Reference manual

STM32H7Pxxx Arm®-based 32-bit MCUs

Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32H7Pxxx microprocessor memory and peripherals.

The STM32H7Pxxx is a family of microprocessors with different packages and peripherals.

Refer to the corresponding datasheets for ordering information, mechanical and electrical device characteristics.

For information on the Cortex®-M7 core, refer to the corresponding Technical Reference Manuals available on http://infocenter.arm.com.

The STM32H7Pxxx microprocessors include ST state-of-the-art patented technology.

Contents

1 Documentation conventions 106

1.1 General information 106

1.2 List of abbreviations for registers 106

1.3 Register reset value 107

1.4 Glossary 107

1.5 Availability of peripherals 107

1.6 Availability of security features 107

2 Memory and bus architecture 108

2.1 System architecture 108

2.1.1 Bus matrices 109

2.1.2 Peripheral buses 110

2.1.3 CPU buses 110

2.1.4 Bus manager peripherals 111

2.2 AXI interconnect matrix (AXIM) 111

2.2.1 AXI introduction 111

2.2.2 AXI interconnect main features 112

2.2.3 Block diagram 112

2.2.4 AXI interconnect registers 115

2.2.5 AXI interconnect register map 122

2.3 Memory organization 132

2.3.1 Introduction 132

2.3.2 Memory map and register boundary addresses 133

2.4 Embedded SRAM 141

2.5 Flash memory overview 142

2.6 Boot configuration 143

3 System security 145

3.1 Key security features 145

3.2 Identification 145

3.2.1 Unique ID 145

3.2.2 Discover command 146

3.3 Secure boot 146

3.3.1 Unique boot entry . . . 146
3.3.2 Embedded flash memory write protection . . . 146
3.3.3 Boot levels isolation with HDP . . . 147
3.4 Isolation . . . 147
3.4.1 Temporal isolation using hide protection levels (HDPL) . . . 147
3.4.2 Isolation using privileged mode . . . 147
3.5 Secure storage . . . 149
3.5.1 Boot data storage . . . 149
3.5.2 Battery-powered volatile secure storage . . . 149
3.6 Cryptographic engines . . . 150
3.6.1 Cryptographic random number generation . . . 150
3.6.2 Cryptographic operations . . . 150
3.7 Tamper detection and response . . . 150
3.7.1 Tamper detection sources . . . 150
3.7.2 Response to tampers . . . 151
3.7.3 Software filtering mechanism . . . 152
3.7.4 Tamper detection and low-power modes . . . 152
3.8 Product life cycle . . . 153
3.8.1 Life cycle management . . . 154
3.9 System memory . . . 154
3.9.1 RSS user functions . . . 154
3.9.2 RSSLIB . . . 155

4 RAM ECC monitoring (RAMECC) . . . 162
4.1 Introduction . . . 162
4.2 RAMECC main features . . . 162
4.3 RAMECC functional description . . . 162
4.3.1 RAMECC internal signals . . . 164
4.3.2 RAMECC monitor mapping . . . 165
4.3.3 ECC fault injection test on SRAM1, SRAM3, and TCM . . . 166
4.3.4 Read access latency . . . 166
4.4 RAMECC low-power modes . . . 166
4.5 RAMECC interrupts . . . 167
4.6 RAMECC registers . . . 168
4.6.1 RAMECC interrupt enable register (RAMECC_IER) . . . 168

4.6.2 RAMECC monitor x configuration register (RAMECC_MxCR) . . . 169
4.6.3 RAMECC monitor x status register (RAMECC_MxSR) . . . 170
4.6.4 RAMECC monitor x failing address register (RAMECC_MxFAR) . . . 170
4.6.5 RAMECC monitor x failing data register (RAMECC_MxFDR) . . . 171
4.6.6 RAMECC monitor x failing ECC error code register (RAMECC_MxFECR) . . . 171
4.6.7 RAMECC register map . . . 171

5 Embedded flash memory (FLASH) . . . 175

5.1 Introduction . . . 175
5.2 FLASH main features . . . 175
5.3 FLASH functional description . . . 176
5.3.1 FLASH block diagram . . . 176
5.3.2 FLASH internal signals . . . 177
5.3.3 FLASH architecture and integration in the system . . . 177
5.3.4 Flash memory architecture and usage . . . 179
5.3.5 Flash hide protection schemes . . . 183
5.3.6 Overview of FLASH operations . . . 184
5.3.7 FLASH read operations . . . 185
5.3.8 FLASH program operations . . . 188
5.3.9 FLASH erase operations . . . 192
5.3.10 FLASH parallel operations . . . 193
5.3.11 Flash memory error protections . . . 193
5.3.12 FLASH one-time programmable (OTP) area . . . 195
5.3.13 FLASH read-only (RO) area . . . 197
5.3.14 FLASH bank and register swapping . . . 197
5.3.15 FLASH reset and clocks . . . 199
5.3.16 Tamper management . . . 200
5.4 FLASH option bytes . . . 200
5.4.1 About option bytes . . . 200
5.4.2 Option byte loading . . . 200
5.4.3 Option byte words modification . . . 200
5.4.4 Option byte key management . . . 202
5.4.5 Option byte user words overview . . . 204

5.4.6 Description of user option byte word 206
5.4.7 Description of security option bytes 207
5.5 FLASH protection mechanisms 208
5.5.1 FLASH configuration protection 208
5.5.2 Write protection 209
5.5.3 Life cycle management 210
5.5.4 Hide protection (HDP) 212
5.6 FLASH low-power modes 215
5.6.1 Introduction 215
5.6.2 Managing the FLASH domain switching to Stop or Standby 215
5.7 FLASH error management 215
5.7.1 Write protection error (WRPERRF) 216
5.7.2 Programming sequence error (PGSERRF) 217
5.7.3 Strobe error (STRBERRF) 217
5.7.4 Inconsistency error (INCERRF) 217
5.7.5 Error correction code error (SNECCERRF/DBECCERRF) 218
5.7.6 Read secure error (RDSERRF) 219
5.7.7 CRC read error (CRCRDERRF) 219
5.7.8 Option byte change error (OPTERRF) 219
5.7.9 Option byte loading error (OBLERRF) 220
5.7.10 Option byte key error flag (OBKERRF) 220
5.7.11 Miscellaneous HardFault errors 220
5.8 FLASH interrupts 221
5.9 FLASH registers 223
5.9.1 FLASH access control register (FLASH_ACCR) 223
5.9.2 FLASH access control register (FLASH_ACCR_ALIAS) 223
5.9.3 FLASH bank x control key register (FLASH_xKEYR) 224
5.9.4 FLASH bank x control register (FLASH_xCR) 225
5.9.5 FLASH bank x status register (FLASH_xSR) 227
5.9.6 FLASH bank x interrupt enable register (FLASH_xIER) 228
5.9.7 FLASH bank x interrupt status register (FLASH_xISR) 230
5.9.8 FLASH bank x interrupt clear register (FLASH_xICR) 231
5.9.9 FLASH bank x CRC control register (FLASH_xCRCCR) 232
5.9.10 FLASH bank x CRC start address register (FLASH_xCRCSADDR) . . 234
5.9.11 FLASH bank x CRC end address register (FLASH_xCRCEADDR) . . 235
5.9.12 FLASH CRC data register (FLASH_CRCDATAR) 235

5.9.13 FLASH bank x ECC single error fail address (FLASH_xECCSFADDR) . . . 236
5.9.14 FLASH bank x ECC double error fail address (FLASH_xECCDFADDR) . . . 236
5.9.15 FLASH bank x write page protection status register (FLASH_xWRPSR) . 237
5.9.16 FLASH bank x write page protection status register programming (FLASH_xWRPSRP) . . . 237
5.9.17 FLASH bank x hide protection status register (FLASH_xHDPSR) . . . 238
5.9.18 FLASH bank x hide protection status register programming (FLASH_xHDPSRP) . . . 238
5.9.19 FLASH bank x HDP extension register (FLASH_xHDPEXTR) . . . 239
5.9.20 FLASH options key register (FLASH_OPTKEYR) . . . 240
5.9.21 FLASH options control register (FLASH_OPTCR) . . . 240
5.9.22 FLASH options interrupt status register (FLASH_OPTISR) . . . 241
5.9.23 FLASH options interrupt clear register (FLASH_OPTICR) . . . 242
5.9.24 FLASH OTP lock status register (FLASH_OTPLSR) . . . 242
5.9.25 FLASH OTP lock status register programming (FLASH_OTPLSRP) . 243
5.9.26 FLASH nonvolatile status register (FLASH_NVSR) . . . 243
5.9.27 FLASH security status register programming (FLASH_NVSRP) . . . 244
5.9.28 FLASH RoT status register (FLASH_ROTSR) . . . 244
5.9.29 FLASH RoT status register programming (FLASH_ROTSRP) . . . 245
5.9.30 FLASH option byte key control register (FLASH_OBKCR) . . . 246
5.9.31 FLASH option byte key clear register (FLASH_OBKCLR) . . . 247
5.9.32 FLASH option bytes key data register x (FLASH_OBKDRx) . . . 247
5.9.33 FLASH option byte word 1 status register (FLASH_OBW1SR) . . . 248
5.9.34 FLASH option byte word 1 status register programming (FLASH_OBW1SRP) . . . 249
5.9.35 FLASH register map . . . 251

6 Power control (PWR) . . . 257

6.1 Introduction . . . 257
6.2 PWR main features . . . 257
6.3 PWR block diagram . . . 258
6.3.1 PWR pins and internal signals . . . 258
6.4 Power supplies . . . 260
6.4.1 System supply startup . . . 262
6.4.2 Core domain . . . 265

6.4.3 Backup domain . . . 268
6.4.4 VBAT battery charging . . . 270
6.4.5 Analog supply . . . 270
6.5 Power supply supervision . . . 271
6.5.1 Power-on reset (POR)/power-down reset (PDR) . . . 272
6.5.2 Brownout reset (BOR) . . . 272
6.5.3 Programmable voltage detector (PVD) . . . 273
6.5.4 Analog voltage detector (AVD) . . . 275
6.5.5 Battery voltage thresholds . . . 276
6.5.6 Temperature thresholds . . . 277
6.5.7 VCORE maximum voltage level detector . . . 278
6.6 Power management . . . 279
6.6.1 Operating modes . . . 279
6.6.2 Voltage scaling . . . 280
6.6.3 Power management examples . . . 281
6.7 Low-power modes . . . 285
6.7.1 Slowing down system clocks . . . 286
6.7.2 Controlling peripheral clocks . . . 286
6.7.3 Entering low-power modes . . . 286
6.7.4 Exiting from low-power modes . . . 286
6.7.5 Sleep mode . . . 288
6.7.6 Stop mode . . . 288
6.7.7 Standby mode . . . 291
6.7.8 Monitoring low-power modes . . . 293
6.8 PWR registers . . . 294
6.8.1 PWR control register 1 (PWR_CR1) . . . 294
6.8.2 PWR status register 1 (PWR_SR1) . . . 295
6.8.3 PWR control status register 1 (PWR_CSR1) . . . 297
6.8.4 PWR control status register 2 (PWR_CSR2) . . . 298
6.8.5 PWR CPU control status register 3 (PWR_CSR3) . . . 299
6.8.6 PWR control status register 4 (PWR_CSR4) . . . 300
6.8.7 PWR wakeup clear register (PWR_WKUPCR) . . . 301
6.8.8 PWR wakeup flag register (PWR_WKUPFR) . . . 302
6.8.9 PWR wakeup enable and polarity register (PWR_WKUPEPR) . . . 303
6.8.10 PWR USB Type-C and power delivery register (PWR_UCPDR) . . . 304
6.8.11 PWR apply pull register (PWR_APCR) . . . 304
6.8.12 PWR I3C pull-up control register (PWR_I3CPUCR) . . . 305

6.8.13 PWR XSPI pull-up control register (PWR_XSPIPUCR) 307
6.8.14 PWR XSPI pull-down control register (PWR_XSPIPDCR) 310
6.8.15 PWR register map 312

7 Reset and clock control (RCC) 314
7.1 RCC main features 314
7.2 RCC block diagram 315
7.3 RCC pins and internal signals 316
7.4 RCC reset block functional description 318
7.4.1 Reset from PWR block 318
7.4.2 The system and application resets (sys_rst and nreset) 320
7.4.3 The NRST reset 320
7.4.4 Low-power mode security reset (lpwr_rst) 320
7.4.5 Backup domain reset 321
7.4.6 Coresight debug reset 321
7.4.7 Option bytes loading 322
7.4.8 Peripheral resets 322
7.4.9 Reset coverage summary 322
7.4.10 Reset source identification 324
7.4.11 Power-on and wakeup sequences 324
7.5 RCC clock block functional description 326
7.5.1 Clock naming convention 328
7.5.2 Oscillators description 328
7.5.3 Clock security system (CSS) 338
7.5.4 Clock output generation (MCO1/MCO2) 341
7.5.5 PLL description 343
7.5.6 System clock (**sys_ck**) 349
7.5.7 Clock protection 351
7.5.8 Clock generation in Stop and Standby modes 352
7.5.9 Peripheral clock distribution 354
7.5.10 General clock concept overview 376
7.5.11 Peripheral allocation 378
7.5.12 Peripheral clock gating control 379
7.5.13 CPU and bus matrix clock gating control 382
7.5.14 Low-power emulation modes 383
7.6 RCC interrupts 384

7.7 RCC Programming examples 385
7.7.1 PLL programming procedure 385
7.7.2 Frequency configuration examples 387
7.8 RCC registers 390
7.8.1 RCC source control register (RCC_CR) 390
7.8.2 RCC clock protection register (RCC_CKPROTR) 393
7.8.3 RCC HSI calibration register (RCC_HSICFGR) 394
7.8.4 RCC clock recovery RC register (RCC_CRRCR) 395
7.8.5 RCC CSI calibration register (RCC_CSICFGR) 395
7.8.6 RCC clock configuration register (RCC_CFGR) 396
7.8.7 RCC CPU domain clock configuration register (RCC_CDCFGR) 398
7.8.8 RCC AHB clock configuration register (RCC_BMCFGR) 399
7.8.9 RCC APB clocks configuration register (RCC_APBCFGR) 400
7.8.10 RCC PLLs clock source selection register (RCC_PLLCKSELR) 401
7.8.11 RCC PLLs configuration register (RCC_PLLCFGR) 402
7.8.12 RCC PLL1 dividers configuration register 1 (RCC_PLL1DIVR1) 406
7.8.13 RCC PLL1 dividers configuration register 2 (RCC_PLL1DIVR2) 407
7.8.14 RCC PLL1 fractional divider register (RCC_PLL1FRACR) 408
7.8.15 RCC PLL1 Spread Spectrum Clock Generator register (RCC_PLL1SSCGR) 409
7.8.16 RCC PLL2 dividers configuration register 1 (RCC_PLL2DIVR1) 410
7.8.17 RCC PLL2 dividers configuration register 2 (RCC_PLL2DIVR2) 411
7.8.18 RCC PLL2 fractional divider register (RCC_PLL2FRACR) 412
7.8.19 RCC PLL2 spread spectrum clock generator register (RCC_PLL2SSCGR) 413
7.8.20 RCC PLL3 dividers configuration register 1 (RCC_PLL3DIVR1) 414
7.8.21 RCC PLL3 dividers configuration register 2 (RCC_PLL3DIVR2) 415
7.8.22 RCC PLL3 fractional divider register (RCC_PLL3FRACR) 416
7.8.23 RCC PLL3 spread spectrum clock generator register (RCC_PLL3SSCGR) 417
7.8.24 RCC peripheral kernel clock selection register 1 (RCC_CCIPR1) . . . 418
7.8.25 RCC peripheral kernel clock selection register 2 . . . . (RCC_CCIPR2) 420
7.8.26 RCC peripheral kernel clock selection register 3 (RCC_CCIPR3) . . . 421
7.8.27 RCC peripheral kernel clock selection register 4 . . . . (RCC_CCIPR4) 422
7.8.28 RCC clock source interrupt enable register (RCC_CIER) 425
7.8.29 RCC clock source interrupt flag register (RCC_CIFR) 426
7.8.30 RCC clock source interrupt clear register (RCC_CICR) 428
7.8.31 RCC Backup domain control register (RCC_BDCR) 430

7.8.32 RCC clock control and status register (RCC_CSR) 432
7.8.33 RCC AHB1 peripheral reset register (RCC_AHB1RSTR) 433
7.8.34 RCC AHB2 peripheral reset register (RCC_AHB2RSTR) 433
7.8.35 RCC AHB3 peripheral reset register (RCC_AHB3RSTR) 434
7.8.36 RCC AHB4 peripheral reset register (RCC_AHB4RSTR) 435
7.8.37 RCC AHB5 peripheral reset register (RCC_AHB5RSTR) 436
7.8.38 RCC APB1 peripheral reset register 1 (RCC_APB1RSTR1) 437
7.8.39 RCC APB1 peripheral reset register 2 (RCC_APB1RSTR2) 440
7.8.40 RCC APB2 peripheral reset register (RCC_APB2RSTR) 441
7.8.41 RCC APB4 peripheral reset register (RCC_APB4RSTR) 443
7.8.42 RCC AXI clocks gating disable register (RCC_CKGDISR) 444
7.8.43 RCC Reset status register (RCC_RSR) 447
7.8.44 RCC AHB1 clock enable register (RCC_AHB1ENR) 448
7.8.45 RCC AHB2 clock enable register (RCC_AHB2ENR) 449
7.8.46 RCC AHB3 clock enable register (RCC_AHB3ENR) 450
7.8.47 RCC AHB4 clock enable register (RCC_AHB4ENR) 451
7.8.48 RCC AHB5 clock enable register (RCC_AHB5ENR) 452
7.8.49 RCC APB1 clock enable register 1 (RCC_APB1ENR1) 453
7.8.50 RCC APB1 clock enable register 2 (RCC_APB1ENR2) 456
7.8.51 RCC APB2 clock enable register (RCC_APB2ENR) 457
7.8.52 RCC APB4 clock enable register (RCC_APB4ENR) 459
7.8.53 RCC AHB5 low-power clock enable register (RCC_AHB5LPENR) . . . 461
7.8.54 RCC AHB1 low-power clock enable register (RCC_AHB1LPENR) . . . 462
7.8.55 RCC AHB2 low-power clock enable register (RCC_AHB2LPENR) . . . 463
7.8.56 RCC AHB3 low-power clock enable register (RCC_AHB3LPENR) . . . 464
7.8.57 RCC AHB4 low-power clock enable register (RCC_AHB4LPENR) . . . 465
7.8.58 RCC APB1 low-power clock enable register 1 (RCC_APB1LPENR1) 466
7.8.59 RCC APB1 low-power clock enable register 2 (RCC_APB1LPENR2) 469
7.8.60 RCC APB2 low-power clock enable register (RCC_APB2LPENR) . . . 470
7.8.61 RCC APB4 low-power clock enable register (RCC_APB4LPENR) . . . 472
7.9 RCC register map 475

8 Clock recovery system (CRS) 483
8.1 CRS introduction 483
8.2 CRS main features 483
8.3 CRS implementation 483
8.4 CRS functional description 484

8.4.1 CRS block diagram . . . 484
8.4.2 CRS internal signals . . . 484
8.4.3 Synchronization input . . . 485
8.4.4 Frequency error measurement . . . 485
8.4.5 Frequency error evaluation and automatic trimming . . . 486
8.4.6 CRS initialization and configuration . . . 487
8.5 CRS in low-power modes . . . 488
8.6 CRS interrupts . . . 488
8.7 CRS registers . . . 488
8.7.1 CRS control register (CRS_CR) . . . 488
8.7.2 CRS configuration register (CRS_CFGR) . . . 490
8.7.3 CRS interrupt and status register (CRS_ISR) . . . 491
8.7.4 CRS interrupt flag clear register (CRS_ICR) . . . 493
8.7.5 CRS register map . . . 493

9 General-purpose I/Os (GPIO) . . . 495
9.1 Introduction . . . 495
9.2 GPIO main features . . . 495
9.3 GPIO functional description . . . 495
9.3.1 General-purpose I/O (GPIO) . . . 497
9.3.2 I/O pin alternate function multiplexer and mapping . . . 498
9.3.3 I/O port control registers . . . 498
9.3.4 I/O port data registers . . . 499
9.3.5 I/O data bitwise handling . . . 499
9.3.6 GPIO locking mechanism . . . 499
9.3.7 I/O alternate function input/output . . . 499
9.3.8 External interrupt/wake-up lines . . . 500
9.3.9 Input configuration . . . 500
9.3.10 Output configuration . . . 501
9.3.11 Alternate function configuration . . . 501
9.3.12 Analog configuration . . . 502
9.3.13 Using the HSE or LSE oscillator pins as GPIOs . . . 502
9.3.14 Using the GPIO pins in the RTC supply domain . . . 503
9.3.15 Privileged and unprivileged modes . . . 503
9.3.16 High-speed low-voltage mode (HSLV) . . . 503
9.3.17 I/O compensation cell . . . 503

9.4 GPIO registers 503
9.4.1 GPIO port mode register . . . . . .(GPIOx_MODER) (x = A to I) 503
9.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to I) 505
9.4.3 GPIO port output speed register . . . (GPIOx_OSPEEDR) (x = A to I) 505
9.4.4 GPIO port pull-up/pull-down register . . . (GPIOx_PUPDR) (x = A to I) 506
9.4.5 GPIO port input data register (GPIOx_IDR) (x = A to I) 506
9.4.6 GPIO port output data register . . . . . (GPIOx_ODR) (x = A to I) 507
9.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to I) 507
9.4.8 GPIO port configuration lock register . . . . (GPIOx_LCKR) (x = A to I) 508
9.4.9 GPIO alternate function low register . . . . .(GPIOx_AFRL) (x = A to I) 509
9.4.10 GPIO alternate function high register . . . (GPIOx_AFRH) (x = A to I) 510
9.4.11 GPIO port bit reset register . . . . . .(GPIOx_BRR) (x = A to I) 511
9.4.12 GPIO register map 512

10 System configuration, boot and security (SBS) 514

10.1 SBS introduction 514
10.2 SBS main features 514
10.3 SBS functional description 515
10.3.1 SBS block diagram 515
10.3.2 SBS internal signals 515
10.3.3 SBS reset and clocks 515
10.3.4 SBS hide protection management 516
10.3.5 SBS boot control 516
10.3.6 SBS debug management 517
10.3.7 SBS voltage booster for I/O analog switches 518
10.3.8 SBS I/O compensation cell management 518
10.3.9 SBS registers access control 519
10.3.10 SBS error management 520
10.4 SBS interrupts 520
10.5 SBS registers 520
10.5.1 SBS boot status register (SBS_BOOTSR) 520
10.5.2 SBS hide protection control register (SBS_HDPLCR) 520
10.5.3 SBS hide protection status register (SBS_HDPLSR) 521
10.5.4 SBS debug control register (SBS_DBGCR) 521
10.5.5 SBS debug lock register (SBS_DBGLOCKR) 522
10.5.6 SBS RSS command register (SBS_RSSCMDR) 522

10.5.7 SBS product mode and configuration register (SBS_PMCR) 523
10.5.8 SBS FPU interrupt mask register (SBS_FPUIMR) 524
10.5.9 SBS memory erase status register (SBS_MESR) 524
10.5.10 SBS I/O compensation cell control and status register (SBS_CCCSR) 525
10.5.11 SBS compensation cell for I/Os value register (SBS_CCVALR) 526
10.5.12 SBS compensation cell for I/Os software value register (SBS_CCSWVALR) 526
10.5.13 SBS break lock register (SBS_BKLOCKR) 527
10.5.14 SBS external interrupt configuration register x (SBS_EXTICRx) 529
10.5.15 SBS register map 531

11 Peripheral interconnect 533
11.1 Introduction 533
11.2 Connection summary 533
11.3 Interconnection details 536
11.3.1 Master to slave interconnection for timers 536
11.3.2 Triggers to ADCs 537
11.3.3 ADC analog watchdogs as triggers to timers 538
11.3.4 Comparator outputs to timers 538
11.3.5 HSP break to PWM timers 540
11.3.6 Triggers on ADF1 540
11.3.7 Internal input and clock sources to timers 541
11.3.8 Triggers to low-power timers 542
11.3.9 RTC wake-up as inputs to timers 542
11.3.10 OTG_FS SOF as trigger to timers 542
11.3.11 System errors as break signals to timers 543
11.3.12 Triggers to GPDMA/HPDMA 543
11.3.13 Internal analog signals to analog peripherals 544
11.3.14 ADC data filtering by the ADF1 545
11.3.15 Internal tamper sources 545
11.3.16 Output from tamper to RTC 545
11.3.17 I3C in-band interrupt acknowledge to timers 545
11.3.18 NPU input triggers 546
11.3.19 HSP input triggers 546

12 High-performance direct memory access controller (HPDMA) 548

12.1 HPDMA introduction . . . 548
12.2 HPDMA main features . . . 548
12.3 HPDMA implementation . . . 549
12.3.1 HPDMA channels . . . 549
12.3.2 HPDMA in low-power modes . . . 550
12.3.3 HPDMA requests . . . 550
12.3.4 HPDMA block requests . . . 554
12.3.5 HPDMA channels with peripheral early termination . . . 554
12.3.6 HPDMA triggers . . . 555
12.4 HPDMA functional description . . . 557
12.4.1 HPDMA block diagram . . . 557
12.4.2 HPDMA channel state and direct programming without any linked-list . . . 558
12.4.3 HPDMA channel suspend and resume . . . 559
12.4.4 HPDMA channel abort and restart . . . 560
12.4.5 HPDMA channel terminate and drain FIFO . . . 561
12.4.6 HPDMA linked-list data structure . . . 563
12.4.7 Linked-list item transfer execution . . . 566
12.4.8 HPDMA channel state and linked-list programming in run-to-completion mode . . . 566
12.4.9 HPDMA channel state and linked-list programming in link step mode . . . 570
12.4.10 HPDMA channel state and linked-list programming . . . 577
12.4.11 HPDMA FIFO-based transfers . . . 579
12.4.12 HPDMA transfer request and arbitration . . . 595
12.4.13 HPDMA triggered transfer . . . 599
12.4.14 HPDMA circular buffering with linked-list programming . . . 600
12.4.15 HPDMA transfer in peripheral flow-control mode . . . 602
12.4.16 HPDMA byte-based padding at the block level . . . 603
12.4.17 HPDMA privileged/unprivileged channel . . . 604
12.4.18 HPDMA error management . . . 605
12.5 HPDMA in debug mode . . . 606
12.6 HPDMA in low-power modes . . . 607
12.7 HPDMA interrupts . . . 607
12.8 HPDMA registers . . . 609
12.8.1 HPDMA privileged configuration register (HPDMA_PRIVCFGR) . . . 609
12.8.2 HPDMA configuration lock register (HPDMA_RCFGLOCKR) . . . 609

12.8.3 HPDMA masked interrupt status register (HPDMA_MISR) 610
12.8.4 HPDMA channel x linked-list base address register (HPDMA_CxLBAR) 611
12.8.5 HPDMA channel x flag clear register (HPDMA_CxFCR) 611
12.8.6 HPDMA channel x status register (HPDMA_CxSR) 612
12.8.7 HPDMA channel x control register (HPDMA_CxCR) 614
12.8.8 HPDMA channel x transfer register 1 (HPDMA_CxTR1) 616
12.8.9 HPDMA channel x transfer register 2 (HPDMA_CxTR2) 620
12.8.10 HPDMA channel x block register 1 (HPDMA_CxBR1) 624
12.8.11 HPDMA channel x alternate block register 1 (HPDMA_CxBR1) 625
12.8.12 HPDMA channel x source address register (HPDMA_CxSAR) 627
12.8.13 HPDMA channel x destination address register (HPDMA_CxDAR) . . 629
12.8.14 HPDMA channel x transfer register 3 (HPDMA_CxTR3) 630
12.8.15 HPDMA channel x block register 2 (HPDMA_CxBR2) 631
12.8.16 HPDMA channel x linked-list address register (HPDMA_CxLLR) 632
12.8.17 HPDMA channel x alternate linked-list address register (HPDMA_CxLLR) 634
12.8.18 HPDMA register map 635

13 General purpose direct memory access controller (GPDMA) 638

13.1 GPDMA introduction 638
13.2 GPDMA main features 638
13.3 GPDMA implementation 639
13.3.1 GPDMA channels 639
13.3.2 GPDMA in low-power modes 640
13.3.3 GPDMA requests 640
13.3.4 GPDMA block requests 644
13.3.5 GPDMA channels with peripheral early termination 645
13.3.6 GPDMA triggers 645
13.4 GPDMA functional description 648
13.4.1 GPDMA block diagram 648
13.4.2 GPDMA channel state and direct programming without any linked-list 648
13.4.3 GPDMA channel suspend and resume 649
13.4.4 GPDMA channel abort and restart 650
13.4.5 GPDMA channel terminate and drain FIFO 651
13.4.6 GPDMA linked-list data structure 652
13.4.7 Linked-list item transfer execution 656

13.4.8 GPDMA channel state and linked-list programming in run-to-completion mode . . . 656
13.4.9 GPDMA channel state and linked-list programming in link step mode . . . 660
13.4.10 GPDMA channel state and linked-list programming . . . 667
13.4.11 GPDMA FIFO-based transfers . . . 669
13.4.12 GPDMA transfer request and arbitration . . . 676
13.4.13 GPDMA triggered transfer . . . 680
13.4.14 GPDMA circular buffering with linked-list programming . . . 681
13.4.15 GPDMA transfer in peripheral flow-control mode . . . 683
13.4.16 GPDMA byte-based padding at the block level . . . 684
13.4.17 GPDMA privileged/unprivileged channel . . . 685
13.4.18 GPDMA error management . . . 686
13.5 GPDMA in debug mode . . . 687
13.6 GPDMA in low-power modes . . . 688
13.7 GPDMA interrupts . . . 688
13.8 GPDMA registers . . . 690
13.8.1 GPDMA privileged configuration register (GPDMA_PRIVCFGR) . . . 690
13.8.2 GPDMA configuration lock register (GPDMA_RCFGLOCKR) . . . 690
13.8.3 GPDMA masked interrupt status register (GPDMA_MISR) . . . 691
13.8.4 GPDMA channel x linked-list base address register (GPDMA_CxLBAR) . . . 691
13.8.5 GPDMA channel x flag clear register (GPDMA_CxFCR) . . . 692
13.8.6 GPDMA channel x status register (GPDMA_CxSR) . . . 693
13.8.7 GPDMA channel x control register (GPDMA_CxCR) . . . 695
13.8.8 GPDMA channel x transfer register 1 (GPDMA_CxTR1) . . . 697
13.8.9 GPDMA channel x transfer register 2 (GPDMA_CxTR2) . . . 700
13.8.10 GPDMA channel x block register 1 (GPDMA_CxBR1) . . . 704
13.8.11 GPDMA channel x alternate block register 1 (GPDMA_CxBR1) . . . 705
13.8.12 GPDMA channel x source address register (GPDMA_CxSAR) . . . 707
13.8.13 GPDMA channel x destination address register (GPDMA_CxDAR) . . 709
13.8.14 GPDMA channel x transfer register 3 (GPDMA_CxTR3) . . . 710
13.8.15 GPDMA channel x block register 2 (GPDMA_CxBR2) . . . 711
13.8.16 GPDMA channel x linked-list address register (GPDMA_CxLLR) . . . 712
13.8.17 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR) . . . 714
13.8.18 GPDMA register map . . . 715

14 Neural-ART accelerator™ (NPU) 718
14.1 NPU introduction 718
14.2 NPU implementation 719
14.3 NPU functional description 720
14.3.1 NPU block diagram 720
14.3.2 NPU pins and internal signals 720
14.3.3 Configuration network 721
14.3.4 Clock/reset manager 721
14.3.5 Stream link 721
14.3.6 Stream switch 722
14.3.7 Stream engines 722
14.3.8 Encryption/Decryption unit 723
14.3.9 Decompression unit 723
14.3.10 Convolutional accelerator 724
14.3.11 Pooling unit 725
14.3.12 Activation unit 726
14.3.13 Arithmetic unit 729
14.3.14 Reconfigurable buffer 730
14.3.15 Epoch controller 730
14.3.16 Interrupt controller 731
14.4 Configuration examples 731
14.4.1 DMA transfer 731
14.4.2 Simple processing 731
14.4.3 Multiple processing 732
14.4.4 Conv-Pool-ReLU 732
14.5 Address space 733

15 Nested vectored interrupt controller (NVIC) 734
15.1 NVIC features 734
15.1.1 SysTick 734
15.1.2 Interrupt and exception vectors 736

16 Extended interrupt and event controller (EXTI) 744
16.1 EXTI main features 744
16.2 EXTI block diagram 744
16.2.1 EXTI connections between peripherals and CPU 745

16.3 EXTI functional description 746
16.3.1 EXTI configurable event input - CPU wake-up 747
16.3.2 EXTI direct event input - CPU wake up 748
16.4 EXTI event input mapping 749
16.5 EXTI functional behavior 751
16.5.1 EXTI CPU interrupt procedure 752
16.5.2 EXTI CPU event procedure 752
16.5.3 EXTI CPU wake-up procedure 752
16.5.4 EXTI software interrupt/event trigger procedure 752
16.6 EXTI registers 753
16.6.1 EXTI rising trigger selection register 1 (EXTI_RTSR1) 753
16.6.2 EXTI falling trigger selection register 1 (EXTI_FTSR1) 753
16.6.3 EXTI software interrupt event register 1 (EXTI_SWIER1) 754
16.6.4 EXTI rising trigger selection register 2 (EXTI_RTSR2) 754
16.6.5 EXTI falling trigger selection register 2 (EXTI_FTSR2) 755
16.6.6 EXTI software interrupt event register 2 (EXTI_SWIER2) 756
16.6.7 EXTI rising trigger selection register 3 (EXTI_RTSR3) 757
16.6.8 EXTI falling trigger selection register 3 (EXTI_FTSR3) 757
16.6.9 EXTI software interrupt event register 3 (EXTI_SWIER3) 758
16.6.10 EXTI interrupt mask register 1 (EXTI_IMR1) 758
16.6.11 EXTI event mask register 1 (EXTI_EMR1) 758
16.6.12 EXTI pending register 1 (EXTI_PR1) 759
16.6.13 EXTI interrupt mask register 2 (EXTI_IMR2) 760
16.6.14 EXTI event mask register 2 (EXTI_EMR2) 760
16.6.15 EXTI pending register 2 (EXTI_PR2) 761
16.6.16 EXTI interrupt mask register 3 (EXTI_IMR3) 762
16.6.17 EXTI event mask register 3 (EXTI_EMR3) 762
16.6.18 EXTI pending register 3 (EXTI_PR3) 763
16.6.19 EXTI register map 764

17 Cyclic redundancy check calculation unit (CRC) 766
17.1 CRC introduction 766
17.2 CRC main features 766
17.3 CRC functional description 767
17.3.1 CRC block diagram 767
17.3.2 CRC internal signals 767

17.3.3 CRC operation . . . 767
17.4 CRC registers . . . 769
17.4.1 CRC data register (CRC_DR) . . . 769
17.4.2 CRC independent data register (CRC_IDR) . . . 769
17.4.3 CRC control register (CRC_CR) . . . 770
17.4.4 CRC initial value (CRC_INIT) . . . 771
17.4.5 CRC polynomial (CRC_POL) . . . 771
17.4.6 CRC register map . . . 772

18 CORDIC coprocessor (CORDIC) . . . 773
18.1 CORDIC introduction . . . 773
18.2 CORDIC main features . . . 773
18.3 CORDIC functional description . . . 773
18.3.1 General description . . . 773
18.3.2 CORDIC functions . . . 773
18.3.3 Fixed point representation . . . 780
18.3.4 Scaling factor . . . 780
18.3.5 Precision . . . 781
18.3.6 Zero-overhead mode . . . 784
18.3.7 Polling mode . . . 785
18.3.8 Interrupt mode . . . 786
18.3.9 DMA mode . . . 786
18.4 CORDIC registers . . . 787
18.4.1 CORDIC control/status register (CORDIC_CSR) . . . 787
18.4.2 CORDIC argument register (CORDIC_WDATA) . . . 789
18.4.3 CORDIC result register (CORDIC_RDATA) . . . 790
18.4.4 CORDIC register map . . . 790

19 Filter math accelerator (FMAC) . . . 791
19.1 FMAC introduction . . . 791
19.2 FMAC main features . . . 791
19.3 FMAC functional description . . . 792
19.3.1 General description . . . 792
19.3.2 Local memory and buffers . . . 793
19.3.3 Input buffers . . . 793
19.3.4 Output buffer . . . 796

19.3.5 Initialization functions . . . 798
19.3.6 Filter functions . . . 799
19.3.7 Fixed point representation . . . 803
19.3.8 Implementing FIR filters with the FMAC . . . 803
19.3.9 Implementing IIR filters with the FMAC . . . 805
19.3.10 Examples of filter initialization . . . 807
19.3.11 Examples of filter operation . . . 808
19.3.12 Filter design tips . . . 810
19.4 FMAC registers . . . 811
19.4.1 FMAC X1 buffer configuration register (FMAC_X1BUFCFG) . . . 811
19.4.2 FMAC X2 buffer configuration register (FMAC_X2BUFCFG) . . . 811
19.4.3 FMAC Y buffer configuration register (FMAC_YBUFCFG) . . . 812
19.4.4 FMAC parameter register (FMAC_PARAM) . . . 813
19.4.5 FMAC control register (FMAC_CR) . . . 814
19.4.6 FMAC status register (FMAC_SR) . . . 815
19.4.7 FMAC write data register (FMAC_WDATA) . . . 816
19.4.8 FMAC read data register (FMAC_RDATA) . . . 817
19.4.9 FMAC register map . . . 817

20 Hardware signal processor (HSP) . . . 819
20.1 HSP introduction . . . 819
20.2 HSP main features . . . 821
20.3 HSP implementation . . . 822
20.4 HSP functional description . . . 823
20.4.1 HSP block diagram . . . 823
20.4.2 HSP pins and internal signals . . . 823
20.4.3 Floating-point format . . . 826
20.4.4 Memory management . . . 827
20.4.5 HSP boot . . . 831
20.4.6 Message box (MSGB) . . . 835
20.4.7 Direct command interface (DCMD) . . . 837
20.4.8 STREAM interface . . . 841
20.4.9 Trigger input interface (TRGITF) . . . 845
20.4.10 Software events generator (SEG) . . . 848
20.4.11 Event controller (EVTC) . . . 851
20.4.12 HSP interrupt controller (HITC) . . . 859
20.4.13 HSP reset and clocking . . . 867

20.4.14 Task comparator unit (TCU) . . . 869
20.4.15 Trigger outputs (TRGO) . . . 871
20.4.16 Time-stamp capture (TSC) . . . 872
20.4.17 BRAM conflict counter . . . 879
20.4.18 Snoop function (SNOOP) . . . 879
20.4.19 Break interface (BKITF) . . . 880
20.5 Debug . . . 884
20.5.1 Register protection . . . 885
20.6 HSP firmware description . . . 887
20.6.1 Processing list mapping . . . 887
20.6.2 Sending commands to the HSP . . . 888
20.6.3 Recording processing lists . . . 891
20.6.4 Executing direct commands (accelerator mode) . . . 892
20.6.5 Data buffer handling . . . 894
20.6.6 Performance monitoring . . . 894
20.6.7 Processing functions summary . . . 894
20.7 HSP registers . . . 900
20.7.1 HSP control register (HSP_CR) . . . 900
20.7.2 HSP CPU-to-HSP semaphore register (HSP_C2HSEMR) . . . 902
20.7.3 HSP CPU-to-HSP message data register (HSP_C2HMSGDR) . . . 902
20.7.4 HSP HSP-to-CPU semaphore register (HSP_H2CSEMR) . . . 903
20.7.5 HSP HSP-to-CPU message data register (HSP_H2CMSGDR) . . . 903
20.7.6 HSP DCMD command status register (HSP_DCMDSR) . . . 904
20.7.7 HSP DCMD pointer status register (HSP_DCMDPTSR) . . . 904
20.7.8 HSP DCMD command ID register (HSP_DCMDIDR) . . . 905
20.7.9 HSP DCMD address pointer register x (HSP_DCMDPTRx) . . . 906
20.7.10 HSP event enable register (HSP_EVTENR) . . . 906
20.7.11 HSP event synchronization enable register (HSP_ESYNCENR) . . . 907
20.7.12 HSP event synchronization source register 0 (HSP_ESYNC0SRCR) . . . 907
20.7.13 HSP event synchronization source register 1 (HSP_ESYNC1SRCR) . . . 909
20.7.14 HSP event synchronization source register 2 (HSP_ESYNC2SRCR) . . . 911
20.7.15 HSP pending event level register (HSP_PEVTLR) . . . 913
20.7.16 HSP interface enable register (HSP_ITFENR) . . . 913
20.7.17 HSP event source register 0 (HSP_EVTSRC0R) . . . 915
20.7.18 HSP event source register 1 (HSP_EVTSRC1R) . . . 917

