4. Ensure that the application does not perform any register read or write operation.

5. Change the frequency of the AHB clock.

6. Enable the MAC Transmitter or the MAC Receiver and the Transmit or Receive DMA. These steps ensure that no valid data is present in the Tx FIFO or Rx FIFO at the time of clock frequency switching and prevent any data corruption.

57.9.8 Programming guidelines for MII link state transitions

Transmit and Receive clocks are running when the link is down

Complete the following steps when the link is down while the Transmit and Receive clocks are running:

1. Disable the Transmit DMA (if applicable) by clearing bit 0 (ST) of Channel control register (ETH_DMACCR).

2. Disable the MAC receiver by clearing RE bit of Operating mode configuration register (ETH_MACCR).

3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Tx queue debug register (ETH_MTLTXQDR) (TRCSTS[1:0] is not 01).

   or

   Flush the Tx FIFO for faster empty operation.

4. Disable the MAC transmitter by clearing TE bit of the Operating mode configuration register (ETH_MACCR) Register.

5. Make sure that both Tx and Rx queues are empty (TXQSTS is set to 0 in Tx queue debug register (ETH_MTLTXQDR) and RXQSTS[1:0] to 00 in Rx queue debug register (ETH_MTLRXQDR)).

6. After the link is up, read the PHY registers to identify the latest configuration and program the MAC registers accordingly.

7. Restart the operation by starting the Tx DMA. Then enable the MAC Transmitter and Receiver.

   The Rx DMA does not need to be enabled: since the Receiver is disabled, there are no data in the Rx FIFO.
Transmit and Receive clocks are stopped when the link is down

Complete the following steps when the link is down and the Transmit and Receive clocks are stopped:

1. Disable the MAC Transmitter and Receiver by clearing RE and TE bits in the Operating mode configuration register (ETH_MACCR). This does not take immediate effect as the clocks are absent.
2. Wait till the link is up and the clocks are restored.
3. Wait until the transfer of any partial frame is complete if any was ongoing when the Transmit/Receive clock is stopped. This can be checked by reading the Debug register (ETH_MACDR) (all bits should be set to 0). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped.
4. Read the PHY registers to identify the latest operating mode and program the MAC registers accordingly.
5. Restart the MAC Transmitter and Receiver by setting RE and TE bits.

57.9.9 Programming guidelines for IEEE 1588 timestamping

Initializing the System time generation

The timestamp feature can be enabled by setting bit 0 of the Timestamp control Register (ETH_MACTSCR). However, it is essential that the timestamp counter is initialized after this bit is set. Complete the following steps to perform the peripheral initialization:

1. Mask the Timestamp Trigger interrupt by clearing bit 12 of Interrupt enable register (ETH_MACIER).
2. Set bit 0 of Timestamp control Register (ETH_MACTSCR) to enable timestamping.
3. Program Subsecond increment register (ETH_MACSSIR) based on the PTP clock frequency.
4. If you use the Fine Correction method, program Timestamp addend register (ETH_MACTSAR) and set bit 5 of Timestamp control Register (ETH_MACTSCR).
5. Poll the Timestamp control Register (ETH_MACTSCR) until bit 5 is cleared.
6. Program bit 1 of Timestamp control Register (ETH_MACTSCR) to select the Fine Update method (if required).
7. Program System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR) with the appropriate time value.
8. Set bit 2 in Timestamp control Register (ETH_MACTSCR). The timestamp counter starts as soon as it is initialized with the value written in the timestamp update registers. If one-step timestamping is required:
   a) Enable one-step timestamping by programming bit 27 of the TDES3 Context Descriptor.
   b) Program Timestamp Ingress asymmetric correction register (ETH_MACTSIACR) to update the correction field in PDelay_Req PTP messages.
9. Enable the MAC receiver and transmitter for proper timestamping.

Note: If timestamp operation is disabled by clearing bit 0 of Timestamp control Register (ETH_MACTSCR), repeat all these steps to restart the timestamp operation.
System time correction

To synchronize or update the system time in one shot (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the timestamp update registers (System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR)).
2. Set bit 3 (TSUPDT) of the Timestamp control Register (ETH_MACTSCR).

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm described in Section: System time register module, calculate at which rate you intend to increment or decrement the system time.
2. Update the Timestamp addend register (ETH_MACTSAR) with the new value and set bit 5 of the Timestamp control Register (ETH_MACTSCR) Register.
3. Wait for the time during which you want the new value of the Addend register to be active. This can be done by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTNTR).
5. Enable the Timestamp interrupt in bit 12 of Interrupt enable register (ETH_MACIER).
6. Set bit 4 in Register Timestamp control Register (ETH_MACTSCR).
7. When this trigger generates an interrupt, read Interrupt status register (ETH_MACISR).
8. Reprogram Timestamp addend register (ETH_MACTSAR) with the old value and set bit 5 again.

57.9.10 Programming guidelines for PTP offload feature

Programming guidelines to enable automatic periodic generation of PTP sync messages

Follow these steps to enable automatic periodic generation of PTP sync messages:

1. Program SNAPYPSE, TSMSTRENA, and TSEVNTEN values of Timestamp control Register (ETH_MACTSCR) to 0, 1, and 1 respectively, to configure the node as Ordinary or Boundary Master (1, 1, and 1 for Transparent Master).
2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to send in egress PTP Sync message.
3. Program the ASYNCE bit of PTP Offload control register (ETH_MACPOCR) to enable periodic generation of PTP Sync messages.
4. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP
**Source port identity 2 register (ETH_MACSPI2R)** to send in egress PTP Sync message.

5. Program the LSI field of **Log message interval register (ETH_MACLMIR)** to program the periodicity of the PTP Sync messages.

For example, a value of 1 corresponds to $2^1$ which translates to PTP Sync message every 2 seconds, and a value of 0xFF (twos complement of -1) corresponds to $2^{-1}$ which translates to PTP Sync message every 0.536 seconds.

6. Program the TSIE bit of **Interrupt enable register (ETH_MACIER)** to enable generation of Timestamp interrupt.

7. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in **Timestamp status register (ETH_MACTSSR)**. It indicates that the timestamp for PTP Sync message is captured in **Tx timestamp status seconds register (ETH_MACTXTSSSR)** and **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)**.

**Programming guidelines to enable periodic generation of PTP Pdelay_Req messages**

Follow these steps to enable automatic periodic generation of PTP Pdelay_Req messages

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of **Timestamp control Register (ETH_MACTSCR)** to 1, 0, and 1 respectively to configure the node as Transparent Slave (1, 1, and 1 for Transparent Master OR 3, X, and X for Peer-to-Peer Transparent).

2. Program the PTOEN bit and DN field of **PTP Offload control register (ETH_MACPOCR)** to enable PTP Offload feature and domain number to send in egress PTP Pdelay_Req message.

3. Program the APDREQEN bit of **PTP Offload control register (ETH_MACPOCR)** to enable periodic generation of PTP Pdelay_Req messages.

4. Program the 80-bit Source Port Identity in **PTP Source Port Identity 0 Register (ETH_MACSPI0R)**, **PTP Source port identity 1 register (ETH_MACSPI1R)** and **PTP Source port identity 2 register (ETH_MACSPI2R)** to send in egress PTP Pdelay_Req message.

5. Program the LMPDRI field of **Log message interval register (ETH_MACLMIR)** to program the periodicity of the PTP Pdelay_Req messages.

For example, a value of 1 corresponds to $2^1$ which translates to PTP Pdelay_Req message every 2 seconds, and a value of 0xFF (twos complement of -1) corresponds to $2^{-1}$ which translates to PTP Pdelay_Req message every 0.536 seconds.

6. Program the TSIE bit of **Interrupt enable register (ETH_MACIER)** to enable generation of Timestamp interrupt.

7. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in **Timestamp status register (ETH_MACTSSR)**. It indicates that the timestamp for PTP Sync message is captured in **Tx timestamp status seconds register (ETH_MACTXTSSSR)** and **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)**.

**Programming guidelines to enable the generation of PTP response messages for Ordinary or Boundary Master mode**

Follow these steps to enable the generation of PTP response messages for Ordinary or Boundary Master mode (Periodic PTP Sync messages generated and PTP Delay_Resp message generated in response to PTP Delay_Req message):

- **Source port identity 2 register (ETH_MACSPI2R)** to send in egress PTP Sync message.
1. Program SNAPTYPESEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 1, and 1 respectively.
2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.
3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.
4. Program the DRSYNCR and LSI fields in Log message interval register (ETH_MACLIMR). The sum of both fields is updated in logMinDelayReqInterval field of PTP Delay_Resp message.

Programming guidelines to enable the generation of PTP response messages for Ordinary or Boundary Slave mode

Follow these steps to enable generation of PTP response messages for Ordinary or Boundary Slave mode (PTP Delay_Req message generated in response to PTP Sync message):

1. Program SNAPTYPESEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 0, and 1 respectively.
2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain Number to match with ingress PTP Sync message and send in egress PTP Delay_Req message.
3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Sync message and send in egress PTP Delay_Req message.
4. Program the DRSYNCR field in Log message interval register (ETH_MACLIMR) to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages.

Programming guidelines to enable the generation of PTP response messages for Transparent Slave mode

Follow these steps to enable generation of PTP response messages for Transparent Slave mode (PTP Delay_Req message generated in response to PTP Sync message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated)

1. Program SNAPTYPESEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 0, and 1 respectively.
2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain Number to match with ingress PTP Sync or Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.
3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Sync or
Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.

4. Program the DRSYNCR and LMPDRI fields in Log message interval register (ETH_MACLMIR) to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages and periodicity of the PTP Pdelay_Req messages.

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) for egress PTP Pdelay_Req and Pdelay_Resp messages.

Programming guidelines to enable the generation of PTP response messages for Transparent Master mode

Follow these steps to enable generation of PTP response messages for Transparent Master mode (PTP Delay_Resp message generated in response to PTP Delay_Req message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req or Sync messages generated):

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 1, and 1 respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.

4. Program the DRSYNCR, LSI and LMPDRI fields in Log message interval register (ETH_MACLMIR), the sum of DRSYNCR and LSI is updated in logMinDelayReqInterval field of PTP Delay_Resp message and periodicity of the PTP Sync or Pdelay_Req messages.

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) for egress PTP Sync, Pdelay_Req and Pdelay_Resp messages.

Programming guidelines to enable the generation of PTP response messages for Peer-to-Peer Transparent mode

Follow these steps to enable generation of PTP response messages for Peer-to-Peer Transparent mode (PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated):
1. Program the SNAPTYPSEL, TSMSTREN and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 3, X, and X respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain Number to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.

4. Program the LMPDRI field in Log message interval register (ETH_MACLMIR) to indicate periodicity of the PTP Pdelay_Req messages

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSNSR) for egress PTP Pdelay_Req and Pdelay_Resp messages.

57.9.11 Programming guidelines for Energy Efficient Ethernet (EEE)

Entering and exiting Tx LPI mode

EEE enables the IEEE 802.3 Media Access Control (MAC) sublayer along with a family of physical layers to operate in the Low-power idle (LPI) mode. In the Transmit path, the software must set the LPIEN bit of the LPI control and status register (ETH_MACLCSR) to indicate to the MAC to stop transmission and initiate the LPI protocol.

Complete the following steps during MAC initialization:

1. Read the PHY register through the MDIO interface and check if the remote end has the EEE capability. Then negotiate the timer values.

2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode or not).

3. Program bits 25 to 16 and bits 15 to 0 in LPI timers control register (ETH_MACLTCR).

4. Read the PHY link status by using the MDIO interface and update bit 17 of LPI control and status register (ETH_MACLCSR).

Update LPI control and status register (ETH_MACLCSR) accordingly. This update should be done whenever the link status in the PHY chip changes.

5. Program One-microsecond-tick counter register (ETH_MAC1USTCR) as per the frequency of the clock used for accessing the CSR slave port.

6. Program the LPIET bit in the LPI entry timer register (ETH_MACLETR) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
7. Set LPITE and LPITXA (bits 20 to 19) of LPI control and status register (ETH_MACLCSR) to enable LPI auto-entry and MAC auto-exit from LPI state.

8. Set bit 16 of LPI control and status register (ETH_MACLCSR) to put the MAC transmitter in LPI state.
   The MAC enters the LPI state when all scheduled packets are completed. It remains IDLE for the time indicated by LPIET bits. It sets the TLPIEN (bit 0) after entering LPI state.

9. When a packet transmission is scheduled (when the TxDMA exits IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter automatically exits LPI state. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.

10. The MAC Transmitter enters again LPI state if it remains IDLE for LPIET time. It then sets the TLPIEN bit and the entry-exit cycle continues.

11. Reset LPNIE bit if the application needs to override the auto-entry/exit modes and directly exit the MAC Transmitter from LPI state.

**Note:** To make sure the MAC enters the LPI state only after the transmission of all the queued frames in the Tx FIFO is complete, set LPITXA bit in LPI control and status register (ETH_MACLCSR).

To switch off the CSR clock or power to the rest of the system during the LPI state, wait for the TLPIEN interrupt of LPI control and status register (ETH_MACLCSR) to be generated. Restore the clocks before performing step 6 when you want to come out of the LPI state.

### Gating Off the CSR Clock in the LPI mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode.

#### Gating off the CSR clock in the Rx LPI mode

The following operations are performed when the MAC receives the LPI pattern from the PHY:

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status (RLPIEN interrupt of LPI control and status register (ETH_MACLCSR)) is set.
2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the LPI control and status register (ETH_MACLCSR).

After the sbd_intr_o interrupt is asserted and the MAC Tx is also in the LPI mode, the CSR clock can be gated off. If the MAC TX is not in LPI mode when the CSR clock is gated off, the events on the MAC transmitter do not get reported or updated in the CSR. To restore the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when LPI control and status register (ETH_MACLCSR) is read.

#### Gating off the CSR clock in the Tx LPI mode

The following operations are performed when bit 16 (LPIEN) of LPI control and status register (ETH_MACLCSR) is set:

1. The Transmit LPI Entry interrupt (TLPIEN bit of LPI control and status register (ETH_MACLCSR)) is set.
2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the LPI control and status register (ETH_MACLCSR).
After the sbd_intr_o interrupt is asserted and the MAC RX is also in the LPI mode, the CSR
clock can be gated off. If the MAC RX is not in LPI mode when the CSR clock is gated off,
the events on the MAC receiver do not get reported or updated in the CSR. To restore the
CSR clock, switch on the CSR clock when the MAC has exited TX LPI mode. After the CSR
clock is resumed, reset bit 16 (LPIEN) of LPI control and status register (ETH_MACLCSR)
to exit the MAC from LPI mode.

57.9.12 Programming guidelines for flexible pulse-per-second (PPS) output

Generating a single pulse on PPS

To generate a single pulse on PPS:
1. Program TRGTMODSEL[1:0] bit to 11 or 10 (for interrupt) in PPS control register
(ETH_MACPPSCR). This instructs the MAC to use the Target Time registers (PPS
target time seconds register (ETH_MACPPTTSR) and PPS target time nanoseconds
register (ETH_MACPPTTNR)) as start time of PPS signal output.
2. Program the start time value in the Target Time registers (register PPS target time
seconds register (ETH_MACPPTTSR) and PPS target time nanoseconds register
(ETH_MACPPTTNR)).
3. Program the width of the PPS signal output in PPS width register (ETH_MACPPSWR)
Register.
4. Program PPSCMD[3:0] of PPS control register (ETH_MACPPSCR) to 0001. This
instructs the MAC to generate a single pulse on the PPS signal output at the time
programmed in the Target Time registers.

Generating next pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by
giving the Cancel Start Command (PPSCMD=0011) before the programmed start time has
elapsed. You can also program the behavior of the next pulse in advance. To program the
next pulse:
1. Program the start time for the next pulse in the Target Time registers. This time should
be higher than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in PPS width register
(ETH_MACPPSWR).
3. Program PPSCMD[3:0] bits of PPS control register (ETH_MACPPSCR) to generate a
single pulse after the previous pulse is deasserted. This instructs the MAC to generate
a single pulse on the PPS signal output at the time programmed in Target Time
registers.

If this command is given before the previous pulse becomes low, then the new
command overwrites the previous command and the peripheral may generate only 1
extended pulse.

Generating a pulse train on PPS

To generate a pulse train on PPS:
1. Program TRGTMODSEL[1:0] bits to 11 or 10 (for interrupt) in PPS control register
(ETH_MACPPSCR). This instructs the MAC to use the Target Time registers (PPS
2. Program the start time value in the Target Time registers (register PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)).

3. Program the interval value between the train of pulses on the PPS signal output in PPS interval register (ETH_MACPPSIR).

4. Program the stop value in the Target Time registers. Ensure that TSTRBUSY bit in PPS target time nanoseconds register (ETH_MACPPSTTNR) is reset before programming the Target Time registers again.

5. Program PPSCMD[3:0] bits in PPS control register (ETH_MACPPSCR) to 0010. This instructs the MAC to generate a train of pulses on the PPS signal output at the start time programmed in Target Time registers.

6. Program the stop value in the Target Time registers. Ensure that TSTRBUSY bit in PPS target time nanoseconds register (ETH_MACPPSTTNR) is reset before programming the Target Time registers again.

7. Program the PPSCMD[3:0] bits in PPS control register (ETH_MACPPSCR) to 0100 to stop the train of pulses on PPS signal output after the programmed stop time specified at step 6 has elapsed.

The pulse train can be stopped at any time by programming 0101 in the PPSCMD[3:0] field. Similarly, the Stop Pulse train command (given in Step 7) can be canceled by programming PPSCMD[3:0] bits to 0110 before the time (programmed at step 6) has elapsed. The pulse train generation can be stopped by programming PPSCMD[3:0] to 0011 before the start time programmed at step 2) has elapsed.

**Generating an interrupt without affecting the PPS**

TRGTMODSEL[1:0] bits in PPS control register (ETH_MACPPSCR) enable you to program the Target Time registers (PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)) to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

To program the Target Time registers to generate only interrupt event:

1. Program TRGTMODSEL[1:0] bits of PPS control register (ETH_MACPPSCR) to 00 (for interrupt). This instructs the MAC to use the Target Time registers for target time interrupt.

2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.

If TRGTMODSEL[1:0] bits are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

**Note:** The TSTRGTER0 bit in Timestamp status register (ETH_MACTSSR) is set when the programmed target time is smaller (that is corresponds to a time in the past) compared to
the system time in the System time seconds register (ETH_MACSTSR) and System time
nanoseconds register (ETH_MACSTNR).

An interrupt is generated (sbd_intr_o) if the TSIE bit in the Interrupt enable register
(ETH_MACIER) is set.

Therefore, to avoid unwanted interrupt, the correct writing order is as follow:
1. PPS target time nanoseconds register (ETH_MACPPSTTNR).
2. PPS target time seconds register (ETH_MACPPSTTSR).
3. PPS interval register (ETH_MACPPSIR).
4. PPS width register (ETH_MACPPSWR).
5. PPSCTRL[3:0] and PPSEN0 bitfields of PPS control register
   (ETH_MACPPSCR).

57.9.13 Programming guidelines for TSO

The TCP Segmentation Offload (TSO) engine is used to offload the TCP segmentation
functions to the hardware. To program the TSO, set the TSE bit to enable TCP packet
segmentation, and program descriptor fields to enable TSO for the current packet.

Follow the steps below to program TSO:
1. Program TSE bit of the corresponding Channel transmit control register
   (ETH_DMACTXCR) to enable TCP packet segmentation in that DMA.
2. In addition to the normal transfer descriptor setting, the following descriptor fields must
   be programmed to enable TSO for the current packet:
   a) Enable TSE of TDES3 (bit 18).
   b) Program the length of the unsegmented TCP/IP packet payload in bits 17 to 0 of
      TDES3, and the TCP header in bits 22 to 19 of TDES3.
   c) Program the maximum size of the segment in:
      – MSS[13:0] of Channel control register (ETH_DMACCR)
      – or MSS in the context descriptor
         If MSS[13:0] field is programmed in both Channel control register
         (ETH_DMACCR) and in the context descriptor, the latest software programmed
         sequence is considered.
3. The unsegmented TCP/IP packet header should be stored in Buffer 1 of the first
   descriptor. This buffer must not hold any payload bytes. The payload is allocated to
   Buffer 2 and the buffers of the subsequent descriptors.

Caution: If TSE is enabled in TDES3 for a non-TCP-IP packet, the result is unpredictable.
57.9.14 Programming guidelines to perform VLAN filtering on the receive

Follow the sequence below to perform VLAN filtering on the receiver:

1. Program VLAN tag register (ETH_MACVTR) for the following bit to select the filtering method:
   - ETV: Enable 12-bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   - VTHM: VLAN Tag Hash Table Match Enable.
   - ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should be enabled by setting EDVLP)
   - ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
   - DOVLTC: Ignores VLAN Type for Tag Match
   - VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching

2. Program VL bit in VLAN tag register (ETH_MACVTR) for the 12-bit or 16-bit VLAN tag.

3. If VLAN tag Hash filtering is enabled, program VLAN Hash table register (ETH_MACVHTR):
   - When the ETV bit is reset, the upper 4 bits of the calculated CRC-32 of VLAN tag are inverted and used to index the content of the VLAN Hash table register (ETH_MACVHTR).
   - When ETV bit is set, the upper 4 bits of the calculated CRC-32 of VLAN tag are used to index the content of VLAN Hash table register (ETH_MACVHTR).

For example, when ETV bit is set, a hash value of 0b1000 selects bit 8 of the VLAN Hash table. When ETV bit is reset, a hash value of 0b1000 selects bit 7 of the VLAN Hash table.

57.10 Descriptors

57.10.1 Descriptor overview

In the Ethernet peripheral, the DMA transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory (SRAM). The following two types of descriptors are supported:

- **Normal descriptors**
  The normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.

- **Context descriptors**
  The context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

There is no limit to the number of descriptors that can be used for a single packet.
57.10.2 Descriptor structure

The Ethernet peripheral supports the ring structure for DMA descriptors.

In a ring structure, descriptors are separated by the 32-bit word number programmed in the DSL field of the Channel control register (ETH_DMACCR). The application needs to program the total ring length, that is the total number of descriptors in ring span, in the following registers of a DMA channel:

- Channel Tx descriptor ring length register (ETH_DMACTXRLR)
- Channel Rx descriptor ring length register (ETH_DMACRXRLR)

The Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) or Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR) contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

**Current Descriptor Pointer == Descriptor Tail Pointer;**

The DMA enters the Suspend state when this condition occurs. The application must perform a write operation to the Descriptor tail pointer register and update the tail pointer so that the following condition is met:

**Current Descriptor Pointer < Descriptor Tail Pointer;**
The DMA automatically wraps around the base address when the end of ring is reached, as shown in Figure 821: DMA descriptor ring.

Figure 821. DMA descriptor ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0.

For descriptors owned by the DMA, the OWN bit is set to 1.

At the beginning, if the application has only one descriptor, it sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA then processes the first descriptor and waits for the application to increment the tail pointer.
57.10.3 Transmit descriptor

The Ethernet peripheral DMA requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor features control fields which can be used to manage the MAC operation on per-transmit packet basis. The Transmit normal descriptor has the following two formats: Read format and Write-back format.

Transmit normal descriptor (read format)

*Figure 822* shows the Read format for Transmit normal descriptor. *Table 653* to *Table 656* provide a detailed description of all Transmit normal descriptors (read format).

| 31   | IOC  | **Interrupt on completion:**  
This bit sets the TI bit in the Channel status register (ETH_DMACSR) when the present packet transmission is complete. |
| 30   | TTSE | **Transmit Timestamp Enable**  
This bit enables the IEEE1588 timestamping for Transmit packet referenced by the descriptor. |
| 29:16| B2L  | **Buffer 2 Length**  
The driver sets this field. When set, this field indicates Buffer 2 length. |
| 15:14| VTIR | **VLAN Tag Insertion or Replacement:**  
These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN tag insertion, replacement, or deletion is enabled for the packet. The values of these bits are as follows:  
00: Do not add a VLAN tag.  
01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets.  
10: Insert a VLAN tag with the tag value programmed in the VLAN inclusion register (ETH_MACVIR) or context descriptor.  
11: Replace the VLAN tag in packets with the tag value programmed in the VLAN inclusion register (ETH_MACVIR) or context descriptor. This option should be used only with the VLAN packets. |

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 13:0 | HL or B1L | Header length or buffer 1 length  
For Header length, only bits [9:0] are taken into account. Bits 13 to 0 are applicable only to buffer 1 length.  
If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length (expressed in bytes) from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes.  
If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length. |

| 31   | OWN    | Own bit  
1: the DMA owns the descriptor.  
0: the application owns the descriptor.  
The DMA clears this bit after it completes the transfer of data given in the associated buffer(s). |
| 30   | CTXT   | Context Type  
This bit should be set to 0 for normal descriptor. |
| 29   | FD     | First Descriptor  
When this bit is set, it indicates that the buffer contains the first segment of a packet. |
| 28   | LD     | Last Descriptor  
When this bit is set, it indicates that the buffer contains the last segment of the packet. B1L or B2L field should have a non-zero value. |
Table 656. TDES3 normal descriptor (read format) (continued)

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 27:26 | CPC   | CRC Pad Control  
This field controls the CRC and Pad Insertion for Tx packet. It is valid only when the first descriptor bit (TDES3[29]) is set. The values of bits[27:26] are the following:  
00: CRC and Pad Insertion  
The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packets whose length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes.  
01: CRC Insertion (Disable Pad Insertion)  
The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes.  
10: Disable CRC Insertion  
The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.  
11: CRC Replacement  
The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.  
When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation. |
| 25:23 | SAIC  | SA Insertion Control  
These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must appropriately set the CRC Pad Control bits when SA Insertion Control is enabled for the packet.  
Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement.  
The following list describes the values of Bits[24:23]:  
00: Do not include the source address  
01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses.  
10: Replace the source address. For reliable transmission, the application must provide frames with source addresses.  
11: Reserved  
These bits are valid when the First Segment control bit (TDES3 [29]) is set. |
| 22:19 | THL   | THL: TCP Header Length  
If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. THL value must be equal to 2 for UDP header. This field is valid only for the first descriptor. |
| 18    | TSE   | TCP Segmentation Enable  
When this bit is set, the DMA performs the TCP/UDP segmentation for a packet. This bit is valid only if the FD bit is set. |
Transmit normal descriptor (write-back format)

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet. 