20.7.19 HSP event source register 2 (HSP_EVTSRC2R) 920
20.7.20 HSP BUFF configuration register (HSP_BUFFCFGR) 922
20.7.21 HSP BUFFx data register x (HSP_BUFFxDR) 923
20.7.22 HSP TRGIN configuration register (HSP_TRGINCFGR) 923
20.7.23 HSP TRGO configuration register (HSP_TRGOCFGR) 924
20.7.24 HSP TRGIN input selection register 0 (HSP_TRGINSELR0) 924
20.7.25 HSP TRGIN input selection register 1 (HSP_TRGINSELR1) 925
20.7.26 HSP TRGIN input selection register 2 (HSP_TRGINSELR2) 926
20.7.27 HSP CPU shared event generator register (HSP_CSEGR) 927
20.7.28 HSP CPU dedicated event generation register (HSP_CDEGR) 928
20.7.29 HSP task comparator unit register (HSP_TCUCFGR) 928
20.7.30 HSP task overlap control register (HSP_TOVLPCR) 930
20.7.31 HSP SNOOP register (HSP_SNPR) 930
20.7.32 HSP conflict counter register (HSP_CCNTR) 931
20.7.33 HSP data capture register (HSP_CAPDR) 932
20.7.34 HSP data capture register [alternate] (HSP_CAPDR) 932
20.7.35 HSP capture control register (HSP_CAPCR) 933
20.7.36 HSP break output configuration register x (HSP_BKOxCFGR) 934
20.7.37 HSP break input configuration register (HSP_BKICFGR) 935
20.7.38 HSP SPE interrupt enable register (HSP_SPE_IER) 937
20.7.39 HSP SPE interrupt status register (HSP_SPE_ISR) 937
20.7.40 HSP error interrupt enable register (HSP_ERR_IER) 938
20.7.41 HSP events interrupt enable register (HSP_EVT_IER) 940
20.7.42 HSP processing event interrupt enable register (HSP_PFCTEVT_IER) 941
20.7.43 HSP error interrupt status register (HSP_ERR_ISR) 942
20.7.44 HSP events interrupt status register (HSP_EVT_ISR) 943
20.7.45 HSP processing event interrupt status register (HSP_PFCTEVT_ISR) 945
20.7.46 HSP error interrupt clear register (HSP_ERR_ICR) 945
20.7.47 HSP events interrupt clear register (HSP_EVT_ICR) 947
20.7.48 HSP processing event interrupt clear register (HSP_PFCTEVT_ICR) 948
20.7.49 HSP error information register (HSP_ERRINFR) 948
20.7.50 HSP firmware error register (HSP_FWERR) 950
20.7.51 HSP parameter register x (HSP_PARAMRx) 950
20.7.52 HSP firmware versions register (HSP_FWVERR) 951
20.7.53 HSP SPE version register (HSP_SPEVERR) 951
20.7.54 HSP register map 952

21.4 AHB interface 961
21.5 AXI interface 961
21.5.1 Supported memories and transactions 962
21.6 External device address mapping 963
21.6.1 NOR/PSRAM address mapping 964
21.6.2 NAND flash memory address mapping 964
21.6.3 SDRAM address mapping 965
21.7 NOR flash/PSRAM controller 968
21.7.1 External memory interface signals 970
21.7.2 Supported memories and transactions 972
21.7.3 General timing rules 973
21.7.4 NOR flash/PSRAM controller asynchronous transactions 973
21.7.5 Synchronous transactions 993
21.7.6 NOR/PSRAM controller registers 999
21.8 NAND flash controller 1008
21.8.1 External memory interface signals 1008
21.8.2 NAND flash supported memories and transactions 1009
21.8.3 Timing diagrams for NAND flash memories 1010
21.8.4 NAND flash operations 1011
21.8.5 NAND flash prewait feature 1012
21.8.6 Computation of the error correction code (ECC) in NAND flash memory 1013
21.8.7 NAND flash controller registers 1014
21.9 SDRAM controller 1020
21.9.1 SDRAM controller main features 1020
21.9.2 SDRAM External memory interface signals 1020
21.9.3 SDRAM controller functional description 1021
21.9.4 Low-power modes 1027
21.9.5 SDRAM controller registers 1029
21.9.6 FMC register map 1036

22 Extended-SPI interface (XSPI) 1039

22.1 XSPI introduction . . . 1039
22.2 XSPI main features . . . 1039
22.3 XSPI implementation . . . 1040
22.4 XSPI functional description . . . 1041
22.4.1 XSPI block diagram . . . 1041
22.4.2 XSPI pins and internal signals . . . 1042
22.4.3 Clock constraints . . . 1043
22.4.4 XSPI interface to memory modes . . . 1043
22.4.5 XSPI regular-command protocol . . . 1043
22.4.6 XSPI regular-command protocol signal interface . . . 1047
22.4.7 HyperBus protocol . . . 1050
22.4.8 Specific features . . . 1054
22.4.9 XSPI operating mode introduction . . . 1055
22.4.10 XSPI indirect mode . . . 1055
22.4.11 XSPI automatic status-polling mode . . . 1057
22.4.12 XSPI memory-mapped mode . . . 1057
22.4.13 XSPI configuration introduction . . . 1059
22.4.14 XSPI system configuration . . . 1059
22.4.15 XSPI device configuration . . . 1059
22.4.16 XSPI regular-command mode configuration . . . 1062
22.4.17 XSPI HyperBus protocol configuration . . . 1065
22.4.18 XSPI error management . . . 1065
22.4.19 XSPI BUSY and ABORT . . . 1066
22.4.20 XSPI reconfiguration or deactivation . . . 1067
22.4.21 NCS behavior . . . 1067
22.4.22 Software control of two external memories . . . 1067
22.4.23 Hardware-controlled extended memory support . . . 1068
22.5 Address alignment and data number . . . 1069
22.6 XSPI interrupts . . . 1070
22.7 XSPI registers . . . 1071
22.7.1 XSPI control register (XSPI_CR) . . . 1071
22.7.2 XSPI device configuration register 1 (XSPI_DCR1) . . . 1074
22.7.3 XSPI device configuration register 2 (XSPI_DCR2) . . . 1076
22.7.4 XSPI device configuration register 3 (XSPI_DCR3) . . . 1077
22.7.5 XSPI device configuration register 4 (XSPI_DCR4) . . . 1077
22.7.6 XSPI status register (XSPI_SR) . . . 1078

22.7.7 XSPI flag clear register (XSPI_FCR) 1079
22.7.8 XSPI data length register (XSPI_DLR) 1079
22.7.9 XSPI address register (XSPI_AR) 1080
22.7.10 XSPI data register (XSPI_DR) 1081
22.7.11 XSPI polling status mask register (XSPI_PSMKR) 1081
22.7.12 XSPI polling status match register (XSPI_PSMAR) 1082
22.7.13 XSPI polling interval register (XSPI_PIR) 1082
22.7.14 XSPI communication configuration register (XSPI_CCR) 1082
22.7.15 XSPI timing configuration register (XSPI_TCR) 1084
22.7.16 XSPI instruction register (XSPI_IR) 1085
22.7.17 XSPI alternate bytes register (XSPI_ABR) 1085
22.7.18 XSPI low-power timeout register (XSPI_LPTR) 1086
22.7.19 XSPI wrap communication configuration register (XSPI_WPCCR) 1086
22.7.20 XSPI wrap timing configuration register (XSPI_WPTCR) 1088
22.7.21 XSPI wrap instruction register (XSPI_WPIR) 1089
22.7.22 XSPI wrap alternate bytes register (XSPI_WPABR) 1089
22.7.23 XSPI write communication configuration register (XSPI_WCCR) 1090
22.7.24 XSPI write timing configuration register (XSPI_WTCR) 1092
22.7.25 XSPI write instruction register (XSPI_WIR) 1092
22.7.26 XSPI write alternate bytes register (XSPI_WABR) 1093
22.7.27 XSPI HyperBus latency configuration register (XSPI_HLCR) 1093
22.7.28 XSPI register map 1094

23 Secure digital input/output MultiMediaCard interface (SDMMC) . . 1097

23.1 SDMMC main features 1097
23.2 SDMMC implementation 1097
23.3 SDMMC bus topology 1098
23.4 SDMMC operation modes 1100
23.5 SDMMC functional description 1101
23.5.1 SDMMC block diagram 1101
23.5.2 SDMMC pins and internal signals 1101
23.5.3 General description 1102
23.5.4 SDMMC adapter 1104
23.5.5 SDMMC AHB slave interface 1126

23.5.6 SDMMC AHB master interface 1127
23.5.7 AHB and SDMMC_CK clock relation 1130
23.6 Card functional description 1130
23.6.1 SD I/O mode 1130
23.6.2 CMD12 send timing 1138
23.6.3 Sleep (CMD5) 1142
23.6.4 Interrupt mode (Wait-IRQ) 1143
23.6.5 Boot operation 1144
23.6.6 Response R1b handling 1147
23.6.7 Reset and card cycle power 1148
23.7 Hardware flow control 1149
23.8 Ultra-high-speed phase I (UHS-I) voltage switch 1150
23.9 SDMMC interrupts 1153
23.10 SDMMC registers 1154
23.10.1 SDMMC power control register (SDMMC_POWER) 1154
23.10.2 SDMMC clock control register (SDMMC_CLKCR) 1155
23.10.3 SDMMC argument register (SDMMC_ARGR) 1157
23.10.4 SDMMC command register (SDMMC_CMDR) 1157
23.10.5 SDMMC command response register (SDMMC_RESPCMDR) 1159
23.10.6 SDMMC response x register (SDMMC_RESPxR) 1160
23.10.7 SDMMC data timer register (SDMMC_DTIMER) 1160
23.10.8 SDMMC data length register (SDMMC_DLENR) 1161
23.10.9 SDMMC data control register (SDMMC_DCTRL) 1162
23.10.10 SDMMC data counter register (SDMMC_DCNTR) 1163
23.10.11 SDMMC status register (SDMMC_STAR) 1164
23.10.12 SDMMC interrupt clear register (SDMMC_ICR) 1167
23.10.13 SDMMC mask register (SDMMC_MASKR) 1169
23.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER) . . . 1172
23.10.15 SDMMC DMA control register (SDMMC_IDMACTRLR) 1172
23.10.16 SDMMC IDMA buffer size register (SDMMC_IDMABSIZER) 1173
23.10.17 SDMMC IDMA buffer base address register (SDMMC_IDMABASER) 1174
23.10.18 SDMMC IDMA linked list address register (SDMMC_IDMALAR) . . . 1174
23.10.19 SDMMC IDMA linked list memory base register (SDMMC_IDMABAR) 1175
23.10.20 SDMMC data FIFO registers x (SDMMC_FIFORx) 1176
23.10.21 SDMMC register map 1176

24 Delay block (DLYB) 1179

24.1 DLYB introduction 1179

24.2 DLYB main features 1179

24.3 DLYB implementation 1179

24.4 DLYB functional description 1179

24.4.1 DLYB diagram 1179

24.4.2 DLYB pins and internal signals 1180

24.4.3 General description 1180

24.4.4 Delay line length configuration procedure 1181

24.4.5 Output clock phase configuration procedure 1182

24.5 DLYB registers 1183

24.5.1 DLYB control register (DLYB_CR) 1183

24.5.2 DLYB configuration register (DLYB_CFGR) 1183

24.5.3 DLYB register map 1184

25 Analog-to-digital converters (ADC) 1185

25.1 ADC introduction 1185

25.2 ADC main features 1186

25.3 ADC implementation 1187

25.4 ADC functional description 1188

25.4.1 ADC block diagram 1188

25.4.2 ADC pins and internal signals 1189

25.4.3 ADC clocks 1194

25.4.4 ADC connectivity 1196

25.4.5 Slave AHB interface 1200

25.4.6 ADC Deep-power-down mode (DEEPPWD) 1200

25.4.7 Single-ended and differential input channels 1200

25.4.8 Pseudodifferential mode 1201

25.4.9 Calibration (ADCAL, ADCALDIF, ADC_CALFACT) 1201

25.4.10 ADC on-off control (ADEN, ADDIS, ADRDY) 1204

25.4.11 Constraints when writing the ADC control bits 1205

25.4.12 Channel selection (ADC_SQRy, ADC_JSQR) 1206

25.4.13 Channel preselection register (ADC_PCSEL) 1207

25.4.14 Channel-wise programmable sampling time (SMPR1, SMPR2) 1207

25.4.15 Single conversion mode 1209

25.4.16 Continuous conversion mode (CONT = 1) 1210

25.4.17 Discontinuous mode (DISCEN, DISCNUM, JDISCEN) 1210
25.4.18 Starting conversions (ADSTART, JADSTART) 1212
25.4.19 Timing 1213
25.4.20 Stopping an ongoing conversion (ADSTP, JADSTP) 1213
25.4.21 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN) 1215
25.4.22 Injected channel management 1216
25.4.23 Queue of context for injected conversions 1217
25.4.24 Programmable resolution (RES) - fast conversion mode 1225
25.4.25 End of conversion and end of sampling phase (EOC, JEOC, EOSMP) 1226
25.4.26 End of conversion sequence (EOS, JEOS) 1226
25.4.27 Timing diagram examples (single/continuous modes, hardware/software triggers) 1227
25.4.28 Data management 1229
25.4.29 Managing conversions using the ADF 1237
25.4.30 Dynamic low-power features 1238
25.4.31 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT) 1241
25.4.32 Oversampler 1246
25.4.33 Parallel injected oversampling mode 1252
25.4.34 Dual ADC modes 1254
25.4.35 Temperature sensor 1270
25.4.36 VBAT supply monitoring 1272
25.4.37 Monitoring the internal voltage reference 1273
25.4.38 Monitoring the DAC output voltage 1274
25.4.39 Monitoring the supply voltage 1274
25.5 ADC interrupts 1275
25.6 ADC registers (for each ADC) 1276
25.6.1 ADC interrupt and status register (ADC_ISR) 1276
25.6.2 ADC interrupt enable register (ADC_IER) 1279
25.6.3 ADC control register (ADC_CR) 1281
25.6.4 ADC configuration register (ADC_CFGR1) 1284
25.6.5 ADC configuration register 2 (ADC_CFGR2) 1287
25.6.6 ADC sample time register 1 (ADC_SMPR1) 1290
25.6.7 ADC sample time register 2 (ADC_SMPR2) 1291
25.6.8 ADC channel preselection register (ADC_PCSEL) 1291

25.6.9 ADC regular sequence register 1 (ADC_SQR1) 1292
25.6.10 ADC regular sequence register 2 (ADC_SQR2) 1293
25.6.11 ADC regular sequence register 3 (ADC_SQR3) 1294
25.6.12 ADC regular sequence register 4 (ADC_SQR4) 1295
25.6.13 ADC regular data register (ADC_DR) 1296
25.6.14 ADC injected sequence register (ADC_JSQR) 1296
25.6.15 ADC offset y configuration register (ADC_OFCFGRy) 1298
25.6.16 ADC offset y register (ADC_OFRy) 1299
25.6.17 ADC gain compensation register (ADC_GCOMP) 1299
25.6.18 ADC analog watchdog y source channel register (ADC_AWDySR) . 1300
25.6.19 ADC injected channel y data register (ADC_JDRy) 1301
25.6.20 ADC configuration register 3 (ADC_CFGR3) 1301
25.6.21 ADC injected oversampling counter register 1 (ADC_JOVSCR1) . . . 1303
25.6.22 ADC injected oversampling counter register 2 (ADC_JOVSCR2) . . . 1304
25.6.23 ADC analog watchdog 2 configuration register (ADC_AWD2CR) . . . 1305
25.6.24 ADC analog watchdog 3 configuration register (ADC_AWD3CR) . . . 1305
25.6.25 ADC analog watchdog 1 lower threshold register (ADC_AWD1LTR) 1306
25.6.26 ADC analog watchdog 1 higher threshold register (ADC_AWD1HTR) 1306
25.6.27 ADC analog watchdog 2 lower threshold register (ADC_AWD2LTR) 1307
25.6.28 ADC analog watchdog 2 higher threshold register (ADC_AWD2HTR) 1307
25.6.29 ADC analog watchdog 3 lower threshold register (ADC_AWD3LTR) 1308
25.6.30 ADC analog watchdog 3 higher threshold register (ADC_AWD3HTR) 1308
25.6.31 ADC differential mode selection register (ADC_DIFSEL) 1309
25.6.32 ADC calibration factors (ADC_CALFACT) 1309
25.6.33 ADC option register (ADC_OR) 1311
25.7 ADC common registers 1313
25.7.1 ADC common status register (ADCC_CSR) 1313
25.7.2 ADC common control register (ADCC_CCR) 1314
25.7.3 ADC common regular data register for dual mode (ADCC_CDR) 1316
25.7.4 ADC common regular data register for dual mode (ADCC_CDR2) 1317
25.8 ADC register map 1317

26 Digital temperature sensor (DTS) 1322

26.1 DTS introduction 1322
26.2 DTS main features 1322
26.3 DTS functional description 1323
26.3.1 DTS block diagram 1323
26.3.2 DTS internal signals 1323
26.3.3 DTS block operation 1324
26.3.4 Operating modes 1324
26.3.5 Calibration 1324
26.3.6 Prescaler 1324
26.3.7 Temperature measurement principles 1325
26.3.8 Sampling time 1326
26.3.9 Quick measurement mode 1326
26.3.10 Trigger input 1327
26.3.11 On-off control and ready flag 1327
26.3.12 Temperature measurement sequence 1328
26.4 DTS low-power modes 1329
26.5 DTS interrupts 1329
26.5.1 Temperature window comparator 1329
26.5.2 Synchronous interrupt 1329
26.5.3 Asynchronous wake-up 1329
26.6 DTS registers 1330
26.6.1 Temperature sensor configuration register 1 (DTS_CFGR1) 1330
26.6.2 Temperature sensor T0 value register 1 (DTS_T0VALR1) 1331
26.6.3 Temperature sensor ramp value register (DTS_RAMPVALR) 1332
26.6.4 Temperature sensor interrupt threshold register 1 (DTS_ITR1) 1332
26.6.5 Temperature sensor data register (DTS_DR) 1333
26.6.6 Temperature sensor status register (DTS_SR) 1333
26.6.7 Temperature sensor interrupt enable register (DTS_ITENR) 1334
26.6.8 Temperature sensor clear interrupt flag register (DTS_ICIFR) 1336
26.6.9 Temperature sensor option register (DTS_OR) 1336
26.6.10 DTS register map 1337

27 Digital-to-analog converter (DAC) 1339
27.1 DAC introduction 1339
27.2 DAC main features 1339
27.3 DAC implementation 1340

27.4 DAC functional description 1341
27.4.1 DAC block diagram 1341
27.4.2 DAC pins and internal signals 1342
27.4.3 DAC channel enable 1344
27.4.4 DAC data format 1345
27.4.5 DAC conversion 1346
27.4.6 DAC output voltage 1347
27.4.7 DAC trigger selection 1348
27.4.8 DMA requests 1348
27.4.9 Noise generation 1349
27.4.10 Triangle-wave generation 1350
27.4.11 DAC sawtooth wave generation 1351
27.4.12 DAC extended sawtooth wave generation 1353
27.4.13 DAC channel modes 1356
27.4.14 DAC channel buffer calibration 1359
27.4.15 DAC channel conversion modes 1360
27.4.16 Dual DAC channel conversion modes (if dual channels are available) 1361
27.5 DAC in low-power modes 1366
27.6 DAC interrupts 1367
27.7 DAC registers 1367
27.7.1 DAC control register (DAC_CR) 1367
27.7.2 DAC software trigger register (DAC_SWTRGR) 1370
27.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1) 1371
27.7.4 DAC channel1 12-bit left aligned data holding register (DAC_DHR12L1) 1372
27.7.5 DAC channel1 8-bit right aligned data holding register (DAC_DHR8R1) 1372
27.7.6 DAC channel2 12-bit right aligned data holding register (DAC_DHR12R2) 1373
27.7.7 DAC channel2 12-bit left aligned data holding register (DAC_DHR12L2) 1373
27.7.8 DAC channel2 8-bit right-aligned data holding register (DAC_DHR8R2) 1374
27.7.9 Dual DAC 12-bit right-aligned data holding register (DAC_DHR12RD) 1374
27.7.10 Dual DAC 12-bit left aligned data holding register (DAC_DHR12LD) 1375

27.7.11 Dual DAC 8-bit right aligned data holding register (DAC_DHR8RD) . . . 1375
27.7.12 DAC channel1 data output register (DAC_DOR1) . . . 1376
27.7.13 DAC channel2 data output register (DAC_DOR2) . . . 1376
27.7.14 DAC status register (DAC_SR) . . . 1377
27.7.15 DAC calibration control register (DAC_CCR) . . . 1378
27.7.16 DAC mode control register (DAC_MCR) . . . 1379
27.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1) . . . 1380
27.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2) . . . 1381
27.7.19 DAC sample and hold time register (DAC_SHHR) . . . 1381
27.7.20 DAC sample and hold refresh time register (DAC_SHRR) . . . 1382
27.7.21 DAC channel1 sawtooth register (DAC_STR1) . . . 1383
27.7.22 DAC channel2 sawtooth register (DAC_STR2) . . . 1383
27.7.23 DAC sawtooth mode register (DAC_STMODR) . . . 1384
27.7.24 DAC extended sawtooth reset control register (DAC_STEXTRST) . 1385
27.7.25 DAC extended sawtooth minimum and maximum value register (DAC_STEXTMM1) . . . 1385
27.7.26 DAC extended sawtooth minimum and maximum value register (DAC_STEXTMM2) . . . 1386
27.7.27 DAC option register (DAC_OR) . . . 1386

30.4 ADF functional description 1416
30.4.1 ADF block diagram 1416
30.4.2 ADF pins and internal signals 1416
30.4.3 Serial input interface (SITF) 1417
30.4.4 ADC slave interface (ADCITF) 1422
30.4.5 Clock generator (CKGEN) 1422

30.4.6 Bitstream matrix (BSMX) . . . 1424
30.4.7 Digital filter processing (DFLT) . . . 1425
30.4.8 Digital filter acquisition modes . . . 1435
30.4.9 Start-up sequence examples . . . 1443
30.4.10 Sound activity detection (SAD) . . . 1444
30.4.11 Data transfer to memory . . . 1452
30.4.12 Autonomous mode . . . 1455
30.4.13 Register protection . . . 1455
30.5 ADF low-power modes . . . 1456
30.6 ADF interrupts . . . 1456
30.7 ADF application information . . . 1458
30.7.1 ADF configuration examples for audio capture . . . 1458
30.7.2 Programming examples . . . 1459
30.7.3 Connection examples . . . 1461
30.7.4 Global frequency response . . . 1462
30.7.5 Total ADF gain . . . 1463
30.7.6 How to compute SAD thresholds . . . 1466
30.8 ADF registers . . . 1470
30.8.1 ADF global control register (ADF_GCR) . . . 1470
30.8.2 ADF clock generator control register (ADF_CKGCR) . . . 1470
30.8.3 ADF serial interface control register 0 (ADF_SITF0CR) . . . 1472
30.8.4 ADF bitstream matrix control register 0 (ADF_BSMX0CR) . . . 1474
30.8.5 ADF digital filter control register 0 (ADF_DFLT0CR) . . . 1474
30.8.6 ADF digital filer configuration register 0 (ADF_DFLT0CICR) . . . 1476
30.8.7 ADF reshape filter configuration register 0 (ADF_DFLT0RSFR) . . . 1477
30.8.8 ADF delay control register 0 (ADF_DLY0CR) . . . 1478
30.8.9 ADF DFLT0 interrupt enable register (ADF_DFLT0IER) . . . 1479
30.8.10 ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR) . . . 1480
30.8.11 ADF SAD control register (ADF_SADCR) . . . 1481
30.8.12 ADF SAD configuration register (ADF_SADCFGR) . . . 1483
30.8.13 ADF SAD sound level register (ADF_SADSDLVR) . . . 1484
30.8.14 ADF SAD ambient noise level register (ADF_SADANLVR) . . . 1485
30.8.15 ADF digital filter data register 0 (ADF_DFLT0DR) . . . 1485
30.8.16 ADF register map . . . 1485

31 True random number generator (RNG) . . . 1488

31.1 RNG introduction . . . 1488

31.2 RNG main features . . . 1488
31.3 RNG functional description . . . 1489
31.3.1 RNG block diagram . . . 1489
31.3.2 RNG internal signals . . . 1489
31.3.3 Random number generation . . . 1490
31.3.4 RNG initialization . . . 1492
31.3.5 RNG operation . . . 1493
31.3.6 RNG clocking . . . 1495
31.3.7 Error management . . . 1495
31.3.8 RNG low-power use . . . 1497
31.4 RNG interrupts . . . 1497
31.5 RNG processing time . . . 1498
31.6 RNG entropy source validation . . . 1498
31.6.1 Introduction . . . 1498
31.6.2 Validation conditions . . . 1498
31.7 RNG registers . . . 1500
31.7.1 RNG control register (RNG_CR) . . . 1500
31.7.2 RNG status register (RNG_SR) . . . 1502
31.7.3 RNG data register (RNG_DR) . . . 1503
31.7.4 RNG noise source control register (RNG_NSCR) . . . 1504
31.7.5 RNG health test control register x (RNG_HTCRx) . . . 1504
31.7.6 RNG health test status register 0 (RNG_HTSR0) . . . 1505
31.7.7 RNG health test status register 1 (RNG_HTSR1) . . . 1505
31.7.8 RNG noise source mask register (RNG_NSMR) . . . 1506
31.7.9 RNG register map . . . 1507

32 Hash processor (HASH) . . . 1508
32.1 HASH introduction . . . 1508
32.2 HASH main features . . . 1508
32.3 HASH implementation . . . 1509
32.4 HASH functional description . . . 1509
32.4.1 HASH block diagram . . . 1509
32.4.2 HASH internal signals . . . 1509
32.4.3 About secure hash algorithms . . . 1510
32.4.4 Message data feeding . . . 1510
32.4.5 Message digest computing . . . 1511

32.4.6 Message padding . . . 1513
32.4.7 HMAC operation . . . 1515
32.4.8 HASH suspend/resume operations . . . 1516
32.4.9 HASH DMA interface . . . 1518
32.4.10 HASH error management . . . 1519
32.4.11 HASH processing time . . . 1519
32.5 HASH interrupts . . . 1520
32.6 HASH registers . . . 1520
32.6.1 HASH control register (HASH_CR) . . . 1520
32.6.2 HASH data input register (HASH_DIN) . . . 1522
32.6.3 HASH start register (HASH_STR) . . . 1523
32.6.4 HASH digest registers . . . 1524
32.6.5 HASH interrupt enable register (HASH_IMR) . . . 1526
32.6.6 HASH status register (HASH_SR) . . . 1526
32.6.7 HASH context swap registers . . . 1527
32.6.8 HASH register map . . . 1528

33 High-resolution timer (HRTIM) . . . 1530
33.1 Introduction . . . 1530
33.2 Main features . . . 1531
33.3 Functional description . . . 1532
33.3.1 General description . . . 1532
33.3.2 HRTIM pins and internal signals . . . 1534
33.3.3 Clocks . . . 1540
33.3.4 Timer A..F timing units . . . 1543
33.3.5 Master timer . . . 1570
33.3.6 Up-down counting mode . . . 1572
33.3.7 Set/reset events priorities and narrow pulses management . . . 1579
33.3.8 External events global conditioning . . . 1580
33.3.9 External event filtering in timing units . . . 1585
33.3.10 Delayed protection . . . 1592
33.3.11 Register preload and update management . . . 1598
33.3.12 PWM mode with “greater than” comparison . . . 1602
33.3.13 Events propagation within or across multiple timers . . . 1603
33.3.14 Output management . . . 1608
33.3.15 Burst mode controller . . . 1610
33.3.16 Chopper . . . 1618

33.3.17 Fault protection . . . 1619
33.3.18 Auxiliary outputs . . . 1624
33.3.19 Synchronizing the HRTIM with other timers or HRTIM instances . . . 1627
33.3.20 ADC triggers . . . 1630
33.3.21 DAC triggers . . . 1634
33.3.22 Interrupts . . . 1638
33.3.23 DMA . . . 1640
33.3.24 HRTIM initialization . . . 1644
33.3.25 Debug . . . 1645
33.4 Application use cases . . . 1646
33.4.1 Buck converter . . . 1646
33.4.2 Buck converter with synchronous rectification . . . 1647
33.4.3 Multiphase converters . . . 1648
33.4.4 Transition mode power factor correction . . . 1649
33.5 HRTIM registers . . . 1652
33.5.1 HRTIM master timer control register (HRTIM_MCR) . . . 1652
33.5.2 HRTIM master timer interrupt status register (HRTIM_MISR) . . . 1655
33.5.3 HRTIM master timer interrupt clear register (HRTIM_MICR) . . . 1656
33.5.4 HRTIM master timer DMA interrupt enable register (HRTIM_MDIER) . . . 1657
33.5.5 HRTIM master timer counter register (HRTIM_MCNTR) . . . 1659
33.5.6 HRTIM master timer period register (HRTIM_MPER) . . . 1659
33.5.7 HRTIM master timer repetition register (HRTIM_MREP) . . . 1660
33.5.8 HRTIM master timer compare 1 register (HRTIM_MCMP1R) . . . 1660
33.5.9 HRTIM master timer compare 2 register (HRTIM_MCMP2R) . . . 1661
33.5.10 HRTIM master timer compare 3 register (HRTIM_MCMP3R) . . . 1661
33.5.11 HRTIM master timer compare 4 register (HRTIM_MCMP4R) . . . 1662
33.5.12 HRTIM timer x control register (HRTIM_TIMxCR) (x = A to F) . . . 1663
33.5.13 HRTIM timer x interrupt status register (HRTIM_TIMxISR) (x = A to F) . . . 1667
33.5.14 HRTIM timer x interrupt clear register (HRTIM_TIMxICR) (x = A to F) . . . 1669
33.5.15 HRTIM timer x DMA interrupt enable register (HRTIM_TIMxDIER) (x = A to F) . . . 1671
33.5.16 HRTIM timer x counter register (HRTIM_CNTxR) (x = A to F) . . . 1674
33.5.17 HRTIM timer x period register (HRTIM_PERxR) (x = A to F) . . . 1674
33.5.18 HRTIM timer x repetition register (HRTIM_REPxR) (x = A to F) . . . 1676
33.5.19 HRTIM timer x compare 1 register (HRTIM_CMP1xR) (x = A to F) . . 1676

33.5.20 HRTIM timer x compare 1 compound register (HRTIM_CMP1CxR) (x = A to F) 1678
33.5.21 HRTIM timer x compare 2 register (HRTIM_CMP2xR) (x = A to F) . . 1678
33.5.22 HRTIM timer x compare 3 register (HRTIM_CMP3xR) (x = A to F) . . 1680
33.5.23 HRTIM timer x compare 4 register (HRTIM_CMP4xR) (x = A to F) . . 1681
33.5.24 HRTIM timer x capture 1 register (HRTIM_CPT1xR) (x = A to F) . . . 1682
33.5.25 HRTIM timer x capture 2 register (HRTIM_CPT2xR) (x = A to F) 1683
33.5.26 HRTIM timer x deadtime register (HRTIM_DTxR) (x = A to F) 1684
33.5.27 HRTIM timer x output 1 set register (HRTIM_SETx1R) (x = A to F) . 1686
33.5.28 HRTIM timer x output 1 reset register (HRTIM_RSTx1R) (x = A to F) 1689
33.5.29 HRTIM timer x output 2 set register (HRTIM_SETx2R) (x = A to F) . 1691
33.5.30 HRTIM timer x output 2 reset register (HRTIM_RSTx2R) (x = A to F) 1694
33.5.31 HRTIM timer x external event filtering register 1 (HRTIM_EEFxR1) (x = A to F) 1697
33.5.32 HRTIM timer x external event filtering register 2 (HRTIM_EEFxR2) (x = A to F) 1700
33.5.33 HRTIM timer A reset register (HRTIM_RSTAR) 1701
33.5.34 HRTIM timer B reset register (HRTIM_RSTBR) 1703
33.5.35 HRTIM timer C reset register (HRTIM_RSTCR) 1705
33.5.36 HRTIM timer D reset register (HRTIM_RSTDR) 1707
33.5.37 HRTIM timer E reset register (HRTIM_RSTER) 1709
33.5.38 HRTIM timer F reset register (HRTIM_RSTFR) 1711
33.5.39 HRTIM timer x chopper register (HRTIM_CHPxR) (x = A to F) 1713
33.5.40 HRTIM timer A capture 1 control register (HRTIM_CPT1ACR) 1714
33.5.41 HRTIM timer B capture 1 control register (HRTIM_CPT1BCR) 1716
33.5.42 HRTIM timer C capture 1 control register (HRTIM_CPT1CCR) 1718
33.5.43 HRTIM timer D capture 1 control register (HRTIM_CPT1DCR) 1720
33.5.44 HRTIM timer E capture 1 control register (HRTIM_CPT1ECR) 1722
33.5.45 HRTIM timer F capture 1 control register (HRTIM_CPT1FCR) 1724
33.5.46 HRTIM timer A capture 2 control register (HRTIM_CPT2ACR) 1726
33.5.47 HRTIM timer B capture 2 control register (HRTIM_CPT2BCR) 1728
33.5.48 HRTIM timer C capture 2 control register (HRTIM_CPT2CCR) 1730
33.5.49 HRTIM timer D capture 2 control register (HRTIM_CPT2DCR) 1732
33.5.50 HRTIM timer E capture 2 control register (HRTIM_CPT2ECR) 1734
33.5.51 HRTIM timer F capture 2 control register (HRTIM_CPT2FCR) 1736
33.5.52 HRTIM timer x output register (HRTIM_OUTxR) (x = A to F) 1738
33.5.53 HRTIM timer x fault register (HRTIM_FLTxR) (x = A to F) 1741

33.5.54 HRTIM timer x control register 2 (HRTIM_TIMxCR2) (x = A to F) . . . 1743
33.5.55 HRTIM timer x external event filtering register 3 (HRTIM_TIMxEEFR3) (x = A to F) . . . 1747
33.5.56 HRTIM timer x external event selection register (HRTIM_EESELxR) (x = A to F) . . . 1749
33.5.57 HRTIM timer x crossbar override trigger register (HRTIM_COTRGxR) (x = A to F) . . . 1752
33.5.58 HRTIM timer x crossbar override forcing event register (HRTIM_COFExR) (x = A to F) . . . 1755
33.5.59 HRTIM timer x crossbar override delayed fault event register (HRTIM_CODExR) (x = A to F) . . . 1758
33.5.60 HRTIM control register 1 (HRTIM_CR1) . . . 1759
33.5.61 HRTIM control register 2 (HRTIM_CR2) . . . 1761
33.5.62 HRTIM interrupt status register (HRTIM_ISR) . . . 1763
33.5.63 HRTIM interrupt clear register (HRTIM_ICR) . . . 1764
33.5.64 HRTIM interrupt enable register (HRTIM_IER) . . . 1765
33.5.65 HRTIM output enable register (HRTIM_OENR) . . . 1766
33.5.66 HRTIM output disable register (HRTIM_ODISR) . . . 1767
33.5.67 HRTIM output disable status register (HRTIM_ODSR) . . . 1768
33.5.68 HRTIM burst mode control register (HRTIM_BMCR) . . . 1769
33.5.69 HRTIM burst mode trigger register (HRTIM_BMTRGR) . . . 1771
33.5.70 HRTIM burst mode compare register (HRTIM_BMCMPR) . . . 1773
33.5.71 HRTIM burst mode period register (HRTIM_BMPER) . . . 1773
33.5.72 HRTIM timer external event control register 1 (HRTIM_EECR1) . . . 1774
33.5.73 HRTIM timer external event control register 2 (HRTIM_EECR2) . . . 1776
33.5.74 HRTIM timer external event control register 3 (HRTIM_EECR3) . . . 1777
33.5.75 HRTIM ADC trigger 1 register (HRTIM_ADC1R) . . . 1778
33.5.76 HRTIM ADC trigger 2 register (HRTIM_ADC2R) . . . 1781
33.5.77 HRTIM ADC trigger 3 register (HRTIM_ADC3R) . . . 1783
33.5.78 HRTIM ADC trigger 4 register (HRTIM_ADC4R) . . . 1785
33.5.79 HRTIM fault input register 1 (HRTIM_FLTINR1) . . . 1787
33.5.80 HRTIM fault input register 2 (HRTIM_FLTINR2) . . . 1789
33.5.81 HRTIM burst DMA master timer update register (HRTIM_BDMUPR) 1791
33.5.82 HRTIM burst DMA timer x update register (HRTIM_BDTxUPR) (x = A to F) . . . 1792
33.5.83 HRTIM burst DMA data register (HRTIM_BDMADR) . . . 1794
33.5.84 HRTIM ADC extended trigger register (HRTIM_ADCER) . . . 1795
33.5.85 HRTIM ADC trigger update register (HRTIM_ADCUR) . . . 1798
33.5.86 HRTIM ADC post scaler register 1 (HRTIM_ADCPS1) . . . 1799

33.5.87 HRTIM ADC post scaler register 2 (HRTIM_ADCPS2) 1800
33.5.88 HRTIM fault input register 3 (HRTIM_FLTINR3) 1801
33.5.89 HRTIM fault input register 4 (HRTIM_FLTINR4) 1803
33.5.90 HRTIM fault input register 5 (HRTIM_FLTINR5) 1805
33.5.91 HRTIM timer external event control register 4 (HRTIM_EECR4) . . . 1807
33.5.92 HRTIM timer external event control register 5 (HRTIM_EECR5) . . . 1809
33.5.93 HRTIM timer external event control register 6 (HRTIM_EECR6) . . . 1811
33.5.94 HRTIM timer external event control register 7 (HRTIM_EECR7) . . . 1812
33.5.95 HRTIM control register 3 (HRTIM_CR3) 1814
33.5.96 HRTIM option register (HRTIM_OR) 1814
33.5.97 HRTIM register map 1816

34 Advanced-control timers (TIM1/TIM8/TIM20) 1827

34.1 TIM1/TIM8/TIM20 introduction 1827
34.2 TIM1/TIM8/TIM20 main features 1827
34.3 TIM1/TIM8/TIM20 functional description 1828
34.3.1 Block diagram 1828
34.3.2 TIM1/TIM8/TIM20 pins and internal signals 1829
34.3.3 Time-base unit 1835
34.3.4 Counter modes 1837
34.3.5 Repetition counter 1849
34.3.6 External trigger input 1850
34.3.7 Clock selection 1851
34.3.8 Capture/compare channels 1855
34.3.9 Input capture mode 1858
34.3.10 PWM input mode 1859
34.3.11 Forced output mode 1860
34.3.12 Output compare mode 1860
34.3.13 PWM mode 1861
34.3.14 Asymmetric PWM mode 1870
34.3.15 Combined PWM mode 1873
34.3.16 Combined 3-phase PWM mode 1876
34.3.17 Complementary outputs and dead-time insertion 1877
34.3.18 Clock dividers for dead-time generators and digital filters 1880
34.3.19 Using the break function 1880
34.3.20 Delayed break 1886
34.3.21 Bidirectional break inputs 1888

34.3.22 Output idle state override 1890
34.3.23 Clearing the tim_ocxref signal on an external event 1891
34.3.24 6-step PWM generation 1894
34.3.25 One-pulse mode 1895
34.3.26 Retriggerable One-pulse mode 1897
34.3.27 Pulse on compare mode 1898
34.3.28 Encoder interface mode 1900
34.3.29 Encoder with built-in debouncer 1917
34.3.30 Direction bit output 1919
34.3.31 Clock drift measurement 1919
34.3.32 UIF bit remapping 1920
34.3.33 Timer input XOR function 1920
34.3.34 Interfacing with Hall sensors 1922
34.3.35 Timer synchronization 1923
34.3.36 ADC triggers 1928
34.3.37 ADC synchronization 1928
34.3.38 DMA burst mode 1929
34.3.39 TIM1/TIM8/TIM20 DMA requests 1930
34.3.40 Debug mode 1931
34.4 TIM1/TIM8/TIM20 low-power modes 1931
34.5 TIM1/TIM8/TIM20 interrupts 1931
34.6 TIM1/TIM8/TIM20 registers 1933
34.6.1 TIM control register 1 (TIM_CR1) 1933
34.6.2 TIM control register 2 (TIM_CR2) 1935
34.6.3 TIM slave mode control register (TIM_SMCR) 1940
34.6.4 TIM DMA/interrupt enable register (TIM_DIER) 1944
34.6.5 TIM status register (TIM_SR) 1945
34.6.6 TIM event generation register (TIM_EGR) 1949
34.6.7 TIM capture/compare mode register 1 (TIM_CCMR1) 1950
34.6.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 1952
34.6.9 TIM capture/compare mode register 2 (TIM_CCMR2) 1956
34.6.10 TIM capture/compare mode register 2 [alternate] (TIM_CCMR2) . . . 1958
34.6.11 TIM capture/compare enable register (TIM_CCER) 1961
34.6.12 TIM counter (TIM_CNT) 1965
34.6.13 TIM prescaler (TIM_PSC) 1965
34.6.14 TIM autoreload register (TIM_ARR) 1966
34.6.15 TIM repetition counter register (TIM_RCR) 1966