Figure 823 shows the write-back format for Transmit normal descriptors. Table 657 to Table 660 provide a detailed description of all Transmit Normal descriptors (Write-Back Format).

1. This format is only applicable to the last descriptor of a packet.
## Error Summary

This bit indicates the logical OR of the following bits:
- TDES3[0]: IP Header Error
- TDES3[14]: Jabber Timeout
- TDES3[13]: Packet Flush
- TDES3[12]: Payload Checksum Error
- TDES3[11]: Loss of Carrier
- TDES3[10]: No Carrier
- TDES3[9]: Late Collision
- TDES3[8]: Excessive Collision
- TDES3[3]: Excessive Deferral
- TDES3[2]: Underflow Error

## Jabber Timeout

This bit indicates that the MAC transmitter has experienced a jabber timeout. This bit is set only when the JD bit of the Operating mode configuration register (ETH_MACCR) is not set.

## Packet Flushed

This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.

## Payload Checksum Error

This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either caused by insufficient bytes, as indicated by the Payload Length field of the IP Header, or by the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when a Bus error is detected during packet transfer.

## Loss of Carrier

This bit indicates that Loss of Carrier occurred during packet transmission (that is, the ETH_CRS signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the Half-duplex mode.

## No Carrier

This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.

## Late Collision

This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode). This bit is not valid if Underflow Error is set.
Table 660. TDES3 normal descriptor (write-back format)(1) (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 8   | EC       | Excessive Collision  
This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the Operating mode configuration register (ETH_MACCR), this bit is set after first collision and the transmission of the packet is aborted. |
| 7:4 | CC       | Collision Count  
This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set. |
| 3   | ED       | Excessive Deferral  
This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times if DC bit is set in the Operating mode configuration register (ETH_MACCR). |
| 2   | UF       | Underflow Error  
This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions:  
The DMA encountered an empty Transmit Buffer while transmitting the packet  
The application filled the MTL Tx FIFO slower than the MAC transmit rate  
The transmission process enters the Suspend state and sets the underflow bit corresponding to a queue in the ETH_MTLISR register. |
| 1   | DB       | Deferred Bit  
This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the Half-duplex mode. |
| 0   | IHE      | IP Header Error  
When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. |

1. This format is only applicable to the last descriptor of a packet.

Transmit context descriptor

The Transmit context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction, and VLAN Tag ID for VLAN insertion feature. Write-back is only done on a context descriptor to reset the OWN bit.

Note: The VLAN tag IDs and MSS values, which are provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA. When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag.
stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

Figure 824 shows the format for Transmit context descriptors. Table 661 to Table 664 provide a detailed description of all Transmit context descriptors.

Figure 824. Transmit context descriptor format

- TDES0 context descriptor (read format)

Table 661. TDES0 context descriptor

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:0</td>
<td>TTSL</td>
<td>Transmit Packet Timestamp Low</td>
</tr>
</tbody>
</table>

For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

- TDES1 context descriptor (read format)
• TDES2 context descriptor (read format)

Table 663. TDES2 context descriptor

<table>
<thead>
<tr>
<th>Bit Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:16 IVT</td>
<td>Inner VLAN Tag</td>
</tr>
<tr>
<td>15:14</td>
<td>Reserved</td>
</tr>
<tr>
<td>13:0 MSS</td>
<td>Maximum Segment Size</td>
</tr>
</tbody>
</table>

- When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[31:16] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.
- This segment size is used while segmenting the TCP/IP payload. This field is valid only if the TCMSSV bit of TDES3 context descriptor is set and the OSTC bit of the TDES3 context descriptor is reset.

• TDES3 context descriptor (read format)

Table 664. TDES3 context descriptor

<table>
<thead>
<tr>
<th>Bit Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Context Type</td>
</tr>
<tr>
<td>29:28</td>
<td>Reserved</td>
</tr>
<tr>
<td>27 OSTC</td>
<td>One-Step Timestamp Correction Enable</td>
</tr>
</tbody>
</table>

- Own bit
  1: the DMA owns the descriptor.
  0: the application owns the descriptor.
  The DMA clears this bit immediately after a read operation.
- Context Type
  This bit should be set to 1 for context descriptor.
- Reserved
- When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
One-Step Timestamp Correction Input or MSS Valid
When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid.
When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.

Context Descriptor Error
When this bit is set, it indicates that the context descriptor is incorrect. The DMA sets this bit during write-back while closing the context descriptor.
The Context Descriptor errors can be:
– Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet.
– All 1s.
– CD, LD, and FD bits set to 1.
Note: When a Context Descriptor error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA sets the TI bit in the Channel status register (ETH_DMACSR).
Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
This error is categorized as an abnormal event; recovery is only by issuing a software reset (DMA stopping-reconfiguring-restarting recovery mechanism is not supported)

Inner VLAN Tag Insert or Replace
When these bits are set, they request the MAC to perform Inner VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes.
This bitfield has the following values:
00: Do not add the inner VLAN tag.
01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames.
10: Insert an inner VLAN tag with the tag value programmed in the Inner VLAN inclusion register (ETH_MACIVIR) or context descriptor.
11: Replace the inner VLAN tag in packets with the tag value programmed in the Inner VLAN inclusion register (ETH_MACIVIR) or context descriptor. This option should be used only with the VLAN frames.

Inner VLAN Tag Valid
When this bit is set, it indicates that the IVT field of TDES2 is valid.
<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 16  | VLTV | VLAN Tag Valid  
When this bit is set, it indicates that the VT field of TDES3 is valid. |
| 15:0 | VT | VLAN Tag  
This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the VLAN inclusion register (ETH_MACVIR) is reset. |
57.10.4 Receive descriptor

The DMA in the Ethernet peripheral attempts to read a descriptor only if the Tail pointer is different from the Base pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC; otherwise, the performance of the DMA is greatly impacted because of the unavailability of the descriptors. In such a situation, the MTL RxFIFO becomes full and starts dropping packets.

The following Receive descriptors are present:

- Normal descriptors with read and write-back formats
- Context descriptors

All received descriptors are prepared by the software and given to the DMA as “normal” descriptors (see Figure 825: Receive normal descriptor (read format) for a description of their content). The DMA reads this descriptor and, after transferring a received packet (or part of it) to the buffers indicated by the descriptor, the Rx DMA closes the descriptor with the corresponding packet status. The status format is given in Figure 826: Receive normal descriptor (write-back format).

For some packets, the normal descriptor bits are not sufficient to write the complete status. For such packets, the Rx DMA writes the extended status to the next descriptor (without processing or using the Buffers pointers embedded in that descriptor). The format and content of this write-back descriptor is described in Figure 827: Receive context descriptor.

Receive normal descriptor (read format)

Figure 825 shows the read format for Receive normal descriptors. Table 665 to Table 668 provide a detailed description of all Receive normal descriptors (read format).

![Figure 825. Receive normal descriptor (read format)](image)

Note: In the Receive descriptor (read format), if the Buffer Address field contains only 0s, the MAC does not transfer data to this buffer and skips to the next buffer or next descriptor.

This bit indicates that an IPv6 header is detected. |
| 4   | IPV4  | IPv4 Header Present  
This bit indicates that an IPv4 header is detected. |
| 3   | IPHE  | IP Header Error  
– When this bit is set, it indicates either of the following:  
  – The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes.  
  – The IP datagram version is not consistent with the Ethernet Type value.  
  – Ethernet packet does not have the expected number of IP header bytes.  
This bit is valid when either bit 5 or bit 4 is set. |
| 2:0 | PT    | Payload Type  
These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE):  
  000: Unknown type or IP/AV payload not processed  
  001: UDP  
  010: TCP  
  011: ICMP  
  100: IGMP if IPV4 Header Present bit is set  
Others: reserved.  
If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000. |

1. The Status fields in write-back format are valid only for the last descriptor (RDES3[28] is set).

- **RDES2 normal descriptor (write-back format)**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31:29 | L3L4FM | **Layer 3 and Layer 4 Filter Number Match**  
These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet:  
– 000: Filter 0  
– 001: Filter 1  
– 010: Filter 2  
– 011: Filter 3  
– 100: Filter 4  
– 101: Filter 5  
– 110: Filter 6  
– 111: Filter 7  
This field is valid only when bit 28 or bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. |
| 28    | L4FM   | **Layer 4 Filter Match**  
When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true:  
– Layer 3 fields are not enabled and all enabled Layer 4 fields match  
– All enabled Layer 3 and Layer 4 filter fields match  
When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by bits[31:29]. |
| 27    | L3FM   | **Layer 3 Filter Match**  
When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true:  
– All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed  
– All enabled filter fields match  
When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by bits[31:29]. |
| 26:19 | MADRM  | **MAC Address Match or Hash Value**  
When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset.  
When the HF bit is set, this field contains the Hash value computed by the MAC. A packet passes the Hash filter when the bit corresponding to the Hash value is set in the Hash filter register. |
| 18    | HF     | **Hash Filter Status**  
When this bit is set, it indicates that the packet passed the MAC address Hash filter. Its[26:19] indicate the Hash value. |
| 17    | DAF    | **Destination Address Filter Fail**  
When this bit is set, it indicates that the packet failed the DA Filter in the MAC. |
| 16    | SAF    | **SA Address Filter Fail**  
When this bit is set, it indicates that the packet failed the SA Filter in the MAC. |
Table 671. RDES2 normal descriptor (write-back format) (continued)

<table>

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 19  | DE   | Dribble Bit Error  
When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode. |
| 18:16 | LT | Length/Type Field  
This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows:  
000: The packet is a length packet  
001: The packet is a type packet.  
011: The packet is a ARP Request packet type  
100: The packet is a type packet with VLAN Tag  
101: The packet is a type packet with Double VLAN Tag  
110: The packet is a MAC Control packet type  
111: The packet is a OAM packet type  
010: Reserved |
| 15  | ES   | Error Summary  
When this bit is set, it indicates the logical OR of the following bits:  
RDES3[19]: Dribble Error  
RDES3[20]: Receive Error  
RDES3[21]: Overflow Error  
RDES3[22]: Watchdog Timeout  
RDES3[23]: Giant Packet  
RDES3[24]: CRC Error  
This field is valid only when the LD bit of RDES3 is set. |
| 14:0 | PL  | Packet Length  
These bits indicate the byte length of the received packet that was transferred to system memory (including CRC).  
This field is valid when both the LD bit of RDES3 is set and the Overflow Error bit is reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet.  
When LD bit of RDES3 is reset, this field contains the accumulated number of bytes (partial) that have been transferred for the current packet. |
Receive context descriptor

This descriptor is read-only for the application. This descriptor can be written only by the DMA.

The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor.

*Figure 827* shows the format for Receive context descriptors. *Table 673* to *Table 676* provide a detailed description of all Receive context descriptors.

*Figure 827. Receive context descriptor*

57.11 Ethernet registers

57.11.1 Ethernet register maps

This section provides the following register maps:

- DMA registers (see Section 57.11.2: Ethernet DMA registers)
- MTL registers (see Section 57.11.3: Ethernet MTL registers)
- MAC registers including MMC register (see Section 57.11.4: Ethernet MAC and MMC registers)

57.11.2 Ethernet DMA registers

DMA mode register (ETH_DMAMR)

Address offset: 0x1000
Reset value: 0x0000 0000

The DMA mode register establishes the bus operating modes for the DMA.

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 INTM[1:0]: Interrupt Mode

This field defines the interrupt mode of the Ethernet peripheral.
The behavior of the interrupt signal and of the RI/TI bits in the ETH_DMACSR register changes depending on the INTM value (refer to Table 652: Transfer complete interrupt behavior).

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 PR[2:0]: Priority ratio

These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set.

- 000: The priority ratio is 1:1
- 001: The priority ratio is 2:1
- 010: The priority ratio is 3:1
- 011: The priority ratio is 4:1
- 100: The priority ratio is 5:1
- 101: The priority ratio is 6:1
- 110: The priority ratio is 7:1
- 111: The priority ratio is 8:1

Bit 11 TXPR: Transmit priority

When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus.
Bits 10:2  Reserved, must be kept at reset value.

Bit 1  **DA**: DMA Tx or Rx Arbitration Scheme

This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels:

0: Weighted Round-Robin with Rx:Tx or Tx:Rx

The priority between the paths is according to the priority specified in Bits[14:12] and the priority weight is specified in the TXPR bit.

1: Fixed priority

The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path.

Bit 0  **SWR**: Software Reset

When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all clock domains. Before reprogramming any register, a value of zero should be read in this bit.

**Note:** The reset operation is complete only when all resets in all active clock domains are deasserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock.
System bus mode register (ETH_DMASBMR)

Address offset: 0x1004
Reset value: 0x0000 0000

The System bus mode register controls the behavior of the AHB master. It mainly controls burst splitting and number of outstanding requests.

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **RB**: Rebuild INCRx Burst
When this bit is set high and the AHB master gets SPLIT, RETRY, or Early Burst Termination (EBT) response, the AHB master interface rebuilds the pending beats of any initiated burst transfer with INCRx and SINGLE transfers. By default, the AHB master interface rebuilds pending beats of an EBT with an unspecified (INCR) burst.

Bit 14 **MB**: Mixed Burst
When this bit is set high and the FB bit is low, the AHB master performs undefined bursts transfers (INCR) for burst length of 16 or more. For burst length of 16 or less, the AHB master performs fixed burst transfers (INCRx and SINGLE).

Bit 13 Reserved, must be kept at reset value.

Bit 12 **AAL**: Address-Aligned Beats
When this bit is set to 1, the master performs address-aligned burst transfers on Read and Write channels.

Bits 11:1 Reserved, must be kept at reset value.

Bit 0 **FB**: Fixed Burst Length
When this bit is set to 1, the AHB master will initiate burst transfers of specified length (INCRx or SINGLE).
When this bit is set to 0, the AHB master will initiate transfers of unspecified length (INCR) or SINGLE transfers.
**Interrupt status register (ETH_DMAISR)**

Address offset: 0x1008  
Reset value: 0x0000 0000  
The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

Bits 31:18 Reserved, must be kept at reset value.

- **Bit 17 MACIS**: MAC Interrupt Status  
  This bit indicates an interrupt event in the MAC. To reset this bit to 1'b0, the software must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source.

- **Bit 16 MTLIS**: MTL Interrupt Status  
  This bit indicates an interrupt event in the MTL. To reset this bit to 1'b0, the software must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source.

Bits 15:1 Reserved, must be kept at reset value.

- **Bit 0 DC0IS**: DMA Channel Interrupt Status  
  This bit indicates an interrupt event in DMA Channel. To reset this bit to 0, the software must read the corresponding register in DMA Channel to get the exact cause of the interrupt and clear its source.

**Debug status register (ETH_DMADSR)**

Address offset: 0x100C  
Reset value: 0x0000 0000  
The Debug status register gives the Receive and Transmit process status for DMA Channel for debugging purpose.

2810/3119  
RM0481 Rev 1
Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **TPS0[3:0]**: DMA Channel Transmit Process State

This field indicates the Tx DMA FSM state for Channel:

- 000: Stopped (Reset or Stop Transmit Command issued)
- 001: Running (Fetching Tx Transfer Descriptor)
- 010: Running (Waiting for status)
- 011: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO))
- 100: Timestamp write state
- 101: Reserved for future use
- 110: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
- 111: Running (Closing Tx Descriptor)

The MSB of this field always returns 0. This field does not generate an interrupt.

Bits 11:8 **RPS0[3:0]**: DMA Channel Receive Process State

This field indicates the Rx DMA FSM state for Channel:

- 000: Stopped (Reset or Stop Receive Command issued)
- 001: Running (Fetching Rx Transfer Descriptor)
- 010: Reserved for future use
- 011: Running (Waiting for Rx packet)
- 100: Suspended (Rx Descriptor Unavailable)
- 101: Running (Closing the Rx Descriptor)
- 110: Timestamp write state
- 111: Running (Transferring the received packet data from the Rx buffer to the system memory)

The MSB of this field always returns 0. This field does not generate an interrupt.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **AXWHSTS**: AHB Master Write Channel

When high, this bit indicates that the write channel of the AHB master FMSs are in non-idle state.

**Channel control register (ETH_DMACCR)**

Address offset: 0x1100

Reset value: 0x0000 0000

The DMA Channel control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.
Bits 31:21  Reserved, must be kept at reset value.

Bits 20:18  **DSL[2:0]: Descriptor Skip Length**
This bit specifies the 32-bit word number to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor.
When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.

Bit 17   Reserved, must be kept at reset value.

Bit 16  **PBLX8: 8xPBL mode**
When this bit is set, the PBL value programmed in Bits[21:16] in *Channel transmit control register (ETH_DMACTXCR)* is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.

Bits 15:14   Reserved, must be kept at reset value.

Bits 13:0  **MSS[13:0]: Maximum Segment Size**
This field specifies the maximum segment size that should be used while segmenting the packet. This field is valid only if the TSE bit of *Channel transmit control register (ETH_DMACTXCR)* is set.
The value programmed in this field must be more than the configured Data width in bytes. It is recommended to use a MSS value of 64 bytes or more.

### Channel transmit control register (ETH_DMACTXCR)

Address offset: 0x1104

Reset value: 0x0000 0000

The DMA Channel Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

Bits 31:22  Reserved, must be kept at reset value.

Bits 21:16  **TXPBL[5:0]: Transmit Programmable Burst Length**

These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.

To transfer more than 32 beats, perform the following steps:

a)  Set the PBLx8 mode in ETH_DMACCR.

b)  Set the TXPBL[5:0].

Note: The maximum value of TXPBL must be less than or equal to half the Tx Queue size (TQS field of *Tx queue operating mode Register (ETH_MTLTXQOMR)*) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. The total locations in Tx Queue of size 2048 bytes is 512, TXPBL and 8xPBL needs to be programmed to less than or equal to 512/2.

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **TSE: TCP Segmentation Enabled**

When this bit is set, the DMA performs the TCP segmentation for packets in Channel x. The TCP segmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor. When this bit is set, the TxPBL value must be greater than or equal to 4.

Bits 11:5  Reserved, must be kept at reset value.

Bit 4  **OSF: Operate on Second Packet**

When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **ST: Start or Stop Transmission Command**

When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions:

-  The current position in the list: this is the base address of the Transmit list set by the ETH_DMACTXDLAR register.

-  The position at which the transmission was previously stopped

If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the ETH_DMACSR is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the ETH_DMACTXDLAR register, the DMA behavior is unpredictable.

When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program ETH_DMACTXDLAR register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state.
Channel receive control register (ETH_DMACRXCR)

Address offset: 0x1108
Reset value: 0x0000 0000

The DMA Channel Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Bit 31 **RPF**: DMA Rx Channel Packet Flush
When this bit is set to 1, the Ethernet peripheral automatically flushes the packet from the Rx queues destined to DMA Rx Channel when the DMA Rx Channel is stopped after a system bus error has occurred. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, are flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx queue. When this bit is set to 0 the Ethernet peripheral does not flush the packet in the Rx queue destined to DMA Rx Channel after the DMA is stopped due to a system bus error. This might cause head-of-line blocking in the corresponding RxQueue.

*Note*: The stopping of packet flow from a Rx DMA Channel to the application by setting RPF works only when there is one-to-one mapping of Rx Queue to Rx DMA channels. In Dynamic mapping mode, setting RPF bit in ETH_DMACRXCR register might flush packets from unintended Rx Queues which are destined to the stopped Rx DMA Channel.

Bits 30:22 Reserved, must be kept at reset value.

Bits 21:16 **RXPBL[5:0]**: Receive Programmable Burst Length
These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.

To transfer more than 32 beats, perform the following steps:

a) Set the PBLx8 mode in the ETH_DMACCCR.
b) Set the RXPBL[5:0].

*Note*: The maximum value of RXPBL must be less than or equal to half the Rx Queue size (RQS field of Rx queue operating mode register (ETH_MTLRXQOMR)) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the MTL Rx Queues Controller is transferring data to MAC. The total locations in Rx Queue of size 2048 bytes is 512, RXPBL and 8xPBL needs to be programmed to less than or equal to 512/2.
Bit 15  Reserved, must be kept at reset value.

Bits 14:1  **RBSZ[13:0]:** Receive Buffer size

This field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16 Kbytes.

**Note:** The buffer size must be a multiple of 4. This is required even if the value of buffer address pointer is not aligned to bus width. If the buffer size is not a multiple of 4, it may result into an undefined behavior.

The LSB bits (1:0) are ignored and the DMA internally takes the LSB bits as all-zero. Therefore, these LSB bits are read-only (RO).

Bit 0  **SR:** Start or Stop Receive

When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets.

The DMA tries to acquire descriptor from either of the following positions:

- The current position in the list: this is the address set by the Channel Rx descriptor list address register (ETH_DMACRXDLAR).
- The position at which the Rx process was previously stopped

If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the ETH_DMACSR is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the Channel Rx descriptor list address register (ETH_DMACRXDLAR), the DMA behavior is unpredictable.

When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state.
Channel Tx descriptor list address register (ETH_DMACTXDLAR)

Address offset: 0x1114
Reset value: 0x0000 0000

Channel Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in ETH_DMACTXCR register. When stopped, this register can be written with a new descriptor list address. When you set ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

TDESLA[15:0]  
rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw

Bits 31:0  TDESLA[31:0]: Start of Transmit List
This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0) for 32-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).
Channel Rx descriptor list address register (ETH_DMACRXDLAR)

Address offset: 0xF1C
Reset value: 0x0000 0000

The Channel Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in ETH_DMACRXCR register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Bits 31:0 **RDESLA[31:0]**: Start of Receive List
This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0) for 32-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).
Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR)

Address offset: 0x1120
Reset value: 0x0000 0000

The Channel Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 TDRL[9:0]: Transmit Descriptor Ring Length
This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. It is recommended to put a minimum ring descriptor length of 4.

For example, you can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.
Channel Rx descriptor ring length register (ETH_DMACRXRLR)

Address offset: 0x1130
Reset value: 0x0000 0000

The Channel Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Bits 31:24  Reserved, must be kept at reset value.
Bits 23:16  **ARBS[7:0]: Alternate Receive Buffer Size**
Indicates size in bytes for Buffer 1 when ARBS[7:0] is programmed to a non-zero value.
When ARBS[7:0] = 0, Rx Buffer1 and Rx Buffer2 sizes are based on RBSZ[13:0] field of
Channel receive control register (ETH_DMACRXCR).

Bits 15:10  Reserved, must be kept at reset value.
Bits 9:0   **RDRL[9:0]: Receive Descriptor Ring Length**
This register sets the maximum number of Rx descriptors in the circular descriptor ring. The
maximum number of descriptors is limited to 1K descriptors.
For example, you can program any value up to 0x3FF in this field. This field is 10-bit wide. If
you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors,
program it to a value of 0x9.

Channel interrupt enable register (ETH_DMACIER)

Address offset: 0x1134
Reset value: 0x0000 0000

The Channel Interrupt Enable register enables the interrupts reported by the Status register.

```
|    |    |    | NIE| AIE| CDEE| FBEE| ERIE| ETIE| RWTE| RSTE| R8UE| RIEE| RSE| Res| Res| TBUET| TXS| TIE |

```
Bits 31:16  Reserved, must be kept at reset value.

Bit 15 **NIE**: Normal Interrupt Summary Enable
When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the Channel status register (ETH_DMACSR):
- Bit 0: Transmit Interrupt
- Bit 2: Transmit Buffer Unavailable
- Bit 6: Receive Interrupt
- Bit 11: Early Receive Interrupt
When this bit is reset, the normal interrupt summary is disabled.

Bit 14 **AIE**: Abnormal Interrupt Summary Enable
When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the Channel status register (ETH_DMACSR):
- Bit 1: Transmit Process Stopped
- Bit 7: Rx Buffer Unavailable
- Bit 8: Receive Process Stopped
- Bit 9: Receive Watchdog Timeout
- Bit 10: Early Transmit Interrupt
- Bit 12: Fatal Bus Error
When this bit is reset, the abnormal interrupt summary is disabled.

Bit 13 **CDEE**: Context Descriptor Error Enable
When this bit is set along with the AIE bit, the Context Descriptor error interrupt is enabled. When this bit is reset, the Context Descriptor error interrupt is disabled.

Bit 12 **FBEE**: Fatal Bus Error Enable
When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled.

Bit 11 **ERIE**: Early Receive Interrupt Enable
When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.

Bit 10 **ETIE**: Early Transmit Interrupt Enable
When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled.

Bit 9 **RWTE**: Receive Watchdog Timeout Enable
When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled.

Bit 8 **RSE**: Receive Stopped Enable
When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled.

Bit 7 **RBUE**: Receive Buffer Unavailable Enable
When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled.

Bit 6 **RIE**: Receive Interrupt Enable
When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled.

Bits 5:3  Reserved, must be kept at reset value.
Bit 2  **TBUE**: Transmit Buffer Unavailable Enable
   When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled.

Bit 1  **TXSE**: Transmit Stopped Enable
   When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled.
   When this bit is reset, the Transmission Stopped interrupt is disabled.

Bit 0  **TIE**: Transmit Interrupt Enable
   When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled.

MSv40824V2
Channel Rx interrupt watchdog timer register (ETH_DMACRXIWTR)

Address offset: 0x1138
Reset value: 0x0000 0000

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the Channel status register (ETH_DMACSR).

### Register Layout

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
<th>Range</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
</tr>
<tr>
<td>15:8</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>7:0</td>
<td>RWT[7:0]: Receive Interrupt Watchdog Timer Count</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the ETH_DMACSR, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30].

When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.
Channel current application transmit descriptor register  
(ETH_DMACCATXDR)

Address offset: 0x1144
Reset value: 0x0000 0000

The Channel Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Bits 31:0 **CURTDESAPTR[31:0]**: Application Transmit Descriptor Address Pointer
The DMA updates this pointer during Tx operation. This pointer is cleared on reset.

Channel current application receive descriptor register  
(ETH_DMACCARXDR)

Address offset: 0x114C
Reset value: 0x0000 0000

The Channel Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Bits 31:0 **CURRDESAPTR[31:0]**: Application Receive Descriptor Address Pointer
The DMA updates this pointer during Rx operation. This pointer is cleared on reset.
Channel current application transmit buffer register (ETH_DMACATXBR)

Address offset: 0x1154
Reset value: 0x0000 0000

The Channel Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

| Bits 31:0 CURTBUFAPTR[31:0]: Application Transmit Buffer Address Pointer |
| The DMA updates this pointer during Tx operation. This pointer is cleared on reset. |

Channel current application receive buffer register (ETH_DMACARXBR)

Address offset: 0x115C
Reset value: 0x0000 0000

The Channel Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

| Bits 31:0 CURRBUFFAPTR[31:0]: Application Receive Buffer Address Pointer |
| The DMA updates this pointer during Rx operation. This pointer is cleared on reset. |

Channel status register (ETH_DMACSR)

Address offset: 0x1160
Reset value: 0x0000 0000

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA.
Bits 31:22  Reserved, must be kept at reset value.

Bits 21:19  **REB[2:0]: Rx DMA Error Bits**
This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface.
- Bit [2]: Error during data transfer by Rx DMA when 1, no Error during data transfer by Rx DMA when 0.
- Bit[1]: Error during descriptor access when 1, Error during data buffer access when 0
- Bit[0]: Error during read transfer when 1, Error during write transfer when 0
This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Bits 18:16  **TEB[2:0]: Tx DMA Error Bits**
This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface.
- Bit[2]: Error during data transfer by Tx DMA when 1, no Error during data transfer by Tx DMA when 0
- Bit[1]: Error during descriptor access when 1, Error during data buffer access when 0
- Bit[0]: Error during read transfer when 1, Error during write transfer when 0
This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Bit 15  **NIS: Normal Interrupt Summary**
Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the ETH_DMACIER register:
- Bit 0: Transmit Interrupt
- Bit 2: Transmit Buffer Unavailable
- Bit 6: Receive Interrupt
- Bit 11: Early Receive Interrupt
Only unmasked bits (interrufts for which interrupt enable is set in ETH_DMACIER register) affect the Normal Interrupt Summary bit.
This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared.

Bit 14  **AIS: Abnormal Interrupt Summary**
Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the ETH_DMACIER register:
- Bit 1: Transmit Process Stopped
- Bit 7: Receive Buffer Unavailable
- Bit 8: Receive Process Stopped
- Bit 10: Early Transmit Interrupt
- Bit 12: Fatal Bus Error
- Bit 13: Context Descriptor Error
Only unmasked bits affect the Abnormal Interrupt Summary bit.
This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared.

Bit 13  **CDE: Context Descriptor Error**
This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one’s descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid.

Bit 12  **FBE: Fatal Bus Error**
This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses.

Channel missed frame count register (ETH_DMACMFCR)

Address offset: 0x116C
Reset value: 0x0000 0000

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programing RPF field in Channel receive control register (ETH_DMACRXCR) register.

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  MFCO: Overflow status of the MFC Counter
When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read.

Bits 14:11  Reserved, must be kept at reset value.

Bits 10:0  MFC[10:0]: Dropped Packet Counters
This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in Channel receive control register (ETH_DMACRXCR). The counter gets cleared when this register is read.

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **CNTCLR**: Counters Reset
When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. If this bit is set along with CNTPRST bit, CNTPRST has precedence.

Bit 8 **CNTPRST**: Counters Preset
When this bit is set:
- Tx queue underflow register (ETH_MTLTXQUR) is initialized/preset to 0x7F0.
- Missed Packet and Overflow Packet counters in Rx queue missed packet and overflow counter register (ETH_MTLRXQMPOCR) is initialized/preset to 0x7F0

This bit is cleared automatically.

Bit 7 Reserved, must be kept at reset value.

Bits 6:2 Reserved, must be kept at reset value.

Bit 1 **DTXSTS**: Drop Transmit Status
When this bit is set, the Tx packet status received from the MAC is dropped in the MTL. When this bit is reset, the Tx packet status received from the MAC is forwarded to the application.

Bit 0 Reserved, must be kept at reset value.
Interrupt status Register (ETH_MTLISR)

Address offset: 0x0C20

Reset value: 0x0000 0000

The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC.

<table>
<thead>
<tr>

</thead>
</table>

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **Q0IS**: Queue interrupt status

This bit indicates that an interrupt has been generated by Queue. To reset this bit, read ETH_MTLQICSR register to identify the interrupt cause and clear the source.

Tx queue operating mode Register (ETH_MTLTXQOMR)

Address offset: 0x0D00

Reset value: 0x0007 0008

The Queue Transmit Operating Mode register establishes the Transmit queue operating modes and commands.

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>

<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **TQS[2:0]**: Transmit queue size

This field indicates the size of the allocated transmit queues in blocks of 256 bytes.

Queue size range from 256 bytes (TQS=0b000) to 2048 bytes (TQS=0b111).

Bits 15:7 Reserved, must be kept at reset value.
Bits 6:4 **TTC[2:0]**: Transmit Threshold Control
These bits control the threshold level of the MTL Tx queue. The transmission starts when the packet size within the MTL Tx queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset.

- 000: 32
- 001: 64
- 010: 96
- 011: 128
- 100: 192
- 101: 256
- 110: 384
- 111: 512

Bits 3:2 **TXQEN[1:0]**: Transmit Queue Enable
This field is used to enable/disable the transmit queue.

- 00: Not enabled
- 10: Enabled

Others: Reserved, must not be used.

**Note**: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field.

Bit 1 **TSF**: Transmit Store and Forward
When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped.

Bit 0 **FTQ**: Flush Transmit Queue
When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the ETH_MTLTXQOMR register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission.

**Note**: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (eth_mii_tx_clk) should be active.

**Tx queue underflow register (ETH_MTLTXQUR)**
Address offset: 0x0D04
Reset value: 0x0000 0000

The Queue Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.
**Tx queue debug register (ETH_MTLTXQDR)**

Address offset: 0x0D08  
Reset value: 0x0000 0000

The Queue Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

<table>
<thead>
<tr>
<th>Bits 31:23</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bits 22:20 | **STXSTSF[2:0]: Number of Status Words in Tx Status FIFO of Queue**  
This field indicates the current number of status in the Tx Status FIFO of this queue.  
When the DTXSTS bit of ETH_MTLOMR register is set to 1, this field does not reflect the number of status words in Tx Status FIFO. |
| Bit 19     | Reserved, must be kept at reset value. |
| Bits 18:16 | **PTXQ[2:0]: Number of Packets in the Transmit Queue**  
This field indicates the current number of packets in the Tx queue.  
When the DTXSTS bit of **Operating mode Register (ETH_MTLOMR)** register is set to 1, this field does not reflect the number of packets in the Transmit queue. |
| Bits 15:6  | Reserved, must be kept at reset value. |
| Bit 5      | **TXSTSFSTS**: MTL Tx Status FIFO Full Status  
When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. |
| Bit 4      | **TXQSTS**: MTL Tx Queue Not Empty Status  
When this bit is high, it indicates that the MTL Tx queue is not empty and some data is left for transmission. |
Bit 3 **TWCSTS**: MTL Tx Queue Write Controller Status
When high, this bit indicates that the MTL Tx queue Write Controller is active, and it is transferring the data to the Tx queue.

Bits 2:1 **TRCSTS[1:0]**: MTL Tx Queue Read Controller Status
This field indicates the state of the Tx Queue Read Controller:
00: Idle state
01: Read state (transferring data to the MAC transmitter)
10: Waiting for pending Tx Status from the MAC transmitter
11: Flushing the Tx queue because of the Packet Abort request from the MAC

Bit 0 **TXQPAUSED**: Transmit Queue in Pause
When this bit is high and the Rx flow control is enabled, it indicates that the Tx queue is in the Pause condition (in the Full-duplex only mode) because of the following:
- Reception of the PFC packet for the priorities assigned to the Tx queue when PFC is enabled
- Reception of 802.3x Pause packet when PFC is disabled

**Queue interrupt control status Register (ETH_MTLQICSR)**

Address offset: 0x0D2C
Reset value: 0x0000 0000

This register contains the interrupt enable and status bits for the queue interrupts.

</table>

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **RXOIE**: Receive Queue Overflow Interrupt Enable
When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **RXOVFS**: Receive Queue Overflow Interrupt Status
This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit.

Bits 15:9 Reserved, must be kept at reset value.
Bit 8 **TXUIE**: Transmit Queue Underflow Interrupt Enable
When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **TXUNFIS**: Transmit Queue Underflow Interrupt Status
This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit.
Rx queue operating mode register (ETH_MTLRXQOMR)

Address offset: 0x0D30
Reset value: 0x0070 0000

The Queue Receive operating Mode register establishes the Receive queue operating modes and command.

<table>

</tr>
</tbody>
</table>

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:20 **RQS[2:0]**: Receive Queue Size

This field is read-only and the configured Rx FIFO size in blocks of 256 bytes is reflected in the reset value. The size of the Queue is (RQS + 1) * 256 bytes.

Bits 19:7 Reserved, must be kept at reset value.

Bit 6 **DIS_TCP_EF**: Disable Dropping of TCP/IP Checksum Error Packets

When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC.

When this bit is reset, all error packets are dropped if the FEP bit is reset.

Bit 5 **RSF**: Receive Queue Store and Forward

When this bit is set, the Ethernet peripheral reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.

Bit 4 **FEP**: Forward Error Packets

When this bit is reset, the Rx queue drops packets with error status (CRC error, receive error, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped.

When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
Bit 3 **FUP**: Forward Undersized Good Packets
When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **RTC[1:0]**: Receive Queue Threshold Control
These bits control the threshold level of the MTL Rx queue (in bytes):

- 00: 64
- 01: 32
- 10: 96
- 11: 128

The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred.

This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
Rx queue missed packet and overflow counter register
(ETH_MTLRXQMPOCR)

Address offset: 0x0D34
Reset value: 0x0000 0000

The Queue missed packet and overflow counter registers contain the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **MISCNTOVF**: Missed Packet Counter Overflow Bit
When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit.

Bits 26:16 **MISPKTCNT[10:0]**: Missed Packet Counter
This field indicates the number of packets missed by the Ethernet peripheral because the application requested to flush the packets for this queue. This counter is reset when this register is read.
This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability.

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **OVFCNTOVF**: Overflow Counter Overflow Bit
When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit.

Bits 10:0 **OVFPKTCNT[10:0]**: Overflow Packet Counter
This field indicates the number of packets discarded by the Ethernet peripheral because of Receive queue overflow. This counter is incremented each time the Ethernet peripheral discards an incoming packet because of overflow. This counter is reset when this register is read.
Rx queue debug register (ETH_MTLRXQDR)

Address offset: 0x0D38
Reset value: 0x0000 0000

The Queue Receive Debug register gives the debug status of various blocks related to the Receive queue.

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:16  **PRXQ[13:0]: Number of Packets in Receive Queue**
This field indicates the current number of packets in the Rx queue. The theoretical maximum value for this field is 256Kbyte/16bytes = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.

Bits 15:6  Reserved, must be kept at reset value.

Bits 5:4  **RXQSTS[1:0]: MTL Rx Queue Fill-Level Status**
This field gives the status of the fill-level of the Rx queue:
00: Rx queue empty
01: Rx queue fill-level below flow-control deactivate threshold
10: Rx queue fill-level above flow-control activate threshold
11: Rx queue full

Bit 3  Reserved, must be kept at reset value.

Bits 2:1  **RRCSTS[1:0]: MTL Rx Queue Read Controller State**
This field gives the state of the Rx queue Read controller:
00: Idle state
01: Reading packet data
10: Reading packet status (or timestamp)
11: Flushing the packet data and status

Bit 0  **RWCSTS: MTL Rx Queue Write Controller Active Status**
When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx queue.

**Bit 31 ARPEN:** ARP Offload Enable

When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus.

When this bit is reset, the MAC receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus.

**Bits 30:28 SARC[2:0]:** Source Address Insertion or Replacement Control

This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]:

- 010: the MAC inserts the content of the MAC Address 0 registers (`MAC Address 0 high register (ETH_MACA0HR)` and `MAC Address x low register (ETH_MACAxLR)`) in the SA field of all transmitted packets.
- 011: the MAC replaces the content of the MAC Address 0 registers (`MAC Address 0 high register (ETH_MACA0HR)` and `MAC Address x low register (ETH_MACAxLR)`) in the SA field of all transmitted packets.
- 110: the MAC inserts the content of the MAC Address 1 registers (`MAC Address x high register (ETH_MACAxHR)` and `MAC Address x low register (ETH_MACAxLR)`) in the SA field of all transmitted packets.
- 111: the MAC replaces the content of the MAC Address 1 registers (`MAC Address x high register (ETH_MACAxHR)` and `MAC Address x low register (ETH_MACAxLR)`) in the SA field of all transmitted packets.
- Others: Reserved, must not be used.

**Note:** Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
Bit 27  **IPC**: Checksum Offload

When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled.

The Layer 3 and Layer 4 Packet Filter feature automatically selects the IPC Full Checksum Offload Engine on the Receive side. When this feature is enabled, you must set the IPC bit.

Bits 26:24  **IPG[2:0]**: Inter-Packet Gap

These bits control the minimum IPG between packets during transmission.

- 000: 96 bit times
- 001: 88 bit times
- 010: 80 bit times
- ...
- 111: 40 bit times

This range of minimum IPG is valid in Full-duplex mode. In the Half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered.

When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG.

The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in ETH_MACECR register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in ETH_MACECR register.

Bit 23  **GPSLCE**: Giant Packet Size Limit Control Enable

When this bit is set, the MAC considers the value in GPSL field in ETH_MACECR register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit.

When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet).

The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status.

Bit 22  **S2KP**: IEEE 802.3as Support for 2K Packets

When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets.

When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see Table 680: Giant Packet Status based on S2KP and JE Bits.

**Note**: When the JE bit is set, setting this bit has no effect on the giant packet status.

Bit 21  **CST**: CRC stripping for Type packets

When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver.

This function is valid when Type 2 Checksum Offload Engine is enabled.

**Note**: For information about how the settings of the ACS bit and this bit impact the packet length, see Table 681: Packet Length based on the CST and ACS bits.
Bit 20  **ACS**: Automatic Pad or CRC Stripping
When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field.
When this bit is reset, the MAC passes all incoming packets to the application, without any modification.

*Note:* For information about how the settings of CST bit and this bit impact the packet length, see Table 681: Packet Length based on the CST and ACS bits.

Bit 19  **WD**: Watchdog Disable
When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes.
When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes.

Bit 18  Reserved, must be kept at reset value.

Bit 17  **JD**: Jabber Disable
When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes.
When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet.

Bit 16  **JE**: Jumbo Packet Enable
When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.
For more information about how the setting of this bit and the JE bit impact the Giant packet status, see Table 680: Giant Packet Status based on S2KP and JE Bits.

Bit 15  Reserved, must be kept at reset value.

Bit 14  **FES**: MAC Speed
This bit selects the speed in the 10/100 Mbps mode:
0: 10 Mbps
1: 100 Mbps

Bit 13  **DM**: Duplex Mode
When this bit is set, the MAC operates in the Full-duplex mode in which it can transmit and receive simultaneously.

Bit 12  **LM**: Loopback Mode
When this bit is set, the MAC operates in the loopback mode at MII. The MII Rx clock input (eth_mii_rx_clk) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.

Bit 11  **ECRSFD**: Enable Carrier Sense Before Transmission in Full-duplex mode
When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the Full-duplex mode. The MAC starts the transmission only when the CRS signal is low.
When this bit is reset, the MAC transmitter ignores the status of the CRS signal.

Bit 10  **DO**: Disable Receive Own
When this bit is set, the MAC disables the reception of packets when the ETH_TX_EN is asserted in the Half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY.
This bit is not applicable in the Full-duplex mode. This bit is reserved and read-only (RO) with default value in the Full-duplex-only configurations.
Bit 9 **DCRS**: Disable Carrier Sense During Transmission
When this bit is set, the MAC transmitter ignores the MII CRS signal during packet transmission in the Half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission.
When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission.

Bit 8 **DR**: Disable Retry
When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status.
When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the Half-duplex mode.

Bit 7 Reserved, must be kept at reset value.

Bits 6:5 **BL[1:0]**: Back-Off Limit
The back-off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision:
- **00**: \( k = \min (n, 10) \)
- **01**: \( k = \min (n, 8) \)
- **10**: \( k = \min (n, 4) \)
- **11**: \( k = \min (n, 1) \)
where \( n \) = retransmission attempt
The random integer \( r \) takes the value in the range \( 0 \leq r < 2^k \).
This bit is applicable only in the Half-duplex mode.

Bit 4 **DC**: Deferral Check
When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode.
Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on MII.
The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted.
When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive.
This bit is applicable only in the Half-duplex mode.

Bits 3:2 **PRELEN[1:0]**: Preamble Length for Transmit packets
These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the Full-duplex mode.
- **00**: 7 bytes of preamble
- **01**: 5 bytes of preamble
- **10**: 3 bytes of preamble
- **11**: Reserved, must not be used
Bit 1 **TE**: Transmitter Enable
When this bit is set, the Tx state machine of the MAC is enabled for transmission on the MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.

Bit 0 **RE**: Receiver Enable
When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the MII interface.

*Table 680* shows how the settings of S2KP and JE bits of the ETH_MACCR register impact the giant packet status.

Bits 31:30: Reserved, must be kept at reset value.

Bits 29:25: **EIPG[4:0]:** Extended Inter-Packet Gap

The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits) along with IPG field in Operating mode configuration register (ETH_MACCR), gives the minimum IPG greater than 96 bit times in steps of 8 bit times. For example:

- EIPG = 0 and IPG = 0 give 104 bit times
- EIPG = 0 and IPG = 1 give 112 bit times
- EIPG = 0 and IPG = 2 give 120 bit times
- ..
- EIPG = 7 and IPG = 31 give 2144 bit times

Bit 24: **EIPGEN:** Extended Inter-Packet Gap Enable

When this bit is set, the MAC interprets EIPG field and IPG field in Operating mode configuration register (ETH_MACCR) as minimum IPG greater than 96 bit times in steps of 8 bit times.

When this bit is reset, the MAC ignores EIPG field and interprets IPG field in Operating mode configuration register (ETH_MACCR) as minimum IPG less than or equal to 96 bit times in steps of 8 bit times.

*Note:* The extended Inter-Packet Gap feature must be enabled when operating in Full-duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-duplex mode.

Bits 23:19: Reserved, must be kept at reset value.

Bit 18: **USP:** Unicast Slow Protocol Packet Detect

When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register MAC Address x low register (ETH_MACAxLR). The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02).

When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5.
Bit 17  **SPEN**: Slow Protocol Detection Enable
When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid subtypes. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets.

Bit 16  **DCRCC**: Disable CRC Checking for Received Packets
When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets.

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:0  **GPSL[13:0]**: Giant Packet Size Limit
If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes.
For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. For double VLAN tagged packets, the MAC adds 8 bytes to the programmed value. The value in this field is applicable when the GPSLCE bit is set in ETH_MACCR register.

**Packet filtering control register (ETH_MACPFR)**
Address offset: 0x0008
Reset value: 0x0000 0000

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Bit 31  **RA**: Receive All
When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word.
When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter.

Bits 30:22  Reserved, must be kept at reset value.

Bit 21  **DNTU**: Drop Non-TCP/UDP over IP Packets
When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets.
Bit 20 **IPFE**: Layer 3 and Layer 4 Filter Enable
When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect.
When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **VTFE**: VLAN Tag Filter Enable
When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **HPF**: Hash or Perfect Filter
When this bit is set, the address filter passes a packet if it matches either the perfect filtering or Hash filtering as set by the HMC or HUC bit.
When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter.

Bit 9 **SAF**: Source Address Filter Enable
When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet.
When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison.

*Note*: According to the IEEE specification, Bit 47 of the SA is reserved. However, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA.

Bit 8 **SAIF**: SA Inverse Filtering
When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter.
When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter.

Bits 7:6 **PCF[1:0]**: Pass Control Packets
These bits control the forwarding of all control packets (including unicast and multicast Pause packets).
00: The MAC filters all control packets from reaching the application.
01: The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter.
10: The MAC forwards all control packets to the application even if they fail the Address filter.
11: The MAC forwards the control packets that pass the Address filter.

Bit 5 **DBF**: Disable Broadcast Packets
When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings.
When this bit is reset, the AFM module passes all received broadcast packets.

Bit 4 **PM**: Pass All Multicast
When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is ‘1’) are passed. When this bit is reset, filtering of multicast packet depends on HMC bit.
Bit 3 **DAIF**: DA Inverse Filtering
When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed.

Bit 2 **HMC**: Hash Multicast
When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the Hash table.
When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers.

Bit 1 **HUC**: Hash Unicast
When this bit is set, the MAC performs the destination address filtering of unicast packets according to the Hash table.
When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers.

Bit 0 **PR**: Promiscuous Mode
When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set.

**Watchdog timeout register (ETH_MACWTR)**
Address offset: 0x000C
Reset value: 0x0000 0000

The Watchdog Timeout register controls the watchdog timeout for received packets.
Hash Table 0 register (ETH_MACHT0R)

Address offset: 0x0010
Reset value: 0x0000 0000

The Hash Table Register 0 contains the first lower 32 bits of the Hash table (64 bits).

The Hash table is used for group address filtering.

For Hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register 0 or 1) and the least significant five bits determine the bit within the register. For example, a hash value of 0b100000 selects Bit 0 of the Hash Table Register 1.

The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 7 or 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in ETH_MACPFR, all multicast packets are accepted regardless of the multicast Hash values.

Bits 31:9  Reserved, must be kept at reset value.

Bit 8  PWE: Programmable Watchdog Enable
When this bit is set and the WD bit of the Operating mode configuration register (ETH_MACCR) register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in Operating mode configuration register (ETH_MACCR) register.

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  WTO[3:0]: Watchdog Timeout
When the PWE bit is set and the WD bit of the Operating mode configuration register (ETH_MACCR) register is reset, this field is used as watchdog timeout for a received packet.

If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet.

Encoding is as follows:
0x0: 2 Kbytes
0x1: 3 Kbytes
0x2: 4 Kbytes
0x3: 5 Kbytes
...
0xC: 14 Kbytes
0xD: 15 Kbytes
0xE: 16383 Bytes
0xF: Reserved, must not be used

Note: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.
Hash Table 1 register (ETH_MACHT1R)

Address offset: 0x0014
Reset value: 0x0000 0000

The Hash Table 1 register contains the upper 32 bits of the Hash table (64 bits).

The Hash table is used for group address filtering.

For Hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register 0 or 1) and the least significant five bits determine the bit within the register.

For example, a hash value of 6'b100000 selects Bit 0 of the Hash Table Register 1.

The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 7 or 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in ETH_MACPFR, all multicast packets are accepted regardless of the multicast Hash values.

Bits 31:0 HT31T0[31:0]: MAC Hash Table First 32 Bits
This field contains the first 32 Bits [31:0] of the Hash table.

Bits 31:0 HT63T32[31:0]: MAC Hash Table Second 32 Bits
This field contains the second 32 Bits [63:32] of the Hash table.
VLAN tag register (ETH_MACVTR)

Address offset: 0x0050
Reset value: 0x0000 0000

The VLAN Tag register identifies the IEEE 802.1Q VLAN type packets.

</tbody>
</table>

| Bit 23 | Reserved, must be kept at reset value. |
Bits 22:21  **EVLS[1:0]: Enable VLAN Tag Stripping on Receive**
- This field indicates the stripping operation on the outer VLAN Tag in received packet:
  - 00: Do not strip
  - 01: Strip if VLAN filter passes
  - 10: Strip if VLAN filter fails
  - 11: Always strip

Bit 20  **DOVLTC: Disable VLAN Type Check**
- When this bit is set, the MAC does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN.
- When this bit is reset, the MAC filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit.

Bit 19  **ERSVLM: Enable Receive S-VLAN Match**
- When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets.
- The ERIVLT bit determines the VLAN tag position considered for filtering or matching.

Bit 18  **ESVL: Enable S-VLAN**
- When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.

Bit 17  **VTIM: VLAN Tag Inverse Match Enable**
- When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched.

Bit 16  **ETV: Enable 12-Bit VLAN Tag Comparison**
- When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used for Hash-based VLAN filtering.
- When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison and VLAN Hash filtering.

Bits 15:0  **VL[15:0]: VLAN Tag Identifier for Receive Packets**
- This field contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field:
  - Bits[15:13]: User Priority
  - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
  - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag
- When the ETV bit is set, only the VID is used for comparison.
- If this field ([11:0] if ETV is set) is all zeros, the MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 0x8100 or 0x88a8 as VLAN packets.
VLAN Hash table register (ETH_MACVHTR)

Address offset: 0x0058
Reset value: 0x0000 0000

When the VTHM bit of **VLAN tag register (ETH_MACVTR)** register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For Hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of **VLAN tag register (ETH_MACVTR)** register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a Hash value of 1000 selects Bit 8 of the VLAN Hash table.

The Hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).
2. Perform bitwise reversal for the value obtained in step 1.
3. Take the upper four bits from the value obtained in step 2.