34.6.16 TIM capture/compare register 1 (TIM_CCR1) 1967
34.6.17 TIM capture/compare register 2 (TIM_CCR2) 1967
34.6.18 TIM capture/compare register 3 (TIM_CCR3) 1968
34.6.19 TIM capture/compare register 4 (TIM_CCR4) 1969
34.6.20 TIM break and dead-time register (TIM_BDTR) 1970
34.6.21 TIM capture/compare register 5 (TIM_CCR5) 1974
34.6.22 TIM capture/compare register 6 (TIM_CCR6) 1976
34.6.23 TIM capture/compare mode register 3 (TIM_CCMR3) 1977
34.6.24 TIM timer deadtime register 2 (TIM_DTR2) 1980
34.6.25 TIM timer encoder control register (TIM_ECR) 1981
34.6.26 TIM timer input selection register (TIM_TISEL) 1982
34.6.27 TIM alternate function option register 1 (TIM_AF1) 1983
34.6.28 TIM alternate function register 2 (TIM_AF2) 1988
34.6.29 TIM capture/compare register 7 (TIM_CCR7) 1992
34.6.30 TIM capture/compare mode register 4 (TIM_CCMR4) 1993
34.6.31 TIM multilevel protection register 1 (TIM_MPR1) 1995
34.6.32 TIM multilevel protection register 2 (TIM_MPR2) 1997
34.6.33 TIM output override register (TIM_OOR) 1999
34.6.34 TIM DMA control register (TIM_DCR) 2000
34.6.35 TIM DMA address for full transfer (TIM_DMAR) 2002
34.6.36 TIM1/TIM8/TIM20 register map 2002

35 General-purpose timers (TIM2/TIM3/TIM4/TIM5) 2006

35.1 TIM2/TIM3/TIM4/TIM5 introduction 2006
35.2 TIM2/TIM3/TIM4/TIM5 main features 2006
35.3 TIM2/TIM3/TIM4/TIM5 implementation 2007
35.4 TIM2/TIM3/TIM4/TIM5 functional description 2008
35.4.1 Block diagram 2008
35.4.2 TIM2/TIM3/TIM4/TIM5 pins and internal signals 2009
35.4.3 Time-base unit 2014

36 Basic timers (TIM6/TIM7) 2134

36.1 TIM6/TIM7 introduction 2134
36.2 TIM6/TIM7 main features 2134
36.3 TIM6/TIM7 functional description 2135
36.3.1 TIM6/TIM7 block diagram 2135
36.3.2 TIM6/TIM7 internal signals 2135
36.3.3 TIM6/TIM7 clocks 2136
36.3.4 Time-base unit 2136
36.3.5 Counting mode 2138
36.3.6 UIF bit remapping 2145
36.3.7 ADC triggers 2146
36.3.8 ADC synchronization 2146
36.3.9 TIM6/TIM7 DMA requests 2147
36.3.10 Debug mode 2147
36.3.11 TIM6/TIM7 low-power modes 2147
36.3.12 TIM6/TIM7 interrupts 2147
36.4 TIM6/TIM7 registers 2148
36.4.1 TIM control register 1 (TIM_CR1) 2148
36.4.2 TIM control register 2 (TIM_CR2) 2150
36.4.3 TIM DMA/interrupt enable register (TIM_DIER) 2150
36.4.4 TIM status register (TIM_SR) 2152
36.4.5 TIM event generation register (TIM_EGR) 2152
36.4.6 TIM counter (TIM_CNT) 2153

36.4.7 TIM prescaler (TIM_PSC) 2153
36.4.8 TIM autoreload register (TIM_ARR) 2154
36.4.9 TIM6/TIM7 register map 2155

37 General-purpose timers (TIM9/TIM10/TIM11/TIM12/TIM13/TIM14) . 2156

37.1 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 introduction 2156
37.2 TIM9/TIM12 main features 2156
37.3 TIM10/TIM11/TIM13/TIM14 main features 2157
37.4 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 functional description 2158
37.4.1 Block diagram 2158
37.4.2 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 pins and internal signals . . 2159
37.4.3 Time-base unit 2162
37.4.4 Counter modes 2164
37.4.5 Clock selection 2167
37.4.6 Capture/compare channels 2169
37.4.7 Input capture mode 2171
37.4.8 PWM input mode (TIM9/TIM12 only) 2172
37.4.9 Forced output mode 2173
37.4.10 Output compare mode 2174
37.4.11 PWM mode 2175
37.4.12 Combined PWM mode (TIM9/TIM12 only) 2180
37.4.13 Clock dividers for digital filters 2181
37.4.14 One-pulse mode 2182
37.4.15 Retriggerable one pulse mode (TIM9/TIM12 only) 2183
37.4.16 UIF bit remapping 2184
37.4.17 Timer input XOR function 2184
37.4.18 TIM9/TIM12 external trigger synchronization 2186
37.4.19 Slave mode – combined reset + trigger mode 2189
37.4.20 Slave mode – combined reset + gated mode 2189
37.4.21 Timer synchronization (TIM9/TIM12 only) 2189
37.4.22 Using timer output as trigger for other timers (TIM10/TIM11/TIM13/TIM14 only) 2189
37.4.23 ADC triggers (TIM9/TIM12 only) 2189
37.4.24 ADC synchronization (TIM9/TIM12 only) 2190
37.4.25 Debug mode 2191
37.5 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 low-power modes 2191
37.6 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 interrupts 2191

37.7 TIM9/TIM12 registers 2191
37.7.1 TIM control register 1 (TIM_CR1) 2192
37.7.2 TIM control register 2 (TIM_CR2) 2193
37.7.3 TIM slave mode control register (TIM_SMCR) 2195
37.7.4 TIM interrupt enable register (TIM_DIER) 2197
37.7.5 TIM status register (TIM_SR) 2198
37.7.6 TIM event generation register (TIM_EGR) 2199
37.7.7 TIM capture/compare mode register 1 (TIM_CCMR1) 2200
37.7.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 2201
37.7.9 TIM capture/compare enable register (TIM_CCER) 2204
37.7.10 TIM counter (TIM_CNT) 2205
37.7.11 TIM prescaler (TIM_PSC) 2206
37.7.12 TIM autoreload register (TIM_ARR) 2206
37.7.13 TIM capture/compare register 1 (TIM_CCR1) 2207
37.7.14 TIM capture/compare register 2 (TIM_CCR2) 2207
37.7.15 TIM timer input selection register (TIM_TISEL) 2208
37.7.16 TIM9/TIM12 register map 2209
37.8 TIM10/TIM11/TIM13/TIM14 registers 2211
37.8.1 TIM control register 1 (TIM_CR1) 2211
37.8.2 TIM interrupt enable register (TIM_DIER) 2212
37.8.3 TIM status register (TIM_SR) 2213
37.8.4 TIM event generation register (TIM_EGR) 2214
37.8.5 TIM capture/compare mode register 1 (TIM_CCMR1) 2215
37.8.6 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 2216
37.8.7 TIM capture/compare enable register (TIM_CCER) 2217
37.8.8 TIM counter (TIM_CNT) 2218
37.8.9 TIM prescaler (TIM_PSC) 2219
37.8.10 TIM autoreload register (TIM_ARR) 2219
37.8.11 TIM capture/compare register 1 (TIM_CCR1) 2220
37.8.12 TIM timer input selection register (TIM_TISEL) 2220
37.8.13 TIM10/TIM11/TIM13/TIM14 register map 2221

38 General purpose timers (TIM15/TIM16/TIM17) 2223

38.1 TIM15/TIM16/TIM17 introduction 2223
38.2 TIM15 main features 2223
38.3 TIM16/TIM17 main features 2224

38.4 TIM15/TIM16/TIM17 functional description 2225

38.4.2 TIM15/TIM16/TIM17 pins and internal signals 2226
38.4.3 Time-base unit 2231
38.4.4 Counter modes 2233
38.4.5 Repetition counter 2245
38.4.6 Clock selection 2247
38.4.7 Capture/compare channels 2249
38.4.8 Input capture mode 2251
38.4.9 PWM input mode (only for TIM15) 2252
38.4.10 Forced output mode 2253
38.4.11 Output compare mode 2254
38.4.12 PWM mode 2255
38.4.13 Asymmetric PWM mode (TIM15 only) 2262
38.4.14 Combined PWM mode (TIM15 only) 2263
38.4.15 Complementary outputs and dead-time insertion 2264
38.4.16 Clock dividers for dead-time generators and digital filters 2267
38.4.17 Using the break function 2267
38.4.18 Delayed break 2272
38.4.19 Bidirectional break input 2274
38.4.20 Output idle state override 2276
38.4.21 Clearing the tim_ocxref signal on an external event 2276
38.4.22 6-step PWM generation 2278
38.4.23 One-pulse mode 2280
38.4.24 Retriggerable one pulse mode (TIM15 only) 2281
38.4.25 Encoder interface mode 2282
38.4.26 Encoder with built-in debouncer (TIM15 only) 2289
38.4.27 Clock drift measurement 2290
38.4.28 UIF bit remapping 2291
38.4.29 Timer input XOR function (TIM15 only) 2291
38.4.30 External trigger synchronization (TIM15 only) 2293
38.4.31 Slave mode – combined reset + trigger mode (TIM15 only) 2296
38.4.32 Slave mode – combined reset + gated mode (TIM15 only) 2296
38.4.33 Timer synchronization (TIM15 only) 2297
38.4.34 Using timer output as trigger for other timers (TIM16/TIM17 only) . . 2297
38.4.35 ADC triggers (TIM15 only) 2297
38.4.36 ADC synchronization (TIM15 only) 2298

38.4.37 DMA burst mode 2298
38.4.38 TIM15/TIM16/TIM17 DMA requests 2299
38.4.39 Debug mode 2300
38.5 TIM15/TIM16/TIM17 low-power modes 2300
38.6 TIM15/TIM16/TIM17 interrupts 2300
38.7 TIM15 registers 2302
38.7.1 TIM control register 1 (TIM_CR1) 2302
38.7.2 TIM control register 2 (TIM_CR2) 2304
38.7.3 TIM slave mode control register (TIM_SMCR) 2307
38.7.4 TIM DMA/interrupt enable register (TIM_DIER) 2310
38.7.5 TIM status register (TIM_SR) 2311
38.7.6 TIM event generation register (TIM_EGR) 2313
38.7.7 TIM capture/compare mode register 1 (TIM_CCMR1) 2314
38.7.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 2316
38.7.9 TIM capture/compare enable register (TIM_CCER) 2319
38.7.10 TIM counter (TIM_CNT) 2322
38.7.11 TIM prescaler (TIM_PSC) 2322
38.7.12 TIM autoreload register (TIM_ARR) 2322
38.7.13 TIM repetition counter register (TIM_RCR) 2323
38.7.14 TIM capture/compare register 1 (TIM_CCR1) 2323
38.7.15 TIM capture/compare register 2 (TIM_CCR2) 2325
38.7.16 TIM break and dead-time register (TIM_BDTR) 2325
38.7.17 TIM timer deadtime register 2 (TIM_DTR2) 2328
38.7.18 TIM input selection register (TIM_TISEL) 2329
38.7.19 TIM alternate function register 1 (TIM_AF1) 2330
38.7.20 TIM alternate function register 2 (TIM_AF2) 2334
38.7.21 TIM multilevel protection register 1 (TIM_MPR1) 2335
38.7.22 TIM multilevel protection register 2 (TIM_MPR2) 2335
38.7.23 TIM output override register (TIM_OOR) 2336
38.7.24 TIM DMA control register (TIM_DCR) 2337
38.7.25 TIM DMA address for full transfer (TIM_DMAR) 2338
38.7.26 TIM15 register map 2339
38.8 TIM16/TIM17 registers 2342
38.8.1 TIM control register 1 (TIM_CR1) 2342
38.8.2 TIM control register 2 (TIM_CR2) 2344
38.8.3 TIM DMA/interrupt enable register (TIM_DIER) 2345
38.8.4 TIM status register (TIM_SR) 2346

38.8.5 TIM event generation register (TIM_EGR) 2347
38.8.6 TIM capture/compare mode register 1 (TIM_CCMR1) 2348
38.8.7 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 2349
38.8.8 TIM capture/compare enable register (TIM_CCER) 2351
38.8.9 TIM counter (TIM_CNT) 2354
38.8.10 TIM prescaler (TIM_PSC) 2354
38.8.11 TIM autoreload register (TIM_ARR) 2355
38.8.12 TIM repetition counter register (TIM_RCR) 2355
38.8.13 TIM capture/compare register 1 (TIM_CCR1) 2356
38.8.14 TIM break and dead-time register (TIM_BDTR) 2357
38.8.15 TIM timer deadtime register 2 (TIM_DTR2) 2360
38.8.16 TIM input selection register (TIM_TISEL) 2361
38.8.17 TIM alternate function register 1 (TIM_AF1) 2361
38.8.18 TIM alternate function register 2 (TIM_AF2) 2365
38.8.19 TIM multilevel protection register 1 (TIM_MPR1) 2366
38.8.20 TIM multilevel protection register 2 (TIM_MPR2) 2367
38.8.21 TIM output override register (TIM_OOR) 2367
38.8.22 TIM DMA control register (TIM_DCR) 2368
38.8.23 TIM DMA address for full transfer (TIM_DMAR) 2369

43 Tamper and backup registers (TAMP) 2494

43.1 Introduction 2494
43.2 TAMP main features 2494
43.3 TAMP functional description 2495
43.3.1 TAMP block diagram 2495
43.3.2 TAMP pins and internal signals 2496
43.3.3 GPIOs controlled by the RTC and TAMP 2498
43.3.4 TAMP register write protection 2500
43.3.5 Backup registers protection zones 2501
43.3.6 TAMP privilege protection modes 2501
43.3.7 Tamper detection 2502
43.3.8 TAMP backup registers and other device secrets erase 2502
43.3.9 Tamper detection configuration and initialization 2504
43.4 TAMP low-power modes 2511
43.5 TAMP interrupts 2511

43.6 TAMP registers 2511
43.6.1 TAMP control register 1 (TAMP_CR1) 2511
43.6.2 TAMP control register 2 (TAMP_CR2) 2513
43.6.3 TAMP control register 3 (TAMP_CR3) 2516
43.6.4 TAMP filter control register (TAMP_FLTCR) 2517
43.6.5 TAMP active tamper control register 1 (TAMP_ATCR1) 2519
43.6.6 TAMP active tamper seed register (TAMP_ATSEEDR) 2520
43.6.7 TAMP active tamper output register (TAMP_ATOR) 2521
43.6.8 TAMP active tamper control register 2 (TAMP_ATCR2) 2521
43.6.9 TAMP configuration register (TAMP_CFGR) 2523
43.6.10 TAMP privilege configuration register (TAMP_PRIVCFGR) 2524
43.6.11 TAMP interrupt enable register (TAMP_IER) 2525
43.6.12 TAMP status register (TAMP_SR) 2527
43.6.13 TAMP masked interrupt status register (TAMP_MISR) 2529
43.6.14 TAMP status clear register (TAMP_SCR) 2530
43.6.15 TAMP monotonic counter 1 register (TAMP_COUNT1R) 2532
43.6.16 TAMP resources protection configuration register (TAMP_RPCFGR) 2532
43.6.17 TAMP backup x register (TAMP_BKPxR) 2533
43.6.18 TAMP register map 2534

44 Inter-integrated circuit interface (I2C) 2536
44.1 I2C introduction 2536
44.2 I2C main features 2536
44.3 I2C implementation 2537
44.4 I2C functional description 2537

44.4.14 SMBus target mode 2574
44.4.15 SMBus controller mode 2578
44.4.16 Wake-up from Stop mode on address match 2581
44.4.17 Error conditions 2582
44.5 I2C in low-power modes 2584
44.6 I2C interrupts 2584
44.7 I2C DMA requests 2585
44.7.1 Transmission using DMA 2585
44.7.2 Reception using DMA 2585
44.8 I2C debug modes 2586
44.9 I2C registers 2586
44.9.1 I2C control register 1 (I2C_CR1) 2586
44.9.2 I2C control register 2 (I2C_CR2) 2589
44.9.3 I2C own address 1 register (I2C_OAR1) 2591
44.9.4 I2C own address 2 register (I2C_OAR2) 2591
44.9.5 I2C timing register (I2C_TIMINGR) 2592
44.9.6 I2C timeout register (I2C_TIMEOUTR) 2593
44.9.7 I2C interrupt and status register (I2C_ISR) 2594
44.9.8 I2C interrupt clear register (I2C_ICR) 2597
44.9.9 I2C PEC register (I2C_PECR) 2598
44.9.10 I2C receive data register (I2C_RXDR) 2598
44.9.11 I2C transmit data register (I2C_TXDR) 2599
44.9.12 I2C register map 2600

45 Improved inter-integrated circuit (I3C) 2601
45.1 I3C introduction 2601
45.2 I3C main features 2601
45.2.1 I3C MIPI® support 2604
45.2.2 I3C without clock stretching by the target 2605
45.3 I3C implementation 2607
45.3.1 I3C instantiation 2607
45.3.2 I3C wake-up from low-power mode(s) 2607
45.3.3 I3C FIFOs 2607
45.3.4 I3C triggers 2607
45.3.5 I3C interrupt(s) 2607

45.4 I3C block diagram 2608
45.5 I3C pins and internal signals 2608
45.6 I3C reset and clocks 2609
45.6.1 I3C reset 2609
45.6.2 I3C clocks and requirements 2609
45.7 I3C peripheral state and programming 2611
45.7.1 I3C peripheral state 2611
45.7.2 I3C controller state and programming sequence 2612
45.7.3 I3C target state and programming sequence 2617
45.8 I3C registers and programming 2624
45.8.1 I3C register set, as controller/target 2624
45.8.2 I3C registers and fields use versus peripheral state, as controller . . 2625
45.8.3 I3C registers and fields usage versus peripheral state, as target . . . 2627
45.9 I3C bus transfers and programming 2629
45.9.1 I3C command set (CCCs), as controller/target 2629
45.9.2 I3C broadcast/direct CCC transfer (except ENTDAA, RSTACT), as controller 2633
45.9.3 I3C broadcast ENTDAA CCC transfer, as controller 2635
45.9.4 I3C broadcast/direct RSTACT CCC transfer, as controller 2635
45.9.5 I3C broadcast/direct CCC transfer (except ENTDAA, DEFTGTS, DEFGRPA), as target 2637
45.9.6 I3C broadcast ENTDAA CCC transfer, as target 2639
45.9.7 I3C broadcast DEFTGTS CCC transfer, as target 2640
45.9.8 I3C broadcast DEFGRPA CCC transfer, as target 2641
45.9.9 I3C direct GETSTATUS CCC response, as target 2642
45.9.10 I3C private read/write transfer, as controller 2643
45.9.11 I3C private read/write transfer, as target 2644
45.9.12 Legacy I2C read/write transfer, as controller 2645
45.9.13 Legacy I2C read/write transfer, as target 2646
45.9.14 I3C IBI transfer, as controller/target 2646
45.9.15 I3C hot-join request transfer, as controller/target 2649
45.9.16 I3C controller-role request transfer, as controller/target 2650
45.10 I3C FIFOs management, as controller 2651
45.10.1 C-FIFO management, as controller 2651
45.10.2 TX-FIFO management, as controller 2652
45.10.3 RX-FIFO management, as controller 2655
45.10.4 S-FIFO management, as controller 2657

45.11 I3C FIFOs management, as target 2659
45.11.1 RX-FIFO management, as target 2659
45.11.2 TX-FIFO management, as target 2662
45.12 I3C error management 2666
45.12.1 Controller error management 2666
45.12.2 Target error management 2668
45.13 I3C wake-up from low-power mode(s) 2669
45.13.1 Wake-up from Stop 2669
45.14 I3C in low-power modes 2672
45.15 I3C interrupts 2673
45.16 I3C registers 2673
45.16.1 I3C message control register (I3C_CR) 2673
45.16.2 I3C message control register [alternate] (I3C_CR) 2675
45.16.3 I3C configuration register (I3C_CFGR) 2677
45.16.4 I3C receive data byte register (I3C_RDR) 2682
45.16.5 I3C receive data word register (I3C_RDWR) 2683
45.16.6 I3C transmit data byte register (I3C_TDR) 2684
45.16.7 I3C transmit data word register (I3C_TDWR) 2685
45.16.8 I3C IBI payload data register (I3C_IBIDR) 2686
45.16.9 I3C target transmit configuration register (I3C_TGTTDR) 2687
45.16.10 I3C status register (I3C_SR) 2688
45.16.11 I3C status error register (I3C_SER) 2689
45.16.12 I3C received message register (I3C_RMR) 2691
45.16.13 I3C event register (I3C_EVR) 2692
45.16.14 I3C interrupt enable register (I3C_IER) 2696
45.16.15 I3C clear event register (I3C_CEVR) 2698
45.16.16 I3C masked interrupt status register (I3C_MISR) 2700
45.16.17 I3C own device characteristics register (I3C_DEVR0) 2701
45.16.18 I3C device x characteristics register (I3C_DEVRx) 2703
45.16.19 I3C maximum read length register (I3C_MAXRLR) 2705
45.16.20 I3C maximum write length register (I3C_MAXWLR) 2706
45.16.21 I3C I2C target configuration register (I3C_I2CCFGR) 2707
45.16.22 I3C timing register 0 (I3C_TIMINGR0) 2708
45.16.23 I3C timing register 1 (I3C_TIMINGR1) 2709
45.16.24 I3C timing register 2 (I3C_TIMINGR2) 2711
45.16.25 I3C bus characteristics register (I3C_BCR) 2713

45.16.26 I3C device characteristics register (I3C_DCR) 2714
45.16.27 I3C get capability register (I3C_GETCAPR) 2715
45.16.28 I3C controller-role capability register (I3C_CRCAPR) 2716
45.16.29 I3C get max data speed register (I3C_GETMXDSR) 2717
45.16.30 I3C extended provisioned ID register (I3C_EPIDR) 2719
45.16.31 I3C register map 2720

46 Universal synchronous/asynchronous receiver transmitter (USART/UART) 2723

46.1 USART introduction 2723
46.2 USART main features 2723
46.3 USART extended features 2724
46.4 USART implementation 2724
46.5 USART functional description 2726
46.5.1 USART block diagram 2726
46.5.2 USART pins and internal signals 2726
46.5.3 USART clocks 2728
46.5.4 USART character description 2728
46.5.5 USART FIFOs and thresholds 2731
46.5.6 USART transmitter 2731
46.5.7 USART receiver 2734
46.5.8 USART baud rate generation 2741
46.5.9 Tolerance of the USART receiver to clock deviation 2743
46.5.10 USART auto baud rate detection 2744
46.5.11 USART multiprocessor communication 2746
46.5.12 USART Modbus communication 2748
46.5.13 USART parity control 2749
46.5.14 USART LIN (local interconnection network) mode 2750
46.5.15 USART synchronous mode 2752
46.5.16 USART single-wire half-duplex communication 2756
46.5.17 USART receiver timeout 2756
46.5.18 USART smartcard mode 2757
46.5.19 USART IrDA SIR ENDEC block 2761
46.5.20 Continuous communication using USART and DMA 2764
46.5.21 RS232 hardware flow control and RS485 driver enable 2766
46.5.22 USART low-power management 2769
46.6 USART in low-power modes 2772

46.7 USART interrupts 2772
46.8 USART registers 2775
46.8.1 USART control register 1 (USART_CR1) 2775
46.8.2 USART control register 1 [alternate] (USART_CR1) 2779
46.8.3 USART control register 2 (USART_CR2) 2782
46.8.4 USART control register 3 (USART_CR3) 2786
46.8.5 USART control register 3 [alternate] (USART_CR3) 2790
46.8.6 USART baud rate register (USART_BRR) 2793
46.8.7 USART guard time and prescaler register (USART_GTPR) 2794
46.8.8 USART receiver timeout register (USART_RTOR) 2795
46.8.9 USART request register (USART_RQR) 2796
46.8.10 USART interrupt and status register (USART_ISR) 2797
46.8.11 USART interrupt and status register [alternate] (USART_ISR) 2803
46.8.12 USART interrupt flag clear register (USART_ICR) 2808
46.8.13 USART receive data register (USART_RDR) 2809
46.8.14 USART transmit data register (USART_TDR) 2810
46.8.15 USART prescaler register (USART_PRESC) 2810
46.8.16 USART register map 2811

47 Low-power universal asynchronous receiver transmitter (LPUART) 2813
47.1 LPUART introduction 2813
47.2 LPUART main features 2813
47.3 LPUART implementation 2814
47.4 LPUART functional description 2816
47.4.1 LPUART block diagram 2816
47.4.2 LPUART pins and internal signals 2817
47.4.3 LPUART clocks 2818
47.4.4 LPUART character description 2818
47.4.5 LPUART FIFOs and thresholds 2820
47.4.6 LPUART transmitter 2820
47.4.7 LPUART receiver 2824
47.4.8 LPUART baud rate generation 2828
47.4.9 Tolerance of the LPUART receiver to clock deviation 2829
47.4.10 LPUART multiprocessor communication 2830
47.4.11 LPUART parity control 2832
47.4.12 LPUART single-wire half-duplex communication 2833

47.4.13 Continuous communication using DMA and LPUART 2833
47.4.14 RS232 hardware flow control and RS485 driver enable 2836
47.4.15 LPUART low-power management 2838
47.5 LPUART in low-power modes 2841
47.6 LPUART interrupts 2842
47.7 LPUART registers 2843
47.7.1 LPUART control register 1 (LPUART_CR1) 2843
47.7.2 LPUART control register 1 [alternate] (LPUART_CR1) 2846
47.7.3 LPUART control register 2 (LPUART_CR2) 2849
47.7.4 LPUART control register 3 (LPUART_CR3) 2851
47.7.5 LPUART control register 3 [alternate] (LPUART_CR3) 2854
47.7.6 LPUART baud rate register (LPUART_BRR) 2856
47.7.7 LPUART request register (LPUART_RQR) 2856
47.7.8 LPUART interrupt and status register (LPUART_ISR) 2857
47.7.9 LPUART interrupt and status register [alternate] (LPUART_ISR) . . . 2862
47.7.10 LPUART interrupt flag clear register (LPUART_ICR) 2865
47.7.11 LPUART receive data register (LPUART_RDR) 2866
47.7.12 LPUART transmit data register (LPUART_TDR) 2866
47.7.13 LPUART prescaler register (LPUART_PRESC) 2867
47.7.14 LPUART register map 2868

48 Serial peripheral interface (SPI) 2870
48.1 SPI introduction 2870

1 Documentation conventions

1.1 General information

The STM32H7Pxxx devices have an Arm® Cortex®-M7 with FPU core.

Note: Arm and Cortex are registered trademarks of Arm Limited (or its subsidiaries or affiliates) in the US and/or elsewhere.

The Arm word and logo are trademarks of Arm Limited (or its subsidiaries) in the US and/or elsewhere. All rights reserved.

1.2 List of abbreviations for registers

The following abbreviations[(a)] are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)	Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)	Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)	Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)	Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)	The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1)	Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.
OBKey	Option byte keys

a. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.

1.3 Register reset value

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is undefined are marked as X.

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is unmodified are marked as U.

1.4 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **AHB**: advanced high-performance bus.

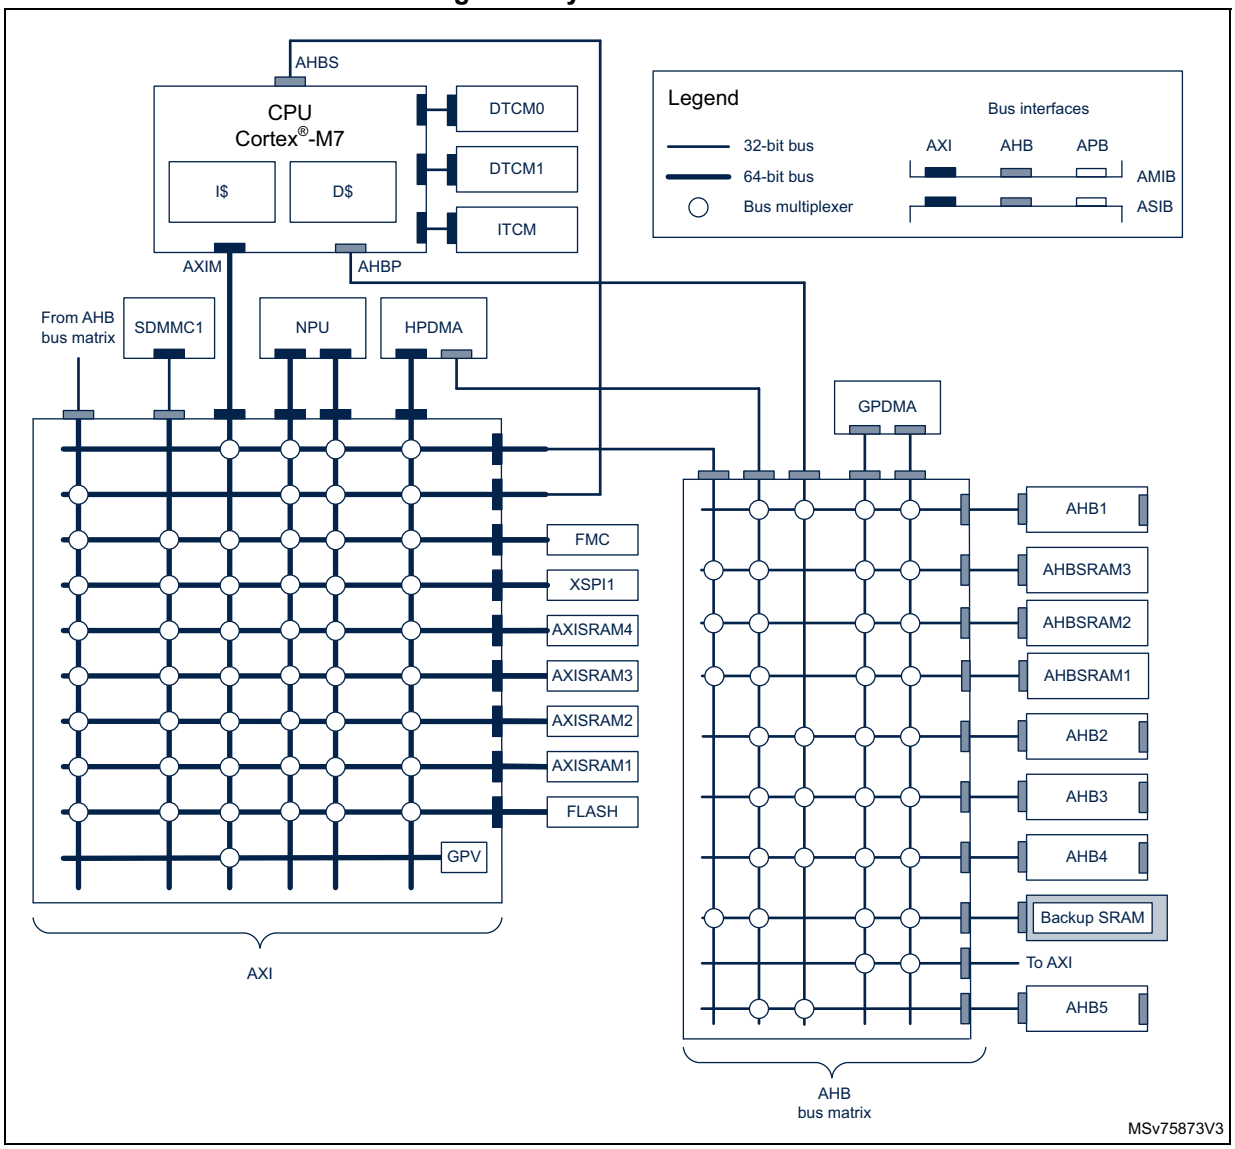
1.5 Availability of peripherals

For availability of peripherals and their number across all devices, refer to the particular device datasheet.

1.6 Availability of security features

For security feature availability refer to the table below:

Table 1. Availability of security features



Security feature	STM32H7Pxxx
Embedded flash memory (FLASH): – Flash secure-only area	Available
Security memory management: – Root secure services (RSS)	
On-the-fly encryption / decryption	Not available
STiRoT	
Cryptographic processor (CRYP and PKA)	
Hash processor (HASH) with PKA verification always available	Available

2 Memory and bus architecture

2.1 System architecture

The STM32H7Pxxx architecture is illustrated in *Figure 1*. It is built around an Arm® Cortex®-M7 processing core optimized for execution by means of cache and tightly coupled memory (TCM). The processor accesses the system memory and peripherals through several bus interfaces.

Figure 1. System architecture

2.1.1 Bus matrices

The architecture features a 64-bit AMBA® AXI interconnect and a 32-bit multilayer AMBA AHB bus matrix, allowing interconnection of bus managers and subordinates. *Table 2* shows which managers can access which subordinates.

Table 2. Bus-manager-to-bus-subordinate interconnect

Bus subordinate / type(1)	Bus manager / type(1)								
	Cortex-M7 - AXIM	Cortex-M7 - AHBP	Cortex-M7 - ITCM	Cortex-M7 - DTCM	SDMMC1	HPDMA - AXI	HPDMA - AHB	GPDMA	NPU
	Interconnect path(2)								
ITCM	-	-	X	-	-	X	-	X	X
DTCM	-	-	-	X	-	X	-	X	X
FLASH	X	-	-	-	X	X	-	X	X
AXI SRAM1	X	-	-	-	X	X	-	X	X
AXI SRAM2	X	-	-	-	X	X	-	X	X
AXI SRAM3	X	-	-	-	X	X	-	X	X
AXI SRAM4	X	-	-	-	X	X	-	X	X
XSPI1	X	-	-	-	X	X	-	X	X
FMC	X	-	-	-	X	X	-	X	X
AHB SRAM1	X	-	-	-	-	X	X	X	X
AHB SRAM2	X	-	-	-	-	X	X	X	X
AHB SRAM3	X	-	-	-	-	X	X	X	X
AHB1 peripherals	-	X	-	-	-	-	X	X	-
APB1 peripherals	-	X	-	-	-	-	X	X	-
AHB2 peripherals	-	X	-	-	-	-	X	X	-
APB2 peripherals	-	X	-	-	-	-	X	X	-
AHB3 peripherals	-	X	-	-	-	-	X	X	-
AHB4 peripherals	-	X	-	-	-	-	X	X	-
APB4 peripherals	-	X	-	-	-	-	X	X	-
AHB5 peripherals	-	X	-	-	-	-	X	-	-
Backup RAM	X	-	-	-	-	X	X	X	-

1. Grey cells denote 64-bit bus, white cells denotes 32-bit bus.
2. “X” = access possible, “-” = access not possible.

AXI bus matrix

The AXI bus matrix arbitrates concurrent accesses from multiple managers to multiple subordinates. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm with QoS capability.

Refer to *Section 2.2: AXI interconnect matrix (AXIM)* for more information on AXI interconnect.

AHB bus matrix

The AHB bus matrix also arbitrates concurrent accesses from multiple managers to multiple subordinates. The arbitration uses a round-robin algorithm.

2.1.2 Peripheral buses

Peripheral functional units are accessed via 32-bit AMBA AHB and APB buses.

The APB1, APB2, and APB4 buses are connected to AHB1, AHB2, and AHB4 respectively, via AHB/APB bridges. These bridges provide semisynchronous interfacing, which allows the APB buses to operate at the same or a fraction of the AHB frequency that they connect to.

The AHB/APB bridges also allow APB1, APB2, and APB4 peripherals to connect to the GPDMA peripheral port, without going through the AHB bus matrix.

The AXI interconnect incorporates AHB/AXI bus bridges in subordinate bus interfaces (ASIBs) where required. External AXI/AHB bus bridges are used to connect AXI manager interfaces (AMIBs) to 32-bit AHB buses.

2.1.3 CPU buses

Cortex-M7 AXIM bus

The Cortex-M7 CPU uses the 64-bit AXIM bus to access all memories except ITCM and DTCM, including external memories on the FMC and XSPI interfaces.

The AXIM bus connects the CPU to the AXI interconnect.

Cortex-M7 ITCM bus

The Cortex-M7 CPU uses the 64-bit ITCM bus for fetching instructions from and accessing data in the ITCM.

Cortex-M7 DTCM bus

The Cortex-M7 CPU uses the dual 32-bit DTCM bus for accessing data in the DTCM. The dual DTCM bus allows load/load and load/store instruction pairs to be issued in parallel to the DTCM memory.

Cortex-M7 AHBP bus

The Cortex-M7 CPU uses the 32-bit AHBP bus for accessing AHB and APB peripherals via the AHB bus matrix.

Cortex-M7 AHBS bus

The Cortex-M7 CPU has a 32-bit AHBS subordinate port, which allows other bus managers (HPDMA controller, GPDMA controller, NPU) to access the ITCM and the DTCM.

2.1.4 Bus manager peripherals

SDMMC1

The SDMMC1 uses a 32-bit bus, connected to the AXI interconnect, through which it can access AXI SRAM and flash memories, and external memories through the XSPI and the FMC.

HPDMA-bus

The HPDMA controller has two bus managers: an AXI 64-bit bus, connected to the AXI interconnect, and an AHB 32-bit bus connected to the AHB bus matrix.

Through its AXI port, the HPDMA has access to all the memories in the system, including the TCM via the CPU AHBS port. Through its AHB port, it has access to all AHB and APB peripherals.

GPDMA-bus

The GPDMA controller has two 32-bit AHB bus managers, denoted M (memory) and P (peripheral). Both are connected to the AHB interconnect.

The managers allow GPDMA data transfers between two peripherals, between two memories or between a peripheral and a memory. Through each bus manager, the GPDMA controller can access all internal memories, external memories through the XSPI and the FMC, and all AHB and APB peripherals. The peripheral bus has a fast path to access the APB peripherals, bypassing the AHB bus matrix.

2.2 AXI interconnect matrix (AXIM)

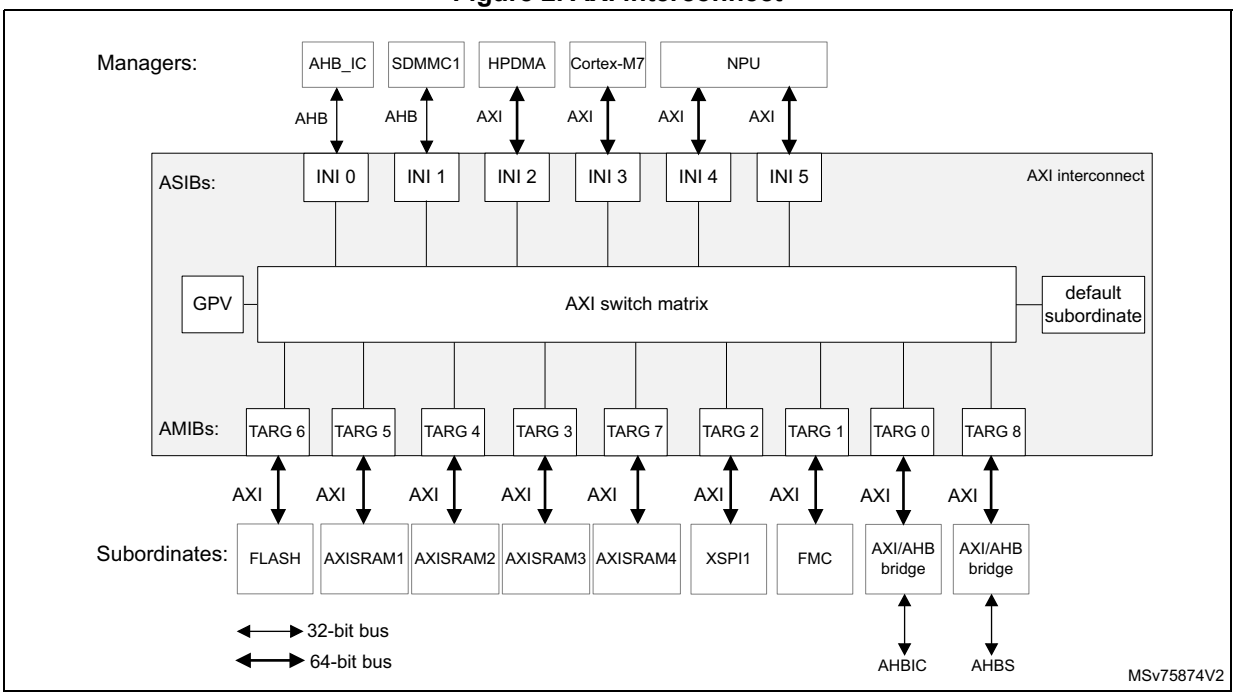
2.2.1 AXI introduction

The AXI (advanced extensible interface) interconnect is based on the Arm® CoreLink™ NIC-400 network interconnect. The interconnect has six initiator ports, or ASIBs (AMBA subordinate interface blocks), and nine target ports, or AMIBs (AMBA manager interface blocks). The ASIBs are connected to the AMIBs via an AXI switch matrix.

Each ASIB is a subordinate on an AXI bus or AHB (advanced high-performance bus). Similarly, each AMIB is a manager on an AXI bus. Where an ASIB is connected to an AHB, it converts between the AHB and the AXI protocol.

The AXI interconnect includes a GPV (global programmer view) which contains registers for configuring certain parameters, such as the QoS (quality of service) level at each ASIB.

Any accesses to unallocated address space are handled by the default subordinate, which generates the return signals. This ensures that such transactions are completed and do not block the issuing manager and ASIB.



2.2.2 AXI interconnect main features

- 64-bit AXI bus switch matrix with six ASIBs and nine AMIBs
- AHB/AXI bridge function built into the ASIBs
- Concurrent connectivity of multiple ASIBs to multiple AMIBs
- Programmable traffic priority management (QoS - quality of service)
- Software-configurable via GPV

2.2.3 Block diagram

The AXI interconnect is shown in *Figure 2*.

Figure 2. AXI interconnect

ASIB configuration

Table 3 summarizes the characteristics of the ASIBs.