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **VLHT[15:0]**: VLAN Hash Table

This field contains the 16-bit VLAN Hash Table.
The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the Transmit packets. It also contains the VLAN tag insertion controls.

### VLAN inclusion register (ETH_MACVIR)

**Address offset:** 0x0060  
**Reset value:** 0x0000 0000

The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the Transmit packets. It also contains the VLAN tag insertion controls.

<table>

</table>

**Bit 20 VLTI:** VLAN Tag Input  
When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor.

**Bit 19 CSVL:** C-VLAN or S-VLAN  
When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.  
0: C-LAN  
1: S-LAN

**Bit 18 VLP:** VLAN Priority Control  
When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, bits[17:16] are ignored.

**Bits 17:16 VLC[1:0]:** VLAN Tag Control in Transmit Packets  
- 00: No VLAN tag deletion, insertion, or replacement  
- 01: VLAN tag deletion. The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags.  
- 10: VLAN tag insertion. The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88A8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag.  
- 11: VLAN tag replacement. The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88A8).  

*Note:* Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.

**Bits 15:0 VLT[15:0]:** VLAN Tag for Transmit Packets  
This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase.  
The following list describes the bits of this field:  
- Bits[15:13]: User Priority  
- Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)  
- Bits[11:0]: VLAN Identifier (VID) field of VLAN tag
Inner VLAN inclusion register (ETH_MACIVIR)

Address offset: 0x0064
Reset value: 0x0000 0000

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 VLTI: VLAN Tag Input
When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor

Bit 19 CSVL: C-VLAN or S-VLAN
When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.
0: C-LAN
1: S-LAN

Bit 18 VLP: VLAN Priority Control
When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the VLC field is ignored.

Bits 17:16 VLC[1:0]: VLAN Tag Control in Transmit Packets
00: No VLAN tag deletion, insertion, or replacement
01: VLAN tag deletion
The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags.
10: VLAN tag insertion
The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag.
11: VLAN tag replacement
The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8).

Note: Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
Bits 15:0 **VLT[15:0]**: VLAN Tag for Transmit Packets

This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase.

The following list describes the bits of this field:
- Bits[15:13]: User Priority
- Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
- Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

**Tx Queue flow control register (ETH_MACQTXFCR)**

Address offset: 0x0070

Reset value: 0x0000 0000

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

<table>
<thead>
<tr>
<th>Bits 31:16</th>
<th><strong>PT[15:0]</strong>: Pause Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>This field holds the value to be used in the Pause Time field in the Tx control packet.</td>
<td></td>
</tr>
<tr>
<td>Bits 15:8</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>

**Bit 7** **DZPQ**: Disable Zero-Quanta Pause

When this bit is set, it disables the automatic generation of the zero-quanta Pause packets. When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.
Bits 6:4  **PLT[2:0]: Pause Low Threshold**

This field configures the threshold of the Pause timer at which the input flow is checked for automatic retransmission of the Pause packet.

The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted at 228 (256-28) slot times after the first Pause packet is transmitted.

The following list provides the threshold values for different values:

- **000**: Pause Time minus 4 Slot Times (PT-4 slot times)
- **001**: Pause Time minus 28 Slot Times (PT-28 slot times)
- **010**: Pause Time minus 36 Slot Times (PT-36 slot times)
- **011**: Pause Time minus 144 Slot Times (PT-144 slot times)
- **100**: Pause Time minus 256 Slot Times (PT-256 slot times)
- **101**: Pause Time minus 512 Slot Times (PT-512 slot times)
- **110 to 111**: Reserved, must not be used

The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.

Bits 3:2  Reserved, must be kept at reset value.

Bit 1  **TFE: Transmit Flow Control Enable**

**Full-duplex mode:** when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets.

**Half-duplex mode:** when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled.

Bit 0  **FCB_BPA: Flow Control Busy or Backpressure Activate**

This bit initiates a Pause packet in the Full-duplex mode and activates the backpressure function in the Half-duplex mode if the TFE bit is set.

**Full-Duplex mode:** this bit should be read as 0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 0. You should not write to this register until this bit is cleared.

**Half-duplex mode:** When this bit is set (and TFE bit is set) in the Half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. When the MAC is configured for the Full-duplex mode, the BPA is automatically disabled.
Rx flow control register (ETH_MACRXFCR)

Address offset: 0x0090
Reset value: 0x0000 0000

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

</tbody>
</table>

Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **UP**: Unicast Pause Packet Detect

A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in **MAC Address 0 high register (ETH_MACA0HR)** and MAC Address 0 low register **MAC Address x low register (ETH_MACAxLR)**.

When this bit is reset, the MAC only detects Pause packets with unique multicast address.

**Note:** The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011.

Bit 0  **RFE**: Receive Flow Control Enable

When this bit is set and the MAC is operating in Full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in Half-duplex mode, the decode function of the Pause packet is disabled.

When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.
Interrupt status register (ETH_MACISR)

Address offset: 0x00B0
Reset value: 0x0000 0000

The Interrupt Status register contains the status of interrupts.

Bits 31:15  Reserved, must be kept at reset value.

Bit 14  RXSTSIS: Receive Status Interrupt
This bit indicates the status of received packets. This bit is set when the RWT bit is set in the Rx Tx status register (ETH_MACRXTXSR). This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR software control register (ETH_MACCSRSWCR) is set) in the ETH_MACISR register.

Bit 13  TXSTSIS: Transmit Status Interrupt
This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the Rx Tx status register (ETH_MACRXTXSR):
- Excessive Collision (EXCOL)
- Late Collision (LCOL)
- Excessive Deferral (EXDEF)
- Loss of Carrier (LCARR)
- No Carrier (NCARR)
- Jabber Timeout (TJT)

This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR software control register (ETH_MACCSRSWCR) is set) in the ETH_MACISR register.
Bit 12 **TSIS**: Timestamp Interrupt Status
If the Timestamp feature is enabled, this bit is set when any of the following conditions is true:
- The system time value is equal to or exceeds the value specified in the Target Time High and Low registers.
- There is an overflow in the Seconds register.
- The Target Time Error occurred, that is, programmed target time already elapsed.
If the Auxiliary Snapshot feature is enabled, this bit is set when the auxiliary snapshot trigger is asserted.
When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) and Tx timestamp status seconds register (ETH_MACTXTSSSR) registers.
When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) and Tx timestamp status seconds register (ETH_MACTXTSSSR) registers, for PTO generated Delay Request and Pdelay request packets.
This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR software control register (ETH_MACCSRSWCR) is set) in the Timestamp status register (ETH_MACTSSR).

Bit 11 Reserved, must be kept at reset value.

Bit 10 **MMCTXIS**: MMC Transmit Interrupt Status
This bit is set high when an interrupt is generated in the MMC Tx interrupt register (ETH_MMC_TX_INTERRUPT). This bit is cleared when all bits in this interrupt register are cleared.

Bit 9 **MMCRXIS**: MMC Receive Interrupt Status
This bit is set high when an interrupt is generated in the MMC Rx interrupt register (ETH_MMC_RX_INTERRUPT). This bit is cleared when all bits in this interrupt register are cleared.

Bit 8 **MMCIS**: MMC Interrupt Status
This bit is set high when MMCTXIS or MMCRXIS is set high. This bit is cleared only when all these bits are low.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **LPIS**: LPI Interrupt Status
This bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the TLPIEN bit of LPI control and status register (ETH_MACLCSR) is read.

Bit 4 **PMTIS**: PMT Interrupt Status
This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in ETH_MACPCSR register). This bit is cleared when Bits[6:5] are cleared because of a Read operation to the PMT control status register (ETH_MACPCSR).

Bit 3 **PHYIS**: PHY Interrupt
This bit is set when rising edge is detected on the ETH_PHY_INTN input. This bit is cleared when this register is read.

Bits 2:0 Reserved, must be kept at reset value.
**Interrupt enable register (ETH_MACIER)**

Address offset: 0x00B4  
Reset value: 0x0000 0000

The Interrupt Enable register contains the masks for generating the interrupts.

<table>

Bits 31:15 Reserved, must be kept at reset value.

- **Bit 14 RXSTSIE**: Receive Status Interrupt Enable  
  When this bit is set, it enables the assertion of the interrupt signal because of the setting of RXSTSIS bit in the Interrupt status register (ETH_MACISR).

- **Bit 13 TXSTSIE**: Transmit Status Interrupt Enable  
  When this bit is set, it enables the assertion of the interrupt signal because of the setting of TXSTSIS bit in the Interrupt status register (ETH_MACISR).

- **Bit 12 TSIE**: Timestamp Interrupt Enable  
  When this bit is set, it enables the assertion of the interrupt signal because of the setting of TSIS bit in Interrupt status register (ETH_MACISR).

Bits 11:6 Reserved, must be kept at reset value.

- **Bit 5 LPIIE**: LPI Interrupt Enable  
  When this bit is set, it enables the assertion of the interrupt signal because of the setting of LPIIS bit in Interrupt status register (ETH_MACISR).

- **Bit 4 PMTIE**: PMT Interrupt Enable  
  When this bit is set, it enables the assertion of the interrupt signal because of the setting of PMTIS bit in Interrupt status register (ETH_MACISR).

- **Bit 3 PHYIE**: PHY Interrupt Enable  
  When this bit is set, it enables the assertion of the interrupt signal because of the setting of PHYIS bit in Interrupt status register (ETH_MACISR).

Bits 2:0 Reserved, must be kept at reset value.
**Rx Tx status register (ETH_MACRXTXSR)**

Address offset: 0x00B8

Reset value: 0x0000 0000

The Receive Transmit Status register contains the Receive and Transmit Error status.

<table>
<thead>
<tr>

</tbody>
</table>
|     | This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the Operating mode configuration register (ETH_MACCR). This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the Operating mode configuration register (ETH_MACCR).  
|     | Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set). |
| 7:6 | Reserved, must be kept at reset value. |
| 5   | **EXCOL**: Excessive Collisions  |
|     | When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR), this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the Operating mode configuration register (ETH_MACCR), this bit is set after the first collision and the packet transmission is aborted.  
|     | Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set). |
| 4   | **LCOL**: Late Collision  |
|     | When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR), this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode.  
|     | This bit is not valid if the Underflow error occurs.  
|     | Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set). |
| 3   | **EXDEF**: Excessive Deferral  |
|     | When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR) and the DC bit is set in the Operating mode configuration register (ETH_MACCR), this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 when Jumbo packet is enabled).  
|     | Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set). |
Bit 2  **LCARR**: Loss of Carrier

When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR), this bit indicates that the loss of carrier occurred during packet transmission, that is, the ETH_CRS signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision.

Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRWCR) is set).

Bit 1  **NCARR**: No Carrier

When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR), this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission.

Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRWCR) is set).

Bit 0  **TJT**: Transmit Jabber Timeout

This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the Operating mode configuration register (ETH_MACCR). This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the Operating mode configuration register (ETH_MACCR).

Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRWCR) is set).

**PMT control status register (ETH_MACPCSR)**

Address offset: 0x00C0
Reset value: 0x0000 0000

| Bit 31 | RWKFILTRST: Remote wake-up Packet Filter Register Pointer Reset |
| Bit 30-29 | Reserved, must be kept at reset value. |
| Bit 28-24 | RWKPTR[4:0]: Remote wake-up FIFO Pointer |
| Bit 23-11 | Reserved, must be kept at reset value. |

| Bit 15-1 | RWKPKTEN: MGKPKTEN |
| Bit 8-7 | RWMPRVD: MGKPRVD |
| Bit 4-3 | RWKPRCVD |
| Bit 2-1 | RWKPFE |
| Bit 0 | GLBLCAST |

### RWKFILTRST

When this bit is set, the remote wake-up packet filter register pointer is reset to 0. It is automatically cleared after 1 clock cycle.

Bits 30:29  Reserved, must be kept at reset value.

Bits 28:24  **RWKPTR[4:0]**: Remote wake-up FIFO Pointer

This field gives the current value (0 to 7) of the Remote wake-up Packet Filter register pointer. When the value of this pointer is equal to 7, the contents of the Remote wake-up Packet Filter Register are transferred to the eth_mii_rx_clk domain when a Write occurs to that register.

Bits 23:11  Reserved, must be kept at reset value.
Bit 10  **RWKPF:** Remote wake-up Packet Forwarding Enable
When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet.

The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low.

The setting of this bit has no effect when PWRDWN is set high.

*Note:* If Magic Packet Enable and wake-up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application.

Bit 9  **GLBLUCAST:** Global Unicast
When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet.

Bits 8:7  Reserved, must be kept at reset value.

Bit 6  **RWKPRCVD:** Remote wake-up Packet Received
When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read.

Bit 5  **MGKPRCVD:** Magic Packet Received
When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read (or written to 1 when RCWE bit in CSR software control register (ETH_MACCSR_SWCR) is set).

Bits 4:3  Reserved, must be kept at reset value.

Bit 2  **RWKPKTEN:** Remote wake-up Packet Enable
When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet.

Bit 1  **MGKPKTEN:** Magic Packet Enable
When this bit is set, a power management event is generated when the MAC receives a magic packet.

Bit 0  **PWRDWN:** Power Down
When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote wake-up Packet Enable bit is set high.

*Note:* You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit.
Remote wake-up packet filter register (ETH_MACRWKPFR)

Address offset: 0x00C4
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:0 MACRWKPFR[31:0]: Remote wake-up packet filter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Refer to Table 649, Table 650 and Table 651 for details on register content and programming sequence.</td>
</tr>
</tbody>
</table>

The ETH_MACRWKPFR register at address 0x00C4 loads the wake-up Packet Filter register.

To load values in a wake-up Packet Filter register, the entire register (ETH_MACRWKPFR) must be written. The ETH_MACRWKPFR register is loaded by sequentially loading the eight, sixteen or thirty two register values in address (0x00C4) for ETH_MACRWKPFR value 0 to 7, respectively. The ETH_MACRWKPFR register is read in a similar way. The Ethernet peripheral updates the ETH_MACRWKPFR register current pointer value in Bits[26:24] of ETH_MACPCSR register.

LPI control and status register (ETH_MACLCSR)

Address offset: 0x00D0
Reset value: 0x0000 0000

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.
RM0481 Ethernet (ETH): media access control (MAC) with DMA controller

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **LPITCSE**: LPI Tx Clock Stop Enable

When this bit is set, the MAC asserts sdb_tck_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sdb_tck_gating_ctrl_o signal high after it enters Tx LPI mode.

If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed.

Bit 20 **LPITE**: LPI Timer Enable

This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPITE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the ETH_MACLETR register.

After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again.

When LPITE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions.

Bit 19 **LPITXA**: LPI Tx Automate

This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side.

If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of ETH_MTLTxFOMR, when the MAC is in the LPI mode, it exits the LPI mode.

When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PLS**: PHY Link Status

This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER.

When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down.

Bit 16 **LPIEN**: LPI Enable

When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission.

This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **RLPIST**: Receive LPI State

When this bit is set, it indicates that the MAC is receiving the LPI pattern on the MII interface.

Bit 8 **TLPIST**: Transmit LPI State

When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the MII interface.

Bits 7:4 Reserved, must be kept at reset value.
Bit 3  **RLPIEX**: Receive LPI Exit

When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or by writing it to 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

*Note: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.*

Bit 2  **RLPIEN**: Receive LPI Entry

When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or by writing it to 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

*Note: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.*

Bit 1  **TLPIEX**: Transmit LPI Exit

When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or by writing it to 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bit 0  **TLPIEN**: Transmit LPI Entry

When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or by writing it to 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

### LPI Timers Control Register (ETH_MACLTCR)

**Address offset**: 0x00D4

**Reset value**: 0x03E8 0000

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-24</td>

<td>LPI Transmit Timer (TX)</td>
</tr>
<tr>
<td>15-12</td>
<td>TWT[15:0]</td>
<td>LPI Receive Timer (RX)</td>
</tr>
</tbody>
</table>

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.
RM0481 Ethernet (ETH): media access control (MAC) with DMA controller

Bits 31:26  Reserved, must be kept at reset value.

Bits 25:16  **LST[9:0]:** LPI LS Timer
This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.

Bits 15:0  **TWT[15:0]:** LPI TW Timer
This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPiEX status bit is set after the expiry of this timer.

**LPI entry timer register (ETH_MACLETR)**
Address offset: 0x00D8
Reset value: 0x0000 0000
This register controls the Tx LPI entry timer. This counter is enabled only when LPITE bit of LPI control and status register (ETH_MACLCSR) register is set to 1.

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **LPIET[19:0]:** LPI Entry Timer
This field specifies the time in microseconds the MAC waits after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1.

Bits [2:0] are read-only so that the granularity of this timer is in steps of 8 micro-seconds.

**One-microsecond-tick counter register (ETH_MAC1USTCR)**
Address offset: 0x00DC
Reset value: 0x0000 0000
This register controls the generation of the Reference time (one-microsecond tick) for all the LPI timers. This timer has to be programmed by the software initially.

| Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9  | Bit 8  | Bit 7  | Bit 6  | Bit 5  | Bit 4  | Bit 3  | Bit 2  | Bit 1  | Bit 0  |

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  TIC_1US_CNTR[11:0]: 1 µs tick Counter

The application must program this counter so that the number of clock cycles of CSR clock is 1 µs (subtract 1 from the value before programming).

For example if the CSR clock is 100 MHz then this field needs to be programmed to 100 - 1 = 99 (which is 0x63).

This is required to generate the 1 µs events that are used to update some of the EEE related counters.

**Version register (ETH_MACVR)**

Address offset: 0x0110

Reset value: 0x0000 3242

The version register identifies the version of the Ethernet peripheral.

</table>
Bits 31:19  Reserved, must be kept at reset value.

Bits 18:17  **TFCSTS[1:0]:** MAC Transmit Packet Controller Status

This field indicates the state of the MAC Transmit Packet Controller module:

00: Idle state
01: Waiting for one of the following:
   - Status of the previous packet
   - IPG or backoff period to be over
10: Generating and transmitting a Pause control packet (in Full-duplex mode)
11: Transferring input packet for transmission

Bit 16  **TPESTS:** MAC MII Transmit Protocol Engine Status

When this bit is set, it indicates that the MAC MII transmit protocol engine is actively transmitting data, and it is not in the Idle state.

Bits 15:3  Reserved, must be kept at reset value.

Bits 2:1  **RFCFCSTS[1:0]:** MAC Receive Packet Controller FIFO Status

This field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Packet Controller module.

Bit 0  **RPESTS:** MAC MII Receive Protocol Engine Status

When this bit is set, it indicates that the MAC MII receive protocol engine is actively receiving data, and it is not in the Idle state.

**HW feature 0 register (ETH_MACHWF0R)**

Address offset: 0x011C

Reset value: 0x0A0D 73F7

This register indicates the presence of first set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.
Bit 31  Reserved, must be kept at reset value.

Bits 30:28  **ACTPHYSSEL[2:0]:** Active PHY Selected
   When you have multiple PHY interfaces in your configuration, this field indicates the sampled value of phy_intf_sel_i during reset de-assertion:
   000: GMII or MII
   001: RGMII
   010: SGMII
   011: TBI
   100: RMII
   101: RTBI
   110: SMII
   Others: Reserved, must not be used

Bit 27  **SAVLININS:** Source Address or VLAN Insertion Enable
   This bit is set to 1 when the Enable SA and VLAN Insertion on Tx option is selected

Bits 26:25  **TSSTSSSEL[1:0]:** Timestamp System Time Source
   This bit indicates the source of the Timestamp system time:
   01: Internal
   10: External
   11: Both
   00: Reserved, must not be used
   This bit is set to 1 when the Enable IEEE 1588 Timestamp Support option is selected

Bit 24  **MACADR64SEL:** MAC Addresses 64-127 Selected
   This bit is set to 1 when the Enable Additional 64 MAC Address Registers (64-127) option is selected

Bit 23  **MACADR32SEL:** MAC Addresses 32-63 Selected
   This bit is set to 1 when the Enable Additional 32 MAC Address Registers (32-63) option is selected

Bits 22:18  **ADDMACADRSEL[4:0]:** MAC Addresses 1-31 Selected
   This bit is set to 1 when the Enable Additional 1-31 MAC Address Registers option is selected

Bit 17  Reserved, must be kept at reset value.

Bit 16  **RXCOESEL:** Receive Checksum Offload Enabled
   This bit is set to 1 when the Enable Receive TCP/IP Checksum Check option is selected

Bit 15  Reserved, must be kept at reset value.

Bit 14  **TXCOESEL:** Transmit Checksum Offload Enabled
   This bit is set to 1 when the Enable Transmit TCP/IP Checksum Insertion option is selected

Bit 13  **EEESEL:** Energy Efficient Ethernet Enabled
   This bit is set to 1 when the Enable Energy Efficient Ethernet (EEE) option is selected

Bit 12  **TSSEL:** IEEE 1588-2008 Timestamp Enabled
   This bit is set to 1 when the Enable IEEE 1588 Timestamp Support option is selected

Bits 11:10  Reserved, must be kept at reset value.

Bit 9  **ARPOFFSEL:** ARP Offload Enabled
   This bit is set to 1 when the Enable IPv4 ARP Offload option is selected

Bit 8  **MMCSEL:** RMON Module Enable
   This bit is set to 1 when the Enable MAC management counters (MMC) option is selected
Bit 7  **MGKSEL**: PMT Magic Packet Enable
This bit is set to 1 when the Enable Magic Packet Detection option is selected

Bit 6  **RWKSEL**: PMT Remote wake-up Packet Enable
This bit is set to 1 when the Enable Remote wake-up Packet Detection option is selected

Bit 5  **SMASEL**: SMA (MDIO) Interface
This bit is set to 1 when the Enable Station Management (MDIO Interface) option is selected

Bit 4  **VLHASH**: VLAN Hash Filter Selected
This bit is set to 1 when the Enable VLAN Hash Table Based Filtering option is selected

Bit 3  **PCSSEL**: PCS Registers (TBI, SGMII, or RTBI PHY interface)
This bit is set to 1 when the TBI, SGMII, or RTBI PHY interface option is selected

Bit 2  **HDSEL**: Half-duplex Support
This bit is set to 1 when the Half-duplex mode is selected

Bit 1  **GMISEL**: 1000 Mbps Support
This bit is set to 1 when 1000 Mbps is selected as operating mode.

Bit 0  **MIISEL**: 10 or 100 Mbps Support
This bit is set to 1 when 10/100 Mbps is selected as operating mode.

**HW feature 1 register (ETH_MACHWF1R)**

Address offset: 0x0120
Reset value: 0x1104 1904

This register indicates the presence of second set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.
Bit 31  Reserved, must be kept at reset value.

Bits 30:27  **L3L4FNUM[3:0]**: Total number of L3 or L4 Filters
           This field indicates the total number of L3 or L4 filters:
           0000: No L3 or L4 Filter
           0001: 1 L3 or L4 Filter
           0010: 2 L3 or L4 Filters
           ..
           1000: 8 L3 or L4

Bit 26  Reserved, must be kept at reset value.

Bits 25:24  **HASHTBLSZ[1:0]**: Hash Table Size
           This field indicates the size of the Hash table:
           00: No Hash table
           01: 64
           10: 128
           11: 256

Bit 23  **POUST**: One Step for PTP over UDP/IP Feature Enable
           This bit is set to 1 when the Enable one step timestamp for PTP over UDP/IP feature is selected.

Bit 22  Reserved, must be kept at reset value.

Bit 21  **RAVSEL**: Rx Side Only AV Feature Enable
           This bit is set to 1 when the Enable Audio video bridging option on Rx Side Only is selected.

Bit 20  **AVSEL**: AV Feature Enable
           This bit is set to 1 when the Enable Audio video bridging option is selected.

Bit 19  **DBGMEMA**: DMA Debug Registers Enable
           This bit is set to 1 when the Debug Mode Enable option is selected

Bit 18  **TSOEN**: TCP Segmentation Offload Enable
           This bit is set to 1 when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected

Bit 17  **SPHEN**: Split Header Feature Enable
           This bit is set to 1 when the Enable Split Header Structure option is selected

Bit 16  **DCBEN**: DCB Feature Enable
           This bit is set to 1 when the Enable Data Center Bridging option is selected

Bits 15:14  **ADDR64[1:0]**: Address width
           This field indicates the configured address width.
           00: 32 bits
           Others: Reserved, must not be used

Bit 13  **ADVTHWORD**: IEEE 1588 High Word Register Enable
           This bit is set to 1 when the Add IEEE 1588 Higher Word Register option is selected

Bit 12  **PTOEN**: PTP Offload Enable
           This bit is set to 1 when the Enable PTP Timestamp Offload Feature is selected.

Bit 11  **OSTEN**: One-Step Timestamping Enable
           This bit is set to 1 when the Enable One-Step Timestamp Feature is selected.
Bits 10:6 **TXFIFOSIZE[4:0]**: MTL Transmit FIFO Size

This field contains the configured value of MTL Tx FIFO in bytes expressed as \( \log_2 \text{TXFIFO\_SIZE} - 7 \):

- 00000: 128 bytes
- 00001: 256 bytes
- 00010: 512 bytes
- 00011: 1,024 bytes
- 00100: 2,048 bytes
- 00101: 4,096 bytes
- 00110: 8,192 bytes
- 00111: 16,384 bytes
- 01000: 32 Kbytes
- 01001: 64 Kbytes
- 01010: 128 Kbytes
- 01011 to 11111: Reserved, must not be used

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **RXFIFOSIZE[4:0]**: MTL Receive FIFO Size

This field contains the configured value of MTL Rx FIFO in bytes expressed as \( \log_2 \text{RXFIFO\_SIZE} - 7 \):

- 00000: 128 bytes
- 00001: 256 bytes
- 00010: 512 bytes
- 00011: 1,024 bytes
- 00100: 2,048 bytes
- 00101: 4,096 bytes
- 00110: 8,192 bytes
- 00111: 16,384 bytes
- 01000: 32 Kbytes
- 01001: 64 Kbytes
- 01010: 128 Kbytes
- 01011 to 11111: Reserved, must not be used
HW feature 2 register (ETH_MACHWF2R)

Address offset: 0x0124

Reset value: 0x4100 0000

This register indicates the presence of third set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bit 31  Reserved, must be kept at reset value.