Table 3. ASIB configuration

ASIB	Connected manager	Protocol	Bus width	R/W issuing
INI 0	GPDMA(1)	AHB-lite	32	1/1
INI 1	SDMMC1	AHB-lite	32	1/1
INI 2	HPDMA	AXI4	64	8/8
INI 3	Cortex-M7	AXI4	64	7/32
INI 4	NPU	AXI4	64	16/16
INI 5		AXI4	64	16/16

1. Via AHB interconnect.

AMIB configuration

Table 4 summarizes the characteristics of the AMIBs.

Table 4. AMIB configuration

AMIB	Connected subordinate	Protocol	Bus width	R/W/Total acceptance
TARG 6	FLASH	AXI4	64	2/2/4
TARG 5	AXISRAM1	AXI4	64	2/2/4
TARG 4	AXISRAM2	AXI4	64	2/2/4
TARG 3	AXISRAM3	AXI4	64	2/2/4
TARG 7	AXISRAM4	AXI4	64	2/2/4
TARG 2	XSPI1	AXI4	64	2/2/4
TARG 1	FMC	AXI4	64	1/1/2
TARG 0	AHBIC	AXI4(1)	64	1/1/2
TARG 8	AHBS	AXI4(1)	64	1/1/2

1. The 64-bit AXI is converted to 32-bit AHB by an AXI/AHB bridge.

Quality of service (QoS)

The AXI switch matrix uses a priority-based arbitration when two ASIB simultaneously attempt to access the same AMIB. Each ASIB has programmable read channel and write channel priorities, known as QoS, from 0 to 15, such that the higher the value, the higher the priority. The read channel QoS value is programmed in the *AXI interconnect - INI x read QoS register (AXI_INIx_READ_QOS)*, and the write channel in the *AXI interconnect - INI x write QoS register (AXI_INIx_WRITE_QOS)*. The default QoS value for all channels is 0 (lowest priority).

If two coincident transactions arrive at the same AMIB, the higher priority transaction passes before the lower priority. If the two transactions have the same QoS value, then a least-recently-used (LRU) priority scheme is adopted.

The QoS values should be programmed according to the latency requirements for the application. Setting a higher priority for an ASIB ensures a lower latency for transactions initiated by the associated bus manager. This can be useful for real-time-constrained tasks. Assigning a high priority to managers (such as the Cortex-M7 CPU) that can make many and frequent accesses to the same subordinate can block access to that subordinate by other lower-priority managers.

Global programmer view (GPV)

The GPV contains configuration registers for the AXI interconnect. These registers are only accessible by the Cortex-M7 CPU.

2.2.4 AXI interconnect registers

AXI interconnect - peripheral ID4 register (AXI_PERIPH_ID_4)

Address offset: 0x1FD0

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

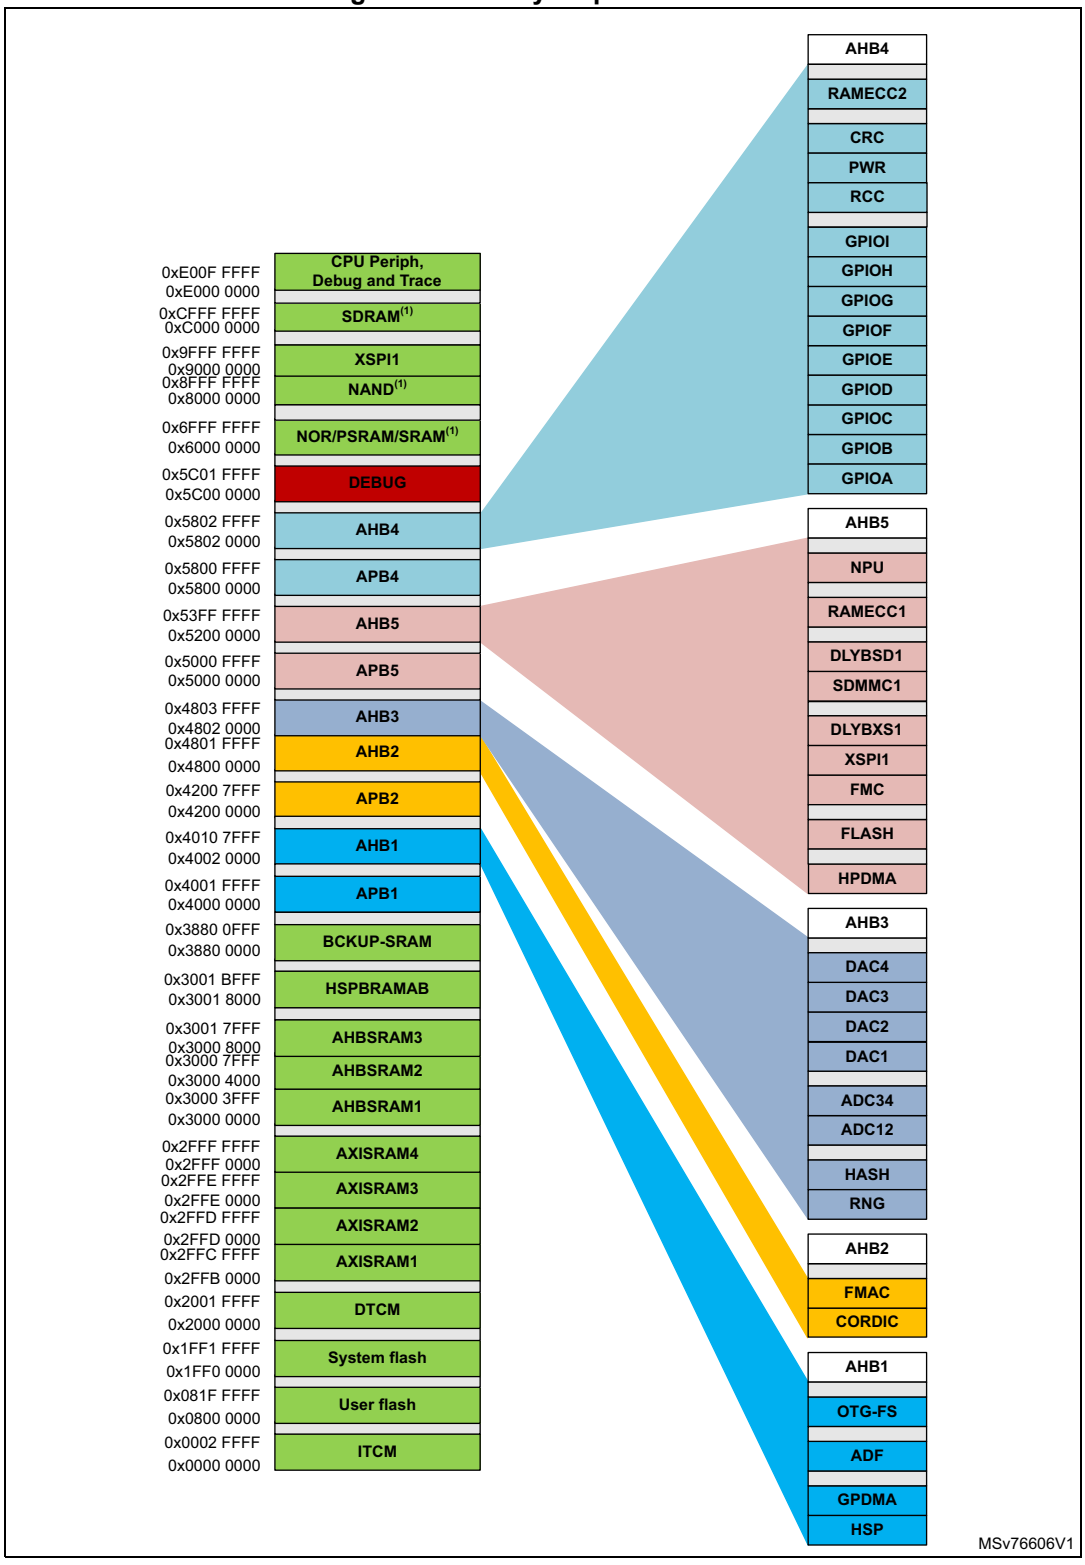
Refer to *Section 2.3: Memory organization* for the register boundary addresses.

2.3 Memory organization



2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

2.3.2 Memory map and register boundary addresses

Figure 3. Memory map

1. External memory accessed via the FMC.

All the memory map areas that are not allocated to on-chip memories and peripheral units are considered “Reserved”.

The default memory attribute and the boundary addresses of the available peripheral units are shown in *Table 6* and *Table 7*.

Table 6. Memory map and default device memory area attribute

Region	Boundary address	Description	Type	Attributes	Execute never
External Devices	0xD0000000 - 0xDFFFFFFF	Reserved	Device	-	Yes
	0xC0000000 - 0xCFFFFFFF	FMC SDRAM or FMC NOR/PSRAM/SRAM remap			
	0xBFF00000 - 0xBFFFFFFF	GPV/AXIM			
	0xA0000000 - 0xBFF00000	Reserved			
External Memories	0x90000000 - 0x9FFFFFFF	XSPI1	Normal	Write-through cache attribute	No
	0x80000000 - 0x8FFFFFFF	FMC NAND flash memory			
	0x70000000 - 0x7FFFFFFF	Reserved		Write-back, write allocate cache attribute	
	0x60000000 - 0x6FFFFFFF	FMC NOR/PSRAM/SRAM or FMC SDRAM remap			
Peripherals	0x40000000 - 0x5FFFFFFF	Peripherals. See *Table 7: Peripheral boundary addresses*.	Device	-	Yes
RAM	0x38801000 - 0x3FFFFFFF	Reserved	Normal	Write-back, write allocate cache attribute	No
	0x38800000 - 0x38800FFF	BKPSRAM			
	0x3001C000 - 0x387FFFFF	Reserved			
	0x38018000 - 0x3001BFFF	HSPBRAMAB			
	0x30008000 - 0x30017FFF	AHBSRAM3			
	0x30004000 - 0x30007FFF	AHBSRAM2			
	0x30000000 - 0x30003FFF	AHBSRAM1			
	0x2FFF0000 - 0x2FFFFFFF	AXISRAM4			
	0x2FFE0000 - 0x2FFEFFFF	AXISRAM3			
	0x2FFD0000 - 0x2FFDFFFF	AXISRAM2			
	0x2FFB0000 - 0x2FFCFFFF	AXISRAM1			
	0x20020000 - 0x2FFAFFFF	Reserved			
	0x20000000 - 0x2001FFFF	DTCM			

Table 6. Memory map and default device memory area attribute

Region	Boundary address	Description	Type	Attributes	Execute never
Code	0x1FF20000 - 0x1FFFFFFF	Reserved	Normal	Write-through cache attribute	No
	0x1FF00000 - 0x1FF1FFFF	System flash			
	0x90000000 - 0x1FEFFFFF	Reserved			
	0x08FFFFF0 - 0x08FFFFFF	Flash Read Only			
	0x08FFFA00 - 0x08FFFFEF	Reserved			
	0x08FFF800 - 0x08FFF9FF	Flash Read Only			
	0x08FFF400 - 0x08FFF7FF	Reserved			
	0x08FFF000 - 0x08FFF3FF	User OTP			
	0x08200000 - 0x08FFEFFF	Reserved			
	0x08100000 - 0x081FFFFF	User flash memory bank 2			
	0x08000000 - 0x080FFFFF	User flash memory bank 1			
	0x00030000 - 0x07FFFFFF	Reserved			
	0x00000000 - 0x0002FFFF	ITCM			

Table 7. Peripheral boundary addresses(1)

Boundary address	Peripheral	Bus	Registers
0x5C00A000 - 0x5FFFFFFF	Reserved	Debug	Reserved

0x40000000 - 0x400003FF	TIM2 (32b)		

1. Accessing a reserved area results in a bus error. Accessing undefined memory space in a peripheral returns zeros.

2.4 Embedded SRAM

The STM32H7Pxxx devices include 736 Kbytes of SRAM.

- 192 Kbytes of tightly coupled instruction memory (ITCM) with ECC.
- 128 Kbytes of tightly coupled data memory (DTCM) with ECC.
- 320 Kbytes of AXISRAM with ECC, accessible via the AXI bus directly.
- 96 Kbytes of AHBSRAM without ECC, accessible via the AXI and AHB interconnects.

The TCM SRAMs are dedicated to the Cortex®-M7:

- DTCM is mapped at the address 0x2000 0000 and accessible by Cortex®-M7 via a dedicated dual 32-bit interface. This allows simultaneous 32-bit accesses, or single 64-bit accesses. It can also be accessed at lower priority by the HPDMA, GPDMA, and NPU through the AHBS port of the Cortex®-M7 CPU, thereby eliminating the overhead of transferring data by software from system memory or peripherals.
- ITCM is mapped at the address 0x0000 0000 and accessible by Cortex®-M7 via a single 64-bit dedicated interface. It is also accessible at lower priority by HPDMA (and GPDMA) through the AHBS port of the Cortex®-M7 CPU. The ITCM can be used to host code for time-critical routines (such as interrupt handlers), or that requires deterministic execution.

The AXISRAM comprises four blocks:

- AXISRAM1 - 128 Kbytes
- AXISRAM2/3/4 - 3 x 64 Kbytes

AXISRAM supports 8-bit, 16-bit, 32-bit, and 64-bit accesses. It can be used for code, large data buffers, general variables, etc. It is optimized for high data throughput when accessed by the Cortex®-M7 CPU, the HPDMA, or the NPU.

AXISRAM1 can be automatically erased in the event of a tamper. It is also erased systematically by hardware after a power-on reset. This feature makes AXISRAM1 suitable for temporary storage of sensitive information in clear (unencrypted) format.

The AHBSRAM comprises three blocks:

- AHBSRAM1/2 - 2 × 16 Kbytes
- AHBSRAM3 - 64 Kbytes

AHBSRAM supports 8-bit, 16-bit, and 32-bit accesses. It is intended for local buffering of data coming from or destined for peripherals such as the ADCs, DACs, serial communications interfaces. Being able to store data locally avoids the need to interrupt the CPU frequently to perform transfers, and optimizes the traffic on the AXI by allowing

occasional large bursts rather than frequent short bursts. Nevertheless, it can also be used by the CPU and the NPU for additional storage, albeit with lower throughput.

AHBSRAM3 is dedicated to the HSP when it is enabled. Part of AHBSRAM3 is aliased as HSPBRAMAB, which is used for data exchange between the HSP and the system (see chapter [HSP]). When the HSP is disabled, the AHBSRAM3 can be used as system SRAM.

The backup SRAM (BKPSRAM) can be retained in all low-power modes, and when V_{DD} is off in V_{BAT} mode with a battery connected to the VBAT pin. Refer to *Section 6.4.3: Backup domain* for more details. The backup SRAM is protected by the tamper detection circuit, and are erased by hardware in case of tamper detection. They are also erased by hardware in case of a backup domain reset. Refer to (link to *Section 43: Tamper and backup registers (TAMP)*) for more details.

Table 8 summarizes the internal SRAM resources:

Table 8. SRAM summary

SRAM	STM32H7Pxxx
ITCM	192 Kbytes with ECC. Tightly coupled to CPU.
DTCM	128 Kbytes with ECC. Tightly coupled to CPU.
AXISRAM1	128 Kbytes with ECC. Automatic erase at power on and in the event of a tamper.
AXISRAM2	64 Kbytes with ECC.
AXISRAM3	64 Kbytes with ECC.
AXISRAM4	64 KBytes with ECC.
AHBSRAM1	16 Kbytes, no ECC.
AHBSRAM2	16 Kbytes, no ECC.
AHBSRAM3	64 Kbytes, no ECC. Dedicated to HSP when enabled.
BKPSRAM	4 Kbytes with ECC. Battery backed-up. Automatic erase in the event of a tamper, a backup domain reset or a life-cycle regression.

ECC error detection is handled by the RAMECC units. Refer to *Section 4: RAM ECC monitoring (RAMECC)*.

2.5 Flash memory overview

The flash memory interface manages accesses to the flash nonvolatile memory. It implements the erase and program flash memory operations and the read and write protection mechanisms.

The flash memory is organized as follows:

- Dual bank main memory block divided into sectors.
  - Supports reading from one bank while reprogramming the other
- An information block:
  - System memory from which the device boots in system memory boot mode
  - Option bytes to configure read and write protection, BOR level, watchdog software/hardware and reset when the device is in Standby or Stop mode.

Refer to *Section 5: Embedded flash memory (FLASH)* for further details.

2.6 Boot configuration

In the STM32H7Pxxx, two different boot areas can be selected through the BOOT0 pin as shown in the *Table 9*.

Table 9. Boot modes

Boot mode selection			Boot area
PRODUCT_STATE	**NVSTATE**	**BOOT0**	
Open	OPEN	0	Boot from the user flash memory at 0x0800 0000
		1	Boot from the bootloader
Provisioning	CLOSE	-	Boot from the RSS in system flash memory Then jump into the bootloader
Closed/Locked			Boot from the RSS in system flash memory Then jump into the user flash memory at 0x0800 0000(1)

1. MPU is enabled when executing OEM firmware in user flash memory; depending on needed resources, OEM firmware should update MPU configuration or disable MPU.

The values on the BOOT0 pin are latched after the power-on reset is released. The user must set the BOOT0 pin level during power-on reset.

The BOOT0 pin is resampled when the device exits Standby mode. Consequently, the values must be kept in the required Boot mode configuration when the device is in Standby mode.

After startup delay, the selection of the boot area is done before releasing the processor reset.

Embedded bootloader

The embedded bootloader code is located in system memory. It is programmed by ST during production. It is used to reprogram the flash memory using one of the following serial interfaces:

- DFU: USB OTG_FS in device mode
- USART1
- USART2
- USART3
- UART4
- FDCAN2
- I2C1
- I2C2
- I2C3
- I3C1
- SPI1
- SPI2
- SPI3

For additional information, refer to *Section 10: System configuration, boot and security (SBS)*.

3 System security

The microcontrollers of the STM32H7Pxxx series are designed with a comprehensive set of security features, which simplify the evaluation of IoT devices against security standards. These features also reduce the cost and complexity of software development for OEMs and third-party developers by facilitating reuse, improving interoperability, and minimizing API fragmentation.

This section describe the security features available on STM32H7Pxxx devices.

3.1 Key security features

- Device identification with device 96-bit unique ID and JTAG 32-bit die-specific ID.
- Boot levels isolation enabled by the HDPL (hide protection level) monotonic counter.
- Resource isolation using the privilege mode of Cortex-M7, extended to HPDMA, GPDMA, RTC, and TAMP peripherals.
- Additional hardware features for secure boot.
  - Unique boot entry in embedded flash memory.
  - Embedded flash memory write protection.
  - Nonvolatile user option bytes dedicated to bank swapping, write protection, and HDP areas control.
- Secure storage, featuring:
  - Boot data storage located in HDP-isolated areas of the embedded flash (option byte keys).
  - Battery-powered volatile secure storage, automatically erased in case of tamper.
- Cryptographic true random number generation, NIST SP800-90B compliant.
- General purpose cryptographic acceleration.
  - HASH processor, supporting SHA-1 checksums and SHA-2 secure hash (SHA-256, SHA-384, SHA-512).
- Device life cycle management, which includes debug and regression control.
- Security services in system flash memory
- Active tamper and protection against temperature, voltage, and frequency attacks.
  - Flexible active tamper I/O management: from three meshes (each input associated with its own exclusive output) to six meshes (single output shared for up to five tamper inputs). Some tamper I/Os remain functional in V_{BAT} mode.

3.2 Identification

3.2.1 Unique ID

The devices store a 96-bit ID that is unique to each device (see *Section 53.1: Unique device ID register (96 bits)*). The application can use this unique identity key to identify the product in the cloud network or make it difficult for counterfeit devices or clones to inject untrusted data into the network.

3.2.2 Discover command

The debug protocol included in the device's immutable code contains a "DISCOVER" command that provides basic information about the target: manufacturer, product name, device identifier, supported protocol version, and available cryptographic scheme for authentication (password only).

3.3 Secure boot

Secure boot is immutable code that always executes after a system reset when the device is not in the open state (see *Section 3.8.1*). As the root of trust, this code verifies the device's static protections and activates available runtime protections, reducing the risk of invalid or malicious code running on the platform. Additionally, secure boot checks the integrity and authenticity of the next-level firmware before executing it.

This section details the features specifically designed for secure boot.

3.3.1 Unique boot entry

As defined in *Section 10.3.5: SBS boot control*, the device has two booting methods after each reset:

- For closed devices (NVSTATE = NVCLOSE): The device boots on a small ST immutable code in the system flash, which jumps to a fixed address in the user flash (address 0x0800 0000).
- For open devices (NVSTATE = NVOPEN): device boots from a fixed address in the user flash (BOOT pin = 1) or from the bootloader in the system flash (BOOT pin = 0).

When the device's nonvolatile state (NVSTATE) equals NVCLOSE, it is recommended that the code located at address 0x0800 0000 is write protected (see *Section 3.3.2*).

When the swapping function is activated (SWAP_BANK option in the FLASH_OBW1SR register), a different physical bank is allocated to the user space address 0x0800 0000. Swapping can be disabled with the nonvolatile BOOT_LOCK option in FLASH_ROTSR register. The FLASH_ROTSR register can only be configured using RSSLIB SetSecOB function. Refer to *Section 3.9.2* for details.

3.3.2 Embedded flash memory write protection

The embedded flash memory in the device includes write protection (WRP) to prevent unwanted modifications to selected embedded nonvolatile code or data.

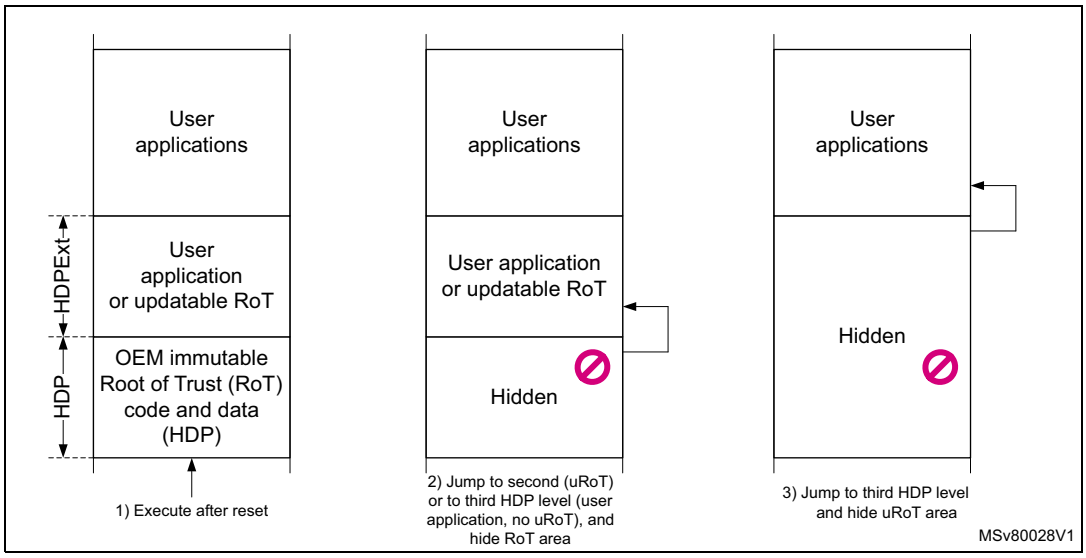
Typical usage of the write protection is to protect the integrity of the boot code stored at the unique boot entry in the user flash. This protection can only be deactivated by the OEM boot code itself, running in HDP level 1. Refer to *Section 5.5.2: Write protection* for details.

As a write-protected area cannot be erased or programmed, a full bank erase cannot be performed if any group of four consecutive pages is write-protected, unless a transition to Open is triggered (see **Regression** in *Section 3.8.1*).

Note: The HDP area in user flash is write- and erase-protected, while system flash cannot be erased by the user application.

3.3.3 Boot levels isolation with HDP

Section 3.4.1 explains how HDPL (hide protection level) hardware isolates boot levels.



3.4 Isolation

The microcontrollers in the STM32H7 series support isolation. Isolating a trustworthy service from less trusted or untrusted services is essential to protect its integrity. This section describes the features specifically designed for isolation.

3.4.1 Temporal isolation using hide protection levels (HDPL)

The hardware and software resources used during each boot level can be isolated. This process relies on a Hide Protection (HDP) monotonic counter that only increments the levels. When the counter increments, the resources from previous levels, including both code and data, become hidden. This feature, summarized in *Figure 4*, is described in *Section 5.5.4: Hide protection (HDP)* and *Section 10.3.4: SBS hide protection management* of this document.

Figure 4. User flash memory HDP area principle

For each bank, activation of the HDP area in user flash memory is linked to HDPL1. Once HDPL is equal to or greater than 2, data read, write, and instruction fetch accesses to the HDP area defined by the HDP_AREA_START and HDP_AREA_END option bytes are denied until the next device reset.

The end of each HDP area can be dynamically extended by the boot application by setting the FLASH_xHDPEXTR register (x = A or B). This extension prevents access to protected sectors used by updatable boot code when runtime code executes in HDPL3.

Note: A bank erase operation aborts if it contains a write-protected area (WRP or HDP area).

3.4.2 Isolation using privileged mode

The hardware and software resources of STM32H7Pxxx devices can be partitioned to restrict access to software running in privileged mode.

This hardware isolation technology protects critical code, data and specific hardware resources against intentional or unintentional tampering.

Memory and peripheral privileged allocation using MPU

The Cortex-M7 includes a memory protection unit (MPU) that restricts read and write accesses to memory regions, including regions mapped to peripherals, based on one or more of the following parameters:

- Cortex-M7 operating mode (privileged or unprivileged).
- Data or instruction fetch.

The memory map and the MPU configuration divide memory into up to sixteen regions, each aligned to a multiple of 32 bytes. Each memory region can be programmed to generate faults when accessed inappropriately by unprivileged software.

Managing accesses in privileged-aware peripherals

The following peripherals implement privileged-only access mode. Peripherals not listed can be read and written by both privileged and unprivileged accesses.

- *Direct memory access controllers (HPDMA and GPDMA)*

  When a DMA channel x is defined as privileged (PRIVx = 1 in xDMA_PRIVCFGR), specific rules (see *Table 10*) apply when accessing privileged or unprivileged sources or destinations.

Table 10. DMA channel use (privilege)

Destination	Privileged DMA channel x (PRIVx = 1)		Unprivileged DMA channel y (PRIVy = 0)	
	Privileged source	Unprivileged source	Privileged source	Unprivileged source
Privileged	OK		Transfer blocked(1)	
Unprivileged			Transfer blocked	OK

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return 0s.

- *Real time clock (RTC)*

  By default, after any backup domain reset, all RTC registers, except RTC_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

  When the PRIV bit is set in privileged-only RTC_PRIVCFGR register:

  – Writing to the RTC registers is possible only in privileged mode.

  – Reading the RTC_PRIVCFGR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER, and RTC_CALR registers is always possible in privileged and unprivileged modes. All other RTC registers can be read only in privileged mode.

  When the PRIV bit is cleared in privileged-only RTC_PRIVCFGR register, it is still possible to restrict access to privileged mode for certain RTC registers by setting

dedicated control bits: INITPRIV, CALPRIV, TSPRIV, WUTPRIV, ALRAPRV, or ALRBPRIV.

See *Section 42: Real-time clock (RTC)* for details.

- *Tamper and backup registers (TAMP)*

  By default, after any backup domain reset, all TAMP registers, except TAMP_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

  When the PRIV bit is set in the privileged-only TAMP_PRIVCFGR register:

  – Writing to the TAMP registers is possible only in privileged mode, except for the backup registers and the monotonic counters, which have their own protection setting.

  – Reading the TAMP_PRIVCFGR register is always possible in both privilege and unprivileged modes. All other TAMP registers can be read only in privilege mode, except for the backup registers and the monotonic counters, which have their own protection settings.

  The application can also:

  – Make the TAMP_COUNT1R register read and write privileged-only by setting the CNTPRIV bit in TAMP_PRIVCFGR.

  – Increase security for two of the three protection zones in backup registers by using the BKPRWPRIV and BKPWPRIV bits in TAMP_PRIVCFGR:

    – Make protection zone 1 read-privileged and write-privileged.

    – Make protection zone 2 read-privileged or unprivileged and write-privileged.

    – Protection zone 3 is always read and write privileged or unprivileged.

  See *Section 42: Real-time clock (RTC)* for details.

3.5 Secure storage

A critical feature of security systems is how long-term keys are stored, protected, and provisioned. These keys are typically used for loading a boot image or managing critical user secrets, such as the regression password.

3.5.1 Boot data storage

As described in *Section 5.4.4: Option byte key management* the device manages 32 key slots of 16-bytes per HDP level (up to level 2, inclusive). A customer application running in HDPL1 can provision keys in both HDPL1 and HDPL2 by using NEXTKL[1:0] field in the FLASH_OBKCR register. An application running in HDPL2 can only provision or update its own keys. HDP protection is detailed in *Section 3.4.1*.

3.5.2 Battery-powered volatile secure storage

The device includes 32 backup registers located in the backup domain, which remain powered by V_{BAT} when the V_{DD} power is switched off. These registers are protected against tampering, as described in *Section 3.7*.

3.6 Cryptographic engines

3.6.1 Cryptographic random number generation

The RNG peripheral in the device is a NIST-compliant true random number generator that provides full-entropy outputs to the application. For more information, refer to *Section 31: True random number generator (RNG)*.

3.6.2 Cryptographic operations

Table 11 lists the accelerated cryptographic operations available in the device. For more information, refer to *Section 32: Hash processor (HASH)*.

Table 11. Device cryptographic operations

Operations	Algorithm	Specification	Length of keys (in bits)	Modes
Secure hash	SHA-2	FIPS PUB 180-4	N/A	SHA-256, SHA-384, SHA-512
Keyed-hashing for message authentication	HMAC	FIPS PUB 198-1 IETF RFC 2104	Short, long (>64 bytes)	-

3.7 Tamper detection and response

The devices include active protection of critical security assets against temperature, voltage, and frequency attacks, with the following features:

- Erasure of device secrets upon tamper detection.
- Improved guarantee of safe execution for the CPU and its associated security peripherals, including:
  - Detection of out-of-range voltage (for example, V_{BAT}, V_{DDA}), temperature, and clocking (LSE).
  - Security watchdog IWDG clocked by the internal oscillator LSI.
  - Possible selection of the internal oscillator HSI as the system clock.
- Power supply protection.
  - RTC/TAMP domain powered automatically with V_{DD} or V_{BAT}.

See *Section 43: Tamper and backup registers (TAMP)* for more details.

3.7.1 Tamper detection sources

The devices support seven active input/output pins, enabling three independent active-tamper meshes or up to six meshes if the same output pin is shared by six meshes.

The active pins are clocked by the LSE and function in various system operating modes: Run, Sleep, Stop, or Standby. Refer to *Table 496: TAMP pins functionality over modes* for a list of tamper pins and their availability, including in V_{BAT} mode.

Detection time is programmable, and digital filtering is available. A tamper is triggered after two false comparisons in four consecutive comparison samples.

Note: Timestamps are automatically generated when a tamper event occurs.

The internal tamper sources are listed in *Table 12*.

Table 12. Internal tampers in TAMP

Tamper input	NOER bit number in TAMP_CR3	Tamper source
itamp1	0	Backup domain voltage continuous monitoring, functional in V_{BAT} mode.
itamp2	1	Temperature monitoring, functional in V_{BAT} mode.
itamp3	2	LSE monitoring.
itamp4	3	HSE monitoring.
itamp5	4	RTC calendar overflow.
itamp6	5	Unexpected debug activation.
itamp7, 12, 13, 14	6, 11, 12, 13	Voltage monitoring (for example, V_{CORE}, V_{REF+}), through ADC analog watchdog.
itamp8	7	Monotonic counter overflow (generated internally).
itamp9	8	Fault generation for cryptographic peripherals (RNG).
itamp11	10	IWDG reset when tamper flag is set (potential tamper timeout).
itamp15	14	System fault detection.

3.7.2 Response to tampers

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt: This interrupt is capable of waking up the device from Stop and Standby modes (see the TAMPxMSK bits in the TAMP_CR2 register).
- Generate a hardware trigger: This trigger is for the low-power timers.
- Erase device secrets: This occurs if the corresponding TAMPxNOER bit is cleared in TAMP_CR2 (for external tamper pins) or TAMP_CR3 (for internal tampers). The erasable secrets include:
  - Symmetric keys stored in backup registers (x32), or in HASH
  - Secrets stored in AXI SRAM1
  - Backup SRAM (depending on configuration bit), erased when V_{DD} is present

Read/write accesses by software to all these secrets can be blocked by setting the BKBLOCK bit in TAMP_CR2. Access to device secrets is possible only when BKBLOCK is cleared, and no tamper flag is set for any enabled tamper source.

If V_{DD} is not present, the secrets that are erased when V_{DD} is present are erased only at the next V_{DD} power-on.

Note: Device secret erase is also triggered by setting the BKERASE bit in TAMP_CR2 or by performing a PRODUCT_STATE regression as defined in Section 3.8.

Device secrets are not reset by a system reset or when the device wakes up from Standby mode.

3.7.3 Software filtering mechanism

Each tamper source can be configured to avoid launching an immediate erase by setting the corresponding TAMPxNOER bit in TAMP_CR2 (for external tamper pins) or TAMP_CR3 (for internal tampers). In this situation, when the tamper flag is raised, the following mechanisms optionally activate until all tamper flags are cleared.

- Backup registers, backup SRAM, AXI SRAM1: Read operation returns 0 and write operations are ignored.
- HASH peripherals: Reset by RCC.

Once the application, notified by the tamper event, analyzes the situation, there are two possible cases:

- The application launches a secrets erase with a software command (confirmed tamper).
- The application clears the flags to release secrets blocking (false tamper).

Note: If the tamper software fails to react to the tamper flag, the tamper input associated with the IWDG reset automatically triggers the erase of secrets.

3.7.4 Tamper detection and low-power modes

The effects of low-power modes on tamper detection are summarized in *Table 13*.

Table 13. Effect of low-power modes on TAMP

Mode	Description
Sleep	No effect on tamper detection features. TAMP interrupts cause the device to exit the Sleep mode.
Stop	No effect on tamper detection features, except for level detection with filtering and active tamper modes that remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Stop mode.
Standby	No effect on tamper detection features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Standby mode.

3.8 Product life cycle

A typical IoT device life cycle is summarized in *Figure 5*. For each step, the devices provide secure life cycle management mechanisms embedded in the hardware. *Table 14* details the various phases and their associated transitions.

Figure 5. Device life cycle security

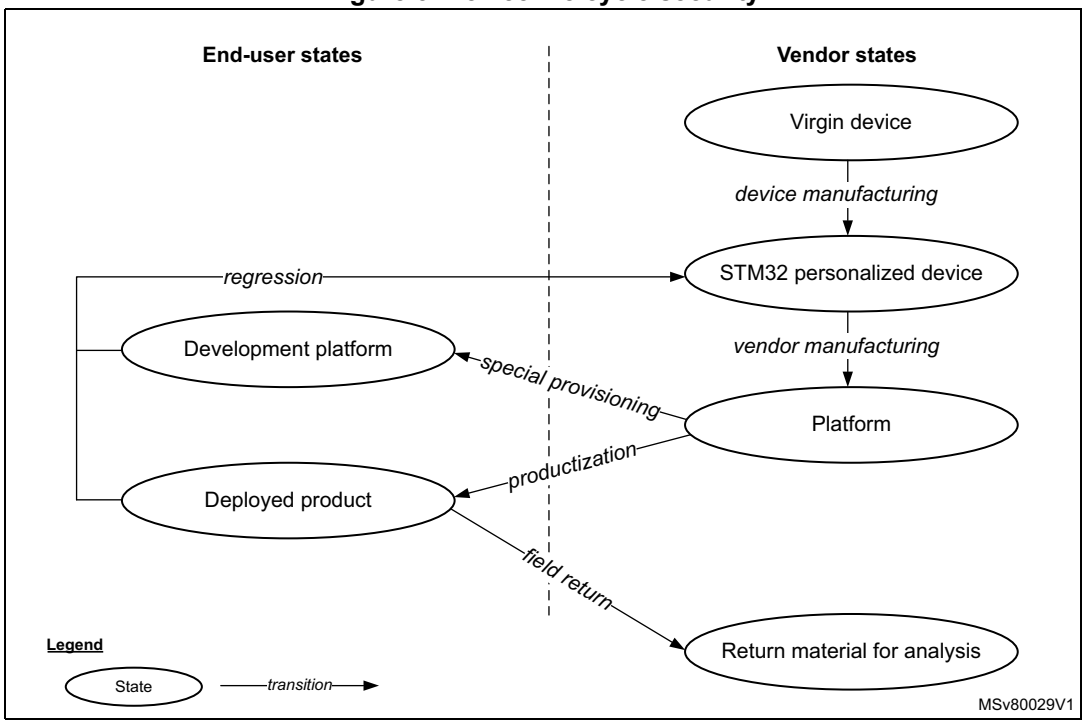


Table 14. Main product life cycle transitions

Transitions	Description
Device manufacturing	ST creates new STM32 devices, always checking for manufacturing defects. During this process, the device is provisioned with ROM firmware, and a public ID.
Vendor manufacturing	One or more vendors are responsible for the platform assembly, initialization, and provisioning before delivery to the end user. This end user can use the final product (referred to as the “productization” transition) or use the platform for software development (referred to as “special provisioning” transition).
Productization	The end user gets a product ready for use. All security functions of the platform are enabled, debugging and testing features are restricted or disabled, and a unique boot entry to immutable code is enforced.
Special provisioning	The platform vendor prepares an individual platform for development, ensuring it is not connected to a production cloud network.
Field return	The end user returns the device as material for analysis and ships it back to the manufacturer. During this process, all data, including user data, is destroyed. Consequently, the devices loses the ability to operate securely, such as connecting to a managed IoT network. This transition is not possible when the PRODUCT_STATE is Locked.

The features described in this section help secure the device life cycle.

3.8.1 Life cycle management

The devices implement the life cycle described in *Section 5.5.3: Life cycle management*. For example, secure boot is enforced when NVSTATE equals NVCLOSE.

Note: STMicroelectronics does not analyze defective parts in the locked state (field return transition in Table 14).

Debug management

As explained in *Section 10.3.6: SBS debug management*, device debugging may or may not be allowed, depending on the device life cycle:

- For open devices (NVSTATE = NVOPEN), debugging is always allowed.
- For closed devices (NVSTATE = NVCLOSE), debugging is disabled at boot with a policy defined by the option byte DBG_AUTH[7:0] in the FLASH_ROTSR register. Possible options are:
  - 0xB4: Locked device (no debugging, no regression)
  - 0x8A: Closed device (no debugging).

The FLASH_ROTSR register can only be configured using RSSLIB SetSecOB function. Refer to *Section 3.9.2* for details.

Regression

When the device is in the “closed” or “provisioning” product state, regression to the “open” state is possible using the 128-bit regression password provisioned during the manufacturing phase of the final product. Upon receiving a valid regression request, the device erases all the OEM secrets, except the regression password, before changing the product state.
Refer to **Flash opening** in *Section 5.5.3: Life cycle management* for details on this opening sequence. Details on the tools available to perform regressions is available in TBD ANxxx.

3.9 System memory

System memory stores root secure services (RSS) firmware programmed by STMicroelectronics during production. The RSS provides runtime services to user firmware when permitted.

3.9.1 RSS user functions

The runtime services are provided by the RSS library. The functions of the RSS library, listed in *Table 16*, are accessible to users through the CMSIS device header file included in the STM32CubeH7P firmware package.

Table 15. Macros for RSS services

C defined macro	Location in system memory
RSSLIB_PFUNC	0x1FF1FD4C

Before calling RSSLIB functions, if MPU is enabled, the user firmware must:

- Define an MPU region to allow read access to the location starting from RSSLIB_SYS_FLASH_PFUNC_START (0x1FF1FD4C) up to RSSLIB_SYS_FLASH_PFUNC_END (0x1FF1FD78). These addresses are provided in the CMSIS device header file.
- Define an MPU region to allow execution of RSSLIB firmware, starting from 0x1FF0E000 up to 0x1FF0FFFF.

3.9.2 RSSLIB

The user firmware calls RSSLIB functions using the RSSLIB_PFUNC C-defined macro.

Table 16. RSS lib interface functions

Library	Callable function
RSSLIB_PFUNC	SetSecOB(1)
	GetRssStatus(1)
	SetProductState(1)
	DataProvisioning(1)
	JumpHDPLvl2
	JumpHDPLvl3
	GetProductState(1)

1. Functions used for OEM personalization are performed using provisioning tools.

SetSecOB

Prototype:

```
uint32_t SetSecOB(uint32_t ObAddr, uint32_t ObMask, uint32_t
ObValue, uint32_t ObPos)
```

User code function call example:

```
RSSLIB_PFUNC->SetSecOB((uint32_t) ObAddr, (uint32_t) ObMask,
(uint32_t) ObValue, (uint32_t) ObPos);
```

Arguments:

- `ObAddr`
  - Input parameter: address of the secure OB to configure. It must be one of the following (x = A or B):

    &(FLASH->xWRPSRP)

    &(FLASH->xHDPSRP)

    &(FLASH->ROTSRP)
- `ObMask`
  - Input parameter, mask of the OB part to be updated (for example, 0x00000FFF for updating HDP_AREA_START OB).
- `ObValue`
  - Input parameter: OB value to be applied.
- `ObPos`
  - Input parameter: Apply the OB bit shift to the ObValue. Ensure that (ObValue<<ObPos) aligns on ObMask.

The user calls the SetSecOB function to enable RSS to configure the secure option bytes after a reset.

Note: This function is available only in the provisioning state of the product.

Returned values:

- On a successful call, the function does not return and does not push LR onto the stack.
- In case of failure (bad product state), SetSecOB returns 0xF5F5F5F5.

To retrieve the OB change status (after RSS execution), call the GetRssStatus function or read back the OB. For example, read the FLASH_AWRPSR register.

GetRssStatus

Prototype:

```
uint32_t GetRssStatus(void)
```

User code function call example:

```
RSSLIB_PFUNC->GetRssStatus();
```

Arguments: None

The user calls `GetRssStatus` to retreive the RSS execution status of the previous RSSLIB function call that triggerred a reset for execution by RSS (`SetSecOB` or `DataProvisioning`).

Returned values:

`0xEAEAEAEA`	Success
`0xF5F5F5F5`	Error

0xF5F5E0E0	Bad input address range
0xF5F50E0E	Bad size
0xF5F5E00E	Bad encryption value in DoEncryption
0xF5F50808	Programming error
0xF5F50008	Bad value in Destination

SetProductState

Prototype:

```
uint32_t SetProductState(uint32_t ProductState)
```

User code function call example:

```
RSSLIB_PFUNC->SetProductState((uint32_t) ProductState);
```

Arguments:

- ProductState
  - Input parameter: STM32 product state to reach. The parameter must be one of the following:

    0x17: Provisioning product state. This state is allowed when the current product state is Open.

    0x72: Closed product state. This state is allowed when current product state is provisioning, and data provisioning has been made.
  - 0x5C: Locked product state. This state is allowed when the current product state is provisioning.

The user calls the SetProductState function to change the STM32 product state. The configuration is completed by the RSS after a reset.

Returned values:

- On successful call, the function does not return and does not push LR onto the stack.
- In the case of failure (invalid product state), the GetProductState function returns 0xF5F5F5F5.

To retrieve the new product state after RSS execution, call the GetProductState function.

DataProvisioning

Prototype:

```
uint32_t DataProvisioning(RSSLIB_DataProvisioningConf_t *pConfig)
```

User code function call example:

```
RSSLIB_PFUNC->DataProvisioning((RSSLIB_DataProvisioningConf_t*)
pConfig));
```

Arguments:

- `pConfig`: input parameter RSSLIB_DataProvisioningConf_t , described below:

```
typedef struct
{
  uint32_t *pSource;
  uint32_t Destination;
  uint32_t Size;
  uint32_t DoEncryption;
  uint32_t Crc;
} RSSLIB_DataProvisioningConf_t;
```

With the structure elements:

`pSource`	Provides the address of the data to be provisioned. The address must be within the AXISRAM3 address range.
`Destination`	Provides the destination information, specifying where to provision the data. 0xDADAHHII: – II specifies the OBKey starting index. – HH specifies the OBKey HDPL. – DADA specifies the debug authentication configuration, which is only relevant when the OBKey is writable only in HDPL0.
`Size`	Provides the size of the data to be provisioned (the number of bytes). The size must be a multiple of 16.
`DoEncryption`	The data can only be 0xCACA0AA0U (OBKeys data in the clear)
`Crc`	The CRC is computed over the full source data buffer, **`pConfig→Destination`** value, **`pConfig→Size`** value and finally **`pConfig->DoEncryption`** value. The CRC computation uses CRC-32 (Ethernet) with the following parameters: – CRC polynomial: 0x04C11DB7U – Initial value: 0xFFFFFFFFU

`DataProvisioning` receives a data buffer as input and programs it as OBKeys. A CRC ensures data and parameter integrity to prevent tampering issues.

Returned values:

`0xEAEAEAEAU` Success

`0xF5F5F5F5U` Error: Bad product state.
Data provisioning only available in open and provisioning product states.

`0xF5F5E0E0U` Error: Bad input address range.
`pConfig` or **`pSource`** are not in AXISRAM3.

`0xF5F50E0EU` Error: Bad provisioning size:
– **Size** is not a multiple of 16.
– OBKey starting index + **Size** does not fit within an OBKey section.

`0xF5F58080U` Error: computed CRC is not the expected one provided within **`pConfig→CRC.`**

`0xF5F5E00EU` Error: wrong **`DoEncryption`** parameter value.

`0xF5F50808U` Error: OBKeys programming error.

`0xF5F50008U` Error: Bad destination information:
– OBKey index is not in the range 0 to 31.
– OBKey HDPL is not in the range 0 to 2 (representing HDPL0, HDPL1 and HDPL2).
– OBKey HDPL0 DBG_AUTH (debug authentication) differs from the Closed or Locked states.

`0xF5F58008` Error: Bad HDPL in open product state. In open product state, Data provisioning service is only available in HDPL1.

JumpHDPLvl2

Prototype:

```
uint32_t JumpHDPLvl2(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
RSSLIB_PFUNC->JumpHDPLvl2((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- `VectorTableAddr`
  - Input parameter, address of the next vector table to apply
  - The vector table format folllows the one used by the Cortex-M7 core
- `MPUIndex`
  - Input parameter, MPU region index (index 0 to 15 allowed). The caller function must define, but keep disabled, the corresponding MPU region before calling JumpHDPLvl2. The function enables the MPU region before jumping to the reset handler of the vector table. The vector table reset handler function belongs to the MPU region.

The user calls `JumpHDPLvl2` to close the user flash HDPL1 area by incrementing HDPL to 2, then jumps to the reset handler embedded within the vector table, whose address is passed as input parameter.

After closing HDPL1, `JumpHDPLvl2` enables the MPU region provided as an input parameter. Once the MPU is enabled, the function sets the new vector table, sets the SP to the address provided in this new vector table, and jumps to the reset handler function supported by it.

Returned values:

- On successful execution, the function does not return and does not push LR onto the stack.
- In case of failure (invalid input parameter value), JumpHDPLvl2 returns 0xF5F5F5F5.

JumpHDPLvl3

Prototype:

```
uint32_t JumpHDPLvl3(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
RSSLIB_PFUNC->JumpHDPLvl3((uint32_t)NextVectorTableAddr, 1U);
```

Arguments:

- `VectorTableAddr`
  - Input parameter: Address of the next vector table to apply.
  - The vector table format follows the one used by the Cortex-M7 core.
- `MPUIndex`
  - Input parameter: MPU region index (index 0 to 15 allowed). The caller function must define but keep the corresponding MPU region disabled before calling JumpHDPLvl3. The function enables the MPU region before jumping to the reset handler of the vector table, which belongs to the MPU region.

The user calls `JumpHDPLvl3` to close the user flash HDPL1 and HDPL2 areas by incrementing HDPL up to 3, then jumps to the reset handler embedded within the vector table, whose address is passed as an input parameter.

After closing HDPL1 and HDPL2, `JumpHDPLvl3` enables the MPU region provided as an input parameter. Once the MPU is enabled, the function sets the new vector table, sets the SP to the address provided in this new vector table, and jumps to the reset handler function supported by it.

Returned values:

- On successful execution, the function does not return and does not push LR onto the stack.
- In the case of failure (invalid input parameter value), the `JumpHDPLvl3` function returns 0xF5F5F5F5.

GetProductState

Prototype:

```
uint32_t GetProductState(void)
```

User code function call example:

```
RSSLIB_PFUNC->GetProductState();
```

Arguments: None

The user calls GetProductState to reteive the STM32 product state.

Returned values:

- On successful call, the function returns one of the following product states:
  - 0x39: Open product state.
  - 0x17: Provisioning product state.
  - 0x72: Closed product state.
  - 0x5C: Locked product state.
- In case of failure (due to invalid product configuration), GetProductState returns 0xF5F5F5F5 (Bad state).

4 RAM ECC monitoring (RAMECC)

4.1 Introduction

STM32H7Pxxx devices feature a RAM error correction code monitoring unit (RAMECC). This provides a means for application software to enable, verify the ECC status, and execute service routines when an error occurs.

4.2 RAMECC main features

The internal SRAM can be protected by ECC when enabled. The ECC mechanism is based on the SECDED algorithm. It supports single- and double-error detection, as well as single-error correction:

- Seven ECC bits are added per 32-bit word.
- Eight ECC bits are added per 64-bit word.

RAM data word integrity is checked at each memory read access, or partial RAM word write operation. Two cycles are required to perform a partial RAM word write (read-modify-write).

The RAM ECC monitoring unit includes the following features:

- RAM ECC monitoring per domain
- RAM failing address/data identification
- Error code correction (ECC)

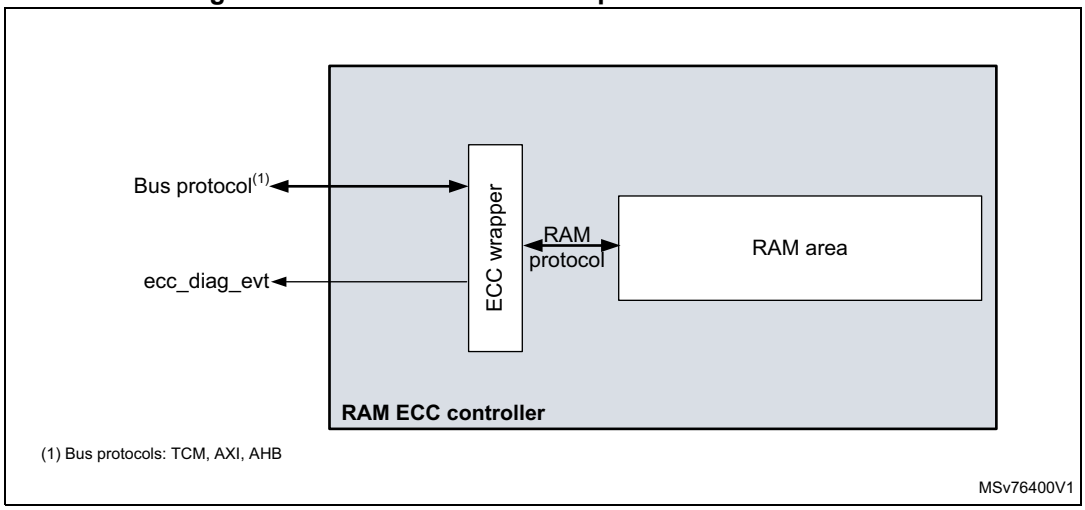
4.3 RAMECC functional description

ECC is supported by AXISRAM1-4, BKPSRAM, data and instruction tightly coupled memory (DTCM/ITCM). The ECC is enabled/disabled by the user option byte ECC_ON_SRAM in *Section 5.9.33: FLASH option byte word 1 status register (FLASH_OBW1SR)*.

Caution: Enabling ECC has a significant impact on performance. Check the device datasheet for the maximum CPU and bus frequencies that can be achieved with and without the ECC enabled.

As the ECC is calculated and checked for a 32/64-bit word, the byte and half-word write accesses are managed by the SRAM interface by first reading the whole word, then write the word again with the new byte/half-word value. ECC double errors are also detected during this byte or half-word AHB write accesses (read/modify/write done by interface). The byte or half-word write access latency is increased by 2 bus clock cycles.

Caution: In case of a byte or half-word write on SRAM with ECC, the read/modify/write operation is done in a buffer. The buffer content is written into the SRAM. The SRAM is then released. If a reset occurs during the operation, the SRAM content is not updated.



RAMECC block diagram

An ECC controller is associated with each RAM area. It performs the following functions:

- ECC encoding: ECC code computation and storage
- ECC decoding: RAM data word loading and ECC code decoding to detect errors
- Error detection: single- and double-error detection
- Error correction: single-error correction

The following figure describes the implementation of RAM ECC controllers.

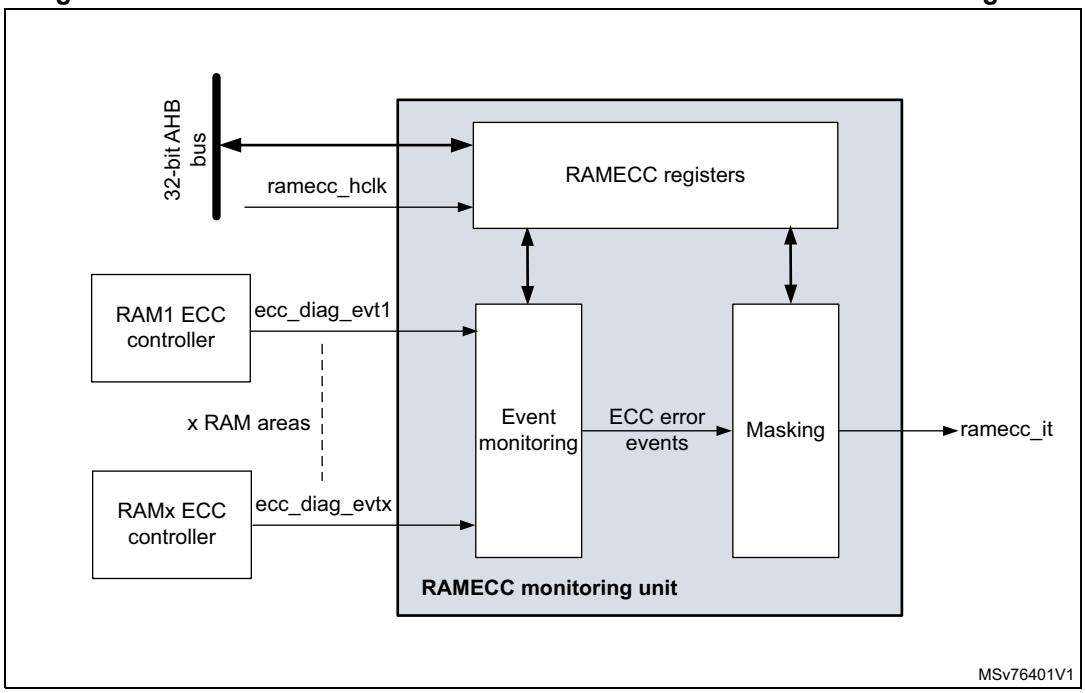


Figure 6. RAM ECC controller implementation schematic

A dedicated RAM ECC monitoring area is defined for each domain (see *Section 4.3.2: RAMECC monitor mapping*. The RAMECC allows the collection of ECC diagnostic events from each RAM ECC controller and provides a means for the CPU to verify the ECC status.

Figure 7 shows the connection schematic between the RAM ECC controller and the RAMECC monitoring unit.

Figure 7. Connection between RAM ECC controller and RAMECC monitoring unit

4.3.1 RAMECC internal signals

Table 17 lists the internal signals that control the RAMECC unit.

Table 17. RAMECC internal input/output signals

Internal signal name	Signal type	Description
ramecc_hclk	Input	AHB clock
ecc_diag_evtx	Input	ECC diagnostic event generated by RAMx ECC controller x
ramecc_it	Output	Interrupt generated by the RAMECC monitoring unit when an ECC error is detected.

4.3.2 RAMECC monitor mapping

STM32H7Pxxx devices feature two RAMECC units, RAMECC1 and RAMECC2. RAMECC1 monitors the AXI and TCM memories. RAMECC2 monitors the backup domain memory. The inputs from the ECC controllers are mapped to monitors as described in *Table 18*. The RAM ECC event monitoring status and configuration registers are described in *Section 4.6: RAMECC registers*.

Table 18. ECC controller mapping

RAMECC unit(1)	Monitor number	Description
RAMECC1	0	AXISRAM1 ECC controller monitoring unit
	1	AXISRAM2 ECC controller monitoring unit
	2	AXISRAM3 ECC controller monitoring unit
	3	AXISRAM4 ECC controller monitoring unit
	4	ITCM-RAM ECC controller monitoring unit
	5	DTCM0-RAM ECC controller monitoring unit
	6	DTCM1-RAM ECC controller monitoring unit
RAMECC2	0	Reserved
	1	BKPRAM ECC controller monitoring unit

1. See *Table 7: Peripheral boundary addresses*.

Single and double ECC errors

When a single error is detected, it is automatically corrected and the SEDCF bit is set in the *RAMECC monitor x status register (RAMECC_MxSR)*. When a double error is detected, the DEDF bit, or the DEBWDF bit in the case of a byte write, is set in the *RAMECC monitor x status register (RAMECC_MxSR)*.

For single and double errors:

- An interrupt is generated if enabled by the appropriate bit in the *RAMECC interrupt enable register (RAMECC_IER)*. Errors cannot be detected while the corresponding flag bit is set.
- The context (failing address, data, ECC code) is stored in the
  - *RAMECC monitor x failing address register (RAMECC_MxFAR)*
  - *RAMECC monitor x failing data register (RAMECC_MxFDR)*
  - *RAMECC monitor x failing ECC error code register (RAMECC_MxFECR)* if enabled by the ECCELEN bit in the *RAMECC monitor x configuration register (RAMECC_MxCR)*

4.3.3 ECC fault injection test on SRAM1, SRAM3, and TCM

A fault injection mechanism allows testing of 1- or 2-bit errors per word (for single or double error test respectively).

- ECCTEA = 0: Normal mode, ECC, and data memory access granted
- ECCTEA = 1: ECC memory access gated, data memory access granted

For example:

Initialization

1. Set the normal mode: ECCTEA = 0
2. Write 0xCAFEDECA, ECC = 0x19 (computed by ECC module)

Data modification

3. Bloc ECC memory access: ECCTEA = 1
4. Grant data modification: Write 0xCAFEDECB (last bit flipped)
5. Return to normal mode: ECCTEA = 0
6. READ 0xCAFEDECB with ECC = 0x19 single error ='1' (if enabled a flag is set and an interrupt to the NVIC is generated)

An ECC fault can trigger a system break event in TIM1/TIM8/TIM15/TIM16/TIM17/TIM20 if one or more of the following bits is set in the SBS_BKLOCKR register:

- ARAM1ECC_BL
- ARAM2ECC_BL
- ARAM3ECC_BL
- ARAM4ECC_BL
- ITCMECC_BL
- DTCMECC_BL

4.3.4 Read access latency

To correctly read data from SRAMs, the number of wait states is automatically set to one when ECC is enabled

4.4 RAMECC low-power modes

Table 19. Effect of low-power modes on RAMECC

Mode	Description
Sleep	No effect. RAMECC interrupt causes the device to exit the Sleep mode.
Stop	The content of RAMECC registers is kept. The ECC is functional and ECC error interrupt causes the device to exit from Stop mode.
Standby	The RAMECC peripheral is powered down and must be reinitialized after exiting Standby mode.

4.5 RAMECC interrupts

Table 20 lists the RAMECC interrupt requests.

Table 20. RAMECC interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit the Sleep/Stop mode	Exit the Standby mode
RAMECC	ECC single error detection and correction	SEDCF	GECCSEIE ECCSEIE GIE	Write 0 in SEDCF	Yes	No
	ECC double error detection	DEDF	GECCDEIE ECCDEIE GIE	Write 0 in DEDF	Yes	No
	ECC double error on byte write detection	DEBWDF	GECCDEBWIE ECCDEBWIE GIE	Write 0 in DEBWF	Yes	No

4.6 RAMECC registers

RAMECC registers can be accessed only in 32-bit (word) mode. Byte and half-word formats are not allowed.

4.6.1 RAMECC interrupt enable register (RAMECC_IER)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GECCDEBWIE	GECCDEIE	GECCSEIE	GIE
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **GECCDEBWIE**: Global ECC double error on byte write (BW) interrupt enable
When GECCDEBWIE bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a byte write operation to RAM (incomplete word write).
0: No interrupt generated when an ECC double detection error occurs on byte write
1: Interrupt generated if an ECC double detection error occurs on byte write

Bit 2 **GECCDEIE**: Global ECC double error interrupt enable
When GECCDEIE bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a read operation from RAM.
0: No interrupt generated when an ECC double detection error occurs
1: Interrupt generated if an ECC double detection error occurs

Bit 1 **GECCSEIE**: Global ECC single error interrupt enable
When GECCSEIE bit is set to 1, an interrupt is generated when an ECC single error occurs during a read operation from RAM.
0: No interrupt generated when an ECC single error occurs
1: Interrupt generated when an ECC single error occurs

Bit 0 **GIE**: Global interrupt enable
When GIE bit is set to 1, an interrupt is generated when any ECC error occurs.
0: No interrupt generated when an ECC error occurs
1: Interrupt generated when an ECC error occurs

4.6.2 RAMECC monitor x configuration register (RAMECC_MxCR)

Address offset: 0x00 + 0x20 * (x+1), (x = 0 to 6)

Reset value: 0x0000 0000

x is the ECC monitoring unit number - see *Table 18: ECC controller mapping*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCTEA
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCELEN	ECCDEBWIE	ECCDEIE	ECCSEIE	Res.	Res.
										rw	rw	rw	rw		

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **ECCTEA:** ECC test ECC access

This bit is used to inject a fault during ECC operation testing. This bit has no effect in RAMECC2.

0: Inactive

1: Write and read access blocked on ECC memory

Bits 15:6 Reserved, must be kept at reset value.

Bit 5 **ECCELEN**: ECC error latching enable

When ECCELEN bit is set to 1, if an ECC error occurs (both for single error correction or double detection) during a read operation, the context (address, data and ECC code) that generated the error are latched to their respective registers.

0: No error context preserved when an ECC error occurs

1: Error context preserved when an ECC error occurs

Bit 4 **ECCDEBWIE:** ECC double error on byte write (BW) interrupt enable

When ECCDEBWIE bit is set to 1, monitor x generates an interrupt when an ECC double detection error occurs during a byte write operation to RAM.

0: No interrupt generated when an ECC double detection error occurs on byte write

1: Interrupt generated if an ECC double detection error occurs on byte write

Bit 3 **ECCDEIE:** ECC double error interrupt enable

When ECCDEIE bit is set to 1, monitor x generates an interrupt when an ECC double detection error occurs during a read operation from RAM.

0: No interrupt generated when an ECC double detection error occurs

1: Interrupt generated if an ECC double detection error occurs

Bit 2 **ECCSEIE**: ECC single error interrupt enable

When ECCSEIE bit is set to 1, monitor x generates an interrupt when an ECC single error occurs during a read operation from RAM.

0: No interrupt generated when an ECC single error occurs

1: Interrupt generated when an ECC single error occurs

Bits 1:0 Reserved, must be kept at reset value.

4.6.3 RAMECC monitor x status register (RAMECC_MxSR)

Address offset: 0x24 + 0x20 * x, (x = 0 to 6)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DEBWDF	DEDF	SEDCF
													rc_w0	rc_w0	rc_w0

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **DEBWDF:** ECC double error on byte write (BW) detected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: No error detected
1: Error detected

Bit 1 **DEDF:** ECC double error detected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: No error detected
1: Error detected

Bit 0 **SEDCF:** ECC single error detected and corrected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: No error detected and corrected
1: Error detected and corrected

4.6.4 RAMECC monitor x failing address register (RAMECC_MxFAR)

Address offset: 0x28 + 0x20 * x, (x = 0 to 6)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FADD[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FADD[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FADD[31:0]:** ECC error failing address
When an ECC error occurs the FADD bit field contains the address that generated the ECC error.

4.6.5 RAMECC monitor x failing data register (RAMECC_MxFDR)

Address offset: 0x2C + 0x20 * x, (x = 0 to 6)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FDATAL[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FDATAL[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FDATA[31:0]:** Failing data

When an ECC error occurs the FDATA bit field contains the data that generated the error.
This bitfield is valid only in RAMECC2. It is reserved in RAMECC1.

4.6.6 RAMECC monitor x failing ECC error code register (RAMECC_MxFECR)

Address offset: 0x34 + 0x20 * x, (x = 0 to 6)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEC[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

FEC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FEC[31:0]:** Failing error code

When an ECC error occurs the FEC bit field contains the ECC failing code that generated the error.
This bitfield is valid only in RAMECC2. It is reserved in RAMECC1.

4.6.7 RAMECC register map

Table 21. RAMECC register map and reset values

Offset	Register name reset value	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

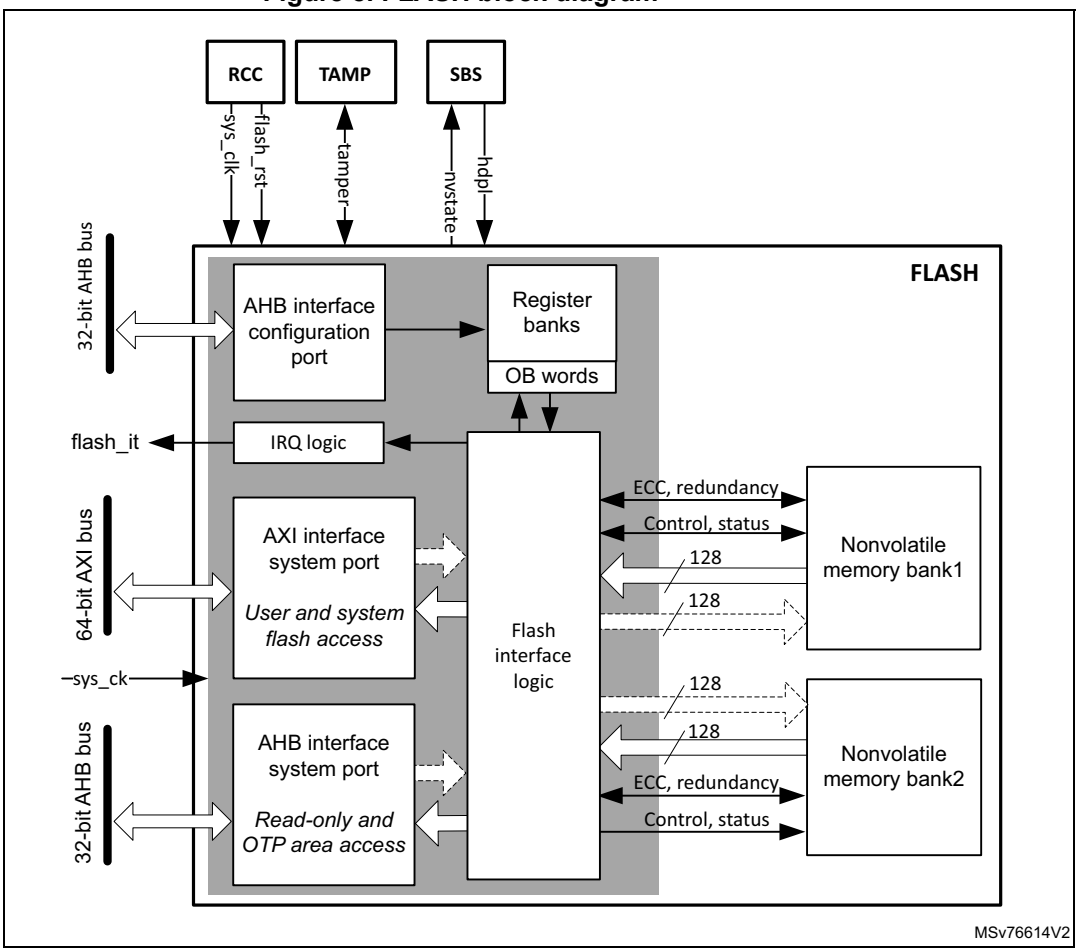
5 Embedded flash memory (FLASH)

5.1 Introduction

The embedded flash memory (FLASH) manages the accesses to 2 Mbytes of embedded nonvolatile memory (NVM). It implements the read, program and erase operations, error corrections as well as various integrity and confidentiality protection mechanisms.

The embedded flash memory manages the automatic loading of nonvolatile user option bytes at power-on reset, and implements the dynamic update of those options.

5.2 FLASH main features



- *(STM32H7PxxI devices only)* 2 Mbytes of nonvolatile user flash memory divided into two physical banks of 1 Mbyte each
- *(STM32H7PxxG devices only)* 1 Mbytes of nonvolatile user flash memory divided into two physical banks of 512 Kbytes each
- Flash memory read operations supporting multiple length (64 bits, 32 bits, 16 bits, or one byte)
- Flash memory programming by 128 bits (user area) and 16 bits (OTP area)
- 8-Kbyte page erase, and bank erase (conditioned)
- Dual-bank organization supporting:
  - Simultaneous operations: two read/program/erase operations executed in parallel on both banks
  - Bank swapping: physical bank allocation to user flash memory bank can be changed with option bytes, along with the corresponding registers. Security flags (write protection, HDPL) remain valid for the physical bank, so the data are not reveled by swapping.
- Error Code Correction (ECC): one error detection/correction or two error detections per 128-bit flash word using 9 ECC bits
- Cyclic redundancy check (CRC) hardware module
- User configurable nonvolatile option byte words
- Nonvolatile security life-cycle management of the device
  - Includes 128-bit password-based regression with RAM and flash automatic erase
- Temporal isolation enforcement based on application HDPL stored in SBS register
  - Securing one user flash area per bank, expandable using a volatile extension
  - Unique boot entry enforcement on a closed device
  - Dedicated nonvolatile option byte keys storage (32x 128-bit keys available for HDP levels 0 to 2)
- Page group write-protection (WRPG) per bank, protecting up to 32 group of 4 pages (32 Kbytes) per bank
- 512 words of 16-bit of one-time programmable (OTP) reserved for user information
- 512-byte read-only area reserved to STMicroelectronics information
- Read command queue to streamline flash operations

5.3 FLASH functional description

5.3.1 FLASH block diagram

Figure 8 shows the embedded flash memory block diagram, with its interaction with the rest of the device.

Figure 8. FLASH block diagram

For more information on RCC, *SBS* and *TAMP*, refer to the respective sections.

5.3.2 FLASH internal signals

Table 22 describes a list of the useful to know internal signals available at embedded flash memory level. These signals are not available on the microcontroller pads.

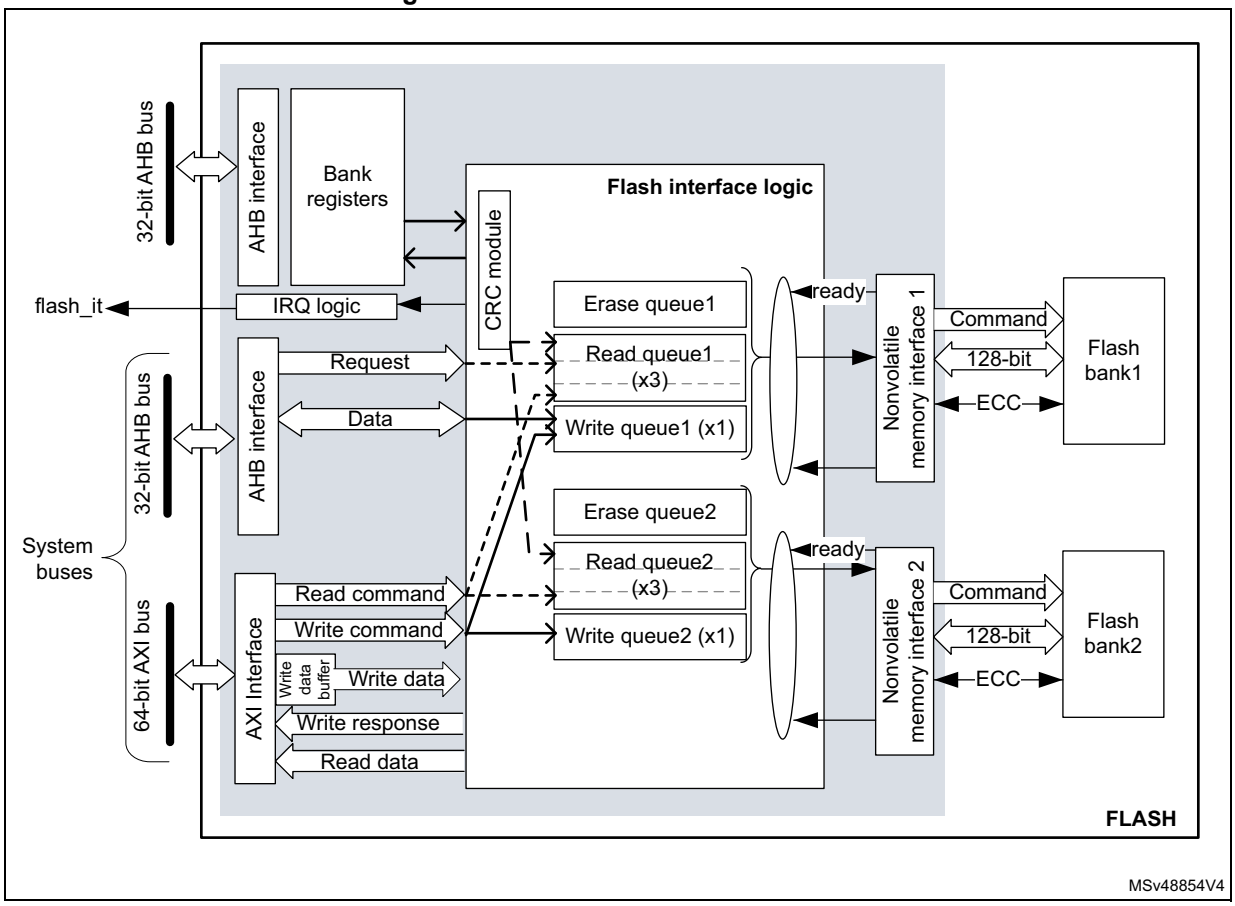
Table 22. FLASH internal input/output signals

Signal name	Signal type (1)	Description
sys_rst	Input	System reset of the device
flash_rst		Device power on reset triggering an option byte loading (see *Section 5.3.6*)
sys_ck		System bus clock
flash_it	Output	Embedded flash memory interrupt request
hdpl[7:0]	Input	Hide protection level stored in SBS_HDPLSR register of SBS peripheral. Used by embedded flash memory.
nvstate[7:0]	Output	Nonvolatile security state stored in FLASH_NVSR register. Used by SBS peripheral
tamper	Input, output	Internal signals managing tamper events in the device (see *Section 5.3.16*).

1. Only digital signals

5.3.3 FLASH architecture and integration in the system

The embedded flash memory is a central resource for the whole microcontroller. It serves as an interface to two nonvolatile memory banks, and organizes the memory in a very specific way. The embedded flash memory also proposes a set of security features to protect the assets stored in the nonvolatile memory at boot time, at runtime and during firmware and configuration upgrades.



The embedded flash memory offers three different interconnect interfaces:

- An AXI 64-bit slave port to access code/data
- An AHB 32-bit system slave port to access read-only and OTP area
- An AHB 32-bit configuration slave port to access the register bank

Note: The application can simultaneously request a read and a write operation through the AXI slave port.

The embedded flash memory micro-architecture is shown in *Figure 9*.

Figure 9. Detailed FLASH architecture

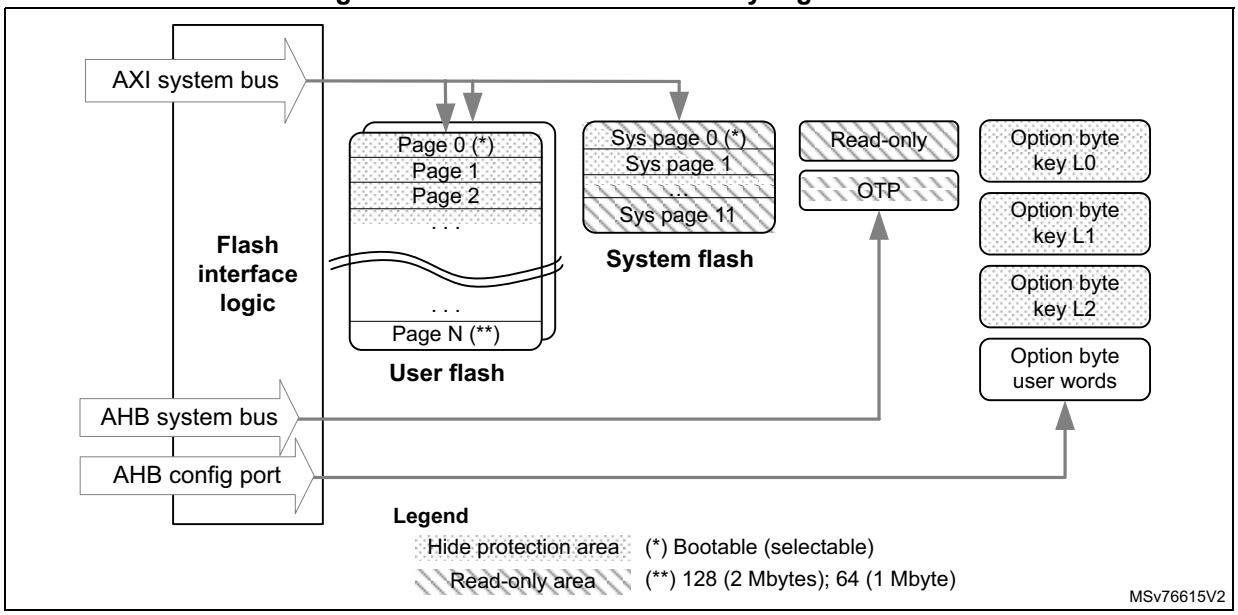
Behind the system interfaces, the embedded flash memory implements various command queues and buffers to perform flash read, write and erase operations with maximum efficiency.

By the addition of a read and write data buffer, the AXI slave port handles the following access types:

- Multiple lengths: 64 bits, 32 bits, 16 bits and 8 bits
- Single or burst accesses
- Write wrap burst must not cross 16-byte aligned address boundaries to target exactly one flash word

The AHB system slave port supports only 16-bit or 32-bit word accesses. For 8-bit accesses, an AHB bus error is generated and write accesses are ignored.

The AHB configuration slave port supports 8-bit, 16-bit and 32-bit word accesses.



The embedded flash memory is built in such a way that only one read or write operation can be executed at a time on a given bank.

5.3.4 Flash memory architecture and usage

Flash memory architecture

Figure 10 shows the nonvolatile memory organization in the embedded flash memory.

Figure 10. Embedded flash memory organization

The embedded flash nonvolatile memory is composed of:

- A main memory block, organized as two banks divided in pages of 8 Kbytes each. It features flash-word rows of 128 bits + 9 bits of ECC per word.
  - *(STM32H7PxxI devices only)* memory size is 2-Mbyte, organized as two banks of 1-Mbyte each. Each bank is in turn divided in 128 pages.
  - *(STM32H7PxxG devices only)* memory size is 1-Mbyte, organized as two banks of 512-Kbyte each. Each bank is in turn divided in 64 pages.
- A 128 Kbytes system memory block, divided into two 64-Kbyte banks. Each bank is in turn divided into eight 8-Kbyte pages. The system flash memory is ECC protected.
- A set of nonvolatile user option byte words, loaded at reset by the embedded flash memory and accessible by the application software only through the AHB configuration register interface.
- A 1 Kbyte one-time-programmable (OTP) area that can be written only once by the application software.
- A 512-byte read-only area written by STMicroelectronics during SoC manufacturing.
- 32 key slots of 16-byte per HDP level (up to level 2, included), loaded by software through the AHB configuration register interface. All the option byte keys benefit from the device hide protection mechanism.

Note: The system flash memory cannot be programmed nor erased by any application.

Since the OTP area has no specific protection, it must not be used to store confidential information.

The overall flash memory architecture and its corresponding access interface is summarized in *Table 23 (STM32H7PxxI devices only)* and *Table 24 (STM32H7PxxG devices only)*.

Table 23. Flash memory organization (2 Mbytes)

Flash memory area		Address range	Size (bytes)	ECC type	Region name	Access interface

1. Cannot be erased by application software.

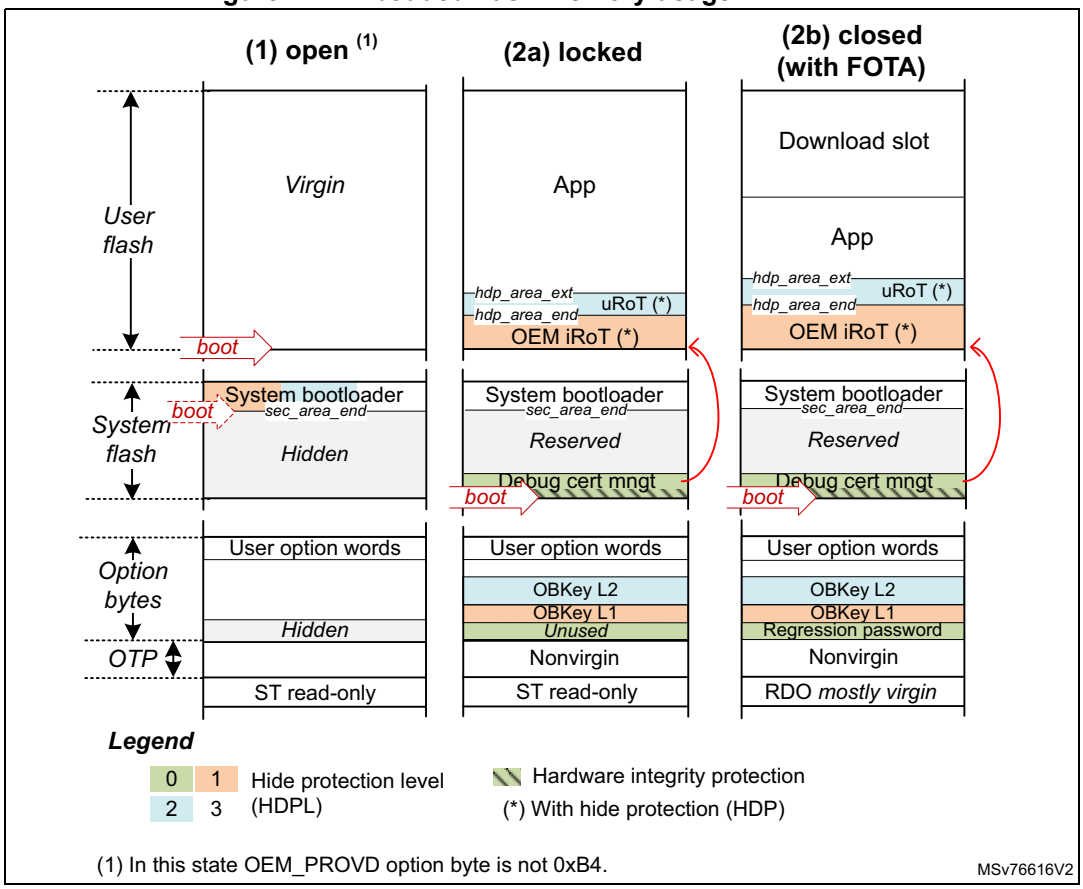
Partition usage

In the life of the product-embedded flash memory stores different kinds of data. Data availability also varies according to the hide protection level (HDPL) selected by the application at any given time. See *Section 10: System configuration, boot and security (SBS)* for more details.

The typical flash usages are described on *Figure 11*.

Figure 11. Embedded flash memory usage



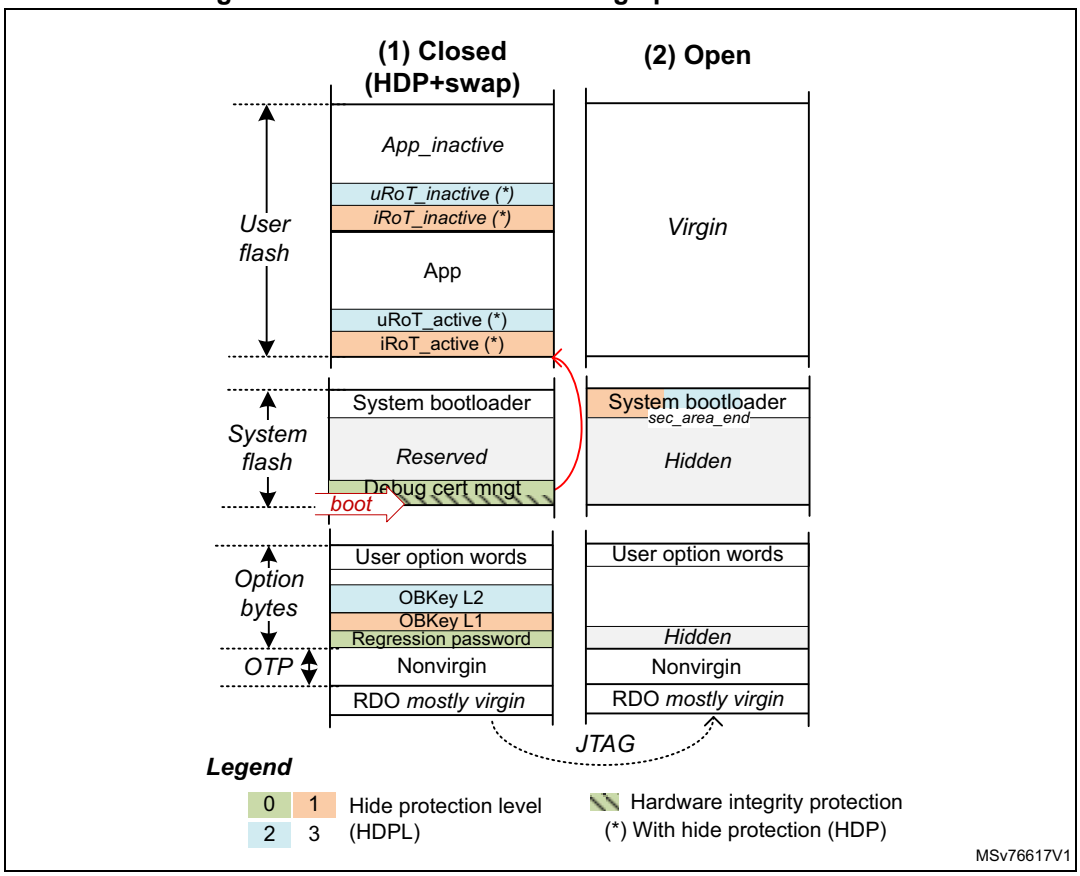


Figure 12 shows how the embedded flash memory is used when an OEM returns a provisioned production device to an open state (for example when returning a part for field return analysis).

Note: In any device, if the application knows the decommissioning key it can open the device using STM32 tools.

Figure 12. Flash decommissioning options

Bank swapping

The embedded flash memory offers a bank swapping feature that can be configured through the SWAP_BANK bit, always available for the application. Bank swap feature can be revoked using the BOOT_LOCK option.

For more information, refer to *Section 5.3.14: FLASH bank and register swapping*.

5.3.5 Flash hide protection schemes

Figure 10 gives an overview of the protection mechanism supported by the embedded flash memory:

- A user flash area can be defined as a user HDP area, with a hardware defined access policy based on STM32 hide protection level (HDPL).
- A system flash starting from page zero is defined as system HDP area, also with a hardware-defined access policy based on STM32 hide protection level (HDPL).
- Three sets of option byte keys are each reserved to a specific hide protection level.

For more information on both HDP areas, refer to *Section 5.5.4: Hide protection (HDP)*. More details on option byte keys can be found in *Section 5.4.4: Option byte key management*.

5.3.6 Overview of FLASH operations

Read operations

The embedded flash memory can perform read operations on the whole nonvolatile memory using various granularities: 64 bits, 32 bits, 16 bits or one byte. User and system flash memories are read through the AXI interface, while the option bytes are read through the register interface. Read-only and OTP special region are read through the system AHB interface.

The embedded flash memory supports read-while-write operations provided the read and write operations target different physical banks. Similarly read-while-read operations are supported when two read operations target different banks.

To increase efficiency, the embedded flash memory implements the buffering of consecutive read requests in the same physical bank.

For more details on read operations, refer to *Section 5.3.7: FLASH read operations*.

Program/erase operations

The embedded flash memory supports the following program and erase operations:

- Single flash word write (128-bit granularity for user flash memory, 16-bit granularity for OTP area), with the possibility for the application to force-write a user flash word with less than 128 bits in user flash memory
- Single page erase
- Bank erase
- Option byte words update (if allowed)

Thanks to its dual bank architecture, the embedded flash memory can perform any of the above write or erase operation on one physical bank while a read or another program/erase operation is executed on the other bank.

Note: Program and erase operations are subject to the various protections that could be set on the embedded flash memory (see next).

For more details, refer to *Section 5.3.8: FLASH program operations* and *Section 5.3.9: FLASH erase operations*.

Protection mechanisms

The embedded flash memory supports different protection mechanisms:

- Configuration protection
- Write protection
- Temporal isolation enforcement of nonvolatile secrets (code/data, keys), based on the hide protection level information stored in SBS_HDPLSR register.
- Life-cycle management, based on flash root of trust option bytes
- OTP locking

For more details refer to *Section 5.5: FLASH protection mechanisms*.

Option byte loading

As part of the life-cycle management, the embedded flash memory reliably loads the nonvolatile option bytes stored in nonvolatile memory after every power on reset, enforcing boot and security options to the whole device when the embedded flash memory becomes functional again. For more details refer to *Section 5.4: FLASH option bytes*.

5.3.7 FLASH read operations

Read operation overview

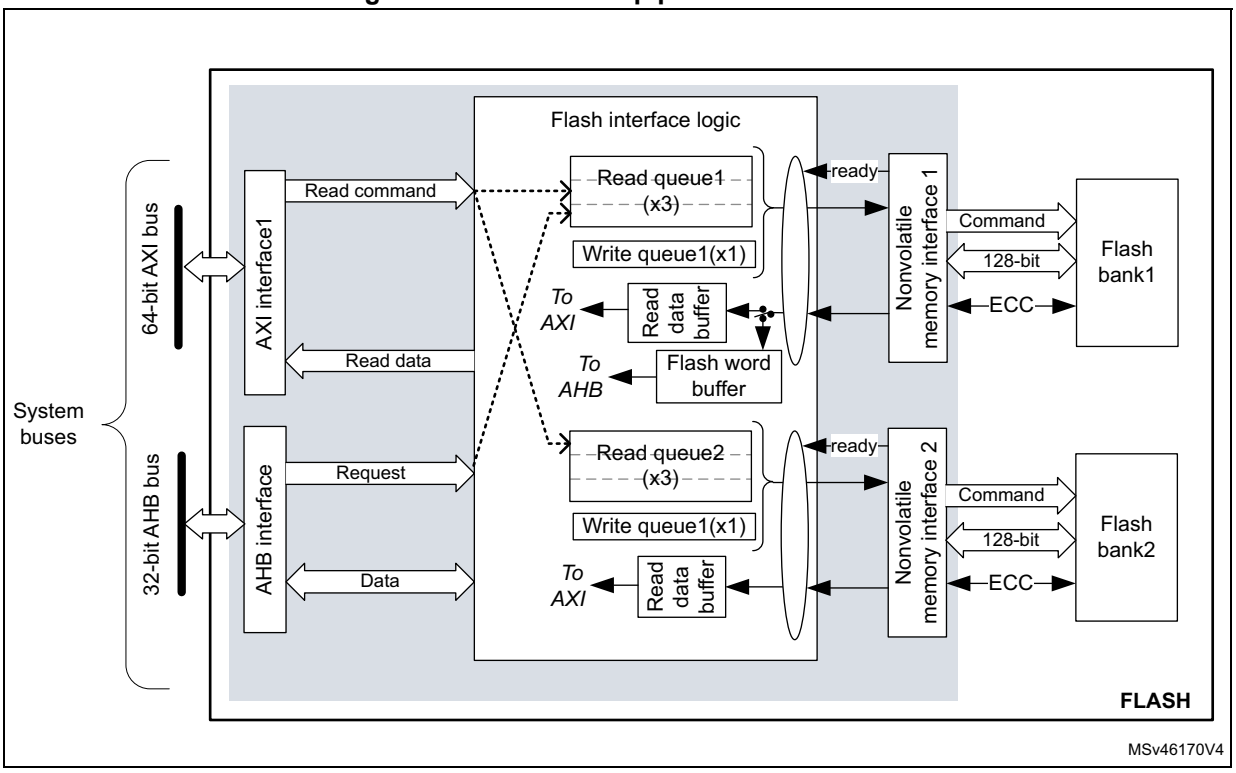
The embedded flash memory supports, for each memory bank, the execution of one read command while two are waiting in the read command queue. Multiple read access types are also supported as defined in *Section 5.3.3: FLASH architecture and integration in the system*.

The read commands to each physical bank are associated with a 128-bit read data buffer. These commands can be issued either by the AHB (OTP or read-only areas) or by the AXI interface (user flash or system flash memory).

Note: The embedded flash memory can perform single error correction and double error detection while read operations are being executed (see Section 5.3.10: FLASH parallel operations).

The AXI interface read channel operates as follows:

- When the read command queue is full, any new AXI read request stalls the bus read channel interface and consequently the master that issued that request.
- If several consecutive read accesses request data that belong to the same flash data word (128 bits), the data are read directly from the current data read buffer, without triggering additional flash read operations. This mechanism occurs each time a read access is granted. When a read access is rejected for security reasons (e.g. HDP protected word), the corresponding read error response is issued by the embedded flash memory and no read operation to flash memory is triggered.



The AHB system interface operates as follows:

- Until the AHB read request has been served, the embedded flash memory stalls the AHB bus and consequently the master that issued that request.

The Read pipeline architecture is summarized in *Figure 13*.

For more information on bus interfaces, refer to *Section 5.3.3: FLASH architecture and integration in the system*.

Figure 13. FLASH read pipeline architecture

Single read sequence

The recommended simple read sequence is the following:

1. For AXI interface: Freely perform read accesses to any AXI-mapped area. For AHB interface: perform either 16-bit or 32-bit read accesses to the AHB-mapped area (byte accesses generate a bus error).
2. The embedded flash memory effectively executes the read operation from the read command queue buffer as soon as the nonvolatile memory is ready and the previously requested operations on this specific bank have been served.

Note: When reading an OTP data that has not been previously written, a double ECC error is reported and only 1's are returned (see Section 5.3.12 for details).

Adjusting read timing constraints

The embedded flash memory clock must be enabled and running before reading data from nonvolatile memory.

To correctly read data from flash memory, the number of wait states (LATENCY) must be correctly programmed in the flash access control register (FLASH_ACCR) according to the embedded flash memory AXI interface clock frequency (rcc_aclk) and the core voltage range of the device (V_{core}).

Table 25 shows the correspondence between the number of wait states (LATENCY), the programming delay parameter (WRHIGHFREQ), the embedded flash memory clock frequency and its supply voltage ranges.

Table 25. FLASH recommended number of wait states and programming delays

Number of wait states (LATENCY)	Programming delay (WRHIGHFREQ)	AXI interface clock maximum frequency versus V_{CORE} range		
		VOS2 range (1.05 V - 1.15 V)	VOS1 range (1.15 V - 1.26 V)	VOS0 range (1.26 V - 1.35 V)
0 WS (1 FLASH clock cycle)	00	40 MHz		
1 WS (2 FLASH clock cycles)		80 MHz		
2 WS (3 FLASH clock cycles)	01	120 MHz		
3 WS (4 FLASH clock cycles)		150 MHz	160 MHz	
4 WS (5 FLASH clock cycles)	10	N/A	200 MHz	
5 WS (6 FLASH clock cycles)		N/A	217 MHz	240 MHz
6 WS (7 FLASH clock cycles)	11	N/A	N/A	260 MHz

Adjusting the system frequency

After power-on, the embedded flash memory is clocked by the 64 MHz high-speed internal oscillator (HSI), with a voltage range set at VOS1.

When changing the AXI bus frequency, the application software must follow the below sequence in order to tune the number of wait states required to access the nonvolatile memory.

To increase the embedded flash memory clock source frequency:

1. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in the FLASH_ACCR register, as described in *Table 25*.
2. Check that the new number of wait states is taken into account by reading back the FLASH_ACCR register.
3. Modify the embedded flash memory clock source and/or the AXI bus clock prescaler in the RCC_CFGR register of the reset and clock controller (RCC).
4. Check that the new embedded flash memory clock source and/or the new AXI bus clock prescaler value are taken in account by reading back the embedded flash memory clock source status and/or the AXI bus prescaler value in the RCC_CFGR register of the reset and clock controller (RCC).

To decrease the embedded flash memory clock source frequency:

1. Modify the embedded flash memory clock source and/or the AXI bus clock prescaler in the RCC_CFGR register of reset and clock controller (RCC).
2. Check that the embedded flash memory new clock source and/or the new AXI bus clock prescaler value are taken into account by reading back the embedded flash memory clock source status and/or the AXI interface prescaler value in the RCC_CFGR register of reset and clock controller (RCC).
3. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in the FLASH_ACCR register, as described in *Table 25*.
4. Check that the new number of wait states has been taken into account by reading back the FLASH_ACCR register.

Read errors

The embedded flash memory embeds an error correction mechanism, as described in *Section 5.3.10*.

Single error correction and double error detection are performed for each read operation. In both cases the embedded flash memory reports read errors as described in *Section 5.7.5: Error correction code error (SNECCERRF/DBECCERRF)*.

Read interrupts

See *Section 5.8: FLASH interrupts* for details.

5.3.8 FLASH program operations

Program operation overview

The virgin state of each nonvolatile memory bitcell is 1. The embedded flash memory supports programming operations that can change any memory bitcell to 0. However these operations do not support the return of a bit to its virgin state. In this case an erase operation of the entire page is required.

Program operation consists in issuing write commands. The embedded flash memory supports the execution of one write command for each memory bank. For write accesses issued by the AXI interface, since a 9-bit ECC code is associated with each 128-bit data flash word, the embedded flash memory must always perform write operations to nonvolatile memory with a 128-bit word granularity.

Note: The application can decide to write as few as 8 bits to a 128-bit flash word. In this case, a force-write mechanism to the 128 bits + ECC is used (see FW bit of FLASH_CR register).

System flash memory cannot be written by the application software.

It is not recommended to overwrite a flash word that is not virgin. The result may lead to an inconsistent ECC code that is systematically reported by the embedded flash memory, as described in *Section 5.7.5: Error correction code error (SNECCERRF/DBECCERRF)*.

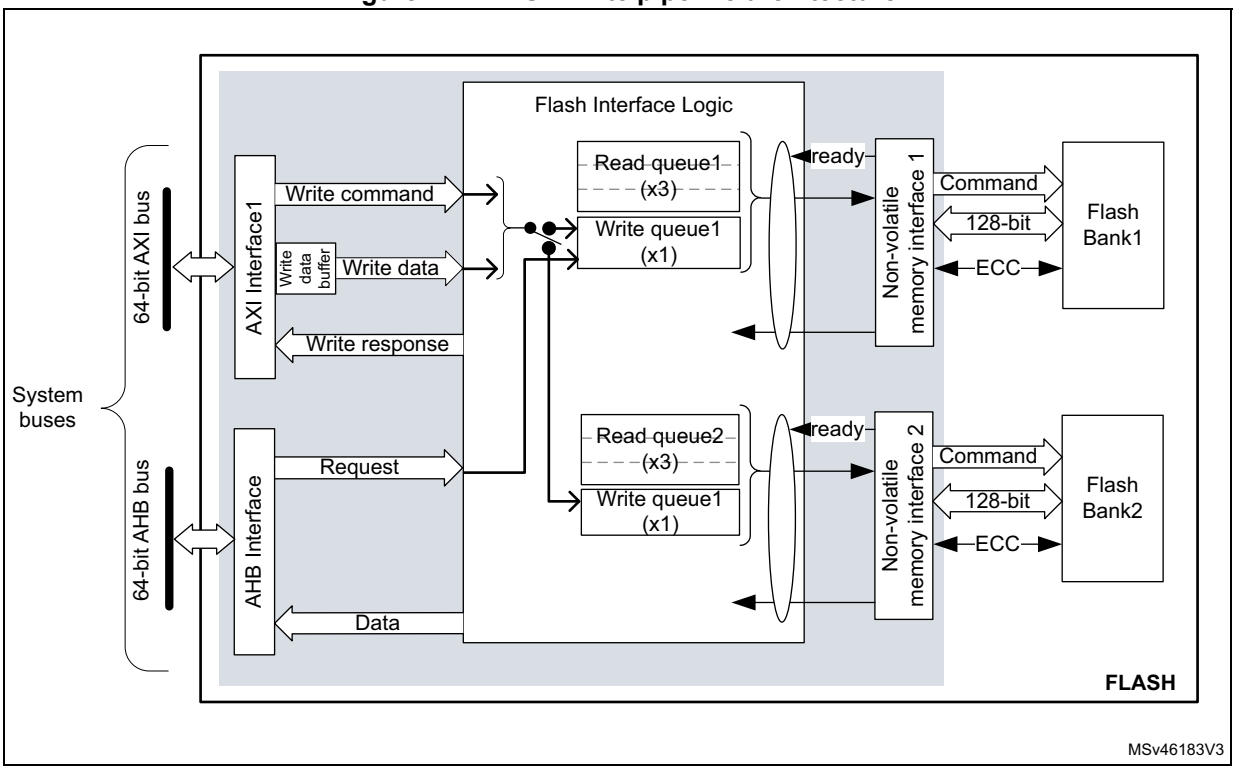
Write access requests issued by the AHB system interface are serialized with AXI commands and can only be used to program the memory OTP area. In this area, since a 6-bit ECC code is associated with each 16-bit data flash word, the embedded flash memory supports 16-bit or 32-bit write operations (8-bit write operations are not supported).

Note: The OTP area is typically write-protected on the final product, as described in Section 5.3.12: FLASH one-time programmable (OTP) area.

Erase operations to the OTP area are not supported.

The AXI interface write channel operates as follows:

- A 128-bit write data buffer is associated with the AXI interface. It supports multiple write access types (64 bits, 32 bits, 16 bits and 8 bits).
- When the write queue is full, any new AXI write request stalls the bus write channel interface and consequently the master that issued that request.



The AHB system interface operates as follows:

- Write commands issued by the AHB system interface are associated with a 137-bit flash word buffer. Byte accesses are not supported.
- When the write queue is full, any new AHB request stalls the bus interface and consequently the master that issued that request.

The write pipeline architecture is described in *Figure 14*.

For more information on bus interfaces, refer to *Section 5.3.3: FLASH architecture and integration in the system*.

Figure 14. FLASH write pipeline architecture

Managing write protections

Before programming a user page, the application software must check the protection of the targeted flash memory area.

The embedded flash memory checks the protection properties of the write transaction target at the output of the write queue buffer, just before the effective write operation to the nonvolatile memory:

- If a write protection violation is detected, the write operation is canceled and write protection error (WRPERRF) is raised in FLASH_xISR register (x = A or B).
- If the write operation is valid, the 9-bit ECC code is concatenated to the 128 bits of data and the write to nonvolatile memory is effectively executed.

Note: No write protection check is performed when the embedded flash memory accepts AXI write requests.

A similar mechanism exists for OTP areas with the following differences:

- If the write operation is valid, the 6-bit ECC code is concatenated to the 16 bits of data and the write to nonvolatile memory is effectively executed.

The write protection flag does not need to be cleared before performing a new programming operation.

Monitoring ongoing write operations

The application software can use three status flags located in FLASH_xSR in order to monitor ongoing write operations in the bank x. These status flags are available for each bank.

- **BUSY**: this bit indicates in real time that an effective write, erase or option byte change operation is ongoing to the nonvolatile memory. It is possible to know what type of operation is being executed polling the bits IS_PROGRAM, IS_ERASE and IS_OPTCHANGE in the same register.
- **QW**: this bit indicates that a write, erase or option byte change operation is pending in the write queue or command queue buffer. It remains high until the write operation is complete. It supersedes the BUSY status bit.
- **WBNE**: this bit indicates that the embedded flash memory is waiting for new data to complete the 128-bit write buffer. In this state the write buffer is not empty. It is reset as soon as the application software fills the write buffer, force-writes the operation using FW bit in FLASH_xCR, or disables all write operations in the bank x.

Enabling write operations

Before programming the user flash memory, the application software must make sure that PG bit is set in FLASH_xCR. If it is not set an unlock sequence must be used once (see *Section 5.5.1: FLASH configuration protection*) and the PG bit must be set.

When the option bytes need to be modified, the application software must make sure that FLASH_OPTCR is unlocked. If it is not the case, an unlock sequence must be used (see *Section 5.5.1: FLASH configuration protection*). For more information on option byte word modification, refer to *Section 5.4.3*.

Note: The application software must not unlock a register that is already unlocked, otherwise this register remains locked until next system reset.

If needed, the application software can update the programming delay as described at the end of this section.

Single write sequence

The recommended single write sequence in the bank x is the following:

1. Unlock the FLASH_xCR register, as described in *Section 5.5.1: FLASH configuration protection* (only if the register is not already unlocked).
2. Enable write operations by setting the PG bit in the FLASH_xCR register.
3. Check the protection of the targeted memory area.
4. Write one flash-word corresponding to 16-byte data starting at 16-byte aligned address.
5. Check that QW has been raised and wait until it is cleared in the FLASH_xSR register.

If step 4 is executed incrementally (for example byte per byte), the write buffer can become partially filled. In this case the application software can decide to force-write what is stored in the write buffer by using the FW bit in FLASH_xCR register. In this particular case, the unwritten bits are automatically set to 1. If no bit in the write buffer is cleared to 0, the FW bit has no effect.

Note: Using a force-write operation prevents the application from updating later the missing bits with a value different from 1, which is likely to lead to a permanent ECC error.

Any write access requested while the PG bit is cleared to 0 is rejected. In this case, no error is generated on the bus, but the PGSERRF flag is raised.

Clearing the programming sequence error (PGSERRF) and inconsistency error (INCERRF) is mandatory before attempting a write operation (see Section 5.7: FLASH error management for details).

Adjusting programming timing constraints

Program operation timing constraints depend on the embedded flash memory clock frequency, which directly impacts the performance. If timing constraints are too tight, the nonvolatile memory does not operate correctly, if they are too lax, the programming speed is not optimal.

The user must therefore trim the optimal programming delay through the WRHIGHFREQ parameter in the FLASH_ACCR register. Refer to *Table 25* in *Section 5.3.7: FLASH read operations* for the recommended programming delay depending on the embedded flash memory clock frequency.

The application software must check that no program/erase operation is ongoing before modifying the WRHIGHFREQ parameter.

Caution: Modifying WRHIGHFREQ while programming/erasing the flash memory might corrupt the flash memory content.

Programming errors

When a program operation fails, an error can be reported as described in *Section 5.7: FLASH error management*.

Programming interrupts

See *Section 5.8: FLASH interrupts* for details.

5.3.9 FLASH erase operations

Erase operation overview

The embedded flash memory can perform erase operations (if allowed) on 8-Kbyte user pages, or on one bank.

Note: System flash memory and read-only/OTP area cannot be erased by the application software.

The erase operation forces all nonvolatile bit cells to high state, which corresponds to the virgin state. It clears existing data and corresponding ECC, allowing a new write operation to be performed. If the application software reads back a word that has been erased or not programmed, all the bits are read at 1. No ECC error is generated if the word is located in user flash memory, while a double ECC error is raised if the word is located in read-only or OTP area.

Erase operations are similar to read or program operations except that the commands are queued in a special buffer (a one-command deep erase queue).

Erase commands are issued through the AHB configuration interface. If the embedded flash memory receives simultaneously a write and an erase request for the same bank, both operations are accepted but the write operation is executed first.

Erase and security

A user page can be erased only if it does not contain write-protected data or data currently protected by the HDP (see *Section 5.5: FLASH protection mechanisms* for details). In other words, if the application software attempts to erase a user page with at least one flash word that is protected in the bank x, the page erase operation is aborted and the WRPERRF flag is raised in the FLASH_xISR register, as described in *Section 5.7.1*.

Note: When triggering an NVSTATE change from NVCLOSE to NVOPEN an automatic erase of the whole user flash occurs, erasing HDP protected pages. See Section 5.5.3 for details.

Enabling erase operations

Before erasing a page, the application software must make sure that FLASH_xCR is unlocked. If it is not the case, an unlock sequence must be used (see *Section 5.5.1: FLASH configuration protection*).

Note: The application software must not unlock a register that is already unlocked, otherwise this register remains locked until the next system reset.

Similar constraints apply to bank erase requests.

Flash page erase sequence

To erase an 8-Kbyte user page in the bank x, proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation. Refer to *Section 5.7: FLASH error management* for details.
2. Unlock the FLASH_xCR register, as described in *Section 5.5.1: FLASH configuration protection* (only if the register is not already unlocked).
3. Set the PER bit and PSN bitfield in the corresponding FLASH_xCR register. PER indicates a page erase operation, while PSN contains the target page number in the bank x.
4. Set the START bit in the FLASH_xCR register.
5. Wait for the QW bit to be cleared in the FLASH_xSR register.

Note: If a bank erase is requested simultaneously to the page erase (BER and PER bits set), the bank erase operation supersedes the page erase operation.

Flash bank erase sequence

To erase all pages of bank x, except for those containing hide protected data, proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation. Refer to *Section 5.7: FLASH error management* for details.
2. Unlock the FLASH_xCR register, as described in *Section 5.5.1: FLASH configuration protection* (only if the register is not already unlocked).
3. Set the BER bit in the FLASH_xCR register.
4. Set the START bit in the FLASH_xCR register to start the bank erase operation. Then wait until the QW bit is cleared in FLASH_xSR register.

Note: BER and START bits can be set together, so above steps 3 and 4 can be merged.

If a page erase is requested simultaneously to the bank erase (PER bit set), the bank erase operation supersedes the page erase operation.

5.3.10 FLASH parallel operations

As the nonvolatile memory is divided into two independent banks, the embedded flash memory interface can drive different operations at the same time on each bank. For example a read, write or erase operation can be executed on bank A while another read, write or erase operation is executed on bank B.

In all cases, the sequences described in *Section 5.3.7: FLASH read operations*, *Section 5.3.8: FLASH program operations* and *Section 5.3.9: FLASH erase operations* apply.

5.3.11 Flash memory error protections

Error correction codes (ECC)

The embedded flash memory supports an error correction code (ECC) mechanism. It is based on the SECDED algorithm in order to correct single errors and detects double errors.

Per 128-bit system and user flash word the embedded flash memory uses 9 ECC bits. During each read operation from a 128-bit flash word, FLASH retrieves the 9-bit ECC information, computes the ECC of the flash word, and compares the result with the

reference value. If they do not match, the corresponding ECC error is raised as described in *Section 5.7.5: Error correction code error (SNECCERRF/DBECCERRF)*. During each program operation, a 9-bit ECC code is associated with each 128-bit data flash word, and the resulting 137-bit flash word information is written in nonvolatile memory.

For read-only and OTP areas, the embedded flash memory uses a stronger 6 ECC bits per 16-bit word. For option byte words and keys a double ECC scheme is used. For more information on read-only and OTP refer to *Section 5.3.12* and *Section 5.3.13*. For more information on option byte words and keys refer to *Section 5.4*.

Note: A double ECC error is generated for an OTP virgin word (for example a word with 22 bits at 1). When this OTP word is no more virgin, the ECC error disappears.

Cyclic redundancy codes (CRC)

The embedded flash memory implements a cyclic redundancy check (CRC) hardware module. This module checks the integrity of a given user flash memory area content.

The area processed by the CRC module can be defined either by pages or by start/end addresses. It can also be defined as the whole user flash bank.

Note: Only one CRC check operation on bank 1 or 2 can be launched at a time. To avoid corruption, do not configure the CRC calculation on the one bank, while calculating the CRC on the other bank.

When enabled, the CRC hardware module performs multiple reads by chunks of 4, 16, 64 or 256 consecutive flash-word (for example chunks of 64, 256, 1024 or 4096 bytes). These consecutive read operations are pushed by the CRC module into the required read command queue together with other AXI read requests, thus avoiding denying AXI read commands.

CRC computation uses CRC-32 (Ethernet) polynomial 0x4C11DB7:

$$X^{32}+ X^{26}+ X^{23}+ X^{22}+ X^{16}+ X^{12}+ X^{11}+ X^{10}+ X^{8}+ X^{7}+ X^{5}+ X^{4}+ X^{2}+ X + 1$$

The CRC operation is concurrent with the reading or writing of option byte user words, keys or OTP, because the same hardware is used for all those operations. To avoid corruption to the CRC computation the flash stalls above incoming requests when a CRC operation is ongoing.

The recommended sequence to configure a CRC operation in the bank x is the following:

1. Unlock FLASH_xCR register, if not already unlocked.
2. Enable the CRC feature by setting the CRC_EN bit in FLASH_xCR.
3. Program the desired data size in the CRC_BURST field of FLASH_xCRCCR.
4. Define the user flash memory area on which the CRC has to be computed. Four solutions are possible:
   - Select all user flash pages by setting the ALL_BANK bit in FLASH_xCRCCR
   - Define the area start and end addresses by programing FLASH_xCRCSADDR and FLASH_xCRCEADDR, respectively,
   - Select the targeted pages by setting the CRC_BY_PAGE bit in FLASH_xCRCCR. Also program consecutively the target page numbers using the CRC_PAGE field

of the FLASH_xCRCCR register. Set the ADD_PAGE bit after each CRC_PAGE programming.

5. When step 4 is completed start the CRC operation by setting the START_CRC bit in FLASH_xCRCCR.
6. Wait until the CRC_BUSY flag is reset in FLASH_xSR.
7. Retrieve the CRC result in FLASH_CRCDATAR.

Note: The application should avoid running a CRC on HDP user flash memory area when the hide protection level prevents access to it. Indeed, doing so may alter the expected CRC value. A special error flag defined in Section 5.7.7: CRC read error (CRCRDERRF) can be used to detect such a case.

CRC computation does not raise standard read error flags such as RDSERRF, SNECCERRF, and DBECCERRF. Only CRCRDERRF is raised.

5.3.12 FLASH one-time programmable (OTP) area

The embedded flash memory offers a 1024-byte memory area dedicated to application non-confidential one-time programmable data (OTP). It is composed of 512 words of 16 bits that cannot be erased, and can be written only once.

Note: The OTP area is virgin when the device is delivered by STMicroelectronics.

OTP data can be accessed through the AHB system port. They are organized as 16 blocks of 32 OTP words, as shown in *Table 26*. An entire OTP block can be protected (locked) from write accesses by setting the corresponding OTPL bit in the FLASH_OTPLSRP register, as shown. There is no special read protection mechanism on the OTP area.

*Note: The OTP block locking operation is **irreversible** and independent from the life-cycle management described in Section 5.5.3.*

A block can be write-protected whether or not it has been programmed (even partially).

Table 26. Flash memory OTP organization

OTP block	AHB address	AHB word		Lock bit
		[31:16]	[15:0]	
Block 0	0x08FF F000	OTP001	OTP000	OTPL[0]
	0x08FF F004	OTP003	OTP002	
	...			
	0x08FF F03C	OTP031	OTP030	
Block 1	0x08FF F040	OTP033	OTP032	OTPL[1]