Bits 30:28  **AUXSNAPNUM[2:0]**: Number of Auxiliary Snapshot Inputs

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>No auxiliary input</td>
</tr>
<tr>
<td>001</td>
<td>1 auxiliary input</td>
</tr>
<tr>
<td>010</td>
<td>2 auxiliary inputs</td>
</tr>

Bits 17:16  **RDCSZ[1:0]**: Rx DMA Descriptor Cache Size in terms of 16-byte descriptors
- 00: Cache not configured
- 01: Four 16-byte descriptors
- 10: Eight 16-byte descriptors
- 11: Sixteen 16-byte descriptors

Bits 15:12  **RXCHCNT[3:0]**: Number of DMA Receive Channels
This field indicates the number of DMA Receive channels:
- 0000: 1 DMA Rx Channel
- 0001: 2 DMA Rx Channels
- ..
- 0111: 8 DMA Rx

Bits 11:10  Reserved, must be kept at reset value.

Bits 9:6  **TXQCNT[3:0]**: Number of MTL Transmit Queues
This field indicates the number of MTL Transmit queues:
- 0000: 1 MTL Tx queue
- 0001: 2 MTL Tx queues
- ..
- 0111: 8 MTL Tx

Bits 5:4  Reserved, must be kept at reset value.

Bits 3:0  **RXQCNT[3:0]**: Number of MTL Receive Queues
This field indicates the number of MTL Receive queues:
- 0000: 1 MTL Rx queue
- 0001: 2 MTL Rx queues
- ..
- 0111: 8 MTL Rx
HW feature 3 register (ETH_MACHWF3R)

Address offset: 0x0128
Reset value: 0x0000 0020

This register indicates the presence of fourth set the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bits 31:6  Reserved, must be kept at reset value.

Bit 5  **DVLAN**: Double VLAN processing enable
This bit is set to 1 when Double VLAN processing is enabled.

Bit 4  **CBTISEL**: Queue/Channel based VLAN tag insertion on Tx enable
This bit is set to 1 when the Enable Queue/Channel based VLAN tag insertion on Tx feature is selected.

Bit 3  Reserved, must be kept at reset value.

Bits 2:0  **NRVF[2:0]**: Number of Extended VLAN Tag Filters Enabled
This field indicates the Number of Extended VLAN Tag Filters selected:
- 000: No Extended Rx VLAN Filters
- 001: 4 Extended Rx VLAN Filters
- 010: 8 Extended Rx VLAN Filters
- 011: 16 Extended Rx VLAN Filters
- 100: 24 Extended Rx VLAN Filters
- 101: 32 Extended Rx VLAN Filters
- 110 to 111: Reserved, must not be used
MDIO address register (ETH_MACMDIOAR)

Address offset: 0x0200
Reset value: 0x0000 0000

The MDIO Address register controls the management cycles to external PHY through a management interface.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Bits 14:12</td>
<td>NTC[2:0]: Number of Training Clocks</td>
</tr>
<tr>
<td></td>
<td>This field controls the number of trailing clock cycles generated on ETH_MDC after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 011 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.</td>
</tr>
</tbody>
</table>
Bits 11:8 **CR[3:0]: CSR Clock Range**

The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design:

- **0000**: CSR clock = 60-100 MHz; MDC clock = CSR clock/42
- **0001**: CSR clock = 100-150 MHz; MDC clock = CSR clock/62
- **0010**: CSR clock = 20-35 MHz; MDC clock = CSR clock/16
- **0011**: CSR clock = 35-60 MHz; MDC clock = CSR clock/26
- **0100**: CSR clock = 150-250 MHz; MDC clock = CSR clock/102
- **0101**: CSR clock = 250-300 MHz; MDC clock = CSR clock/124
- **0110** to **0111**: Reserved, must not be used

The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits to 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3.

Program the following values only if the interfacing chips support faster MDC clocks:

- **1000**: CSR clock/4
- **1001**: CSR clock/6
- **1010**: CSR clock/8
- **1011**: CSR clock/10
- **1100**: CSR clock/12
- **1101**: CSR clock/14
- **1110**: CSR clock/16
- **1111**: CSR clock/18

Bits 7:5 **Reserved, must be kept at reset value.**

Bit 4 **SKAP**: Skip Address Packet

When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set.
Bits 3:2 **GOC[1:0]:** MII Operation Command
This bit indicates the operation command to the PHY.
00: Reserved, must not be used
01: Write
10: Post Read Increment Address for Clause 45 PHY
11: Read
When Clause 22 PHY is enabled, only Write and Read commands are valid.

Bit 1 **C45E: Clause 45 PHY Enable**
When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO.

Bit 0 **MB: MII Busy**
The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIOS. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in **MDIO address register (ETH_MACMDIOAR)** and **MDIO data register (ETH_MACMDIODR)** as long as this bit is set.

For write transfers, the application must first write 16-bit data in the MD field (and also RA field when C45E is set) in **MDIO data register (ETH_MACMDIODR)** register before setting this bit. When C45E is set, it should also write into the RA field of **MDIO data register (ETH_MACMDIODR)** before initiating a read transfer. When a read transfer is completed (MII busy=0), the data read from the PHY register is valid in the MD field of the **MDIO data register (ETH_MACMDIODR)**.

Note: *Even if the addressed PHY is not present, there is no change in the functionality of this bit.*

**MDIO data register (ETH_MACMDIODR)**
Address offset: 0x0204
Reset value: 0x0000 0000

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in **MDIO address register (ETH_MACMDIOAR)**. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

Bits 31:16 **RA[15:0]:** Register Address
This field is valid only when C45E is set. It contains the Register Address in the PHY to which the MDIO frame is intended for.

Bits 15:0 **MD[15:0]:** MII Data
This field contains the 16-bit data value read from the PHY after a Management Read operation or the 16-bit data value to be written to the PHY before a Management Write operation.
ARP address register (ETH_MACARPAR)

Address offset: 0x0210
Reset value: 0x0000 0000

The ARP Address register contains the IPv4 Destination Address of the MAC.

ARPPA[15:0]

Bits 31:0 **ARPPA[31:0]**: ARP Protocol Address

This field contains the IPv4 Destination Address of the MAC. This address is used for perfect match with the Protocol Address of Target field in the received ARP packet.

CSR software control register (ETH_MACCSRSWCR)

Address offset: 0x0230
Reset value: 0x0000 0000

This register contains software-programmable controls for changing the CSR access response and status bits clearing.

</table>

| Bits 31:9 Reserved, must be kept at reset value. |

Bit 8 **SEEN**: Slave Error Response Enable

When this bit is set, the MAC responds with a Slave Error for accesses to reserved registers in CSR space.
When this bit is reset, the MAC responds with an Okay response to any register accessed from CSR space.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **RCWE**: Register Clear on Write 1 Enable

When this bit is set, the access mode to some register fields changes to rc_w1 (clear on write) meaning that the application needs to set that respective bit to 1 to clear it.
When this bit is reset, the access mode to these register fields remains rc_r (clear on read).
MAC Address 0 high register (ETH_MACA0HR)

Address offset: 0x0300
Reset value: 0x8000 FFFF

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Bit 31 **AE**: Address Enable
This bit is always set to 1.

Bits 30:16 **Reserved, must be kept at reset value.**

Bits 15:0 **ADDRHI[15:0]**: MAC Address0[47:32]
This field contains the upper 16 bits [47:32] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

MAC Address x low register (ETH_MACAxLR)

Address offset: 0x0304 + 0x8 * x, (x = 0 to 3)
Reset value: 0xFFFF FFFF

The MAC Address x Low register holds the lower 32 bits of the 6-byte first MAC address of the station.

Bits 31:0  **ADDRLO[31:0]**: MAC Address x [31:0] (x = 0 to 3)  
This field contains the lower 32 bits of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

**MAC Address x high register (ETH_MACAxHR)**

Address offset: 0x0308 + 0x8 * (x-1), (x = 1 to 3)

Reset value: 0x0000 FFFF

The MAC Address x High register holds the upper 16 bits of the second 6-byte MAC address of the station.

Bit 31  **AE**: Address Enable  
When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

Bit 30  **SA**: Source Address  
When this bit is set, the MAC Addressx[47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address x[47:0] is used to compare with the DA fields of the received packet.  
0: DA  
1: SA

Bits 29:24  **MBC[5:0]**: Mask Byte Control  
These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows:  
Bit 29: ETH_MACAxHR[15:8]  
Bit 28: ETH_MACAxHR[7:0]  
Bit 27: ETH_MACAxLR[31:24]  
Bit 26: ETH_MACAxLR[23:16]  
Bit 25: ETH_MACAxLR[15:8]  
Bit 24: ETH_MACAxLR[7:0]  
You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.

Bits 23:16  **Reserved**, must be kept at reset value.

Bits 15:0  **ADDRHI[15:0]**: MAC Address1 [47:32]  
This field contains the upper 16 bits[47:32] of the second 6-byte MAC address.
### MMC control register (ETH_MMC_CONTROL)

Address offset: 0x0700  
Reset value: 0x0000 0000

This register configures the MMC operating mode.

</table>

Bits 31:9  Reserved, must be kept at reset value.

Bit 8 **UCDBC**: Update MMC Counters for Dropped Broadcast Packets

The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.

When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of *Packet filtering control register (ETH_MACPFR)*.

When reset, the MMC Counters are not updated for dropped Broadcast packets.

Bits 7:6  Reserved, must be kept at reset value.

Bit 5 **CNTPRSTLVL**: Full-Half Preset

When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2Kbytes) and all packet-counters get preset to 0x7FFF_FFF0 (Half 16).

When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0x7FFF_F800 (Half 2Kbytes) and all packet-counters get preset to 0x7FFF_FFF0 (Half 16).

For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0x800 and 0xFFFF.

Bit 4 **CNTPRST**: Counters Preset

When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle.

This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.

Bit 3 **CNTFREEZ**: MMC Counter Freeze

When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.
Bit 2 **RSTONRD**: Reset on Read  
When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset).  
The counters are cleared when the least significant byte lane (Bits[7:0]) is read.

Bit 1 **CNTSTOPRO**: Counter Stop Rollover  
When this bit is set, the counter does not roll over to zero after reaching the maximum value.

Bit 0 **CNTRST**: Counters Reset  
When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle.

**MMC Rx interrupt register (ETH_MMC_RX_INTERRUPT)**  
Address offset: 0x0704  
Reset value: 0x0000 0000  
This register maintains the interrupts generated from all Receive statistics counters.

The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:

- Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter).
- Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter).

When the CNTSTOPRO is set in **MMC control register (ETH_MMC_CONTROL)**, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

<table>
<thead>
<tr>
<th>Bit 31:28</th>
<th>Reserved, must be kept at reset value.</th>
</tr>

</table>
| Bit 27 **RXLPIITRCIS**: MMC Receive LPI transition counter interrupt status  
This bit is set when the **Rx LPI transition counter register (ETH_RX_LPI_TRAN_CNTR)** counter reaches half of the maximum value or the maximum value. |
| Bit 26 **RXLPIUSCIS**: MMC Receive LPI microsecond counter interrupt status  
This bit is set when the **Rx LPI microsecond counter register (ETH_RX_LPI_USEC_CNTR)** counter reaches half of the maximum value or the maximum value. |
| Bits 25:18 | Reserved, must be kept at reset value. |
Bit 17 **RXUCGPIS**: MMC Receive Unicast Good Packet Counter Interrupt Status

This bit is set when the *Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD)* counter reaches half of the maximum value or the maximum value.

Bits 16-7 Reserved, must be kept at reset value.

Bit 6 **RXALGNERPIS**: MMC Receive Alignment Error Packet Counter Interrupt Status

This bit is set when the *Rx alignment error packets register (ETH_RX_ALIGNMENT_ERROR_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bit 5 **RXCRCEPIS**: MMC Receive CRC Error Packet Counter Interrupt Status

This bit is set when the *Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bits 4:0 Reserved, must be kept at reset value.

**MMC Tx interrupt register (ETH_MMC_TX_INTERRUPT)**

Address offset: 0x0708

Reset value: 0x0000 0000

This register maintains the interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFF for 16-bit counter).

When CNTSTOPRO is set in *MMC control register (ETH_MMC_CONTROL)*, the interrupts are set but the counter remains at all-ones.

The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

| Bits 31:28 | Reserved, must be kept at reset value.

**Bit 27** **RXLPITRCIM**: MMC Receive LPI transition counter interrupt Mask  
Setting this bit masks the interrupt when the Rx LPI transition counter register (ETH_RX_LPI_TRAN_CNTR) counter reaches half of the maximum value or the maximum value.

**Bit 26** **RXLPIUSCIM**: MMC Receive LPI microsecond counter interrupt Mask  
Setting this bit masks the interrupt when the Rx LPI microsecond counter register (ETH_RX_LPI_USEC_CNTR) counter reaches half of the maximum value or the maximum value.

**Bits 25:18** Reserved, must be kept at reset value.

**Bit 17** **RXUCGPIM**: MMC Receive Unicast Good Packet Counter Interrupt Mask  
Setting this bit masks the interrupt when the Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD) counter reaches half of the maximum value or the maximum value.

**Bits 16:7** Reserved, must be kept at reset value.

**Bit 6** **RXALGNERPM**: MMC Receive Alignment Error Packet Counter Interrupt Mask  
Setting this bit masks the interrupt when the Rx alignment error packets register (ETH_RX_ALIGNMENT_ERROR_PACKETS) counter reaches half of the maximum value or the maximum value.

**Bit 5** **RXCRCERPIM**: MMC Receive CRC Error Packet Counter Interrupt Mask  
Setting this bit masks the interrupt when the Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS) counter reaches half of the maximum value or the maximum value.

**Bits 4:0** Reserved, must be kept at reset value.
MMC Tx interrupt mask register (ETH_MMC_TX_INTERRUPT_MASK)

Address offset: 0x0710
Reset value: 0x0000 0000

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

Bit 27 **TXLPITRCIM**: MMC Transmit LPI transition counter interrupt Mask
Setting this bit masks the interrupt when the Tx LPI transition counter register (ETH_TX_LPI_TRAN_CNTR) counter reaches half of the maximum value or the maximum value.

Bit 26 **TXLPIUSCIM**: MMC Transmit LPI microsecond counter interrupt Mask
Setting this bit masks the interrupt when the Tx LPI microsecond timer register (ETH_TX_LPI_USEC_CNTR) counter reaches half of the maximum value or the maximum value.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **TXGPKTIM**: MMC Transmit Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD) counter reaches half of the maximum value or the maximum value.

Bits 20:16 Reserved, must be kept at reset value.

Bit 15 **TXMCOLGPIM**: MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the Tx multiple collision good packets register (ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS) counter reaches half of the maximum value or the maximum value.

Bit 14 **TXSCOLGPIM**: MMC Transmit Single Collision Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the Tx single collision good packets register (ETH_TX_SINGLE_COLLISION_GOOD_PACKETS) counter reaches half of the maximum value or the maximum value.

Bits 13:0 Reserved, must be kept at reset value.
**Tx single collision good packets register**  
(ETH_TX_SINGLE_COLLISION_GOOD_PACKETS)

Address offset: 0x074C  
Reset value: 0x0000 0000  
This register provides the number of successfully transmitted packets by Ethernet peripheral after a single collision in the Half-duplex mode.

</table>

Bits 31:0 **RXALGNERR[31:0]: Rx Alignment Error Packets**
This field indicates the number of packets received with alignment (dribble) error. It is valid only in 10/100 mode.

Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD)
Address offset: 0x07C4
Reset value: 0x0000 0000
This register provides the number of good unicast packets received by Ethernet peripheral.

<table>

|      | When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching.  
The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set. |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |
Bits 15:11 **L3HDBM0[4:0]**: Layer 3 IP DA higher bits match

Condition: IPv4 packets

This field contains the number of higher bits of IP Destination Address that are masked in the IPv4 packets:

0: No bits are masked.
1: Lsb[0] is masked
2: Two Lsbs [1:0] are masked
.. 
31: All bits except MSb are masked.

Condition: IPv6 packets

Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. Number of bits masked is given by concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits:

0: No bits are masked.
1: Lsb[0] is masked
2: Two Lsbs [1:0] are masked
.. 
31: All bits except MSb are masked.

This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.

Bits 10:6 **L3HSBM0[4:0]**: Layer 3 IP SA higher bits match

Condition: IPv4 packets

This field contains the number of lower bits of IP source address that are masked for matching in the IPv4 packets. The following list describes the values of this field:

0: No bits are masked.
1: Lsb[0] is masked
2: Two Lsbs [1:0] are masked
.. 
31: All bits except MSb are masked.

Condition: IPv6 packets:

This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP source or destination address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.

Bit 5 **L3DAIM0**: Layer 3 IP DA Inverse Match Enable

When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching.

This bit is valid and applicable only when the L3DAM0 bit is set high.

Bit 4 **L3DAM0**: Layer 3 IP DA Match Enable

When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching.

*Note:* When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.

Bit 3 **L3SAIM0**: Layer 3 IP SA Inverse Match Enable

When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Source Address field is enabled for perfect matching.

This bit is valid and applicable only when the L3SAM0 bit is set.
Bit 2  **L3SAM0**: Layer 3 IP SA Match Enable
When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching.

*Note:* When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.

Bit 1  Reserved, must be kept at reset value.

Bit 0  **L3PEN0**: Layer 3 Protocol Enable
When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets.

The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set.

**Layer4 Address filter 0 register (ETH_MACL4A0R)**

Address offset: 0x0904
Reset value: 0x0000 0000

Bits 31:16  **L4DP0[15:0]**: Layer 4 Destination Port Number Field
When the L4PEN0 bit is reset and the L4DPM0 bit is set in the **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets.

When the L4PEN0 and L4DPM0 bits are set in **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.

Bits 15:0  **L4SP0[15:0]**: Layer 4 Source Port Number Field
When the L4PEN0 bit is reset and the L4DPM0 bit is set in the **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets.

When the L4PEN0 and L4DPM0 bits are set in **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.
**Layer3 Address 0 filter 0 register (ETH_MACL3A00R)**

Address offset: 0x0910  
Reset value: 0x0000 0000  
For IPv4 packets, the Layer 3 Address 0 filter 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Layer 3 Address 2 filter 0 register (ETH_MACL3A20R)

Address offset: 0x0918
Reset value: 0x0000 0000

The Layer 3 Address 2 filter 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[95:64] of 128-bit IP Source Address or Destination Address field.

Layer 3 Address 3 filter 0 register (ETH_MACL3A30R)

Address offset: 0x091C
Reset value: 0x0000 0000

The Layer 3 Address 3 filter 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[127:96] of 128-bit IP Source Address or Destination Address field.
RM0481 Ethernet (ETH): media access control (MAC) with DMA controller

Bits 31:0  **L3A30[31:0]:** Layer 3 Address 3 Field
When the L3PEN0 and L3SAM0 bits are set in the **L3 and L4 control 0 register (ETH_MACL3L4C0R),** this field contains the value to be matched with Bits[127:96] of the IP Source Address field in the IPv6 packets.
When the L3PEN0 and L3DAM0 bits are set in the **L3 and L4 control 0 register (ETH_MACL3L4C0R),** this field contains the value to be matched with Bits[127:96] of the IP Destination Address field in the IPv6 packets.
When the L3PEN0 bit is reset in the **L3 and L4 control 0 register (ETH_MACL3L4C0R),** this field is not used.

**L3 and L4 control 1 register (ETH_MACL3L4C1R)**

Address offset: 0x0930
Reset value: 0x0000 0000

The Layer 3 and Layer 4 Control register controls the operations of filter 1 of Layer 3 and Layer 4.

Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **L4DPM1:** Layer 4 Destination Port Match Enable
When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.
This bit is valid and applicable only when the L4DPM1 bit is set high.

Bit 20  **L4DPM1:** Layer 4 Destination Port Match Enable
When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.

Bit 19  **L4SPIM1:** Layer 4 Source Port Inverse Match Enable
When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.
This bit is valid and applicable only when the L4SPIM1 bit is set high.

Bit 18  **L4SPM1:** Layer 4 Source Port Match Enable
When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.

Bit 17  Reserved, must be kept at reset value.
Bit 16 **L4PEN1**: Layer 4 Protocol Enable

When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching.

The Layer 4 matching is done only when the L4SPM1 or L4DPM1 bit is set.

Bits 15:11 **L3HDBM1[4:0]**: Layer 3 IP DA higher bits match

Condition: IPv4 packets

This field contains the number of lower bits of IP Destination Address that are masked for matching in the IPv4 packets. The following list describes the values of this field:

0: No bits are masked.
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
...
31: All bits except MSb are masked.

Condition: IPv6 packets

Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM1, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM1[1:0] and L3HSBM1 bits:

0: No bits are masked
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
...
127: All bits except MSb are masked

This field is valid and applicable only when the L3DAM1 or L3SAM1 bit is set.

Bits 10:6 **L3HSBM1[4:0]**: Layer 3 IP SA Higher Bits Match

Condition: IPv4 packets

This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field:

0: No bits are masked.
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
...
31: All bits except MSb are masked.

Condition: IPv6 packets

This field contains Bits[4:0] of L3HSBM1. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM1 or L3SAM1 bit is set high.

Bit 5 **L3DAIM1**: Layer 3 IP DA Inverse Match Enable

When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching.

This bit is valid and applicable only when the L3DAM1 bit is set high.

Bit 4 **L3DAM1**: Layer 3 IP DA Match Enable

When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching.

*Note*: When the L3PEN1 bit is set, you should set either this bit or the L3SAM1 bit because either IPv6 DA or SA can be checked for filtering.
Bit 3 **L3SAIM1**: Layer 3 IP SA Inverse Match Enable  
When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching.  
When this bit is reset, the Layer 3 IP Source Address field is enabled for perfect matching.  
This bit is valid and applicable only when the L3SAM1 bit is set.

Bit 2 **L3SAM1**: Layer 3 IP SA Match Enable  
When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching.  
**Note:** When the L3PEN01 bit is set, you should set either this bit or the L3DAM1 bit because either IPv6 SA or DA can be checked for filtering.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **L3PEN1**: Layer 3 Protocol Enable  
When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets.  
The Layer 3 matching is done only when the L3SAM1 or L3DAM1 bit is set.

Bits 31:16 **L4DP1[15:0]**: Layer 4 Destination Port Number Field  
When the L4PEN1 bit is reset and the L4DPM1 bit is set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets.  
When the L4PEN1 and L4DPM1 bits are set in L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.

Bits 15:0 **L4SP1[15:0]**: Layer 4 Source Port Number Field  
When the L4PEN1 bit is reset and the L4DPM1 bit is set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets.  
When the L4PEN1 and L4DPM1 bits are set in L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.
Layer3 address 0 filter 1 Register (ETH_MACL3A01R)

Address offset: 0x0940
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 0 filter 1 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Bits 31:0 **L3A31[31:16]**: Layer 3 Address 3 Field
When the L3PEN1 and L3SAM1 bits are set in the **L3 and L4 control 1 register** ([ETH_MACL3L4C1R](#)), this field contains the value to be matched with Bits[95:64] of the IP Source Address field in the IPv6 packets.
When the L3PEN1 and L3DAM1 bits are set in the **L3 and L4 control 1 register** ([ETH_MACL3L4C1R](#)), this field contains the value to be matched with Bits[95:64] of the IP Destination Address field in the IPv6 packets.
When the L3PEN1 bit is reset in the **L3 and L4 control 1 register** ([ETH_MACL3L4C1R](#)), this field is not used.
Bits 31:0  **L3A31[31:0]: Layer 3 Address 3 Field**  
When the L3PEN1 and L3SAM1 bits are set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with Bits[127:96] of the IP Source Address field in the IPv6 packets.

When the L3PEN1 and L3DAM1 bits are set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with Bits[127:96] of the IP Destination Address field in the IPv6 packets.

When the L3PEN1 bit is reset in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field is not used.

**Timestamp control Register (ETH_MACTSCR)**

Address offset: 0x0B00

Reset value: 0x0000 2000

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

</tbody>
</table>

Bits 31:29  Reserved, must be kept at reset value.

**Bit 28 AV8021ASMEN: AV 802.1AS Mode Enable**

When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS operating mode.

When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit.

Bits 27:25  Reserved, must be kept at reset value.

**Bit 24 TTXTSSTM: Transmit Timestamp Status Mode**

When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TTXTSSMIS bit of the **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)** register.

When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TTXTSSMIS bit of the **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)**.

Bits 23:19  Reserved, must be kept at reset value.
Bit 18 **TSENMACADDR**: Enable MAC Address for PTP Packet Filtering  
When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet.  
When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet.  
For normal timestamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching.  
For PTP offload, only MAC address register 0 is considered for unicast destination address matching.

Bits 17:16 **SNAPTYPESEL[1:0]**: Select PTP packets for Taking Snapshots  
These bits, along with Bits 15 and 14, define the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Table 635: Timestamp Snapshot Dependency on ETH_MACTSCR bits.

Bit 15 **TSMSTRENA**: Enable Snapshot for Messages Relevant to Master  
When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.

Bit 14 **TSEVNTENA**: Enable Timestamp Snapshot for Event Messages  
When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Table 635: Timestamp Snapshot Dependency on ETH_MACTSCR bits.

Bit 13 **TSIPV4ENA**: Enable Processing of PTP Packets Sent over IPv4-UDP  
When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default.

Bit 12 **TSIPV6ENA**: Enable Processing of PTP Packets Sent over IPv6-UDP  
When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.

Bit 11 **TSIPENA**: Enable Processing of PTP over Ethernet Packets  
When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets.