	0x08FF F044	OTP035	OTP034	
	...			
	0x08FF F07C	OTP063	OTP062	
Block 2	0x08FF F080	OTP065	OTP064	OTPL[2]
	0x08FF F084	OTP067	OTP066	
	...			
	0x08FF F0BC	OTP127	OTP126	

Table 26. Flash memory OTP organization (continued)

OTP block	AHB address	AHB word		Lock bit
		[31:16]	[15:0]	
...				
Block 15	0x08FF F3C0	OTP481	OTP480	OTPL[15]
	0x08FF F3C4	OTP483	OTP482	
	...			
	0x08FF F3FC	OTP511	OTP510	

OTP error protection

OTP data are organized as 16 blocks of 32 OTP words, as shown on *Table 26*. Each 16-bit half-word is protected by 6 bits of ECC. Hence the application must avoid overwriting a 16-bit half-word that has already been programmed, as it is leading to systematic ECC error. Similarly, do not write twice a 16-bit OTP word, as it could lead to systematic ECC error.

When reading OTP data with a single error corrected or a double error detected, the embedded flash memory reports the corresponding error, as described in *Section 5.7.5: Error correction code error (SNECCERRF/DBECCERRF)*.

When reading OTP data that has not been written by the application software (that is, virgin OTP), the ECC correction reports a double error detection (DBECCERRF), and all 1's are returned. It is therefore recommended that the application always writes the OTP data before trying to read it.

OTP write sequence

Follow the sequence below to write an OTP word:

1. Check the protection status of the target OTP word (see *Table 26*). The corresponding OTPLi bit must be cleared in FLASH_OTPLSR register.
2. Unlock FLASH_xCR if the register is not already unlocked, and then set the PG_OTP bit in the FLASH_xCR register.
3. Write two OTP words (32 bits) corresponding to the 4-byte aligned address shown in *Table 26*. Alternatively, the application software can program separately the 16-bit MSB or 16-bit LSB. In this case the first 16-bit write operation starts immediately without waiting for the second one.
4. Check that the QW bit in FLASH_xSR has been set and wait until it is cleared.
5. Read back the target OTP word to confirm the value
6. Optionally, lock the OTP block using OTPLi bit in FLASH_OTPLSRP in order to prevent further data changes. PG_OTP bit in the FLASH_xCR register can also be cleared if needed.

Note: To avoid data corruption, it is important to complete the OTP write process (for example by reading back the OTP value), before starting a new option byte change.

OTP write operations can trigger PGSERRF or WRPERRF errors (see Section 5.7).

Writing OTP data at byte level is not supported and generates a bus error.

5.3.13 FLASH read-only (RO) area

The embedded flash memory offers a 512-byte memory area dedicated to non-confidential and read-only information usable by application software.

Read-only area can be accessed through the AHB system port. It is organized as shown in *Table 27*. This information is provisioned by STMicroelectronics during the device manufacturing.

Table 27. read-only public data organization

AHB address (read-only)	Read-only data name and usage
0x08FF F800	U_ID[31:0]
0x08FF F804	U_ID[63:32]
0x08FF F808	U_ID[95:64]
0x08FF F80C	Flash memory size[15:0] || Package code[15:0]
0x08FF F810 to 0x08FF F9FF	Reserved information

Read-only area error protection

Read-only area is protected by a robust ECC scheme. When reading a 32-bit word in this area with a single error corrected or a double error detected, the embedded flash memory reports the corresponding error, as described in *Section 5.7.5: Error correction code error (SNECCERRF/DBECCERRF)*.

5.3.14 FLASH bank and register swapping

Allocation of physical banks 1 & 2 to embedded flash user banks A & B depends on the SWAP_BANK bit in FLASH_xSR registers (see *Section 5.9.5* for details). Application can change this allocation by writing to the SWAP_BANK option in FLASH_OBW1SRP register, for example after a firmware upgrade to restart the device on a new firmware.

Since some registers of the embedded flash are not specific to any particular physical bank they are not affected by the SWAP_BANK bit, as shown on *Table 28*. *Table 29* summarizes the impact of SWAP_BANK bit on embedded flash's typical operation flags.

Table 28. Flash registers versus swapping option

Register name (x= A or B)	Affected by SWAP_BANK(1)
FLASH_xKEYR	Yes
FLASH_xCR, FLASH_xSR	Yes
FLASH_xIER/xISR/xICR	Yes
FLASH_xCRCCR	Yes
FLASH_xCRCSADDR	
FLASH_xCRCEADDR	
FLASH_xECCSFADDR	Yes
FLASH_xECCDFADDR	

Table 28. Flash registers versus swapping option

Register name (x= A or B)	Affected by SWAP_BANK(1)
FLASH_xWRPSR/xWRPSRP	Yes(2)
FLASH_xHDPSR/xHDPSRP	
FLASH_xHDPEXTR	Yes
FLASH_OPTKEYR	No
FLASH_OPTCR	No
FLASH_OPTISR/OPTICR	
FLASH_OTPLSR/OTPLSRP	No
FLASH_NVSR/NVSRP	
FLASH_ROTSR/ROTSRP	
FLASH_OBKCR/OBKCLR	No
FLASH_OBKDR0 to OBKDR3	
FLASH_OBW1SR/OBW1SRP	
FLASH_ACCR	

1. No means: behavior of the register is unchanged whether SWAP_BANK = 0 or 1.
2. This protection is tied to the underlying physical bank. In case of swapping the register values is also swapped to follow the physical bank.

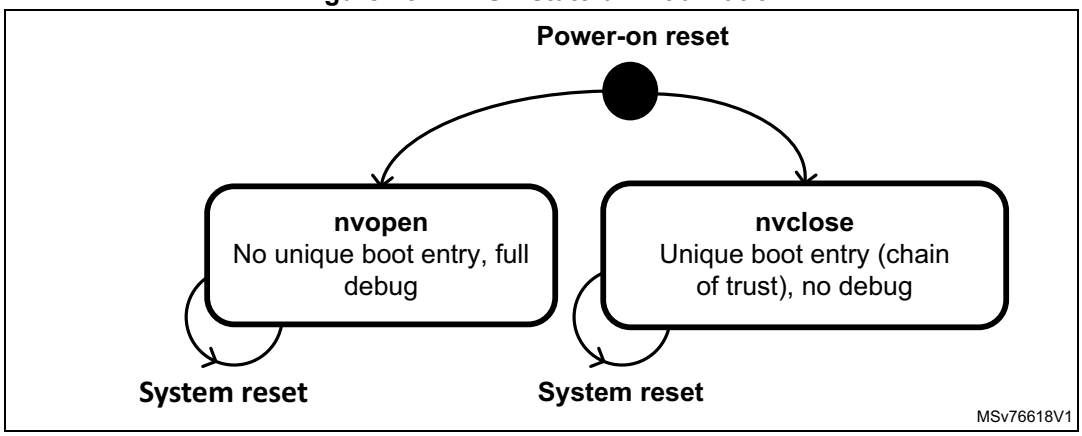
Table 29. Flash operation flags versus swapping option

FLASH operation	SWAP_BANK = 0		SWAP_BANK = 1		Comment
	xSR	xISR	xSR	xISR	
User flash R/W/E (bank 1)	A		B		Typical flags: QW, IS_PROGRAM, IS_ERASE, error flags
User flash R/W/E (bank 2)	B		A		
System flash R/W (bank 1)	-	A	-	B	Only error flags are impacted as no write or erase operations are allowed.
System flash R/W (bank 2)	-	B	-	A	
Option Byte change	A		B		Typical flags: QW, EOPF, IS_OPTCHANGE, OPTERRF, OBLERRF
Option byte key change	B	-	A	-	Typical flags: QW
OTP R/W	A		B		Typical flags: QW, PG_OTP, WRPERRF

SWAP_BANK bit usage

The read-only SWAP_BANK bit in FLASH_xSR registers are loaded from the SWAP_BANK option bit only after system reset or power on reset. To change it, for example to apply a new firmware update, respect the sequence below:

1. Unlock FLASH_OPTCR register as described in *Section 5.5.1: FLASH configuration protection* (only if the register is not already unlocked).
2. Set the new desired SWAP_BANK value in the FLASH_OBW1SRP register.
3. Set the OPTSTART bit in the FLASH_OPTCR register.
4. Wait for the QW bit to be cleared in the FLASH_xSR register. Once cleared, the corresponding FLASH_OBW1SR registers are updated, if security allows it. The SWAP_BANK bit in FLASH_xSR registers has not yet been modified however, making the bank swapping not yet effective.
5. Force a system reset or a power on reset. Following this reset the embedded flash updates SWAP_BANK in FLASH_xSR according to the FLASH_OBW1SR value. The bank swapping is now effective and the new firmware executes.



Note: The SWAP_BANK option bit in FLASH_OBW1SRP can be modified whatever the product state. ST RSS can however lock its value using the BOOT_LOCK option in FLASH_ROTSR.

5.3.15 FLASH reset and clocks

Reset management

Following a power-on reset, the embedded flash selects two security states, as shown on *Figure 15*. For more details on those states, refer to *Section 5.5.3*.

Figure 15. FLASH stateful initialization

Embedded flash memory stateful initialization is based on the overloading of option bytes default values by nonvolatile values automatically loaded when the flash_rst signal rises (see *Table 22*). During this loading sequence, the other parts of the device remain under reset and the embedded flash memory is not accessible from its interfaces.

The embedded flash memory can be reset at any time by the application through the RCC peripheral, with the following effects:

- All registers, except for user option byte registers, are cleared, including read and write latencies. User option byte words are listed in *Section 5.4.5*.
- Most control registers are automatically protected against write operations, as described in *Section 5.5.1: FLASH configuration protection*.

It is important to note that the contents of the flash memory (except option bytes) are not guaranteed if a power-on-reset occurs during a flash memory write or erase operation. For option bytes a valid content is always guaranteed, as embedded flash uses the old option

byte values when an option byte modification is interrupted by a reset. In this case a new option byte change request must be issued to modify those option bytes.

Clock management

The embedded flash memory uses the AXI interface clock. Depending on the device clock and internal supply voltage, specific read and write latency settings usually need to be set in the flash access control register (FLASH_ACCR), as explained in *Section 5.3.7: FLASH read operations* and *Section 5.3.8: FLASH program operations*.

5.3.16 Tamper management

When option bytes stored in either FLASH_NVSR or FLASH_ROTSR are corrupted an internal tamper 15 is issued to the TAMP peripheral.

When a tamper event is activated by the TAMP peripheral all option byte keys stored in the embedded flash read as zero. It is also not possible to modify or delete option byte keys. Those protections are de-activated when the tamper event is cleared in TAMP.

5.4 FLASH option bytes

5.4.1 About option bytes

The embedded flash memory includes a set of nonvolatile option bytes that are either freely modified through configuration registers (option byte words), or are managed as nonvolatile keys with a special temporal isolation protection mechanism.

This section explains:

- How option byte words and keys are loaded
- How application software can change option byte words, under which conditions
- How application software can program option byte keys
- What is the detailed list of option byte words, together with their default factory values (that is, before the first option byte change).

5.4.2 Option byte loading

When the device is first powered, the embedded flash memory automatically loads all the option byte words. During the option byte loading sequence, the device remains under reset and the embedded flash memory cannot be accessed. In case of security issue, the option bytes may be loaded with default values (see *Section 5.4.3: Option byte words modification*).

When an ECC issue is detected during this option byte loading sequence, the OBLERRF flag is raised as described in *Section 5.7.9*.

5.4.3 Option byte words modification

Changing option byte words

An option byte word change operation can modify the configuration and the protection settings saved in the nonvolatile option byte area of memory bank A, if allowed.

The embedded flash memory features two sets of option byte words registers:

- The first register set contains the current values of the option bytes. Their names have the SR extension. All “SR” registers are read only. Unless documented otherwise, their values are automatically loaded from the nonvolatile memory after power-on reset, wake-up from system standby or after a successful option byte change operation.
- The second register set allows the modification of the option bytes. Their names end with the SRP extension. All “SRP” registers can be accessed in read/write mode.

Note: When the OPTLOCK bit in the FLASH_OPTCR register is set, writes to SRP registers are ignored.

When OPTSTART bit is set the embedded flash memory checks if at least one option byte needs to be programmed by comparing the current values (in registers “SR”) with the new ones (in corresponding registers “SRP”). If a change is detected, if associated change conditions are met (see *Changing security option bytes*), the embedded flash memory launches the option byte modification in its nonvolatile memory and update the “SR” register.

If one of the conditions described in *Changing security option bytes* is not respected, the embedded flash memory sets the OPTERRF flag in the FLASH_OPTISR register and aborts the option byte change operation. In this case, the “SRP” registers are not overwritten by the current option value in the corresponding “SR” registers. The user application can check what was wrong in their configuration.

Unlocking the option byte modifications

After reset, the OPTLOCK bit is set and the FLASH_OPTCR is locked. As a result, the application software must unlock the option configuration register before attempting to change the option byte words, setting OPTSTART bit. The FLASH_OPTCR unlock sequence is described in *Section 5.5.1*

Option byte modification sequence

To modify an option byte word, follow the sequence below:

1. Unlock FLASH_OPTCR register as described in *Section 5.5.1: FLASH configuration protection* (only if the register is not already unlocked).
2. Write the desired new option byte values in the corresponding option byte word registers (FLASH_xxSRP).
3. Set the OPTSTART bit in the FLASH_OPTCR register.
4. Wait until QW is cleared in FLASH_xSR register. Once cleared, the corresponding FLASH_xxSR registers are updated, if security allows it (see next section).

If a reset or a power-down occurs while the option byte words modification is ongoing, the original option byte value are kept. A new option byte modification sequence is required to program the new value.

The application must not modify the SRP registers until the option byte change operation has been completed.

Changing security option bytes

On top of OPTLOCK bit, there is a second level of protection for security-sensitive option bytes. They are described hereafter.

- **Page write protection (WRPG)**

  Those user options managing groups of page write protection in bank x can be changed using FLASH_xWRPSRP register, if the application is RSS or the immutable root of trust.

- **Nonvolatile state (NVSTATE)**

  A detailed description of NVSTATE option bits is given in *Section 5.5.3*. The following rules must be respected to modify NVSTATE using the FLASH_NVSRP register.

  – Writes to the FLASH_NVSRP register are ignored if HDPL is different from 0 or 1 in the SBS_HDPLSR register.

  – NVSTATE option change is triggered only after the RAM erase signal has confirmed that Backup RAM has been successfully erased.

  – When NVSTATE = NVOPEN, option byte change to NVCLOSE is allowed. Writing any other value than 0x51 triggers an OPTERRF flag, without option change.

  – When NVSTATE = NVCLOSE, option byte change to NVOPEN is allowed, triggering a global erase explained in *Section 5.5.3*. Writing any other value than 0xB4 triggers an OPTERRF flag, without option change.

- **OEM provisioned (OEM_PROVD)**

  As defined in *Table 34: Boot level and HDP area protections,* OEM_PROVD defines the protection of the HDP area. OEM_PROVD can only be changed by RSS in FLASH_ROTSRP.

- **Hide protection area size (HDP_AREA_START and HDP_AREA_END)**

  These user options configure the size of the user flash area in bank x that can be accessed while HDPL equals to the value defined in *Section 5.5.4*. Writes to FLASH_xHDPSRP register are ignored if HDPL is different from 0 or 1 in the SBS_HDPLSR register.

- **Debug authentication method (DBG_AUTH)**
  DBG_AUTH defines if the device is closed or locked. See *Section 5.5.3* for details. It has no hardware effect in embedded flash memory.
  DBG_AUTH can only be changed by RSS in FLASH_ROTSRP.

- **Bank swapping (SWAP_BANK)**
  BANK_SWAP defines if the device needs to swap its physical banks. See *Section 5.3.14* for details. Option byte change is ignored when BOOT_LOCK is set in FLASH_ROTSR.

Note: For all user option bytes in this section: default values are loaded when a double ECC error occurs. OBLERRF error flag is also raised.

Hide protection area end address in system flash is fixed by STMicroelectronics.

5.4.4 Option byte key management

The device can manage 32 key slots of 16-bytes per HDP level (up to level 2, included).

Unlocking the option byte key modifications

After reset, the OPTLOCK bit is set and the FLASH_OBKCR is locked. As a result, the application software must unlock the option byte key configuration register before

attempting to change the option byte keys, setting KEYSTART bit. The FLASH_OPTCR unlock sequence is described in *Section 5.5.1*

Option byte key modification

To write a virgin option byte key, follow the sequence below:

1. Unlock the FLASH_OPTCR register as described in *Section 5.5.1: FLASH configuration protection* (only if the register is not already unlocked).
2. Write the desired option byte key value in FLASH_OBKDRx registers.
   - Key[31:0] goes to OBKDR0[31:0], Key[63:32] to OBKDR1[31:0], Key[95:64] to OBKDR2[31:0], and Key[127:96] to OBKDR3[31:0].
3. Fill the following information to FLASH_OBKCR register:
   - OBKINDEX[4:0]: index of the new key, corresponding to the selected HDP level.
   - NEXTKL[1:0]: when HDPL = 1 in SBS_HDPLSR register the RoT application can set those bit to 0x1 to provision a key for the next HDPL level (2).
   - Set both KEYSTART and KEYPROG bits to start the programming sequence.
4. Wait until the KEYSTART bit is cleared in FLASH_OBKCR register. Once cleared read back the key to verify its value (recommended). See *Option byte key loading*.
   - In SBS_HDPLSR, if HDPL = 3 during above step 3 the key returns all ones (programming was ignored). No error is triggered.

Note: When HDPL value changes in SBS peripheral FLASH_OBKDRx registers are cleared.

For a given hide protection level, an authorized application cannot overwrite an option byte key that was successfully written before. Therefore before modifying this key it must be erased, using the sequence below.

1. Unlock the FLASH_OPTCR register as described in *Section 5.5.1: FLASH configuration protection* (only if the register is not already unlocked).
2. In FLASH_OBKCLR register set the key erase bit on each existing key that the application wants to overwrite/ update.
3. In FLASH_OBKCR register, set both KEYSTART and KEYERASE bits to start the erasing of all selected keys.
4. Wait until the KEYSTART bit is cleared in the FLASH_OBKCR register. Once cleared the FLASH_OBKCLR register is zeroed.

If the application tries to write a key that is not virgin or erased OBKERRF error flag is set (see *Section 5.7.10*).

Option byte key loading

The following sequence is required to read a 16-byte option byte key stored in embedded flash memory:

1. Fill the following information to FLASH_OBKCR:
   - OBKINDEX[4:0]: index of the key for this hide protection level.
   - NEXTKL[1:0]: when HDPL = 1 in SBS_HDPLSR register, the RoT application can set those bits to 0x1 to read a key provisioned for the next HDPL level (2).
   - Set KEYSTART bit with KEYPROG bit cleared to start the read sequence.
2. When KEYSTART is cleared read the value of the key using the FLASH_OBKDRx registers. A virgin key returns all ones.
   - In SBS_HDPLSR, if HDPL = 3 during above step 1 the key returns all ones (virgin key). No error is triggered.

If OBKERRF error flag is set following a key loading FLASH_OBKDRx registers reads as zero. After clearing the error try loading the option byte key again.

Note: When HDPL value changes in SBS peripheral FLASH_OBKDRx registers are cleared.

5.4.5 Option byte user words overview

Table 30 lists all the user option bytes managed through the embedded flash memory registers, as well as their default values before the first option byte change (default factory value). They are configured by the end user depending on the application requirements. Some option bytes might have been initialized by STMicroelectronics during the manufacturing stage.

5.4.6 Description of user option byte word

The general-purpose option bytes that can be used by the application are listed below. They are accessed through the FLASH_OBWSR register.

- Watchdog management
  - IWDG_FZ_STOP: independent watchdog IWDG counter active in Stop mode if 1 (stop counting or freeze if 0)
  - IWDG_FZ_STBY: independent watchdog IWDG counter active in Standby mode if 1 (stop counting or freeze if 0)
  - IWDG_HW: hardware (0) or software (1) IWDG watchdog control selection

Note: If the hardware watchdog "control selection" feature is enabled (set to 0), the watchdog is automatically enabled at power-on, thus generating a reset unless the watchdog key register is written to or the down-counter is reloaded before the end-of-count is reached.

Depending on the configuration of IWDG_STOP and IWDG_STBY options, the IWDG can continue counting (1) or not (0) when the device is in Stop or Standby mode respectively.

When the IWDG is kept running during Stop or Standby mode, it can wake up the device from these modes.

- Reset management
  - BOR_LEV: Brownout level option, indicating the supply level threshold that activates/releases the reset
  - NRST_STBY: The independent watchdog generates a reset when entering Standby mode if cleared to 0
  - NRST_STOP: The independent watchdog generates a reset when entering Stop mode if cleared to 0.

Note: Whenever a Standby (respectively Stop) mode entry sequence is successfully executed, the device is reset instead of entering Standby (respectively Stop) mode if NRST_STBY (respectively NRST_STOP) is cleared to 0.

- Bank swapping option (SWAP_BANK). See *Section 5.3.14* for details.
- Device options
  - VDDIO_HSLV: enables the configuration of pads below 2.5 V for VDDIO power rail if set to 1.
  - VDDMMC_HSLV: enables the configuration of pads below 2.7 V for VDDMMC power rail if set to 1.

When STMicroelectronics delivers the device, the values programmed in the general-purpose option bytes are the following:

- Watchdog management
  - IWDG reset active in Standby and Stop modes (option value = 0x1)
  - IWDG not automatically enabled at power-on (option byte value = 0x1)
- Reset management:
  - BOR: brownout level option (reset level) equals 2.1 V (option byte value = 0x0). A reset is not generated when the device enters Standby or Stop low-power mode (option byte value = 0x1)
- The speed of the device I/Os is optimized when the device voltage is low (VDDIO_HSLV = VDDMMC_HSLV = 1)

Refer to *Section 5.9: FLASH registers* for details.

5.4.7 Description of security option bytes

The option bytes that are used by root of trust application to enhance security are listed below:

- NVSTATE[7:0]: Nonvolatile state (see *Section 5.5.3* for details).
- WRPG[127:0]: Write protection option of user flash pages (one word per bank). It is active low. Refer to *Section 5.9.26* for details.
- OTPL[15:0]: Write protection option of OTP blocks. It is active high. Refer to *Section 5.3.12* for details.
- HDP_AREA: Hide protection user flash area definitions. Refer to *Section 5.5.4*.
  - HDP_AREA_START (respectively HDP_AREA_END) contains the first (respectively last) 256-byte block of the HDP area.

When STMicroelectronics delivers the device, the values programmed in the security option bytes are the following:

- NVOPEN device (NVSTATE value = 0xB4)
- SWAP_BANK = 0
- HDP area protection disabled (start addresses higher than end addresses)
- Write protection disabled (all option byte bits set to 1)
- All OTP blocks are writable, as they are virgin (all option byte bits set to 0)

Refer to *Section 5.9: FLASH registers* for details.

5.5 FLASH protection mechanisms

Since sensitive information is stored in the flash memory, it is important to protect it against unwanted operations such as reading confidential areas, illegal programming of immutable pages, or malicious flash memory erasing.

For this purpose FLASH implements the following protection mechanisms:

- Configuration protection
- User flash write protection
- Device nonvolatile security life cycle and application temporal isolation management
- OTP locking

This section provides a detailed description of all these security mechanisms.

5.5.1 FLASH configuration protection

The embedded flash memory uses hardware mechanisms to protect the following assets against unwanted or spurious modifications (e.g. software bugs):

- Option bytes change
- Write operations
- Erase commands
- Interrupt masking

More specifically, write operations to embedded flash memory control registers (FLASH_xCR, FLASH_OPTCR and FLASH_OBKCR) are not allowed after reset.

The following sequence must be used to unlock FLASH_xCR register:

1. Program KEY1 to 0x45670123 in the FLASH_xKEYR key register.
2. Program KEY2 to 0xCDEF89AB in FLASH_xKEYR key register.
3. LOCK bit is now cleared and FLASH_xCR is unlocked.

The following sequence must be used to unlock FLASH_OPTCR and FLASH_OBKCR registers. Registers unlocked with FLASH_OPTCR are listed in *Table 31*.

1. Program OPTKEY1 to 0x08192A3B in FLASH_OPTKEYR option key register.
2. Program OPTKEY2 to 0x4C5D6E7F in FLASH_OPTKEYR option key register.
3. OPTLOCK bit is now cleared. FLASH_OPTCR and FLASH_OBKCR registers are unlocked.

Any wrong sequence locks up the corresponding register/bit until the next system reset, and generates a bus error.

The above registers can be locked again by software by setting the LOCK bit in the corresponding control register.

The FLASH_xCR register remains locked and a bus error is generated when the following operations are executed:

- Programming a third key value
- Writing to a different register belonging to the same bank than FLASH_xKEYR before FLASH_xCR has been completely unlocked (KEY1 programmed but KEY2 not yet programmed)
- Writing less than 32 bits to KEY1 or KEY2.

Similarly the FLASH_OPTCR, FLASH_OBKCR, and related registers (see *Table 31*) remain locked and a bus error is generated when the following operations are executed:

- Programming a third key value
- Writing to a different register before FLASH_OPTCR or FLASH_OBKCR have been completely unlocked (OPTKEY1 programmed but OPTKEY2 not yet programmed)
- Writing less than 32 bits to OPTKEY1 or OPTKEY2.

The embedded flash memory configuration registers protection is summarized in *Table 31*. Registers not present in this table are not protected by any key.

Table 31. Flash interface register protection summary

Register name	Unlocking register	HDP level(1)	Protected asset
FLASH_xCR	FLASH_xKEYR	Any	Flash write operations, erase commands
FLASH_xIER	FLASH_xCR		Interrupt generation masking sources
FLASH_xCRCCR			Flash bank CRC operations
FLASH_OPTCR	FLASH_OPTKEYR		Option bytes changes
FLASH_OBKCR			Option byte key changes
FLASH_NVSRP	FLASH_OPTCR	0 or 1	Nonvolatile state change
FLASH_ROTSRP		0	Root of trust parameter change
FLASH_xHDPSRP		0 or 1	Hide protect area change for bank x
FLASH_OBWSRyP		Any	User option byte word y change
FLASH_xWRPSRP			User flash write protection change for bank x
FLASH_OTPLSRP	FLASH_OPTCR(2)	Any	OTP write protection

1. Required HDP level in the device
2. Once set, the OTP Block Lock bits cannot be reset by the application.

5.5.2 Write protection

The purpose of embedded flash memory write protection is to prevent unwanted modifications to embedded nonvolatile code and/or data.

Any group of four consecutive 8 Kbyte pages can be independently write-protected or unprotected by clearing/setting the corresponding WRPG bit in the FLASH_xWRPSR register.

A write-protected group of pages can neither be erased nor programmed. As a result, a full bank erase cannot be performed if one group of pages is write-protected, unless an NVSTATE transition to NVOPEN is triggered.

The embedded flash memory write-protection user option bits can be modified when HDPL=0 or 1 in SBS_HDPLSR register, using FLASH_xWRPSRP.

Note: The HDP area in user flash is write and erase protected, while system flash cannot be erased by user application.

Write protection flags remain valid for the physical bank, so they follow the bank when it is swapped. See *Section 5.3.14* for details.

Write protection errors are documented in *Section 5.7: FLASH error management*.

5.5.3 Life cycle management

Introduction

Figure 16 shows how embedded flash manages the nonvolatile security life cycle of the device.

Figure 16. Life cycle management scheme

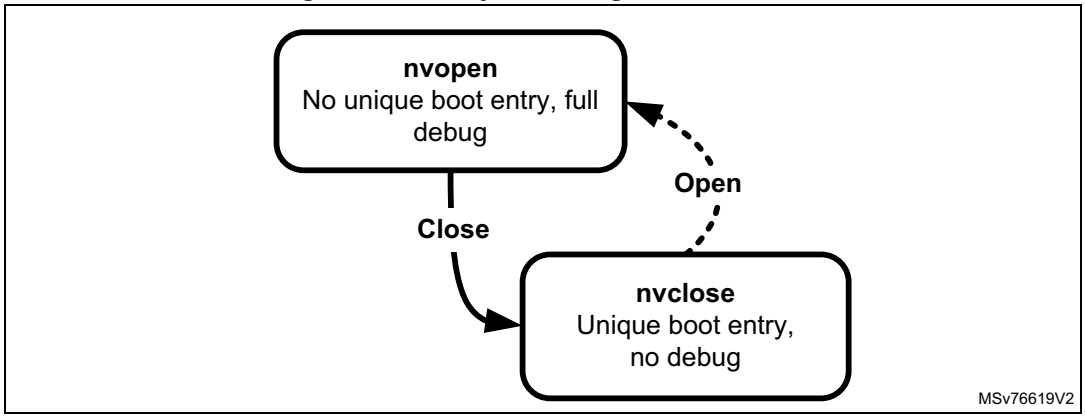

Table 32 details the nonvolatile security lifecycle NVSTATE and its effects on the product.

Table 32. Flash security lifecycle definition

NVSTATE	Boot address(1)	Debug level	Regression to
NVOPEN	0x0800 0000 or Bootloader	Unconstrained	n/a
NVCLOSE	0x1FF0 0000	Closed (2)	NVOPEN

1. Enforced outside flash.
2. Application debug is closed, with option described in *Table 33*. STMicroelectronics engineering test modes are not available.

Table 33 details the other nonvolatile security option bytes and their effects on the product.

Table 33. Option bytes versus lifecycle definition

Product state	NVSTATE	OEM_PROVD	DBG_AUTH	Description
Open	NVOPEN (0xB4)	Ignored (0x6A)	Ignored (0x6F)	Device delivered by ST. User flash memory usage is open, and debug access is enabled (see *Table 32*).
Provisioning	NVCLOSE (0x51)	Not provisioned (0x6A)	Closed (0x6F)	Device on the production line. RSS user function *DataProvisioning* is used to provision regression password, and optionally root of trust OBKeys.
Locked		Provisioned (0xB4)	Locked (0xB4)	Final product with no debug and no regression possible (which means transition to another product state is forbidden).
Closed			Closed (0x6F or 0x8A)	Final product with no debug out of reset, and transition to open state is possible (see *Flash opening*).

Flash opening

When the regression process code on the device (system flash code, or OEM code running in HDPL1) receives a valid regression request, it must first erase OBKeys (except the regression password) using the method defined in *Option byte key modification*. After confirming the keys have been destroyed, the regression process code opens the device by writing 0xB4 to FLASH_NVSRP, then triggers an option byte change as defined in *Section 5.4.3*.

Detecting this option byte changes the flash memory requests:

- The Backup RAM to be zeroed,
- An automatic erase of the whole user flash (write protected or not),
- A reset to their default manufacturing values (protections disabled) for the write protection registers (FLASH_xWRPSR), and the hide protection registers (FLASH_xHDPSR, FLASH_xHDPEXTR).

Once the embedded flash memory changes the FLASH_NVSRP the device triggers a power-on-reset, as described in *Figure 15*.

The system flash memory and the read-only region are not affected by flash opening and remain unchanged. If the regression process code is an OEM code running in HDPL1, no option byte stored in FLASH_ROTSR can be changed.

If the regression request fails (NVSTATE = NVCLOSE unchanged), the application must trigger it again using the same password.

Flash closing

Writing 0x51 to the FLASH_NVSRP register triggers a change of NVSTATE from NVOPEN to NVCLOSE, confirmed when NVSTATE=0x51 in the FLASH_NVSR register.

5.5.4 Hide protection (HDP)

Hide protection in system flash

System flash pages included between 0x1FF0 0000 and SEC_AREA_END addresses store STM32 secure bootloader and password management code.

Embedded flash system area can only be accessed by Cortex M7 in read or execute. The hide protected area can only be accessed when NVSTATE is NVCLOSE and when hide protection level in SBS_HDPLSR is 0.

In all other cases, one of the following events is triggered:

- Data read transactions return zero. Data write transactions are ignored. No bus error is generated but an error flag is raised (RDSERR for read, WRPERR for write).
- Read instruction transactions generate a bus error and the RDSERR error flag is raised.

Embedded flash system area is immutable, that is, it cannot be erased by any application code. This area includes the system bootloader area from SEC_AREA_END to 0x1FF1FFF.

Note: When FLASH transitions from NVCLOSE to NVOPEN state, the embedded flash system area is kept.

Hide protection in user flash

User flash pages included between HDP_AREA_START and HDP_AREA_END addresses are used to store the root of trust code and data, with the associated keys stored in HDPL1 option byte keys.

User flash pages located inside an active HDP extension area are used to store updatable root of trust code and data, with the associated keys stored in HDPL2 option byte keys.

Embedded flash hide protected (HDP) user area and active HDP extension area can only be accessed:

- By Cortex M7 in read, write or execute
- According to the conditions defined in *Table 34*

Table 34. Boot level and HDP area protections

<table>
<tr><th rowspan="2">Product state</th><th colspan="2">FLASH user options(1)</th><th colspan="3">HDP level(2) to activate protection</th><th rowspan="2">Boot address (HDPL)</th><th rowspan="2">Comment</th></tr>
<tr><th>NV STATE</th><th>OEM_ PROVD</th><th>HDP area in system flash</th><th>HDP area in user flash</th><th>HDP extension area</th></tr>
<tr><td>Open</td><td>NV OPEN</td><td rowspan="2">not 0xB4</td><td rowspan="3">>0</td><td>>1</td><td rowspan="3">>2 (if active)</td><td>User flash or bootloader (HDPL1)</td><td>RSS not visible</td></tr>
<tr><td>Provisioning</td><td rowspan="2">NV CLOSE</td><td>>0(3)</td><td rowspan="2">RSS (HDPL0)</td><td>Via RSSLib/ DataProvisioning service user provisions OBKeys and firmware in user flash.</td></tr>
<tr><td>Closed or Locked</td><td>0xB4</td><td>>1</td><td>Firmware provisioned in user flash. All related OBKeys are also provisioned.</td></tr>
</table>

1. In FLASH_NVSR and FLASH_ROTSR registers
2. Level for which hide protection is activated. Current HDP level is available in SBS_HDPLSR register.
3. Because of this condition firmware in user flash cannot execute in this product state (OBKeys not yet provisioned).

For more details on HDPL level following a reset, refer to the *SBS* section of the manual.

HDP programming in user flash

HDP user flash area of bank x (x = A or B) is programmed in FLASH_xHDPSRP by setting the HDP_AREA_START and HDP_AREA_END so that the END address is strictly higher than the START address.

HDP_AREA_START and HDP_AREA_END are defined with a granularity of 256 bytes. This means that the actual HDP user flash area size (in bytes) is defined by:

(HDP_AREA_END - HDP_AREA_START + 1) x 256

As an example, to set the HDP user flash area on the first 8 Kbytes (that is, from address 0x0800 0000 to address 0x0800 1FFF, both included), the embedded flash memory must be configured as follows:

HDP_AREA_START[15:0] = 0x0

HDP_AREA_END[15:0] = 0x001F

The HDP user flash area size defined above is equal to:

(HDP_AREA_END - HDP_AREA_START + 1) x 256 = 32 x 256 bytes = 8 Kbytes.

The minimum HDP user flash area that can be set is 32 flash words (or 512 bytes). The maximum area is the whole user flash memory bank, configured by setting HDP_AREA_START = HDP_AREA_END.

Note: It is recommended to align the HDP user area size with 8 Kbytes flash page granularity to always be able to erase non-HDP code and data.

It is possible to disable HDP protections by setting HDP_AREA_END lower than HDP_AREA_START.

HDP properties in user flash

- Embedded flash hide protected user area can only be accessed in the conditions described in *Table 34*. In all other cases, one of the following events is triggered:
  - Data read transactions return zero. Data write transactions are ignored. No bus error is generated but an error flag is raised (RDSERR for read, WRPERR for write).
  - Read instruction transactions generate a bus error and the RDSERR error flag is raised.
- HDP user flash area is erase-protected. As a result:
  - No erase operations to a page located in this area are possible (including the page containing the area end address), unless HDPL=0 or 1.
  - In HDPL = 2 or 3 the only possibility to fully erase the user flash bank is to perform a device opening sequence (see *Section 5.5.3*).
- Rules to change the HDP user flash area are detailed in *Changing option byte words* in *Section 5.4.3*.
- When FLASH transitions from NVCLOSE to NVOPEN state, the whole user flash (hide protected or not) is automatically erased, with all the HDP area disabled (see *Section 5.5.3*).
- HDP user flash area remains valid for the physical bank, so it follows the bank when it is swapped. See *Section 5.3.14* for details.

For more information on HDP user flash area errors, refer to *Section 5.7: FLASH error management*.

HDP extension

For each bank x, the nonvolatile HDP area can be extended, using a volatile extension defined in FLASH_xHDPEXTR register (see *Section 5.9.19*). Accesses to an active HDP extension area are ignored (for writes) or zeroed (for reads) when HDPL is different from 0, 1 or 2 in the SBS_HDPLSR register.

Like HDP user flash area an active HDP area extension is erase-protected. The same rules as HDP user flash area apply when HDPEXT_ACCDIS[7:0] is different from 0xA3 (default), and HDP_AREA_EXT[11:0] is different from zero (default).

Controlling the size of the HDP extended area depends on the value of bitfield HDPEXT_ACCDIS[7:0]:

- If it equals 0xA3 any value can be written in HDP_EXT_END[11:0].
- If it equals 0x5C the value stored in HDP_EXT_END[11:0] can only be increased (writing a lower value is ignored).
- For any other value of HDPEXT_ACCDIS any writes to FLASH_xHDPEXTR is ignored.

Note: Out of reset HDP extension is not active.

5.6 FLASH low-power modes

5.6.1 Introduction

Table 35 summarizes the behavior of the embedded flash memory in microcontroller low-power modes. The embedded flash memory belongs to the Core domain.

Table 35. Effect of low-power modes on the embedded flash memory

Power mode System state	Core domain voltage range	Allowed if FLASH busy	FLASH power mode (in Core domain)
Run	VOS0,1,2	Yes	Run
Stop	SVOS low / high	No	Clock gated or Stopped
Standby	Off	No	Off

When the system state changes, or within a given system state, the embedded flash memory might be subjected to a different voltage supply range (VOS) depending on the application. The procedure to switch the embedded flash memory into various power modes (run, clock gated, stopped, off) is described below.

Note: For more information on microcontroller power states, refer to the Power control section (PWR).

5.6.2 Managing the FLASH domain switching to Stop or Standby

As explained in *Table 35*, if the embedded flash memory informs the reset and clock controller (RCC) that it is busy (that is, BUSY, QW, WBNE is set), the microcontroller cannot switch the Core domain to Stop or Standby mode.

Note: CRC_BUSY is not taken into account.

There are two ways to release the embedded flash memory:

- For each bank x, reset the WBNE busy flag in the FLASH_xSR register by any of the following actions:
  - Complete the write buffer with missing data.
  - Force the write operation without filling-in the missing data, by activating the FW bit in the FLASH_CR register. This forces all missing data “high”.
  - Reset the PG bit in the FLASH_CR register. This disables the write buffer and consequently leads to the loss of its content.
- Poll the QW busy bits in the FLASH_xSR register until they are cleared. This indicates that all recorded write, erase and option change operations are complete in both banks.

The microcontroller can then switch the domain to Stop or Standby mode.

5.7 FLASH error management

The embedded flash memory automatically reports when an error occurs during a read, program or erase operation. A wide range of errors are reported:

- *Write protection error (WRPERRF)*

- *Programming sequence error (PGSERRF)*
- *Strobe error (STRBERRF)*
- *Inconsistency error (INCERRF)*
- *Error correction code error (SNECCERRF/DBECCERRF)*
- *Read secure error (RDSERRF)*
- *CRC read error (CRCRDERRF)*
- *Option byte change error (OPTERRF)*
- *Option byte loading error (OBLERRF)*
- *Option byte key error flag (OBKERRF)*

The application software can individually enable the interrupt for each error, as detailed in *Section 5.8: FLASH interrupts*.

Note: For some errors, the application software must clear the error flag before attempting a new operation.

Note: General-purpose errors (for example INCERRF) are taken into account when queues are loaded.
Temporal isolation and other protection errors (for example WRPERRF, RDSERRF) are taken into account at FSM level, in front of the flash bank interface controller.

5.7.1 Write protection error (WRPERRF)

When an illegal erase/program operation is attempted to the nonvolatile memory of bank x, the embedded flash memory sets the write protection error flag WRPERRF in FLASH_xISR register.

An erase operation is rejected and flagged as illegal if it targets one of the following memory areas:

- A page belonging to a valid HDP user flash area (even partially).
- A page write-locked with WRPG
- The read-only/OTP area

A program operation is ignored and flagged as illegal if it targets one of the following memory areas:

- A user page currently protected by HDP (see *Section 5.5.4*)
- A user page write-locked with WRPG
- An OTP block, locked with OTPL
- A read-only section
- The system flash memory (protected or not)
- A reserved area

When the WRPERRF flag is raised, the operation is rejected and nothing is changed in the corresponding bank. If a write burst operation was ongoing, WRPERRF is raised each time a flash word write operation is processed by the embedded flash memory.

Note: The WRPERRF flag does not block any new erase/program operation.

Not clearing the WRPERRF flag does not generate a programming sequence error (see below).

The WRPERRF flag is cleared by setting the corresponding bit in the FLASH_xICR register.

If the WRPERRIE bit in the FLASH_xIER register is set, an interrupt is generated when the WRPERRF flag is raised (see *Section 5.8: FLASH interrupts* for details).

5.7.2 Programming sequence error (PGSERRF)

When the programming sequence is incorrect in bank x, the embedded flash memory sets the programming sequence error flag PGSERRF in FLASH_xISR register.

More specifically, the PGSERRF flag is set if one of the conditions below is met:

- A write operation is requested but the program enable bit (PG or PG_OTP) has not been set in the FLASH_xCR register prior to the request. This program enable bit must stay at 1 until write is added to the operation queue (QW rises).
- The inconsistency error (INCERRF) has not been cleared before requesting a new write operation.

When the PGSERRF flag is raised, the current program operation is aborted and nothing is changed in the corresponding bank. The corresponding write data buffer is also flushed. If a write burst operation was ongoing, PGSERRF is raised at the end of the burst.

Note: When the PGSERRF flag is raised, there is a risk that the last write operation performed by the application has been lost because of the above protection mechanism. Hence it is recommended to generate interrupts on PGSERRF and verify in the interrupt handler if the last write operation has been successful by reading back the value in the flash memory.

The PGSERRF flag also blocks any new program operation. This means that PGSERRF must be cleared before starting a new program operation on the corresponding bank.

The PGSERRF flag is cleared by setting the corresponding bit in the FLASH_xICR register.

If the PGSERRIE bit in FLASH_xIER register is set, an interrupt is generated when the PGSERRF flag is raised. See *Section 5.8: FLASH interrupts* for details.

5.7.3 Strobe error (STRBERRF)

When the application software writes several times to the same byte write buffer toward the bank x, the embedded flash memory sets the strobe error flag STRBERRF in the FLASH_xISR register.

When the STRBERRF flag is raised, the current program operation is not aborted and new byte data replaces the old data. The application can ignore the error, proceed with the current write operation and request new write operations. If a write burst was ongoing, STRBERRF is raised at the end of the burst.

The STRBERRF flag is cleared by setting the corresponding bit in the FLASH_xICR register.

If the STRBERRIE bit in the FLASH_xIER register is set, an interrupt is generated when the STRBERRF flag is raised. See *Section 5.8: FLASH interrupts* for details.

5.7.4 Inconsistency error (INCERRF)

When a programming inconsistency is detected to bank x, the embedded flash memory sets the inconsistency error flag INCERRF in the FLASH_xISR register.

More specifically, the INCERRF flag is set when one of the following conditions is met:

- A write operation is attempted before completion of the previous write operation, for example:
  - The application software starts a write operation to fill the 128-bit write buffer, but sends a new write burst request to a different flash memory address before the buffer is full.
  - One master starts a write operation, but before the buffer is full, another master starts a new write operation to the same address or to a different address.
- A wrap burst request issued by a master overlaps two or more 128-bit flash-word addresses, that is, wrap bursts must be done within 128-bit flash-word address boundaries.

Following the sequence below is recommended to avoid losing data when an inconsistency error occurs:

1. Execute a handler routine when the INCERRF flag is raised.
2. Stop all write requests to embedded flash memory.
3. Verify that the write operations that have been requested just before the INCERRF event have been successful by reading back the programmed values from the memory.
4. Clear the INCERRF bit in the FLASH_xICR register.
5. Restart the write operations where they have been interrupted.

Note: The INCERRF flag must be cleared before starting a new write operation, otherwise a sequence error (PGSERRF) is raised.

Any write triggering inconsistency error is discarded by embedded flash memory.

5.7.5 Error correction code error (SNECCERRF/DBECCERRF)

When a single error correction is detected during a read to the bank x the embedded flash memory sets the single error correction flag SNECCERRF in the FLASH_xISR register.

When two ECC errors are detected during a read to the bank x, the embedded flash memory sets the double error detection flag DBECCERRF in the FLASH_xISR register.

When the SNECCERRF flag is raised, the corrected read data are returned. Hence the application can ignore the error and request new read operations.

If a read burst operation was ongoing, the SNECCERRF or DBECCERRF flag is raised each time a new data is sent back to the requester through the corresponding system bus.

When the SNECCERRF (or DBECCERRF respectively) flag is raised, the address of the flash word that generated the error is saved in the FLASH_xECCSFAR (or FLASH_xECCDFAR respectively) register. This register is automatically cleared when the associated flag that generated the error is cleared.

Note: In the case of successive single correction (or double detection respectively) errors, only the address corresponding to the first error is stored in the *FLASH_xECCSFAR (or FLASH_xECCDFAR respectively) register.*

When the DBECCERRF flag is raised reading the user flash memory, a bus error is generated. In the case of successive double error detections, a bus error is generated each time a new data is sent back to the requester through the AXI interface.

Note: It is not mandatory to clear the *SNECCERRF or DBECCERRF flags before starting a new read operation.*

The SNECCERRF and DBECCERRF flags are cleared by setting the corresponding bit in the FLASH_xICR register.

If the SNECCERRIE (or respectively DBECCERRIE) bit in the FLASH_xISR register is set, an interrupt is generated when the SNECCERRF (or respectively DBECCERRF) flag is raised. See *Section 5.8: FLASH interrupts* for details.

5.7.6 Read secure error (RDSERRF)

When an illegal read or execute operation is attempted to a hide protected area of bank x, the embedded flash memory sets the read secure the error flag RDSERRF in the FLASH_xISR register. For more information on illegal access definition, refer to *Section 5.5.4: Hide protection (HDP)*.

When the RDSERRF flag is raised, the current read operation is aborted and the application can request new read operations. If a read burst was ongoing, RDSERRF is raised each time a data is sent back to the requester through the AXI interface.

Note: The bus error is raised only if the illegal access is due to an instruction fetch.

The RDSERRF flag is cleared by setting the corresponding bit in the FLASH_xICR register.

If the RDSERRIE bit in the FLASH_xIER register is set, an interrupt is generated when the RDSERRF flag is raised (see *Section 5.8: FLASH interrupts* for details).

5.7.7 CRC read error (CRCRDERRF)

After a CRC computation in bank x, the embedded flash memory sets the CRC read error flag CRCERR in the FLASH_xISR register when one or more address belonging to a protected area was read by the CRC module. A protected area corresponds to a valid HDP area in user flash, for which any read is currently illegal (see *Section 5.5.4* for details).

The CRCRDERRF flag is raised when the CRCEND bit is set (end of CRC calculation). In this case, it is likely that the CRC result is wrong since illegal read operations to protected areas return null values.

The CRCRDERRF flag is cleared by setting the corresponding bit in the FLASH_xICR register.