Bit 10 **TSVER2ENA**: Enable PTP Packet Processing for Version 2 Format  
When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'.

Bit 9 **TSCTRLSSR**: Timestamp Digital or Binary Rollover Control  
When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of subsecond register is 0x7FFF_FFFF. The subsecond increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit.

Bit 8 **TSENALL**: Enable Timestamp for All Packets  
When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5  **TSADDR**: Update Addend Register
When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set.

Bit 4  Reserved, must be kept at reset value.

Bit 3  **TSUPDT**: Update Timestamp
When this bit is set, the system time is updated (added or subtracted) with the value specified in System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR).
This bit should be zero before updating it. This bit is reset when the update is complete in hardware.

Bit 2  **TSINIT**: Initialize Timestamp
When this bit is set, the system time is initialized (overwritten) with the value specified in the System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR).
This bit should be zero before it is updated. This bit is reset when the initialization is complete.

Bit 1  **TSCFUPDT**: Fine or Coarse Timestamp Update
When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp.

Bit 0  **TSENA**: Enable Timestamp
When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode.
On the Receive side, the MAC processes the 1588 packets only if this bit is set.

**Subsecond increment register (ETH_MACSSIR)**
Address offset: 0x0B04
Reset value: 0x0000 0000

In Coarse Update mode (bit TSCFUPDT in Timestamp control Register (ETH_MACTSCR)), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

</table>
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **SSINC[7:0]**: Subsecond Increment Value

The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the subsecond register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [TSCTRLSSR bit is set in *Timestamp control Register (ETH_MAC_TSCR)*]. When TSCTRLSSR is cleared, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.

Bits 15:0  Reserved, must be kept at reset value.
**System time seconds register (ETH_MACSTSR)**

Address offset: 0xB08
Reset value: 0x0000 0000

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Bits 31:0 **TSS[31:0]:** Timestamp Second

The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

**System time nanoseconds register (ETH_MACSTNR)**

Address offset: 0xB0C
Reset value: 0x0000 0000

The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

<table>
<thead>

Bit 31 **Reserved, must be kept at reset value.**

Bits 30:0 **TSSS[30:0]:** Timestamp subseconds

The value in this field has the subsecond representation of time, with an accuracy of 0.46 ns. When TSCTRLSSR is set in **Timestamp control Register (ETH_MACTSCR)**, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.
System time seconds update register (ETH_MACSTSUR)

Address offset: 0x0B10
Reset value: 0x0000 0000

The System Time Seconds Update register, along with the System Time Nanoseconds update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in Timestamp control Register (ETH_MACTSCR).

</thead>
</table>

Bits 31:0 TSS[31:0]: Timestamp Seconds
The value in this field is the seconds part of the update.
When ADDSUB is reset, this field must be programmed with the seconds part of the update value.
When ADDSUB is set, this field must be programmed with the complement of the seconds part of the update value.
For example, to subtract 2.000000001 seconds from the system time, the TSS field in the ETH_MACSTSUR register must be 0xFFFF_FFFE (that is, 2^32 – 2).

Caution: When the ADDSUB bit is set, TSS[30:0] field cannot be set to 0 in System time nanoseconds update register (ETH_MACSTNUR). The TSSS bitfield must be programmed to 0x7FFF FFFF (resulting in −0.46 ns) even if 0 ns must be subtracted.
For example, to subtract 2.000000000 seconds from the system time, the TSS field in the System time seconds update register (ETH_MACSTSUR) must be 0xFFFF FFFF (that is, 2^32 – 1) and the System time nanoseconds update register (ETH_MACSTNUR) must be 0xFFFF FFFF (ADDSUB = 1 and TSSS[30:0] field = 0x7FFF_FFFF)

System time nanoseconds update register (ETH_MACSTNUR)

Address offset: 0x0B14
Reset value: 0x0000 0000

</table>
Ethernet (ETH): media access control (MAC) with DMA controller

Bit 31 ADDSUB: Add or Subtract Time
   When this bit is set, the time value is subtracted with the contents of the update register.
   When this bit is reset, the time value is added with the contents of the update register.

Bits 30:0 TSSS[30:0]: Timestamp subseconds
   The value in this field is the subseconds part of the update.
      ADDSUB is 1: This field must be programmed with the complement of the subseconds part of the update value as described.
      ADDSUB is 0: This field must be programmed with the subseconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the Timestamp control Register (ETH_MACTSCR).
   TSCTRLSSR field in the Timestamp control Register (ETH_MACTSCR) is 1:
      - The programmed value must be 10^9 – <subsecond value>.
      - Each bit represents 1 ns and the programmed value should not exceed 0xB9A_C9FF.
   TSCTRLSSR field in the Timestamp control Register (ETH_MACTSCR) is 0:
      - The programmed value must be 2^31 - <subsecond_value>.
      - Each bit represents an accuracy of 0.46 ns.
For example, to subtract 2.000000001 seconds from the system time, then the TSSS field in the ETH_MACSTNUR register must be 0x7FFF_FFFF (that is, 2^31 – 1), when TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is reset and 0xB9A_C9FF (that is, 10^9 –1), when TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is set.

Caution: When the ADDSUB bit is set, TSSS[30:0] field cannot be set to 0. The TSSS bitfield must be programmed to 0x7FFF_FFFF (resulting in –0.46 ns) even if 0 ns must be subtracted.
For example, to subtract 2.000000000 seconds from the system time, System time nanoseconds update register (ETH_MACSTNUR) must be 0xFFFF_FFFF (ADDSUB = 1 and TSSS[30:0] = 0) and the TSS field in the System time seconds update register (ETH_MACSTSUR) must be 0xFFFF_FFFE (that is, 2^32 – 1).

Timestamp addend register (ETH_MACTSAR)
Address offset: 0x0B18
Reset value: 0x0000 0000
This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the Timestamp control Register (ETH_MACTSCR)). The content of this register is added to a 32-bit accumulator in every clock cycle of clk_ptp_ref_i and the system time is updated whenever the accumulator overflows.

Bits 31:0 TSAR[31:0]: Timestamp Addend Register
This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.
**Timestamp status register (ETH_MACTSSR)**

Address offset: 0x0B20

Reset value: 0x0000 0000

All bits except Bits[27:25] gets cleared when the application reads this register.

```

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:25  **ATSSN[4:0]**: Number of Auxiliary Timestamp Snapshots

This field indicates the number of Snapshots available in the FIFO. A value equal to the depth of FIFO (4) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set.

Bit 24  **ATSS TM**: Auxiliary Timestamp Snapshot Trigger Missed

This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO.

Bits 23:20  Reserved, must be kept at reset value.

Bits 19:16  **ATSSSTN[3:0]**: Auxiliary Timestamp Snapshot Trigger Identifier

These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list:

- Bit 16: Auxiliary trigger 0
- Bit 17: Auxiliary trigger 1
- Bit 18: Auxiliary trigger 2
- Bit 19: Auxiliary trigger 3

The software can read this register to find the triggers that are set when the timestamp is taken.

Bit 15  **TXTSSIS**: Tx Timestamp Status Interrupt Status

When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) and Tx timestamp status seconds register (ETH_MACTXTSSSR).

When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) and Tx timestamp status seconds register (ETH_MACTXTSSSR), for PTO generated Delay Request and Pdelay request packets.

This bit is cleared when the **Tx timestamp status seconds register (ETH_MACTXTSSSR)** is read (or written to 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bits 14:4  Reserved, must be kept at reset value.
Bit 3 **TSTRGTE0**: Timestamp Target Time Error
This bit is set when the latest target time programmed in the ETH_MACPPSTTSR and ETH_MACPPSTTSNR elapses (see PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)). This bit is cleared when the application reads this bit (or writes it to 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bit 2 **AUXSTRIG**: Auxiliary Timestamp Trigger Snapshot
This bit is set high when the auxiliary snapshot is written to the FIFO. This bit is cleared when the application reads this bit (or writes it to 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bit 1 **TSTARGT0**: Timestamp Target Time Reached
When set, this bit indicates that the value of system time is greater than or equal to the value specified in the ETH_MACPPSTTSR and ETH_MACPPSTTSNR registers (see PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)). This bit is cleared when the application reads this bit (or writes of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bit 0 **TSSOVF**: Timestamp Seconds Overflow
When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. This bit is cleared when the application reads this bit (or writes it to 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

**Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)**
Address offset: 0x0B30
Reset value: 0x0000 0000
This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

Bit 31 **TXTSSMIS**: Transmit Timestamp Status Missed
When this bit is set, it indicates one of the following:
- The timestamp of the current packet is ignored if TXTSSTSM bit of the Timestamp control Register (ETH_MACTSCR) is reset
- The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the Timestamp control Register (ETH_MACTSCR) is set.

Bits 30:0 **TXTSSL[30:0]**: Transmit Timestamp Status Low
This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.
**Tx timestamp status seconds register (ETH_MACTXTSSSR)**

Address offset: 0x0B34  
Reset value: 0x0000 0000  
The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

<table>

Bits 31:0 **TXTSSH[31:0]**: Transmit Timestamp Status High  
This field contains the lower 32 bits of the Seconds field of Transmit packet's captured timestamp.

**Auxiliary control register (ETH_MACACR)**

Address offset: 0x0B40  
Reset value: 0x0000 0000  
The Auxiliary Timestamp Control register controls the Auxiliary Timestamp snapshot.

</tbody>
</table>

Bits 31:8  
**Reserved, must be kept at reset value.**

**Bit 7 **ATSEN3: Auxiliary Snapshot 3 Enable  
– This bit controls the capturing of Auxiliary Snapshot Trigger 3. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg3 input is enabled. When this bit is reset, the events on this input are ignored.

**Bit 6 **ATSEN2: Auxiliary Snapshot 2 Enable  
– This bit controls the capturing of Auxiliary Snapshot Trigger 2. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg2 input is enabled. When this bit is reset, the events on this input are ignored.

**Bit 5 **ATSEN1: Auxiliary Snapshot 1 Enable  
– This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg1 input is enabled. When this bit is reset, the events on this input are ignored.
Bit 4 **ATSEN0**: Auxiliary Snapshot 0 Enable
This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg0 input is enabled. When this bit is reset, the events on this input are ignored.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **ATSFC**: Auxiliary Snapshot FIFO Clear
When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO.

**Auxiliary timestamp nanoseconds register (ETH_MACATSNR)**

Address offset: 0x0B48
Reset value: 0x0000 0000

The *Auxiliary timestamp nanoseconds register (ETH_MACATSNR)*, along with *Auxiliary timestamp seconds register (ETH_MACATSSR)*, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4 words.

You can store multiple snapshots in this FIFO. Bits[29:25] in *Timestamp status register (ETH_MACTSSR)* indicate the fill-level of the FIFO. The top of the FIFO is removed only when *Auxiliary timestamp seconds register (ETH_MACATSSR)* is read.

2920/3119
Bits 31:0  **AUXTSHI[31:0]**: Auxiliary Timestamp  
Contains the lower 32 bits of the Seconds field of the auxiliary timestamp.

**Timestamp Ingress asymmetric correction register (ETH_MACTSIACR)**  
Address offset: 0x0B50  
Reset value: 0x0000 0000  
The MAC Timestamp Ingress Asymmetry Correction register contains the Ingress Asymmetry Correction value to be used while updating correction field in PDelay_Resp PTP messages.

<table>

</tr>
</tbody>
</table>

Bits 31:0  **OSTIAC[31:0]**: One-Step Timestamp Ingress Asymmetry Correction  
This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 31 representing the sign bit.

**Timestamp Egress asymmetric correction register (ETH_MACTSEACR)**  
Address offset: 0x0B54  
Reset value: 0x0000 0000  
The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

</tr>
</tbody>
</table>

Bits 31:0  **OSTEAC[31:0]**: One-Step Timestamp Egress Asymmetry Correction  
This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFF_8000, which is the 2's complement of 0x0002_8000(2.5 * 2^16). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003_4CCC (3.3 * 2^16).
Timestamp Ingress correction nanosecond register (ETH_MACTSICNR)

Address offset: 0x0B58

Reset value: 0x0000 0000

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:5 TRGTMODSEL[1:0]: Target Time Register Mode for PPS Output
This field indicates the Target Time registers (PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)) mode for PPS output signal:
00: Target Time registers are programmed only for generating the interrupt event.
01: Reserved, must not be used
10: Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS output signal generation.
11: Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.

Bit 4 PPSEN0: Flexible PPS Output Mode Enable
When this bit is set, PPSCTRL[3:0] function as PPSCMD[3:0]. When this bit is reset, PPSCTRL[3:0] function as PPSCTRL (Fixed PPS mode).

Bits 3:0 PPSCTRL[3:0]: PPS Output Frequency Control
This field controls the frequency of the PPS output (eth_ptp_pps_out) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies:
0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz.
0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz.
0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz.
0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz.

.. 1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz.

Note: In the binary rollover mode, the PPS output (eth_ptp_pps_out) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:
- When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms
- When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of
  One clock of 50 percent duty cycle and 537 ms period
  Second clock of 463 ms period (268 ms low and 195 ms high)
- When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of
  Three clocks of 50 percent duty cycle and 268 ms period
  Fourth clock of 195 ms period (134 ms low and 61 ms high)

This behavior is because of the non-linear toggling of bits in the digital rollover mode in the ETH_MACSTNR register.
**PPS control register [alternate] (ETH_MACPPSCR)**

Address offset: 0x0B70  
Reset value: 0x0000 0000

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:5 **TRGTMODSEL0[1:0]**: Target Time Register Mode for PPS Output

- This field indicates the Target Time registers ([**PPS target time seconds register (ETH_MACPPSTTSR)**](#) and **PPS target time nanoseconds register (ETH_MACPPSTTNR)**) mode for PPS output signal:
  - 00: Target Time registers are programmed only for generating the interrupt event.
  - 01: Reserved, must not be used
  - 10: Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS output signal generation.
  - 11: Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.

Bit 4 **PPSEN0**: Flexible PPS Output Mode Enable

When this bit is set, Bits[3:0] function as PPSCMD[3:0]. When this bit is reset, Bits[3:0] function as PPSCTRL(Fixed PPS mode).
Bits 3:0 **PPSCMD[3:0]**: Flexible PPS Output (eth_ptp_pps_out) Control

Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all zero'. The following list describes the values of PPSCMD[3:0]:

- **0000**: No Command
- **0001**: START Single Pulse.
  This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS Width Register.
- **0010**: START Pulse Train.
  This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands.
- **0011**: Cancel START.
  This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time.
- **0100**: STOP Pulse Train at time.
  This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD[3:0] = 0010) after the time programmed in the Target Time registers elapses.
- **0101**: STOP Pulse Train immediately.
  This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD[3:0] = 0010).
- **0110**: Cancel STOP Pulse train.
  This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command.
- **0111 to 1111**: Reserved, must not be used

**PPS target time seconds register (ETH_MACPPSTTSR)**

Address offset: 0x0B80
Reset value: 0x0000 0000

The PPS output Target Time Seconds register, along with **PPS target time nanoseconds register (ETH_MACPPSTTNR)**, is used to schedule an interrupt event (Bit TSSOVF of Timestamp status register (ETH_MACTSSR)) when the system time exceeds the value programmed in these registers.

**ST**

RM0481 Rev 1  2925/3119
Bits 31:0 **TSTRH0[31:0]**: PPS Target Time Seconds Register
This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the **PPS control register (ETH_MACPPSCR)**.

**PPS target time nanoseconds register (ETH_MACPPSTTNR)**
Address offset: 0x0B84
Reset value: 0x0000 0000
The PPS Target Time Nanoseconds register is present only when more than one Flexible PPS output is selected.

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

| TTSL0[15:0] |
| rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw |

Bit 31 **TRGTBUSY0**: PPS Target Time Register Busy
The MAC sets this bit when the PPSCMD0 field in the **PPS control register (ETH_MACPPSCR)** is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers with the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.

**PPS interval register (ETH_MACPPPSIR)**
Address offset: 0x0B88
Reset value: 0x0000 0000
The PPS Interval register contains the number of units of subsecond increment value between the rising edges of PPS output.
RM0481 Ethernet (ETH): media access control (MAC) with DMA controller

PPS INT0[31:16]: PPS Output Signal Interval

These bits store the interval between the rising edges of PPS signal output. The interval is stored in terms of number of units of subsecond increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS signal output is 100 ns (that is, 5 units of subsecond increment value), you should program value 4 (5-1) in this register.

**PPS width register (ETH_MACPPSWR)**

Address offset: 0x0B8C
Reset value: 0x0000 0000
The PPS Width register contains the number of units of subsecond increment value between the rising and corresponding falling edges of PPS output.

Bits 31:0 PPS WIDTH0[31:0]: PPS Output Signal Width

These bits store the width between the rising edge and corresponding falling edge of PPS signal output. The width is stored in terms of number of units of subsecond increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS signal output is 80 ns (that is, four units of subsecond increment value), you should program value 3 (4-1) in this register.

**Note:** The value programmed in this register must be lesser than the value programmed in PPS interval register (ETH_MACPPSIR).
PTP Offload control register (ETH_MACPOCR)

Address offset: 0x0BC0
Reset value: 0x0000 0000

This register controls the PTP Offload Engine operation.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 DN[7:0]: Domain Number
This field indicates the domain Number in which the PTP node is operating.

Bit 7 Reserved, must be kept at reset value.

Bit 6 DRRDIS: Disable PTO Delay Request/Response response generation
When this bit is set, the Delay Request and Delay response are not generated for received
SYNC and Delay request packet respectively, as required by the programmed mode.

Bit 5 APDREQTRIG: Automatic PTP Pdelay_Req message Trigger
When this bit is set, one PTP Pdelay_Req message is transmitted. This bit is automatically
cleared after the PTP Pdelay_Req message is transmitted. The application should set the
APDREQEN bit for this operation.

Bit 4 ASYNCTRIG: Automatic PTP SYNC message Trigger
When this bit is set, one PTP SYNC message is transmitted. This bit is automatically cleared
after the PTP SYNC message is transmitted. The application should set the ASYNCE bit for
this operation.

Bit 3 Reserved, must be kept at reset value.

Bit 2 APDREQEN: Automatic PTP Pdelay_Req message Enable
When this bit is set, PTP Pdelay_Req message is generated periodically based on interval
programmed or trigger from application, when the MAC is programmed to be in Peer-to-Peer
Transparent mode.

Bit 1 ASYNCE: Automatic PTP SYNC message Enable
When this bit is set, PTP SYNC message is generated periodically based on interval
programmed or trigger from application, when the MAC is programmed to be in Clock Master
mode.

Bit 0 PTOEN: PTP Offload Enable
When this bit is set, the PTP Offload feature is enabled.

PTP Source Port Identity 0 Register (ETH_MACSPI0R)

Address offset: 0x0BC4
Reset value: 0x0000 0000

This register contains Bits[31:0] of the 80-bit Source Port Identity of the PTP node.
RM0481  Ethernet (ETH): media access control (MAC) with DMA controller

**PTP Source port identity 1 register (ETH_MACSPI1R)**

Address offset: 0x0BC8  
Reset value: 0x0000 0000  
This register contains Bits[63:32] of the 80-bit Source Port Identity of the PTP node.

**PTP Source port identity 2 register (ETH_MACSPI2R)**

Address offset: 0x0BCC  
Reset value: 0x0000 0000  
This register contains Bits[79:64] of the 80-bit Source Port Identity of the PTP node.

Bits 31:0  **SPI0[31:0]**: Source Port Identity 0  
This field indicates bits [31:0] of sourcePortIdentity of PTP node.

Bits 31:0  **SPI1[31:0]**: Source Port Identity 1  
This field indicates bits [63:32] of sourcePortIdentity of PTP node.

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **SPI2[15:0]**: Source Port Identity 2  
This field indicates bits [79:64] of sourcePortIdentity of PTP node.
Log message interval register (ETH_MACLMIR)

Address offset: 0x0BD0
Reset value: 0x0000 0000

This register contains the periodic intervals for automatic PTP packet generation.

Bits 31:24 **LMPDRI[7:0]**: Log Min Pdelay_Req Interval
This field indicates logMinDelayReqInterval of PTP node. This is used to schedule the periodic Pdelay request packet transmission. Allowed values are -15 to 15. Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.

Bits 23:11 Reserved, must be kept at reset value.

Bits 10:8 **DRSYNCR[2:0]**:
Delay_Req to SYNC Ratio
In Slave mode, it is used for controlling frequency of Delay_Req messages transmitted.
0: DelayReq generated for every received SYNC
1: DelayReq generated every alternate reception of SYNC
2: for every 4 SYNC messages
3: for every 8 SYNC messages
4: for every 16 SYNC messages
5: for every 32 SYNC messages
Others: Reserved, must not be used
The master sends this information (logMinDelayReqInterval) in the DelayResp PTP messages to the slave. The reception processes this value from the received DelayResp messages and updates this field accordingly. In the Slave mode, the host must not write/update this register unless it has to override the received value. In Master mode, the sum of this field and logSyncInterval (LSI) field is provided in the logMinDelayReqInterval field of the generated multicast Delay_Resp PTP message.

Bits 7:0 **LSI[7:0]**:
Log Sync Interval
This field indicates the periodicity of the automatically generated SYNC message when the PTP node is Master. Allowed values are -15 to 15. Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.

58  Debug support (DBG)

58.1  Introduction

A comprehensive set of debug features is provided to support software development and system integration:

- Breakpoint debugging of the CPU core
- Code execution tracing
- Software instrumentation
- Cross-triggering

The debug features can be controlled via a JTAG/Serial-wire debug access port, using industry standard debugging tools. A trace port allows data to be captured for logging and analysis.

The debug features are based on Arm® CoreSight™ components.

- SWJ-DP: JTAG/Serial-wire debug port
- AHB-AP: AHB access port
- ROM table
- System control space (SCS)
- Breakpoint unit (BPU)
- Data watchpoint and trace unit (DWT)
- Instrumentation trace macrocell (ITM)
- Embedded Trace Macrocell™ (ETM)
- Cross trigger interface (CTI)
- Trace port interface unit (TPU)

The debug features are accessible by the debugger via the AHB-AP.

Additional information can be found in the Arm® documents referenced in Section 58.13.

58.2.3  **DBG reset and clocks**

The debug port (SWJ-DP) is reset by a power-on reset and when waking up from Standby mode.

The debugger supplies the clock for the debug port via the debug interface pin JTCK/SWCLK. This clock is used to register the serial input data in both serial-wire and JTAG modes, as well as to operate the state machines and internal logic of the debug port. This clock must therefore continue to toggle for several cycles after the end of an access, to ensure that the debug port returns to the idle state.

The SWJ-DP contains an asynchronous interface to the DCLK domain that covers the rest of the SWJ-DP and the access port.

The DCLK is a gated version of the system clock.

The DCLK domain is enabled by the debugger using the CDBGPWRUPREQ bit in the **DP control and status register (DP_CTRL/STATR)**. The clock must be enabled before the debugger can access any of the debug features on the device. The availability of the clock is reflected in the CDBGPWRUPACK bit in DP_CTRL/STATR. The DCLK is disabled at power-up, and must be disabled when the debugger is disconnected, to avoid wasting energy.

The debug and trace components included in the processor are clocked with the processor clock.

58.2.4  **DBG power domains**

The debug components are located in the core power domain. This means that the debugger connection is not possible in Shutdown or Standby low-power mode. To avoid losing the connection when the device enters Standby mode, the power can be maintained to the core by setting a bit in the **DBGMCU configuration register (DBGMCU_CR)**. This also keeps the processor clocks active and holds off the reset, so that the debug session is maintained.

58.2.5  **Debug and low-power modes**

The devices include power saving features that allow the core power domain to be switched off or stopped when not required. If the power is switched off or if the core is not clocked, all debug components are inaccessible to the debugger. To avoid this, power-saving mode emulation is implemented. If the emulation is enabled for a domain, the domain still enters power-saving mode, but its clock and power are maintained. In other words, the domain behaves as if it is in power-saving mode, but the debugger does not lose the connection.

The emulation mode is programmed in the microcontroller debug (DBGMCU) unit. For more information refer to **Section 58.12: Microcontroller debug unit (DBGMCU)**.

### Table 686. Single-wire trace port pins

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1. TRACESWO is multiplexed with JTDO. This means that single-wire trace is only available when using the serial-wire debug interface, and not when using JTAG.
58.2.6 Security

The trace and debug components allow a high degree of access to the processor and system during product development. In order to protect user code and ensure that the debug features cannot be used to alter or compromise the normal operation of the finished product, these features can be disabled or limited in scope. For example, secure software debug and trace can be disabled without preventing the debug of non-secure code.

Debugger access to secure memory (when permitted) must be performed using secure transactions on the debug AHB, that is, with the PROT[6] bit set in the AP1 control/status word register (AP1_CSWR).

Debugger access is disabled while the processor is booting from system flash memory.

The following authentication signals are used by the system to determine which debug features are enabled or disabled:

- **dbgen**: global enable for all debug features
  - 0: All debug features are disabled.
  - 1: Debug features in non-secure state are enabled. Debug features in secure state are dependent on the state of the **spiden** signal.

- **spiden**: enables debug in secure state when **dbgen** = 1.
  - 0: Debug features are disabled in secure state.
  - 1: Debug features are enabled in secure state.

- **niden**: enables trace and performance monitoring (non-invasive debug).
  - 0: Trace generation is disabled.
  - 1: Trace generation in non-secure state is enabled. Trace generation in secure state is dependent on the state of the **spniden** signal.

- **spniden**: enables trace and performance monitoring in secure state when **niden** = 1.
  - 0: Trace generation is disabled in secure state.
  - 1: Trace generation is enabled in secure state.

For detailed information on the behavior of each component according to the state of the authentication signals, refer to the relevant chapter, or to the relevant Arm® technical documentation.

The state of the signals are set according to the debug state as shown in Table 687, when TrustZone is enabled (TZEN = 0xB4), and Table 688 when TrustZone is disabled (TZEN = 0xC3).

<table>
<thead>
<tr>
<th>Debug state</th>
<th>Authentication signal state</th>

1. Depends on authorization level.
58.2.7 Debug authentication

Figure 830. Product life cycle states and debug authentication

Figure 830 shows the product life cycle and debug authentication states.

If the device is in CLOSED (product life cycle) state, the debug state is CLOSED. The debug authentication procedure allows a trusted debugger to reopen access without compromising sensitive information called the Root Of Trust (ROT).

Reopening the debug is possible only if sensitive asset security is ensured (and TrustZone is enabled (TZEN = 0xB4). This is called Constrained Debug, as constraints ensure the security of the ROT information.

Alternatively, a partial or full regression mechanism can be used when security of sensitive information cannot be guaranteed. This is called Regression, as regression ensures removal of the sensitive information before reopening the debug.

- Partial regression corresponds to releasing non-secure code and assets. The intermediate state which allows partial regression management is called NS-Regression.
- Full regression corresponds to releasing all code and assets. The intermediate state allowing full regression management is called Regression.

Debug authentication control principle

The debug authentication is one of the most critical security features of the system considering that with a debugger the user can access a large part of the system.

To control re-opening of the debug, the device imposes a debug authentication protocol.
The protocol implements a challenge response mechanism based on asymmetric cryptography to authenticate the host. It relies on a key pair, with a Public Key stored in the device, and a Private Key from the host library, used to sign a random value (the challenge) generated by the device.

The protocol implements a bidirectional communication between the host and the device through a mailbox interface located in the DBGMCU.

The host can write to the mailbox via the JTAG/SWD interface. It expects to get responses and messages from the device via the same mailbox.

The debug authentication protocol is launched on a power-on reset of the device, when an “open request” message is posted by the host.

The protocol is based on:
- Initial message: posted by the host combined with a reset to launch the debug authentication process on the device.
- Challenge message: the device generates a random value, to be signed by the host, when sending back the response.
- Response: the host sends a message to the device proving its authenticity. This is done using a tool to generate a token.

The implementation is ensured by code embedded in the system flash. This code is called automatically after reset if an initial message has been posted by the host in the mailbox.

After a first sequence of mutual authentication to align on protocol version, type of device, and similar parameters, the device generates a random value that to be signed by the host with a private key when building the response.

The STMicroelectronics implementation is based on the Arm® PSA-ADAC solution for debug authentication.

The debug authentication can be implemented using a proprietary or open source protocol. As this feature is critical for security, the STM32H5 devices come with debug authentication provisioned in system flash. STMicroelectronics provides the host tools integrated with some debug environments (IDEs).

### Debug authentication provisioning

Debug authentication is natively supported by STM32H5 platform. It means that the data used by ST debug authentication (ST-DA) must be provisioned at a defined location in secure key storage area (OBKeys defined in flash memory).

The debug authentication configuration must be done only when the PRODUCT_STATE is “Provisioning”, cannot be performed when PRODUCT_STATE is “Open”.

The following data must be provisioned (refer to Section 7.7.2: RSS user functions):
- Data must be provisioned at the very beginning of the OBK_HDPL1 mapping (0x0FFD 0100) (see Section 7.5.2: OBK access per HDPL level)
- RSS_Lib encryption option must be set for STM32H57x devices
- RSS_Lib encryption option must be reset for STM32H56x devices

The data to provision are defined in Table 690, they depend upon the TZEN option byte setting (enabled or disabled).
Caution: Configure debug authentication as explained above before changing to states different from Open or Provisioning.

58.3 Serial-wire and JTAG debug port (SWJ-DP)

The SWJ-DP is a CoreSight™ component that implements an external access port for connecting debugging equipment.

Two types of interface can be configured:
- a 5-pin standard JTAG interface (JTAG-DP)
- a 2-pin (clock + data) serial-wire debug port (SW-DP)

These two modes are mutually exclusive, since they share the same IO pins.

By default, the JTAG-DP is selected after a system or a power-on reset. The five IO pins are configured by hardware in debug alternative function mode. The SWJ-DP incorporates pull-up resistors on JTDI, JTMS/SWDIO, and nJTRST, as well as a pull-down resistor on JTCK/SWCLK.

A debugger can select the SW-DP by transmitting the following serial data sequence on JTMS/SWDIO:

... (50 or more ones) ..., 0, 1, 1, 1, 1, 0, 0, 1, 1, 1, 1, 0, 0, 1, 1, 1, ... (50 or more ones) ...
JTCK/SWCLK must be cycled for each data bit.

In SW-DP mode, the unused JTAG pins JTDI, JTDO and nJTRST can be used for other functions.

**Note:** All SWJ port IOs can be reconfigured to other functions by software, but debugging is no longer possible.

### 58.3.1 JTAG debug port

The JTAG-DP implements a TAP state machine (TAPSM), shown in the figure below, based on IEEE Std 1149.1-1990. The state machine controls two scan chains, one associated with an instruction register (IR) and the other one with a number of data registers (DR).

---

**Figure 831. JTAG TAP state machine**

---
The operation of the JTAG-DP is as follows:

1. When the TAPSM goes through the Capture-IR state, 0b0001 is transferred to the instruction register (IR) scan chain. The IR scan chain is connected between JTDI and JTDO.

2. While the TAPSM is in the Shift-IR state, the IR scan chain shifts one bit for each rising edge of JTCK. This means that on the first tick:
   - The LSB of the IR scan chain is output on JTDO.
   - Bit[n] of the IR scan chain is transferred to bit[n-1].
   - The value on JTDI is transferred to the MSB of the IR scan chain.

3. When the TAPSM goes through the Update-IR state, the value scanned into the IR scan chain is transferred to the instruction register.

4. When the TAPSM goes through the Capture-DR state, a value is transferred from one of the data registers to one of the DR scan chains, connected between JTDI and JTDO.

5. The value held in the instruction register determines which data register, and associated DR scan chain, are selected.

6. This data is then shifted while the TAPSM is in the Shift-DR state, in the same manner as the IR shifts in the Shift-IR state.

7. When the TAPSM goes through the Update-DR state, the value scanned into the DR scan chain is transferred to the selected data register.

8. When the TAPSM is in the Run-Test/Idle state, no special actions occurs. The IDCODE instruction is loaded in IR.

When active, the nJTRST signal resets the state machine asynchronously to the test-logic-reset state.

The data registers corresponding to the 4-bit IR instructions are listed in the table below.

### Table 692. JTAG-DP data registers

<table>
<thead>
<tr>
<th>IR instruction</th>

<th>Scan chain length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000 to 0111 (BYPASS)</td>
<td>1</td>
<td>Not implemented: BYPASS selected</td>
<td></td>
</tr>
</tbody>
</table>
| 1000 | ABORT | 35 | ABORT register
   - bits 34:3 = APABORT[31:0]: Write 0x0000 0001 to abort an ongoing access port transaction
   - bits 2:1 = A[3:2] = 00
   - bit 0 = RnW = 0: write only |
| 1001 (BYPASS) | 1 | Reserved: BYPASS selected |
The DR registers are described in more detail in the Arm® Debug Interface Architecture Specification (see Section 58.13).

### 58.3.2 Serial-wire debug port

The serial-wire debug protocol uses the following pins:
- **SWCLK**: clock from host to target
- **SWDIO**: bi-directional serial data (100 kΩ pull-up required)

Serial data is transferred LSB first, synchronously with the clock.

A transfer comprises three phases:

<table>
<thead>
<tr>
<th>IR instruction</th>
<th>DR register</th>
<th>Scan chain length</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1010           | DPACC       | 35                | Debug port access register

### Table 694. ACK response

<table>
<thead>
<tr>
<th>Bit field</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 2:0       | ACK  | – 000: FAULT  
            |       | – 010: WAIT  
            |       | – 100: OK    |

### Table 695. Data transfer

<table>
<thead>
<tr>
<th>Bit field</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:0</td>
<td>WDATA or RDATA</td>
<td>Write or read data</td>
</tr>
<tr>
<td>32</td>
<td>Parity</td>
<td>Single-bit parity of 32 data bits</td>
</tr>
</tbody>
</table>

In the case of a FAULT or WAIT ACK response from the target, the data transfer phase is canceled, unless overrun detection is enabled: in this case, the data is ignored by the target (in the case of a write), or not driven (in the case of a read).

A line reset must be generated by the host when it is first connected, or following a protocol error. The line reset consists in 50 or more SWCLK cycles with SWDIO high, followed by two SWCLK cycles with SWDIO low.

For more details on the serial-wire debug protocol, refer to the Arm® Debug Interface Architecture Specification [1].

**Note:** The SWJ-DP implements SWD protocol version 2.
58.3.3 Debug port registers

Both the SW-DP and the JTAG-DP access the debug port (DP) registers listed in Table 697. The debugger can access the DP registers as follows:

1. Program the A(3:2) field in the DPACC register, if using JTAG, with the register address within the bank. Program the RnW bit to select a read or write. In the case of a write, program the data field with the write data. If using SWD, the A(3:2) and RnW fields are part of the packet request word sent to the SW-DP with the APnDP bit reset (see Table 693). The write data are sent in the data phase.

2. To access one of the banked DP registers at address 0x4, the register number must first be written to the DP_SELECTR register at address 0x8. Any subsequent read or write to address 0x4 accesses the register corresponding to the contents of the DP_SELECTR register.

### Table 696. Debug port registers

<table>
<thead>

Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **CDBGPWRUPACK**: debug power-up acknowledge
See description in *Section 58.2.5: Debug and low-power modes*.
0: DCLK gated
1: DCLK enabled

Bit 28  **CDBGPWRUPREQ**: debug power-up request
This bit controls the DCLK enable request signal.
0: requests DCLK gating
1: requests DCLK enable
Bits 27:8  Reserved, must be kept at reset value.

Bit 7  **WDATAERR**: write data error (read-only) in SW-DP
This bit indicates that there is a parity or framing error on the data phase of a write, or a write accepted by the DP is then discarded without being submitted to the AP. This bit is reset by writing 1 to the ABORT.WDERRCLR bit.

0: no error
1: an error occurred

*Note: This bit is reserved in JTAG-DP.*

Bit 6  **READOK**: AP read response (read-only) in SW-DP
This bit indicates the response to the last AP read access.

0: read not OK
1: read OK

*Note: This bit is reserved in JTAG-DP.*

Bit 5  **STICKYERR**: transaction error (read-only in SW-DP, read/write in JTAG-DP)
This bit indicates that an error occurred in an AP transaction. It is reset by writing 1 to the DP_ABORTR.STKERRCLR bit (in SW-DP and JTAG-DP)

0: no error
1: an error occurred

Bits 4:2  Reserved, must be kept at reset value.

Bit 1  **STICKYORUN**: overrun (read-only in SW-DP, read/write in JTAG-DP).
This bit indicates that an overrun occurred (new transaction received before previous transaction completed). This bit is only set if the ORUNDETECT bit is set. It is reset by writing 1 to the DP_ABORTR.ORUNERRCLR bit (in SW-DP and JTAG-DP).

0: no overrun
1: an overrun occurred

Bit 0  **ORUNDETECT**: overrun detection mode enable.

0: disabled
1: enabled. In the event of an overrun, the STICKYORUN bit is set and subsequent transactions are blocked until the STICKYORUN bit is cleared.

---

0x01: AP1 - Cortex®-M33 debug access port (AHB-AP)
Others: reserved
58.3.4 Debug port register map and reset values

These registers are not on the CPU memory bus, they are accessed only through SW-DP and JTAG-DP debug interface.

The debug port address offset is 4-bit wide, where the two most significant bits are defined in the JTAG-DP register DPACC or SW-DP packet request A[3:2] field. The two least significant bits are 00.

2960/3119 RM0481 Rev 1
There are two access ports (AP) attached to the DP.

- System debug access port (AP0): Enables access to the DBGMCU and the system ROM table via an APB bus.
- Cortex®-M33 debug access port (AP1): Enables access to the debug and trace features integrated in the Cortex®-M33 processor core via its internal AHB bus.
58.4.1 Access port registers

The access ports are of type MEM-AP: the debug and trace component registers are mapped in the address space of the AHB. The AP is seen by the debugger as a set of 32-bit registers organized in banks of four registers each. Some of these registers are used to configure or monitor the AP itself, while others are used to perform a transfer on the bus. The AP registers are listed in Table 699.

The address of the AP registers is composed of the following fields:

- bits [7:4]: content of the APBANKSEL[3:0] field in the DP access port select register (DP_SELECTR)
- bits [3:2]: content of the A(3:2) field of the APACC data register in the JTAG-DP (see Table 692), or of the SW-DP packet request (see Table 693), depending on the debug interface used
- bits [1:0]: always set to 0

The content of the DP_SELECTR.APSEL[3:0] field defines which MEM-AP is being accessed.

The debugger can access the AP registers as follows:

1. Program the APSEL[3:0] field in the DP access port select register (DP_SELECTR) to choose the AP, and the APBANKSEL[3:0] field in DP_SELECTR to select the register bank to be accessed.

2. Program the A(3:2) field in the APACC data register, if using JTAG, with the register address within the bank. Program the RnW bit to select a read or write. In the case of a write, program the DATA field with the write data. If using SWD, the A(3:2) and RnW fields are part of the packet request word sent to the SW-DP with the APnDP bit set (see Table 693). The write data is sent in the data phase.

The debugger can access the memory mapped debug component registers through the AP registers (using the above AP register access procedure) as follows:

1. Program the transaction target address in the APx transfer address register (APx_TAR) (x = 0, 1).

2. Program the AP1 control/status word register (AP1_CSWR), if necessary, with the transfer parameters (AddrInc for example).

3. Write to or read from the APx data read/write register (APx_DRWR) (x = 0, 1) to initiate a bus transaction at the address held in AP_TAR. Alternatively, a read or write to the APx banked data n register (APx_BDnR) (x = 0, 1) triggers an access to TAR[31:4] + n address, allowing up to four consecutive addresses to be accessed without changing the address in the AP_TAR register.

For more detailed information on the MEM-AP refer to the Arm® Debug Interface Architecture Specification [1].

0: disable software access
1: enable software access

Bits 30:12 Reserved, must be kept at reset value.

Bits 11:8 MODE[3:0]: mode of operation
0b0000: normal download or upload
other: reserved

Bit 7 TRINPROG: transfer in progress (read only)
This field indicates whether a transfer is currently in progress on the APB master port
0: no APB transfer in progress
1: APB transfer in progress

Bit 6 DEVICEEN: device enable status (read only)
1: APB transfers always enabled

Bits 5:4 ADDRINC[1:0]: auto-increment mode
Defines whether TAR address is automatically incremented after a transaction.
0x0: no auto-increment
0x1: address incremented by the size in bytes of the transaction (SIZE field)
other: reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 SIZE[2:0]: size of next memory access transaction
0x2: word (32-bit)
Bit 31  Reserved, must be kept at reset value.

Bit 30  **SPROT**: secure transfer request
This field sets the protection attribute HPROT[6] of the bus transfer.
0: secure transfer, HPROT[6] = low
1: non-secure transfer, HPROT[6] = high
If SPIDEN = 0 and SPROT = 0, no bus transfer occurs

Bits 29:28  Reserved, must be kept at reset value.

Bits 27:24  **PROT[3:0]**: bus transfer protection
This field sets the protection attributes HPROT[3:0] of the bus transfer.
0bXXX0: instruction access
0bXXX1: data access
0bXXOX: user mode
0bXX1X: privilege mode
0bX0XX: non-bufferable
0bX1XX: bufferable
0b0XXX: non-shareable, no look-up, non-modifiable
0b1XXX: shareable, look-up, modifiable

Bit 23  **SPISTATUS**: secure debug authentication status
This field indicates the state of the SPIDEN signal
0: No secure AHB transfers allowed
1: Secure AHB transfers allowed

Bits 22:8  Reserved, must be kept at reset value.

Bit 7  **TRINPROG**: transfer in progress (read only)
This field indicates whether a transfer is currently in progress on the APB master port
0: No AHB transfer in progress
1: AHB transfer in progress

Bit 6  **DBGSTATUS**: debug enable (DBGEN) status
0: AHB transfers blocked
1: AHB transfers enabled

Bits 5:4  **ADDRINC[1:0]**: auto-increment mode
Defines whether TAR address is automatically incremented after a transaction.
0x0: no auto-increment
0x1: address incremented by the size of the transaction (SIZE field), in bytes. Single transfer.
0x2: address incremented by the size of the transaction (SIZE field), in bytes. Packs four 8-bit transfers or two 16-bit transfers into a 32-bit DAP transfer. Multiple transactions are carried out on the AHB interface.
Others: reserved

Bit 3  Reserved, must be kept at reset value.

Bits 2:0  **SIZE[2:0]**: size of next memory access transaction
0x0: byte (8-bit)
0x1: halfword (16-bit)
0x2: word (32-bit)
Others: reserved
APx transfer address register (APx_TAR) (x = 0, 1)
Address offset: 0x04
Reset value: 0xXXXX XXXX

</table>

Bits 31:12 **BASEADDR[31:12]**: base address (bits 31 to 12) of the first ROM table

The 12 LSBs are zero since the ROM table must be aligned on a 4-Kbyte boundary.

- 0xE00E0: AP0
- 0xE00FE: AP1

Bits 11:2 Reserved, must be kept at reset value.

- Bit 1 **FORMAT**: base-address register format
  - 1: Arm® debug interface v5

- Bit 0 **ENTRYPRESENT**: debug components presence
  - Indicates that debug components are present on the access port bus.
  - 1: debug components present

### APx identification register (APx_IDR) (x = 0, 1)

</table>

Reset value for each register is shown in the table.
The ROM table is a CoreSight™ component that contains the base addresses of the CoreSight™ debug components accessible via the access port to which it is attached. These tables allow a debugger to discover the topology of the CoreSight™ system automatically.

There is one top level ROM table behind each access port, APn. The base address of this ROM table can be obtained by reading the APn_BASER register of the access port. The top level ROM table may point in turn to other ROM tables.

The system ROM table is pointed to by the AP0 base register, AP0_BASER. It contains the base address pointer for the DBGMCU.

The system ROM table occupies a 4-Kbyte, 32-bit wide chunk of address space, from 0xE00E 0000 to 0xE00E 0FFC, when accessed by the debugger. It can be accessed by the CPU at address range 0x4402 0000 to 0x4402 0FFC.
There are two ROM tables in the CPU sub-system. The MCU ROM table is pointed to by the AP1 base register, AP1_BASER. It contains the base-address pointer for the processor ROM table and for the TPIU registers.

The MCU ROM table (see the table below) occupies a 4-Kbyte, 32-bit wide chunk of address space, from 0xE00F E000 to 0xE00F EFFC.

<table>

There are two ROM tables in the CPU sub-system. The MCU ROM table is pointed to by the AP1 base register, AP1_BASER. It contains the base-address pointer for the processor ROM table and for the TPIU registers.

The MCU ROM table (see the table below) occupies a 4-Kbyte, 32-bit wide chunk of address space, from 0xE00F E000 to 0xE00F EFFC.

The processor ROM table contains the base-address pointer for the system control space (SCS) registers, that allow the debugger to identify the CPU core, as well as for the BPU, DWT, ITM, ETM and CTI.

The processor ROM table (see the table below) occupies a 4-Kbyte, 32-bit wide chunk of address space, from 0xE00F F000 to 0xE00F FFFC.

Refer to Table 702: Processor ROM table for register boundary addresses.

58.6 Data watchpoint and trace unit (DWT)

The DWT provides four comparators that can be used as one of the following:
- watchpoint
- ETM trigger
- PC sampling trigger
- data address sampling trigger
- data comparator (COMP 1 only)
- clock cycle counter comparator (COMP 0 only)

It also contains counters for:
- clock cycles
- folded instructions
- load store unit (LSU) operations
- sleep cycles
- number of cycles per instruction
- interrupt overhead
A DWT comparator compares the value held in its DWT comparator \textit{x} register (\textit{DWT_COMP}x\textit{R}) with one of the following:

- a data address
- an instruction address
- a data value
- the cycle-count value, for COMP 0 only

For address matching, the comparator can use a mask, so it matches a range of addresses.

On a successful match, the comparator generates one of the following:

- one or more DWT data trace packets, containing one or more of:
  - the address of the instruction that caused a data access
  - an address offset, bits[15:0] of the data access address
  - the matched data value
- a watchpoint debug event, on either the PC value or the accessed data address
- a CMPMATCH[N] event, that signals the match outside the DWT unit

A watchpoint debug event either generates a DebugMonitor exception, or causes the processor to halt execution and enter debug state.

For more details on how to use the DWT, refer to the Arm®v8-M Architecture Reference Manual [4].

### 58.6.1 DWT registers

The DWT registers are located at address range 0xE000 1000 to 0xE000 1FFC.

#### DWT control register (DWT_CTRLR)

Address offset: 0x000

Reset value: 0x4000 0000

</table>
Bits 31:28 **NUMCOMP[3:0]**: number of comparators implemented (read only)
- 0x4: four comparators

Bit 27 **NOTRCPKT**: trace sampling and exception tracing support (read only)
- 0: supported

Bit 26 **NOEXTRIG**: external match signal, CMPMATCH support (read only)
- 0: supported

Bit 25 **NOCYCNCNT**: cycle counter support (read only)
- 0: supported

Bit 24 **NOPRFCNT**: profiling counter support (read only)
- 0: supported

Bit 23 **CYCDISS**: cycle counter disabled secure.
- Controls whether the cycle counter is disabled in secure mode.
- 0: no effect
- 1: disable incrementing of the cycle counter when the processor is in secure state

Bit 22 **CYCEVTENA**: enable for POSTCNT underflow event counter packet generation
- 0: disabled
- 1: enabled

Bit 21 **FOLDEVTENA**: enable for folded instruction counter overflow event generation
- 0: disabled
- 1: enabled

Bit 20 **LSUEVTENA**: enable for LSU counter overflow event generation
- 0: disabled
- 1: enabled

Bit 19 **SLEEPEVTENA**: enable for sleep counter overflow event generation
- 0: disabled
- 1: enabled

Bit 18 **EXCEVTENA**: enable for exception overhead counter overflow event generation
- 0: disabled
- 1: enabled

Bit 17 **CPIEVTENA**: enable for CPI counter overflow event generation
- 0: disabled
- 1: enabled

Bit 16 **EXTRCEVA**: enable for exception trace generation
- 0: disabled
- 1: enabled

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **PCSAMPLENA**: enable for POSTCNT counter to be used as a timer for periodic PC sample packet generation
- 0: disabled
- 1: enabled
Bits 11:10 SYNCTAP[1:0]: position of the synchronization packet counter tap on the CYCCNT counter
   This field determines the synchronization packet rate.
   00: disabled, no synchronization packets
   01: Tap at CYCCNT[24]
   10: Tap at CYCCNT[26]
   11: Tap at CYCCNT[28]

Bit 9 CYCTAP: Selects the position of the POSTCNT tap on the CYCCNT counter.
   0: Tap at CYCCNT[6]
   1: Tap at CYCCNT[10]

Bits 8:5 POSTINIT[3:0]: initial value of the POSTCNT counter
   Writes to this field are ignored if POSTCNT counter is enabled. CYCEVTENA or PCSAMPLENA bits must be reset prior to writing POSTINIT.

Bits 4:1 POSTRESET[3:0]: reload value of the POSTCNT counter

Bit 0 CYCCNTENA: enable CYCCNT counter
   0: disabled
   1: enabled

**ID[4:0]**
Identifies the capability for match for comparator 0.
0b01011: Cycle Counter, Instruction Address, Data Address and Data Address With Value

Bits 26:25  Reserved, must be kept at reset value.

Bit 24  **MATCHED**: comparator match
Indicates if a comparator match has occurred since the register was last read.
0: no match
1: a match occurred

Bits 23:12  Reserved, must be kept at reset value.
Bits 11:10 **DATAVSIZE[1:0]**: data value size
- Defines the size of the object being watched for by Data Value and Data Address comparators.
- \(0x0\): 1 byte
- \(0x1\): 2 bytes
- \(0x2\): 4 bytes
- \(0x3\): reserved

Bits 9:6 Reserved, must be kept at reset value.

Bits 5:4 **ACTION[1:0]**: action on match
- \(0x0\): trigger only
- \(0x1\): generate debug event
- \(0x2\): For a Cycle Counter, Instruction Address, Data Address, Data Value or Linked Data Value comparator, generate a Data Trace Match packet. For a Data Address With Value comparator, generate a Data Trace Data Value packet.
- \(0x3\): For a Data Address Limit comparator, generate a Data Trace Data Address packet. For a Cycle Counter, Instruction Address Limit, or Data Address comparator, generate a Data Trace PC Value packet. For a Data Address With Value comparator, generate both a Data Trace PC Value packet and a Data Trace Data Value packet.

Bits 3:0 **MATCH[3:0]**: match type
- Controls the type of match generated by comparator 0.
- For possible values of this field, refer to [4].

**DWT function register 1 (DWT_FUNCTR1)**

Table 706. DWT register map and reset values (continued)
Refer to Table 702: Processor ROM table for register boundary addresses.

### 58.7 Instrumentation trace macrocell (ITM)

The ITM generates trace information in packets. Three sources can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The three sources in decreasing order of priority are the following:

- **Software trace**
  
  The software can write directly to any of 32 x 32-bit ITM stimulus registers to generate packets. The permission level for each port can be programmed. When software writes to an enabled stimulus port, the ITM combines the identity of the port, the size of the write access and the data written, into a packet that it writes to a FIFO. The ITM outputs packets from the FIFO onto the trace bus. Reading a stimulus port register returns the status of the stimulus register (empty or pending) in bit 0.

- **Hardware trace**
  
  The DWT generates trace packets in response to a data trace event, a PC sample or a performance profiling counter wraparound. The ITM outputs these packets on the trace bus.

- **Local timestamping**
  
  The ITM contains a 21-bit counter clocked by the (pre-divided) processor clock. The counter value is output in a timestamp packet on the trace bus. The counter is reset to zero every time a timestamp packet is generated. The timestamps thus indicate the time elapsed since the previous timestamp packet.

For more information on the ITM and how to use it, refer to [4].

---

</thead>
</table>

Bits 31:24 Reserved, must be kept at reset value.

- **Bit 23 BUSY**: indicates whether the ITM is currently processing events
  - 0: not busy
  - 1: busy

Bits 22:16 **TRACEBUSID[6:0]**: identifier for multi-source trace stream formatting  
If multi-source trace is in use, the debugger must write a non-zero value to this field.  

*Note*: Different identifiers must be used for each trace source in the system.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **TSPRESCALE[1:0]**: local timestamp prescaler, used with the trace packet reference clock  
- 0x0: no prescaling
- 0x1: Divide by 4.
- 0x2: Divide by 16.
- 0x3: Divide by 64.

Bits 7:6 Reserved, must be kept at reset value.

- **Bit 5 STALENA**: stall enable
  - 0: Drop hardware source packets and generate an overflow if the ITM output is stalled.
  - 1: Stall the processor to guarantee delivery of data trace packets.

- **Bit 4 SWOENA**: SWO enable  
  Enables asynchronous clocking of the timestamp counter (read only).  
  0: Timestamp counter uses processor clock.

- **Bit 3 TXENA**: transmit enable  
  Enables forwarding of hardware event packets from the DWT unit to the trace port.  
  0: disabled
  1: enabled
Bit 2 **SYNCENA**: synchronization packet transmission enable
The debugger setting this bit must also configure the DWT_CTRLR.SYNCTAP field for the correct synchronization speed.
0: disabled
1: enabled

Bit 1 **TSENA**: local timestamp generation enable
0: disabled
1: enabled

Bit 0 **ITMENA**: ITM enable
0: disabled
1: enabled

**ITM device type architecture register (ITM_DEVARCHR)**

Address offset: 0xFBC

Reset value: 0x4770 1A01

Refer to *Table 702: Processor ROM table* for register boundary addresses.

### 58.8 Breakpoint unit (BPU)

The BPU allows the user to set hardware breakpoints. It contains eight comparators that monitor the instruction fetch address. If a match occurs, the instruction comparators can be configured to generate a breakpoint instruction.

For more information on the breakpoint unit and how to use it, refer to [4].

#### 58.8.1 BPU registers

The BPU registers are located at address range 0xE0002000 to 0xE0002FFC.

**BPU control register (BPU_CTRLR)**

Refer to Table 702: Processor ROM table for register boundary addresses.

### 58.9 Embedded Trace Macrocell (ETM)

The ETM is a CoreSight™ component closely coupled to the CPU. The ETM generates trace packets that allow the execution of the Cortex®-M33 core to be traced. In the STM32H563/H573 and STM32H562, the ETM is configured for instruction trace only. Data accesses are not included in the trace information.
The ETM receives information from the CPU over the processor trace interface, including:

- number of instructions executed in the same cycle
- changes in program flow
- current processor instruction state
- addresses of memory locations accessed by load and store instructions
- type, direction and size of a transfer
- Condition code information
- exception information
- wait for interrupt state information

For more information, refer to the Arm® CoreSight™ ETM-M33 Technical Reference Manual [6].

58.9.1 ETM registers

The ETM registers are located at address range 0xE004 1000 to 0xE004 1FFC.

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LPOVERRIDE**: low-power state behavior override
- 0: normal low-power state behavior
- 1: The resources and event trace generation are not affected by entry to a low-power state.

Bit 11 **ATB**: ATB trigger enable
- 0: disabled
- 1: enabled

Bits 10:2 Reserved, must be kept at reset value.

Bits 1:0 **INSTEN[1:0]**: instruction event generation
- Enables generation of an event element in the instruction stream.
  - 0bX0: Event0 does not cause an event element.
  - 0bX1: Event0 causes an event element when it occurs.
  - 0b0X: Event1 does not cause an event element.
  - 0b1X: Event1 causes an event element when it occurs.

- **ATB**: ATB trigger enable
- **INSTEN[1:0]**: instruction event generation
- **INSTPRIORITY**: instruction priority
- **ISTALL**: instruction stall
- **LEVEL[3:0]**: level [3:0]
Bits 31:11  Reserved, must be kept at reset value.

Bit 10  **INSTPRIORITY**: instruction trace priority
Prioritizes instruction trace if instruction trace buffer space is less than LEVEL[3:0].
0: The ETM must not prioritize instruction trace.
1: The ETM can prioritize instruction trace.

Bit 9  Reserved, must be kept at reset value.

Bit 8  **INSTALL**: processor stalling
Stalls processor based on instruction trace buffer space.
0: The ETM must not stall the processor.
1: The ETM can stall the processor.

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **LEVEL[3:0]**: Threshold at which stalling becomes active
This field provides four levels. This level can be varied to optimize the level of invasion
caused by stalling, balanced against the risk of a FIFO overflow.
0x0: zero invasion, but greater risk of FIFO overflow
... 0xF: maximum invasion but less risk of FIFO overflow

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:25 **NUMPROC[2:0]**: number of processors
0x0: 2 processors

Bits 24:20 **SYSTAL**: system stall
0x0: system stall supported

Bits 23:15 **STALLCL**: stall count
0x0: stall count not supported

Bits 14:10 **SYNC/PR**: sync/processor synchronisation
0x0: sync/processor synchronisation not supported

Bits 9:5 **TRCERR**: tracing error
0x0: tracing error not supported

Bits 4:0 **EXLEVEL_S[3:0]**: exception level
0x3: exception level 3
Bit 31  **NOOVERFLOW**: ETM_STALLCTRL.NOOVERFLOW implementation
0: not implemented

Bits 30:28  **NUMPROC[2:0]**: number of processors available for tracing
0x0: one processor

Bit 27  **SYSSTALL**: system support for stall control of the processor
1: system supports stall control

Bit 26  **STALLCTL**: stall control support
1: ETM_STALLCTRL implemented

Bit 25  **SYNCR**: trace synchronization period support
1: ETM_SYNCR is read-only for instruction trace only configuration. The trace synchronization period is fixed.

Bit 24  **TRCERR**: ETM_VICTLR.TRCErr implementation
0x1: implemented

Bits 23:20  Reserved, must be kept at reset value.

Bits 19:16  **EXLEVEL_S[3:0]**: privilege levels implementation
0x9: privilege levels thread and handler implemented

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:0  **CCITMIN[11:0]**: minimum value that can be programmed to TRCCCTLR.THRESHOLD
0x4: minimum of four-instruction trace cycles

**ETM identification register 4 (ETM_IDR4)**

Address offset: 0x1F0

Refer to *Table 702: Processor ROM table* for register boundary addresses.

### 58.10 Trace port interface unit (TPIU)

The TPIU formats the trace stream and outputs it on the external trace port signals. As shown in the figure below, the TPIU has two ATB slave ports for incoming trace data from the ETM and ITM respectively. The trace port is a synchronous parallel port, comprising a clock output, TRACECLK, and four data outputs, TRACEDATA(3:0). The trace port width is programmable in the range 1 to 4. Using a smaller port width reduces the number of test points/connector pins needed, and frees up IOs for other purposes, at the expenses of bandwidth restriction of the trace port, and hence of the quantity of trace information that can be output in real time.

![Figure 833. Trace port interface unit (TPIU)](image)
Trace data can also be output on the serial-wire output, TRACESWO.

For more information on the trace port interface in the Cortex®-M33, refer to the Arm® Cortex®-M33 Technical Reference Manual [5].

### 58.10.1 TPIU registers

**TPIU supported port size register (TPIU_SPSR)**

Address offset: 0x000

Reset value: 0x0000 000F

</table>

Bits 31:4 Reserved, must be kept at reset value.

- **Bit 3** **FTNONSTOP**: formatter stop
  Indicates whether formatter can be stopped or not.
  1: The formatter cannot be stopped.

- **Bit 2** **TCPRESENT**: TRACECTL output pin availability
  Indicates whether the optional TRACECTL output pin is available for use.
  0: TRACECTL pin is not present in this device.

- **Bit 1** **FTSTOPPED**: formatter stop
  The formatter has received a stop request signal and all trace data and post-amble is sent. Any additional trace data on the ATB interface is ignored.
  0: The formatter has not stopped.

- **Bit 0** **FLINPROG**: flush in progress
  Indicates whether a flush on the ATB slave port is in progress. This bit reflects the status of the AFVALIDS output. A flush can be initiated by the flush control bits in the TPIU_FFCR register.
  0: no flush in progress
  1: flush in progress

TPIU formatter and flush control register (TPIU_FFCR)

- **Bit 31** **FONMAN**: flush on MAN
- **Bit 30** **TRIGIN**: trace input
- **Bit 29** **ENFCONT**: enable context

3058/3119 RM0481 Rev 1
Bits 31:9  Reserved, must be kept at reset value.

Bit 8  **TRIGIN**: trigger on trigger in
  1: Indicates a trigger in the trace stream when the TRIGIN input is asserted.

Bit 7  Reserved, must be kept at reset value.

Bit 6  **FONMAN**: flush on manual
  0: flush completed
  1: Generates a flush.

Bits 5:2  Reserved, must be kept at reset value.

Bit 1  **ENFCONT**: continuous formatting enable
  Setting this bit to zero in SWO mode bypasses the formatter and only ITM/DWT trace is output. ETM trace is discarded.
  0: continuous formatting disabled
  1: continuous formatting enabled

Bit 0  Reserved, must be kept at reset value.

</tbody>
</table>

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:0  **PSCOUNT[12:0]**: formatter frames counter
  Enables effective use of different sized TPAs without wasting large amounts of the storage capacity of the capture device. This counter contains the number of formatter frames since the last synchronization packet of 128 bits. It is a 12-bit counter with a maximum count value of 4096. This equates to synchronization every 65536 bytes, that is, 4096 packets x 16 bytes per packet. The default is set up for a synchronization packet every 1024 bytes, that is, every 64 formatter frames. If the formatter is configured for continuous mode, full and half-word synchronization frames are inserted during normal operation. Under these circumstances, the count value is the maximum number of complete frames between full synchronization packets.
TPIU claim tag set register (TPIU_CLAIMSETR)

Address offset: 0xFA0
Reset value: 0x0000 000F

Refer to *Table 701: MCU ROM table* for register boundary addresses.
58.11 Cross-trigger interface (CTI)

The CTI allows cross triggering between the processor and the ETM (see the figure below).

The CTI enables events from various sources to trigger debug and/or trace activity. For example, a watchpoint reached in the processor can start or stop code trace, or a trace comparator can halt the processor.

The trigger input and output signals for the CTI are listed in the tables below.

**Table 711. CTI inputs**

<table>
<thead>
<tr>

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **TRIGINEN[3:0]**: trigger input event enable

Enables or disables a cross trigger event on each of the four channels when CTITRIGINx is activated (x = 0 to 7).

0000: Trigger does not generate events on channels.
XXX1: Trigger x generates events on channel 0.
XX1X: Trigger x generates events on channel 1.
X1XX: Trigger x generates events on channel 2.
1XXX: Trigger x generates events on channel 3.

**CTI trigger output x enable register (CTI_OUTENxR)**

Address offset: 0x0A0 + 0x004 * x, (x = 0 to 7)

Reset value: 0x0000 0000

<table>
<thead>
<tr>

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **TRIGOUTEN[3:0]**: trigger output event enable

For each channel, defines whether an event on that channel generates a trigger on CTITRIGOUTx (x = 0 to 7).

0000: Channel events do not generate triggers on trigger outputs.
XXX1: Channel 0 events generate triggers on trigger output x.
XX1X: Channel 1 events generate triggers on trigger output x.
X1XX: Channel 2 events generate triggers on trigger output x.
1XXX: Channel 3 events generate triggers on trigger output x.

Refer to Table 702: Processor ROM table for register boundary addresses.

### 58.12 Microcontroller debug unit (DBGMCU)

The DBGMCU is a component containing a number of registers that control the power and clock behavior in debug mode. It allows the debugger (or the software) to:

- maintain the clock and power to the processor cores when in low-power modes (Sleep, Stop or Standby)
- maintain the clock and power to the system debug and trace components when in low-power modes
- stop the clock to certain peripherals (SMBUS timeout, watchdogs, timers, RTC) when either processor core is stopped in debug mode

#### 58.12.1 Device ID

The DBGMCU includes an identity code register, DBGMCU_IDCODE. This register contains the ID code for the device. Debug tools can locate this register via the CoreSight™ discovery procedure described in Section 58.5: ROM tables.

#### 58.12.2 Low-power mode emulation

When the device enters either Stop mode (clocks are stopped) or Standby mode (core power is switched off), the debugger can no longer access the debug access port and loses the connection with the device. To avoid this, the debugger (or software) can set the
DBG_STANDBY and/or DBG_STOP bits in the **DBGMCU configuration register (DBGMCU_CR)**. These bits, when set, maintain the clock and power to the processor while the device is in the corresponding low-power mode. The processor remains in Sleep mode, and exits the low-power mode in the normal way. However, peripheral devices continue to operate, so the device behaviour may not be identical to that of the actual low-power mode.

### 58.12.3 Peripheral clock freeze

The DBGMCU peripheral clock freeze registers allow the operation of certain peripherals to be suspended in debug mode. The peripheral units which support this feature are listed in the table below.

<table>
<thead>
<tr>

<td>TIM1</td>
<td>General purpose timer 1</td>
</tr>
</tbody>
</table>
Each peripheral unit or DMA channel has a corresponding control bit, DBG_xxx_STOP, where xxx is the acronym of the peripheral (or DMA channel). The control bits are organized in DBGMCU_zzzFZR registers, where zzz corresponds to the name of the bus (AHB or APB). For example, DBGMCU_APB1LFZR contains the control bits for peripherals on the APB1L bus.

The control bit, when set, causes the corresponding peripheral operation to be suspended when the CPU is stopped in debug (HALTED = 1), according to the table below:

<table>
<thead>
<tr>
<th>HALTED</th>
<th>DBG_xxx_STOP</th>
<th>Peripheral behaviour</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>X</td>
<td>The operation continues.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>The operation continues.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The operation is suspended.</td>
</tr>
</tbody>
</table>

The accessibility of the bits DBG_xxx_STOP by the debugger depends on the state of the authentication signal spiden.

When spiden = 1 (secure privilege debug enabled), all bits can be modified and read by both debugger and software (secure or non-secure).

When spiden = 0 (secure privilege debug disabled), only bits corresponding to non-secure peripherals (or DMA channels) can be modified by debugger or software. All bits can be read.

The status (secure or non-secure) of a TrustZone–aware peripheral or a DMA channel, is signaled to the DBGMCU by the peripheral.

### Table 715. Peripheral behaviour in debug mode
58.12.4 **DBGMCU registers**

The DBGMCU registers are not reset by a system reset, only by a power-on reset. They are accessible to the debugger via the AHB access port at base address 0xE004 4000, and to software at base address 0x4402 4000.

**DBGMCU identity code register (DBGMCU_IDCODE)**

Address offset: 0x00  
Reset value: 0xXXXX 6XXX  
This register is always accessible.

<table>
<thead>
<tr>

</tbody>
</table>

**DBGMCU configuration register (DBGMCU_CR)**

Address offset: 0x04  
Reset value: 0x0000 0000  
This register is accessible to the debugger and to the CPU after successful authentication. Prior to this, debugger accesses are ignored.

<table>

Bits 31:17  Reserved, must be kept at reset value.

Bit 16  **DCRT**: Debug credentials reset type
This bit selects which type of reset is used to revoke the debug authentication credentials
- 0: System reset
- 1: Power reset

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:6  **TRACE_MODE[1:0]**: trace pin assignment
- 0x0: trace pins assigned for asynchronous mode (TRACESWO)
- 0x1: trace pins assigned for synchronous mode with a port width of 1 (TRACECK, TRACED0)
- 0x2: trace pins assigned for synchronous mode with a port width of 2 ((TRACECK, TRACED0-1)
- 0x3: trace pins assigned for synchronous mode with a port width of 4 ((TRACECK, TRACED0-3)

Bit 5  **TRACE_EN**: trace port and clock enable.
This bit enables the trace port clock, TRACECK.
- 0: disabled
- 1: enabled

Bit 4  **TRACE_IOEN**: trace pin enable
- 0: disabled - trace pins not assigned
- 1: enabled - trace pins assigned according to the value of TRACE_MODE field

Bit 3  Reserved, must be kept at reset value.

Bit 2  **DBG_STANDBY**: Allows debug in Standby mode
- 0: normal operation
  - All clocks are disabled and the core powered down automatically in Standby mode.
  - 1: automatic clock stop/power down disabled
  - All active clocks and oscillators continue to run during Standby mode, and the core supply is maintained, allowing full debug capability. On exit from Standby mode, a system reset is performed.

Bit 1  **DBG_STOP**: Allows debug in Stop mode
- 0: normal operation
  - All clocks are disabled automatically in Stop mode.
- 1: automatic clock stop disabled
  - All active clocks and oscillators continue to run during Stop mode, allowing full debug capability. On exit from Stop mode, the clock settings are set to the Stop mode exit state.

Bit 0  Reserved, must be kept at reset value.

**DBGMCU APB1L peripheral freeze register (DBGMCU_APB1LFZR)**

Address offset: 0x08
Reset value: 0x0000 0000
This register is accessible to the debugger and to the CPU after successful authentication. Prior to this, accesses are ignored.

Bits 31:24 Reserved, must be kept at reset value.

- **Bit 23 DBG_I3C1_STOP**: I3C1 SCL stall counter stop in debug
  - 0: normal operation. I3C1 SCL stall timeout counter continues to operate while CPU is in debug mode.
  - 1: stop in debug. I3C1 SCL stall timeout counter is frozen while CPU is in debug mode.

- **Bit 22 DBG_I2C2_STOP**: I2C2 SMBUS timeout stop in debug
  - 0: normal operation. I2C2 SMBUS timeout continues to operate while CPU is in debug mode.
  - 1: stop in debug. I2C2 SMBUS timeout is frozen while CPU is in debug mode.

- **Bit 21 DBG_I2C1_STOP**: I2C1 SMBUS timeout stop in debug
  - 0: normal operation. I2C1 SMBUS timeout continues to operate while CPU is in debug mode.
  - 1: stop in debug. I2C1 SMBUS timeout is frozen while CPU is in debug mode.

Bits 20:13 Reserved, must be kept at reset value.

- **Bit 12 DBG_IWDG_STOP**: IWDG stop in debug
  - 0: normal operation. IWDG continues to operate while CPU is in debug mode.
  - 1: stop in debug. IWDG is frozen while CPU is in debug mode.

- **Bit 11 DBG_WWDG_STOP**: WWDG stop in debug
  - 0: normal operation. WWDG continues to operate while CPU is in debug mode.
  - 1: stop in debug. WWDG is frozen while CPU is in debug mode.

Bits 10:9 Reserved, must be kept at reset value.

- **Bit 8 DBG_TIM14_STOP**: TIM14 stop in debug
  - 0: normal operation. TIM14 continues to operate while CPU is in debug mode.
  - 1: stop in debug. TIM14 is frozen while CPU is in debug mode.

- **Bit 7 DBG_TIM13_STOP**: TIM13 stop in debug
  - 0: normal operation. TIM13 continues to operate while CPU is in debug mode.
  - 1: stop in debug. TIM13 is frozen while CPU is in debug mode.

- **Bit 6 DBG_TIM12_STOP**: TIM12 stop in debug
  - 0: normal operation. TIM12 continues to operate while CPU is in debug mode.
  - 1: stop in debug. TIM12 is frozen while CPU is in debug mode.
### DBGMCU APB1H peripheral freeze register (DBGMCU_APB1HFZR)

Bits 31:16  **AP_ENABLED[15:0]**: Bit n identifies whether access port AP n is open (can be accessed via the debug port) or locked (debug access to the AP is blocked)
- Bit n = 0: APn locked
- Bit n = 1: APn enabled

Bits 15:0  **AP_PRESENT[15:0]**: Bit n identifies whether access port AP n is present in device
- Bit n = 0: APn absent
- Bit n = 1: APn present

DBGMCU debug authentication mailbox host register (DBGMCU_DBG_AUTH_HOST)

Address offset: 0x100
Reset value: 0xXXXX XXXX

This register is read only when accessed by the CPU, writes have no effect.

This register can be written and read by an external debugger when system reset is asserted, or when access is granted during the authentication process.

Bits 31:0  **MESSAGE[31:0]**: Debug host to device mailbox message.
The debug host requests authentication by writing a value to this register prior to releasing the system reset. During debug authentication the debug host communicates with the device (CPU) via this register.
### DBGMCU debug authentication mailbox device register

**(DBGMCU_DBG_AUTH_DEVICE)**

Address offset: 0x104

Reset value: 0xXXXX XXXX

This register is read only when accessed via the debug port, writes have no effect.

This register can be written and read by the CPU.

Bits 31:0 **MESSAGE[31:0]**: Device to debug host mailbox message.

During debug authentication the device (CPU) communicates with the debug host via this register.

### DBGMCU debug authentication mailbox acknowledge register

**(DBGMCU_DBG_AUTH_ACK)**

Address offset: 0x108

Reset value: 0x0000 0000

This register is always accessible.
Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **DEV_ACK**: Device to host acknowledge.
This bit is set by hardware when the device (CPU) writes a message in the DBGMCU_DBG_AUTH_DEVICE register. It is reset automatically when the host (debugger) reads the message.
0: DBGMCU_DBG_AUTH_DEVICE register is empty
1: DBGMCU_DBG_AUTH_DEVICE register contains an unread message

Bit 0  **HOST_ACK**: Host to device acknowledge.
This bit is set by hardware when the host (debugger) writes a message in the DBGMCU_DBG_AUTH_HOST register. It is reset automatically when the device (CPU) reads the message.
0: DBGMCU_DBG_AUTH_HOST register is empty
1: DBGMCU_DBG_AUTH_HOST register contains an unread message

**DBGMCU CoreSight peripheral identity register 4 (DBGMCU_PIDR4)**
Address offset: 0xFD0
Reset value: 0x0000 0000
This register is always accessible.

59 **Device electronic signature**

The device electronic signature is stored in the system memory area of the Flash memory module and can be read using the debug interface or by the CPU. It contains factory-programmed identification and calibration data that allow the user firmware or other external devices to automatically match to the characteristics of the devices.

59.1 **Unique device ID register (96 bits)**

The unique device identifier is ideally suited:

- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as part of the security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits cannot be altered by the user.

Base address: 0x08FF F800

Important security notice

The STMicroelectronics group of companies (ST) places a high value on product security, which is why the ST product(s) identified in this documentation may be certified by various security certification bodies and/or may implement our own security measures as set forth herein. However, no level of security certification and/or built-in security measures can guarantee that ST products are resistant to all forms of attacks. As such, it is the responsibility of each of ST’s customers to determine if the level of security provided in an ST product meets the customer needs both in relation to the ST product alone, as well as when combined with other components and/or software for the customer end product or application. In particular, take note that:

- ST products may have been certified by one or more security certification bodies, such as Platform Security Architecture (www.psacertified.org) and/or Security Evaluation standard for IoT Platforms (www.trustcb.com). For details concerning whether the ST product(s) referenced herein have received security certification along with the level and current status of such certification, either visit the relevant certification standards website or go to the relevant product page on www.st.com for the most up to date information. As the status and/or level of security certification for an ST product can change from time to time, customers should re-check security certification status/level as needed. If an ST product is not shown to be certified under a particular security standard, customers should not assume it is certified.

- Certification bodies have the right to evaluate, grant and revoke security certification in relation to ST products. These certification bodies are therefore independently responsible for granting or revoking security certification for an ST product, and ST does not take any responsibility for mistakes, evaluations, assessments, testing, or other activity carried out by the certification body with respect to any ST product.

- Industry-based cryptographic algorithms (such as AES, DES, or MD5) and other open standard technologies which may be used in conjunction with an ST product are based on standards which were not developed by ST. ST does not take responsibility for any flaws in such cryptographic algorithms or open technologies or for any methods which have been or may be developed to bypass, decrypt or crack such algorithms or technologies.

- While robust security testing may be done, no level of certification can absolutely guarantee protections against all attacks, including, for example, against advanced attacks which have not been tested for, against new or unidentified forms of attack, or against any form of attack when using an ST product outside of its specification or intended use, or in conjunction with other components or software which are used by customer to create their end product or application. ST is not responsible for resistance against such attacks. As such, regardless of the incorporated security features and/or any information or support that may be provided by ST, each customer is solely responsible for determining if the level of attacks tested for meets their needs, both in relation to the ST product alone and when incorporated into a customer end product or application.

- All security features of ST products (inclusive of any hardware, software, documentation, and the like), including but not limited to any enhanced security features added by ST, are provided on an "AS IS" BASIS. AS SUCH, TO THE EXTENT PERMITTED BY APPLICABLE LAW, ST DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE, unless the applicable written and signed contract terms specifically provide otherwise.

IMPORTANT NOTICE – READ CAREFULLY

STMicroelectronics NV and its subsidiaries ("ST") reserve the right to make changes, corrections, enhancements, modifications, and improvements to ST products and/or to this document at any time without notice. Purchasers should obtain the latest relevant information on ST products before placing orders. ST products are sold pursuant to ST’s terms and conditions of sale in place at the time of order acknowledgment.

Purchasers are solely responsible for the choice, selection, and use of ST products and ST assumes no liability for application assistance or the design of purchasers’ products.

No license, express or implied, to any intellectual property right is granted by ST herein.

Resale of ST products with provisions different from the information set forth herein shall void any warranty granted by ST for such product.

ST and the ST logo are trademarks of ST. For additional information about ST trademarks, refer to www.st.com/trademarks. All other product or service names are the property of their respective owners.

Information in this document supersedes and replaces information previously supplied in any prior versions of this document.