If the CRCRDERRIE bit in the FLASH_xIER register is set, an interrupt is generated when the CRCRDERRF flag is raised together with the CRCEND bit (see *Section 5.8: FLASH interrupts* for details).

5.7.8 Option byte change error (OPTERRF)

When the embedded flash memory finds an error during an option change operation, it aborts the operation and sets the option byte change the error flag OPTERRF in the FLASH_OPTISR register. Refer to *Section 5.4.3: Option byte words modification* for details.

The OPTERRF flag is cleared by setting the corresponding bit in the FLASH_OPTICR register.

If the OPTERRIE bit in the FLASH_OPTCR register is set, an interrupt is generated when the OPTERRF flag is raised (see *Section 5.8: FLASH interrupts* for details).

It is mandatory to clear the OPTERRF flag before starting a new option byte change, or an option byte key programming.

5.7.9 Option byte loading error (OBLERRF)

OBLERRF error flag is set in the FLASH_xISR register when a double error detection was found when loading one or more option bytes during an option byte loading sequence (see *Section 5.4.2*). In this case, the application should verify the correctness of the option byte information comparing FLASH_xxSR and FLASH_xxSRP registers.

The OBLERRF flag is cleared by setting the corresponding bit in the FLASH_xICR register. If the OBLERRIE bit in the FLASH_xIER register is set, an interrupt is generated when the OBLERRF flag is raised (see *Section 5.8: FLASH interrupts* for details).

5.7.10 Option byte key error flag (OBKERRF)

The OBKERRF error flag is set in the FLASH_OPTISR register in two cases:

- A double error detection was found when loading the requested option byte key. In this case, if this key is provisioned again the error should disappear.
- The application tried to program a nonvirgin option byte key, or the key corresponding to OBKINDEX[4:0] was not requested to be erased using FLASH_OBKCLR register.
- The application tried to program and erase keys at the same time (KEYPROG and KEYERASE set when KEYSTART is set).

It is mandatory to clear the OBKERRF flag before doing any operation on option byte keys because when OBKERRF is set, writes to the KEYSTART bit in the FLASH_OBKCR are ignored.

The OBKERRF flag is cleared by setting the corresponding bit in the FLASH_OPTICR register.

If the OBKERRIE bit in the FLASH_OPTCR register is set, an interrupt is generated when the OBKERRF flag is raised (see *Section 5.8: FLASH interrupts* for details).

5.7.11 Miscellaneous HardFault errors

The following events generate a bus error on the corresponding bus interface:

- On the AXI system bus:
  - Illegal instruction fetch to HDP protected area because of the life cycle (e.g. protected system flash when NVSTATE = NVOPEN).
- On AHB configuration or system bus:
  - Wrong key input to FLASH_KEYR or FLASH_OPTKEYR
  - 8-bit accesses to system AHB interface

5.8 FLASH interrupts

The embedded flash memory can generate a maskable interrupt to signal the following events on a given bank:

- Read and write errors (see *Section 5.7: FLASH error management*)
  - Single ECC error correction during read operation
  - Double ECC error detection during read operation
  - Write inconsistency error
  - Bad programming sequence
  - Strobe error during write operations
  - Option change error
  - Option byte keys error
- Security errors (see *Section 5.7: FLASH error management*)
  - Write protection error
  - Read security error
  - CRC computation on HDP area error

Option byte loading error

- Miscellaneous events (described below)
  - End of programming
  - CRC computation complete

These multiple sources are combined into a single interrupt signal, flash_it, which is the only interrupt signal from the embedded flash memory that drives the NVIC (nested vectored interrupt controller).

The user can individually enable or disable embedded flash memory interrupt sources by changing the mask bits in the FLASH_xIER and OPTCR registers. Setting the appropriate mask bit enables the interrupt.

Note: Prior to writing, the FLASH_xIER register must be unlocked as explained in Section 5.5.1: FLASH configuration protection

Table 36 gives a summary of the available embedded flash memory interrupt features.

Note: Some flags need to be cleared before a new operation is triggered.

Table 36. Flash interrupt request

Interrupt event	Event flag	Enable control bit	Clear flag to resume operation	Bus error
End-of-program event	EOPF	EOPIE	N/A	N/A
CRC complete event	CRCENDF	CRCENDIE	N/A	N/A
Write protection error	WRPERRF	WRPERRIE	No	No
Programming sequence error	PGSERRF	PGSERRIE	**Yes**(1)	No
Strobe error	STRBERRF	STRBERRIE	No	No
Inconsistency error	INCERRF	INCERRIE	**Yes**(1)	No
ECC single error correction event	SNECCERRF	SNECCERRIE	No	No

Table 36. Flash interrupt request

Interrupt event	Event flag	Enable control bit	Clear flag to resume operation	Bus error
ECC double error detection event	DBECCERRF	DBECCERRIE	No	**Yes**(2)
Read secure error	RDSERRF	RDSERRIE	No	No (data) **Yes** (fetch)
CRC error	CRCRDERRF	CRCRDERRIE	No	No

1. Programming still possible on the AXI interface that did not trigger the inconsistency error, on the flash bank that does not have the flag bit raised. See *Section 5.7.4: Inconsistency error (INCERRF)* for details.
2. AXI bus only

The status of the individual maskable interrupt sources described in *Table 36* (except for option byte error) can be read from the FLASH_xISR registers. They can be cleared by setting the corresponding bit in the FLASH_xICR register.

No unlocking mechanism is required to clear an interrupt.

End-of-program event

Setting the end-of-operation interrupt enable bit (EOPIE) in the FLASH_xIER register enables the generation of an interrupt at the end of an erase operation, a program operation or an option byte change. The EOPF bit in the FLASH_xISR register is also set when one of these events occurs.

Setting the EOPF bit in the FLASH_xICR register clears the EOPF flag in the FLASH_xISR register.

CRC end of calculation event

Setting the CRC end-of-calculation interrupt enable bit (CRCENDIE) in the FLASH_xIER register enables the generation of an interrupt at the end of a CRC operation. The CRCENDF bit in the FLASH_xISR register is also set when this event occurs.

Setting the CRCENDF bit in the FLASH_xICR register clears the same flag in the FLASH_xISR register.

5.9 FLASH registers

5.9.1 FLASH access control register (FLASH_ACCR)

Address offset: 0x000

Reset value: 0x0000 0013

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRHIGHFREQ[1:0]		LATENCY[3:0]			
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **WRHIGHFREQ[1:0]**: Flash signal delay

These bits are used to control the delay between nonvolatile memory signals during programming operations. Application software has to program them to the correct value depending on the embedded flash memory interface frequency. Refer to *Table 25* for details.

Note: Embedded flash does not verify that the configuration is correct.

Bits 3:0 **LATENCY[3:0]**: Read latency

These bits are used to control the number of wait states used during read operations on both nonvolatile memory banks. The application software has to program them to the correct value depending on the embedded flash memory interface frequency and voltage conditions. Refer to *Table 25* for details.

0x0: Zero wait state used to read a word from nonvolatile memory

0x1: One wait state used to read a word from nonvolatile memory

0x2: Two wait states used to read a word from nonvolatile memory

...

0xF: Fifteen wait states used to read from nonvolatile memory

Note: Embedded flash does not verify that the configuration is correct.

5.9.2 FLASH access control register (FLASH_ACCR_ALIAS)

Address offset: 0x100

Reset value: 0x0000 0013

This register is an alias of FLASH_ACCR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRHIGHFREQ[1:0]		LATENCY[3:0]			
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **WRHIGHFREQ[1:0]**: Flash signal delay

These bits are used to control the delay between nonvolatile memory signals during programming operations. Application software has to program them to the correct value depending on the embedded flash memory interface frequency. Refer to *Table 25* for details.

Note: Embedded flash does not verify that the configuration is correct.

Bits 3:0 **LATENCY[3:0]**: Read latency

These bits are used to control the number of wait states used during read operations on both nonvolatile memory banks. The application software has to program them to the correct value depending on the embedded flash memory interface frequency and voltage conditions. Refer to *Table 25* for details.

0x0: Zero wait state used to read a word from nonvolatile memory

0x1: One wait state used to read a word from nonvolatile memory

0x2: Two wait states used to read a word from nonvolatile memory

...

0xF: Fifteen wait states used to read from nonvolatile memory

Note: Embedded flash does not verify that the configuration is correct.

5.9.3 FLASH bank x control key register (FLASH_xKEYR)

Address offset: 0x004 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0000 0000

This register is impacted by the swapping function (see *Section 5.3.14*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CUKEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CUKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **CUKEY[31:0]**: Control unlock key

Following values must be written to FLASH_xKEYR consecutively to unlock FLASH_xCR register:

1st key = 0x4567 0123

2nd key = 0xCDEF 89AB

Reads to this register returns zero. If above sequence is wrong or performed twice, the FLASH_xCR register is locked until the next system reset, and access to it generates a bus error.

5.9.4 FLASH bank x control register (FLASH_xCR)

Address offset: 0x010 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0000 0001

When the LOCK bit in this register is set writes to all other bits are ignored.

Write access to this register is controlled by FLASH_KEYR. This register is impacted by the swapping function (see *Section 5.3.14*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRC_EN	PG_OTP
														rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	PSN[6:0]							START	FW	BER	PER	PG	LOCK
			rw	rw	rw	rw	rw	rw	rw	rw	w	rw	rw	rw	rs

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **CRC_EN**: CRC enable

Setting this bit enables the CRC calculation. CRC_EN does not start CRC calculation but enables CRC configuration through FLASH_xCRCCR register.

When CRC_BUSY flag is cleared in FLASH_xSR, CRC calculation is disabled by clearing CRC_EN bit. Doing so sets CRCDATA to 0x0, clears CRC configuration and resets the content of FLASH_xCRCDATAR register.

Bit 16 **PG_OTP**: Program enable for OTP area

Set this bit to enable write operations to OTP area.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:6 **PSN[6:0]**: Page erase selection number

These bits are used to select the target page for an erase operation in the bank x (they are unused otherwise).

0x0: Page 0 selected

0x1: Page 1 selected

...

0x3F: Page 63 selected

0x40: Page 64 selected *(STM32H7PxxI devices only)*

...

0x7F: Page 127 selected *(STM32H7PxxI devices only)*

Bit 5 **START**: Erase start control bit

This bit is used to start a page erase or a bank erase operation in the bank x. The embedded flash memory resets START when the corresponding operation has been acknowledged. The user application cannot access any embedded flash memory register until the operation is acknowledged.

Bit 4 **FW**: Force write

This bit forces a write operation in the bank x even if the write buffer is not full. In this case all bits not written are set by hardware. FW reads as zero.

Note: Using a force-write operation prevents the application from updating later the missing bits with something other than 1, because this would likely to lead to a permanent ECC error.

When FW is set when write buffer is empty no programming is done (BUSY and EOP stays clear).

Bit 3 **BER**: Bank erase request

Setting this bit requests a bank erase operation in the bank x (user flash memory only).
Write protection error is triggered when a bank erase is required and some pages are protected.
BER has a higher priority than PER: if both are set, the embedded flash memory executes a bank erase.
0: Bank erase is not requested
1: Bank erase is requested. Actual erase is started setting START bit in this register.

Bit 2 **PER**: Page erase request

Setting this bit requests a page erase in the bank x.
Write protection error is triggered when a page erase is required on at least one protected page.
BER has a higher priority than PER: if both bits are set, the embedded flash memory executes a bank erase.
0: Page erase not requested
1: Page erase requested

Bit 1 **PG**: Programming control bit

Setting this bit allows write operations in bank x. In the bank x, when PG is cleared, the internal buffer is cleared.
0: Programming disabled
1: Programming enabled

Bit 0 **LOCK**: Configuration lock bit

When this bit is set write to all other bits in this register, and to FLASH_xIER register, are ignored.
Clearing this bit requires the correct write sequence to FLASH_xKEYR register (see this register for details). If a wrong sequence is executed, or if the unlock sequence is performed twice, this bit remains locked until the next system reset.
During the write access to set LOCK bit from 0 to 1, it is possible to change the other bits of this register.
0: FLASH_xCR and FLASH_xIER registers are unlocked
1: Writes to FLASH_xIER, and to other bits than LOCK in FLASH_xCR, are ignored

5.9.5 FLASH bank x status register (FLASH_xSR)

Address offset: 0x014 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0000 0000

Some bits in this register are impacted by the swapping function (see *Table 29* in *Section 5.3.14*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IS_OPTCHANGE	IS_ERASE	IS_PROGRAM	CRC_BUSY	QW	WBNE	BUSY
									r	r	r	r	r	r	r

Bit 31 **SWAP_BANK**: Swapped bank

This bit is set following a power-on-reset if SWAP_BANK is set in FLASH_OBW1SR. It controls the physical bank allocation to the bank x.

0: Physical bank 1 is allocated to the bank if x = A (bank 2 if x = B)

1: Physical bank 2 is allocated to the bank if x = A (bank 1 if x = B)

Bits 30:7 Reserved, must be kept at reset value.

Bit 6 **IS_OPTCHANGE**: Is an option change

This bit is set together with BUSY when an option change operation is ongoing in the bank x. It is cleared when BUSY is cleared.

This flag can also raise with IS_PROGRAM or IS_ERASE, because a program or erase step is ongoing during option change.

Bit 5 **IS_ERASE**: Is an erase

This bit is set together with BUSY when an erase operation is ongoing in the bank x. It is cleared when BUSY is cleared.

This flag can also raise with IS_PROGRAM or IS_OPTCHANGE, because different operations can run in parallel on different banks or because an erase operation can happen during an option change.

Bit 4 **IS_PROGRAM**: Is a program

This bit is set together with BUSY when a program operation is ongoing in the bank x. It is cleared when BUSY is cleared.

This flag can also raise with IS_ERASE or IS_OPTCHANGE, because different operations can run in parallel on different banks or because an program operation can happen during an option change.

Bit 3 **CRC_BUSY**: CRC busy flag

This bit is set when a CRC calculation is ongoing in the bank x. This bit cannot be forced to 0. The user must wait until the CRC calculation has completed or disable CRC computation using CRC_EN bit in FLASH_xCR register.

0: No CRC calculation ongoing

1: CRC calculation ongoing

Bit 2 **QW**: Wait queue flag

This bit is set when a write, erase or option byte change operation (including option byte key change) is pending in the command queue buffer of this bank x. It is not possible to know what type of programming operation is present in the queue.

This flag is reset by hardware when all write, erase or option byte change operations have been executed and thus removed from the waiting queue(s). This bit cannot be forced to 0. It is reset after a deterministic time if no other operations are requested.

0: No write, erase or option byte change operations waiting in the operation queues

1: At least one write, erase or option byte change operation is waiting in the operation queue

Bit 1 **WBNE**: Write buffer not empty flag

This bit is set when the embedded flash memory is waiting for new data to complete the write buffer. In this state, the write buffer is not empty. WBNE is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the event below:

- the application software forces the write operation using FW bit in FLASH_xCR
- the embedded flash memory detects an error that involves data loss
- the application software has disabled write operations in this bank

This bit cannot be forced to 0. To reset it, clear the write buffer by performing any of the above listed actions, or send the missing data.

0: Write buffer empty or full

1: Write buffer waiting data to complete

Bit 0 **BUSY**: Busy flag

This bit is set when an effective write, erase or option byte change operation is ongoing on this bank x. It is possible to know what type of operation is being executed reading the flags IS_PROGRAM, IS_ERASE and IS_OPTCHANGE.

BUSY cannot be cleared by application. It is automatically reset by hardware every time a step in a write, erase or option byte change operation completes. It is not recommended to do software polling on BUSY to know when one operation completed because, depending of operation, more pulses are possible for one only operation. For software polling it is therefore better to use QW flag or to check the EOPF flag.

0: No programming, erase or option byte change operation are being executed

1: Programming, erase or option byte change operation are being executed. See flags IS_PROGRAM, IS_ERASE and IS_OPTCHANGE for details.

5.9.6 FLASH bank x interrupt enable register (FLASH_xIER)

Address offset: 0x020 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0000 0000

Writes to this register are ignored if the LOCK bit is set in the FLASH_CR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERRIE**: CRC read error interrupt enable bit
0: No interrupt is generated when CRCRDERRF bit is set in FLASH_xISR register
1: An interrupt is generated when CRCRDERRF bit is set in FLASH_xISR register

Bit 27 **CRCENDIE**: CRC end of calculation interrupt enable bit
0: No interrupt is generated when CRCEN bit is set in FLASH_xISR register
1: An interrupt is generated when CRCEN bit is set in FLASH_xISR register

Bit 26 **DBECCERRIE**: ECC double detection error interrupt enable bit
0: No interrupt is generated when DBECCERRF bit is set in FLASH_xISR register
1: An interrupt is generated when DBECCERRF bit is set in FLASH_xISR register

Bit 25 **SNECCERRIE**: ECC single correction error interrupt enable bit
0: No interrupt is generated when SNECCERRF bit is set in FLASH_xISR register
1: An interrupt is generated when SNECCERRF bit is set in FLASH_xISR register

Bit 24 **RDSERRIE**: Read security error interrupt enable bit
0: No interrupt is generated when RDSERRF bit is set in FLASH_xISR register
1: An interrupt is generated when RDSERRF bit is set in FLASH_xISR register

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **INCERRIE**: Inconsistency error interrupt enable bit
0: No interrupt is generated when INCERRF bit is set in FLASH_xISR register
1: An interrupt is generated when INCERRF bit is set in FLASH_xISR register

Bit 20 **OBLERRIE**: Option byte loading error interrupt enable bit
0: No interrupt is generated when OBLERRF bit is set in FLASH_xISR register
1: An interrupt is generated when OBLERRF bit is set in FLASH_xISR register

Bit 19 **STRBERRIE**: Strobe error interrupt enable bit
0: No interrupt is generated when STRBERRF bit is set in FLASH_xISR register
1: An interrupt is generated when STRBERRF bit is set in FLASH_xISR register

Bit 18 **PGSERRIE**: Programming sequence error interrupt enable bit
0: No interrupt is generated when PGSERRF bit is set in FLASH_xISR register
1: An interrupt is generated when PGSERRF bit is set in FLASH_xISR register

Bit 17 **WRPERRIE**: Write protection error interrupt enable bit
0: No interrupt is generated when WRPERRF bit is set in FLASH_xISR register
1: An interrupt is generated when WRPERRF bit is set in FLASH_xISR register

Bit 16 **EOPIE**: End-of-program interrupt control bit
0: No interrupt is generated when OEPF bit is set in FLASH_xISR register
1: An interrupt is generated when OEPF bit is set in FLASH_xISR register

Bits 15:0 Reserved, must be kept at reset value.

5.9.7 FLASH bank x interrupt status register (FLASH_xISR)

Address offset: 0x024 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0000 0000

Some bits in this register are impacted by the swapping function (see *Table 29* in *Section 5.3.14*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERRF**: CRC read error flag

This bit is set when a word is found read protected during a CRC operation. An interrupt is generated if CRCRDIE is set. Setting CRCRDERRF bit in FLASH_ICR register clears this bit.

0: No protected area detected inside addresses read by CRC

1: At least one protected area has been detected inside address read by CRC. As a result CRC result is very likely incorrect.

This flag is valid only when CRCEND bit is set.

Bit 27 **CRCENDF**: CRC end flag

This bit is set when the CRC computation has completed. An interrupt is generated if CRCENDIE is set. It is not necessary to reset CRCEND before restarting CRC computation. Setting CRCENDF bit in FLASH_ICR register clears this bit.

0: CRC computation not complete

1: CRC computation complete

Bit 26 **DBECCERRF**: ECC double error flag

This bit is set when an ECC double detection error occurs during a read operation. An interrupt is generated if DBECCERRIE is set. Setting DBECCERRF bit in FLASH_ICR register clears this bit.

0: No ECC double detection error occurred

1: ECC double detection error occurred

Bit 25 **SNECCERRF**: ECC single error flag

This bit is set when an ECC single correction error occurs during a read operation. An interrupt is generated if SNECCERRIE is set. Setting SNECCERRF bit in FLASH_ICR register clears this bit.

0: No ECC single correction error occurred

1: ECC single correction error occurred

Bit 24 **RDSERRF**: Read security error flag

This bit is set when a read security error occurs (read access to hide protected area with incorrect hide protection level). An interrupt is generated if RDSERRIE is set. Setting RDSERRF bit in FLASH_ICR register clears this bit.

0: No security error occurred

1: A security error occurred

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **INCERRF:** Inconsistency error flag

This bit is set when a inconsistency error occurs. An interrupt is generated if INCERRIE is set. Setting INCERRF bit in the FLASH_ICR register clears this bit.

0: No inconsistency error occurred

1: A inconsistency error occurred

Bit 20 **OBLERRF:** Option byte loading error flag

This bit is set when an error is found during the option byte loading sequence. An interrupt is generated if OBLERRIE is set.

Setting OBLERRF bit in the FLASH_ICR register clears this bit.

0: No error found during option byte loading sequence

1: Some errors found during option byte loading sequence

Bit 19 **STRBERRF:** Strobe error flag

This bit is set when a strobe error occurs (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE bit is set. Setting STRBERRF bit in FLASH_ICR register clears this bit.

0: No strobe error occurred

1: Astrobe error occurred

Bit 18 **PGSERRF:** Programming sequence error flag

This bit is set when a sequence error occurs. An interrupt is generated if the PGSERRIE bit is set. Setting PGSERRF bit in FLASH_ICR register clears this bit.

0: No sequence error occurred

1: Asequence error occurred

Bit 17 **WRPERRF**: Write protection error flag

This bit is set when a protection error occurs during a program operation. An interrupt is also generated if the WRPERRIE is set. Setting WRPERRF bit in FLASH_ICR register clears this bit.

0: No write protection error occurred

1: A write protection error occurred

Bit 16 **EOPF**: End-of-program flag

This bit is set at the end of an erase operation, a program operation or an option byte change. An interrupt is generated if the EOPIE is set. It is not necessary to reset EOPF before starting a new operation. Setting EOPF bit in FLASH_ICR register clears this bit.

0: No programming or erase operation completed

1: Programming, or erasing operation completed. Possible option byte change completion if x = A (SWAP_BANK cleared in FLASH_xSR) or x = B (SWAP_BANK set).

Bits 15:0 Reserved, must be kept at reset value.

5.9.8 FLASH bank x interrupt clear register (FLASH_xICR)

Address offset: 0x028 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0000 0000

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERRF**: CRC error flag clear
Setting this bit clears CRCRDERRF flag in FLASH_ISR register.

Bit 27 **CRCENDF**: CRC end flag clear
Setting this bit clears CRCENDF flag in FLASH_ISR register.

Bit 26 **DBECCERRF**: ECC double error flag clear
Setting this bit clears DBECCERRF flag in FLASH_ISR register. If the SNECCERRF flag of FLASH_ISR register is also cleared, FLASH_ECCDFADDR register is reset to zero as well.

Bit 25 **SNECCERRF**: ECC single error flag clear
Setting this bit clears SNECCERRF flag in FLASH_ISR register. If the DBECCERRF flag of FLASH_ISR register is also cleared, FLASH_ECCSFADDR register is reset to zero as well.

Bit 24 **RDSERRF**: Read security error flag clear
Setting this bit clears RDSERRF flag in FLASH_ISR register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **INCERRF**: Inconsistency error flag clear
Setting this bit clears INCERRF flag in FLASH_ISR register.

Bit 20 **OBLERRF**: Option byte loading error flag clear
Setting this bit clears OBLERRF flag in FLASH_ISR register.

Bit 19 **STRBERRF**: Strobe error flag clear
Setting this bit clears STRBERRF flag in FLASH_ISR register.

Bit 18 **PGSERRF**: Programming sequence error flag clear
Setting this bit clears PGSERRF flag in FLASH_ISR register.

Bit 17 **WRPERRF**: Write protection error flag clear
Setting this bit clears WRPERRF flag in FLASH_ISR register.

Bit 16 **EOPF**: End-of-program flag clear
Setting this bit clears EOPF flag in FLASH_ISR register.

Bits 15:0 Reserved, must be kept at reset value.

5.9.9 FLASH bank x CRC control register (FLASH_xCRCCR)

Address offset: 0x030 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0018 0000

Writes to this register are ignored if the CRC_EN bit is cleared in FLASH_xCR or if CRC_BUSY is set in FLASH_xSR. Reads to this registers return default values when the

CRC_EN bit is cleared. This register is impacted by the swapping function (see *Section 5.3.14*).

Res.	Res.	Res.	Res.	CLEAN_PAGE	ADD_PAGE	CRC_BY_PAGE	Res.	Res.	CRC_PAGE[6:0]						
				w	w	rw			rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **ALL_BANK**: All pages in bank selection

Set this write-only bit to add all pages of bank x to the list of pages on which the CRC is calculated. Reading this bit returns zero.

Bits 21:20 **CRC_BURST[1:0]**: CRC burst size

CRC_BURST bits set the size of the bursts that are generated by the CRC calculation unit. A flash word is 128-bit.

00: every burst has a size of 4 flash words (64 Bytes)

01: every burst has a size of 16 flash words (256 Bytes)

10: every burst has a size of 64 flash words (1 Kbytes)

11: every burst has a size of 256 flash words (4 Kbytes)

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CLEAN_CRC**: CRC clear bit

Setting CLEAN_CRC to 1 clears the current CRC result stored in the FLASH_CRCDATAR register.

Bit 16 **START_CRC**: CRC start bit

START_CRC bit triggers a CRC calculation in the bank x using the current configuration. No CRC calculation can launched when an option byte change operation is ongoing because all read accesses to embedded flash memory registers are put on hold until the option byte change operation has completed.

This bit is cleared when CRC computation starts.

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **CLEAN_PAGE**: CRC page list clear bit

When this bit is set the list of pages on which the CRC is calculated is cleared.

Bit 10 **ADD_PAGE**: CRC page select bit

When this bit is set the page in this bank x whose number is written in CRC_PAGE is added to the list of pages on which the CRC is calculated.

Bit 9 **CRC_BY_PAGE**: CRC page mode select bit

When this bit is set the CRC calculation is performed in the bank x at page level, on the pages present in the list of pages. To add a page to this list, use ADD_PAGE and CRC_PAGE bits. To clean the list, use CLEAN_PAGE bit.

When CRC_BY_PAGE is cleared the CRC calculation is performed on all addresses defined between start and end addresses defined in FLASH_CRCSADDR and FLASH_CRCEADDR registers.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **CRC_PAGE[6:0]**: CRC page number

CRC_PAGE is used to select one user flash page of bank x to be added to the list of pages on which the CRC is calculated. The CRC can be computed either between two addresses (using registers FLASH_xCRCSADDR and FLASH_xCRCEADDR) or on a list of pages using this register. If this latter option is selected, it is possible to add a page to the list of pages by programming the page number in CRC_PAGE and then setting ADD_PAGE bit.

The list of pages can be erased either by setting CLEAN_PAGE bit or by disabling the CRC computation.

5.9.10 FLASH bank x CRC start address register (FLASH_xCRCSADDR)

Address offset: 0x034 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0000 0000

Writes to this register are ignored if the CRC_BUSY bit is set in the FLASH_xSR register, or CRC_EN bit is set in FLASH_xCR register.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:2 **CRC_START_ADDR[19:2]**: CRC start address

This register is used when CRC_BY_PAGE is cleared. It must be programmed to the address of the start address on which the CRC calculation is done on bank x.

Bits 1:0 Reserved, must be kept at reset value.

5.9.11 FLASH bank x CRC end address register (FLASH_xCRCEADDR)

Address offset: 0x038 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0000 0000

Writes to this register are ignored if the CRC_BUSY bit is set in the FLASH_xSR register, or CRC_EN bit is set in FLASH_xCR register..

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:2 **CRC_END_ADDR[19:2]**: CRC end address

This register is used when CRC_BY_PAGE is cleared. It must be programmed to the end address of the memory area on which the CRC calculation is performed on bank x.

Bits 1:0 Reserved, must be kept at reset value.

5.9.12 FLASH CRC data register (FLASH_CRCDATAR)

Address offset: 0x03C, 0x13C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CRC_DATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **CRC_DATA[31:0]**: CRC result

This bitfield contains the result of the last CRC calculation that occurred on either bank. The value is valid only when CRC calculation completed (CRCENDF is set in FLASH_xISR register). CRC_DATA is cleared when CRC_EN bit is cleared in both FLASH_xCR register, or when application clears CLEAN_CRC bit in either FLASH_xCRCCR register.

5.9.13 FLASH bank x ECC single error fail address (FLASH_xECCSFADDR)

Address offset: 0x040 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SEC_FADD[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SEC_FADD[31:0]**: ECC single error correction fail address

When a single ECC error correction occurs during a read operation, the SEC_FADD bitfield contains the system bus address that generated the error.

This register is automatically cleared when SNECCERRF flag that generated the error is cleared.

Note that only the first address that generated an ECC single error correction error is saved in this register.

5.9.14 FLASH bank x ECC double error fail address (FLASH_xECCDFADDR)

Address offset: 0x044 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0000 0000

DED_FADD[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **DED_FADD[31:0]**: ECC double error detection fail address

When a double ECC detection occurs during a read operation, the DED_FADD bitfield contains the system bus address that generated the error.

This register is automatically cleared when the DBECCERRF flag that generated the error is cleared.

Note: Only the first address that generated an ECC double error detection error is saved in this register.

5.9.15 FLASH bank x write page protection status register (FLASH_xWRPSR)

Address offset: 0x050 + 0x100 * (x-1), (x = A to B)

Reset value: 0xXXXX XXXX

This read-only register reflects the current values of the corresponding option bits. This register is impacted by the swapping function (see *Section 5.3.14*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

WRPG[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **WRPG[31:0]**: Write protection for page group n in bank x (n = 0 to 127)
Each bit reflects the write protection status of the corresponding group of four consecutive pages in bank (0: the group is write protected; 1: the group is not write protected).

Bit 0: Group 0, comprising pages 0 to 3
Bit 1: Group 1, comprising pages 4 to 7
Bit N: Group N, comprising pages 4 x N to 4 x N + 3

Note: In STM32H7PxxG devices with 1 Mbyte flash, bits 31:16 are reserved.

5.9.16 FLASH bank x write page protection status register programming (FLASH_xWRPSRP)

Address offset: 0x054 + 0x100 * (x-1), (x = A to B)

Reset value: 0xXXXX XXXX

(The reset value is the same as for FLASH_xWRPSR)

Application must not write to this register when BUSY and IS_OPTCHANGE bits are set in FLASH_xSR. Writes are ignored if HDPL is different from 0 or 1 in the SBS_HDPLSR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

WRPG[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **WRPG[31:0]**: Write protection for page group n in bank x programming (n = 0 to 127)
Write to change corresponding bit in FLASH_xWRPSR

Note: In STM32H7PxxG devices with 1 Mbyte flash, bits 31:16 are reserved and must be kept at reset value.

5.9.17 FLASH bank x hide protection status register (FLASH_xHDPSR)

Address offset: 0x058 + 0x100 * (x-1), (x = A to B)

Reset value: 0x0XXX 0XXX

This read-only register reflects the current values of the corresponding option bits. This register is impacted by the swapping function (see *Section 5.3.14*).

Res.	Res.	Res.	Res.	HDP_AREA_END[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HDP_AREA_START[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HDP_AREA_END[11:0]**: Hide protection user flash area end for bank x

This option sets the end address that contains the last 256-byte block of the hide protection (HDP) area in user flash area of bank x.
If HDP_AREA_END = HDP_AREA_START all the pages in bank are protected.
If HDP_AREA_END < HDP_AREA_START no pages in bank are protected.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HDP_AREA_START[11:0]**: Hide protection user flash area start for bank x

This option sets the start address that contains the first 256-byte block of the hide protection (HDP) area in user flash area of bank x.
If HDP_AREA_END = HDP_AREA_START all the pages in bank are protected.
If HDP_AREA_END < HDP_AREA_START no pages in bank are protected.

5.9.18 FLASH bank x hide protection status register programming (FLASH_xHDPSRP)

Address offset: 0x05C + 0x100 * (x-1), (x = A to B)

Reset value: 0x0XXX 0000

(The reset value is the same as for FLASH_xHDPSR.)

Application must not write to this register when BUSY and IS_OPTCHANGE bits are set in FLASH_xSR. Write are ignored if HDPL is different from 0 or 1 in the SBS_HDPLSR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	HDP_AREA_END[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HDP_AREA_START[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HDP_AREA_END[11:0]**: Hide protection user flash area end programming for bank x
Write to change corresponding option byte bits in FLASH_xHDPSR.
If HDP_AREA_END = HDP_AREA_START all the pages in bank are protected.
If HDP_AREA_END < HDP_AREA_START no pages in bank are protected.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HDP_AREA_START[11:0]**: Hide protection user flash area start programming for bank x
Write to change corresponding option byte bits in FLASH_xHDPSR.
If HDP_AREA_END = HDP_AREA_START all the pages in bank are protected.
If HDP_AREA_END < HDP_AREA_START no pages in bank are protected.

5.9.19 FLASH bank x HDP extension register (FLASH_xHDPEXTR)

Address offset: 0x060 + 0x100 * (x-1), (x = A to B)

Reset value: 0x00A3 0000

This register is impacted by the swapping function (see *Section 5.3.14*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDPEXT_ACCDIS[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HDP_AREA_EXT[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **HDPEXT_ACCDIS[7:0]**: HDP extension area access disable for bank x
Set this bitfield to configure the HDP extension in user flash of bank x. Access to this bitfield depends on its value.
0xA3: HDP extension area is not active and can be configured with HDP_AREA_EXT[11:0]. Any value can be written in this bitfield.
0x5C: HDP extension area is active, and can be increased (not decreased) with HDP_AREA_EXT[11:0]. Writing 0xA3 to this bitfield is ignored.
Others: HDP extension area is active, and writes to this bitfield and HDP_AREA_EXT[11:0] are ignored.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HDP_AREA_EXT[11:0]**: HDP extension area end for bank x
This bitfield defines the number of 256-byte pages added to the nonvolatile HDP user flash area of bank x (HDP extension). If the bitfield equals to zero the HDP extension area is not active, regardless of the value in HDPEXT_ACCDIS[7:0].
Accesses to an active HDP extension area is ignored (for writes) or zeroed (for reads) when HDPL is different from 0, 1 or 2 in SBS_HDPLSR register.

More specifically, if the nonvolatile HDP area size is at least two pages, this bitfield is the number of HDP pages added starting at block offset HDP_AREA_END[11:0] +1 included. Otherwise, if the HDP area size is zero, this bitfield is the number of HDP pages added starting at block offset HDP_AREA_END[11:0] included. HDP_AREA_END[11:0] is defined in FLASH_xHDPSR register.

5.9.20 FLASH options key register (FLASH_OPTKEYR)

Address offset: 0x200

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OCUKEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OCUKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OCUKEY[31:0]**: Options configuration unlock key

Following values must be written to FLASH_OPTKEYR consecutively to unlock FLASH_OPTCR register:

- 1st key = 0x0819 2A3B
- 2nd key = 0x4C5D 6E7F

Reads to this register returns zero. If above sequence is performed twice locks up the corresponding register/bit until the next system reset, and generates a bus error.

5.9.21 FLASH options control register (FLASH_OPTCR)

Address offset: 0x204

Reset value: 0xX000 0001

When the OPTLOCK bit in this register is set writes to all other bits are ignored.

Write access to this register is controlled by the FLASH_OPTKEYR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	OPTERRIE	Res.	Res.	OBKERRIE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw			rw											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPTSTART	OPTLOCK
														w	rs

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OPTERRIE**: Option byte change error interrupt enable bit

This bit controls if an interrupt has to be generated when an error occurs during an option byte change.

0: No interrupt is generated when an error occurs during an option byte change

1: An interrupt is generated when and error occurs during an option byte change.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **OBKERRIE**: Option byte key error interrupt enable bit

This bit controls if an interrupt has to be generated when OBKERRF is set in FLASH_OPTISR.

0: No interrupt is generated when an OBkey error occurs

1: An interrupt is generated when an OBkey error occurs

Bits 26:2 Reserved, must be kept at reset value.

Bit 1 **OPTSTART**: Options update start

Setting this bit triggers an option byte change operation. Write to this bit is ignored when OPTLOCK bit is cleared.

0: No action or option byte change acknowledged

1: Option byte change requested

Refer to *Section 5.4.3: Option byte words modification* for more details.

It is not possible to start an option byte change operation if a CRC calculation is ongoing. Hence setting OPTSTART is ignored when CRC_BUSY is set in FLASH_xSR register.

Bit 0 **OPTLOCK**: Options lock

When this bit is set write to all other bits in this register, and write to OTP words, option bytes and option bytes keys control registers, are ignored.

0: OTP words, FLASH_OPTCR, and FLASH_xSRP registers are unlocked

1: Writes to OTP words, FLASH_xSRP and to other bits than OPTLOCK in FLASH_OPTCR, are ignored

Clearing this bit requires the correct write sequence to FLASH_OPTKEYR register (see this register for details). If a wrong sequence is executed, or the unlock sequence is performed twice, this bit remains locked until next system reset.

During the write access to set LOCK bit from 0 to 1, it is possible to change the other bits of this register.

5.9.22 FLASH options interrupt status register (FLASH_OPTISR)

Address offset: 0x208

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	OPTERRF	Res.	Res.	OBKERRF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OPTERRF**: Option byte change error flag

When OPTERRF is set, the option byte change operation did not successfully complete. An interrupt is generated when this flag is raised if the OPTERRIE bit of FLASH_OPTCR register is set. Setting OPTERRF of register FLASH_OPTICR clears this bit.

0: No option byte change errors occurred

1: One or more errors occurred during an option byte change operation.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **OBKERRF**: Option byte key error flag

When OBKERRF is set, the last option byte key reading or programming operation did not successfully complete. An interrupt is generated when this flag is raised if the OBKERRIE bit of FLASH_OPTCR register is set. Setting OBKERRF of register FLASH_OPTICR clears this bit.

0: No option byte key reading or programming error occurred

1: A double error detection was found when loading the requested option byte key, or the programming of a nonvirgin key was detected during the last programming operation.

When OBKERRF is set write to KEYSTART bit in FLASH_OBKCR is ignored.

Bits 26:0 Reserved, must be kept at reset value.

5.9.23 FLASH options interrupt clear register (FLASH_OPTICR)

Address offset: 0x20C

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	OPTERRF	Res.	Res.	OBKERRF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OPTERRF**: Option byte change error flag

Set this bit to clear OPTERRF flag in FLASH_OPTISR register.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **OBKERRF**: Option byte key error flag

Set this bit to clear OBKERRF flag in FLASH_OPTISR register.

Bits 26:0 Reserved, must be kept at reset value.

5.9.24 FLASH OTP lock status register (FLASH_OTPLSR)

Address offset: 0x210

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

OTPL[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTPL[15:0]**: OTP lock n (n = 0 to 15)

Block *n* corresponds to OTP 16-bit word 32 x *n* to 32 x *n* + 31.
OTPL[n] = 1 indicates that all OTP 16-bit words in OTP Block *n* are locked and can no longer be programmed.
OTPL[n] = 0 indicates that all OTP 16-bit words in OTP Block *n* are not locked and can still be modified.

5.9.25 FLASH OTP lock status register programming (FLASH_OTPLSRP)

Address offset: 0x214

Reset value: 0x0000 XXXX (same as for FLASH_OTPLSR)

Application must not write to this register when BUSY and IS_OPTCHANGE bits are set in FLASH_xSR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

OTPL[15:0]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTPL[15:0]**: OTP lock n programming (n = 0 to 15)

Write to change corresponding option byte bit in FLASH_OTPLSR.
OTPL bits can be only be set, not cleared.

5.9.26 FLASH nonvolatile status register (FLASH_NVSR)

Address offset: 0x220

Reset value: 0x0000 XXXX

This read-only register reflects the current values of the corresponding option bits. The default value is used when there is an issue with option byte loading.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NVSTATE[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **NVSTATE[7:0]**: Nonvolatile state

This bitfield defines the nonvolatile state of the device:

0xB4: NVOPEN

0x51: NVCLOSED (default)

others: invalid configuration.

5.9.27 FLASH security status register programming (FLASH_NVSRP)

Address offset: 0x224

Reset value: 0x0000 XXXX (same as FLASH_NVSR)

Application must not write to this register when BUSY and IS_OPTCHANGE bits are set in FLASH_xSR. Write are ignored if HDPL is different from 0 or 1 in the SBS_HDPLSR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NVSTATE[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **NVSTATE[7:0]**: Nonvolatile state programming

Write to change corresponding bits in FLASH_NVSR register:

0xB4: NVOPEN

0x51: NVCLOSE

Detailed sequence to grant option byte change from NVCLOSE to NVOPEN is defined in Flash opening of *Section 5.5.3*. When NVSTATE = 0xB4 (resp. 0x51) writing any other value than 0x51 (resp. 0xB4) triggers an option byte change error (OPTERRF).

5.9.28 FLASH RoT status register (FLASH_ROTSR)

Address offset: 0x228

Reset value: 0xXX00 XXXX

This read-only register reflects the current values of the corresponding option bits. Default values are used when there is an issue with option byte loading.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BOOT_LOCK[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBG_AUTH[7:0]								OEM_PROVD[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 **BOOT_LOCK[7:0]**: boot lock
0xB4: Change to SWAP_BANK option bit is always ignored (default).
0x6A: Change to SWAP_BANK option bit is allowed.
Others: invalid configuration.

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **DBG_AUTH[7:0]**: Debug authentication method
Every boot RSS uses this information to enforce a specific debug and regression policy when NVSTATE = NVCLOSE in FLASH_NVSR.
0xB4: No debug allowed, no regression (Locked device) (default).
0x8A, 0x6F: No debug allowed, regression with password (Closed device)
Others: invalid configuration.

Bits 7:0 **OEM_PROVD[7:0]**: OEM provisioned device
Every boot RSS uses this information to select the boot image when NVSTATE = NVCLOSE in FLASH_NVSR.
0xB4: Device has been provisioned by the OEM.
0x6A: Device is not provisioned by the OEM (default).
Others: invalid configuration.

5.9.29 FLASH RoT status register programming (FLASH_ROTSRP)

Address offset: 0x22C

Reset value: 0x0000 XXXX (same as FLASH_ROTSR)

Application must not write to this register when BUSY and IS_OPTCHANGE bits are set in FLASH_xSR. Writes are ignored if HDPL is different from 0 in the SBS_HDPLSR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BOOT_LOCK[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBG_AUTH[7:0]								OEM_PROVD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **BOOT_LOCK[7:0]**: Boot lock programming
Write to change corresponding bits in FLASH_ROTSR register.
Writing any other value than 0xB4 or 0x6A is possible, but it triggers an option byte change error (OPTERRF), and no option byte change occurs.

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **DBG_AUTH[7:0]**: Debug authentication method programming
Write to change corresponding bits in FLASH_ROTSR register.
Writing any other value than 0xB4, 0x8A or 0x6F is possible, but it triggers an option byte change error (OPTERRF), and no option byte change occurs.

Bits 7:0 **OEM_PROVD[7:0]**: OEM provisioned device
Write to change corresponding bits in FLASH_ROTSR register.
Writing any other value than 0xB4 or 0x6A is possible, but it triggers an option byte change error (OPTERRF), and no option byte change occurs.

5.9.30 FLASH option byte key control register (FLASH_OBKCR)

Address offset: 0x230

Reset value: 0x0000 0000

Writes are ignored when KEYSTART is set in this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEYSTART	KEYPROG	KEYERASE	Res.	Res.	Res.	NEXTKL[1:0]		Res.	Res.	Res.	OBKINDEX[4:0]				
rw	rw	rw				rw	rw				rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **KEYSTART**: Key option start

Set this bit to start the option byte key operation defined by the KEYPROG and KEYERASE bits (refer to those bitfield for details). The embedded flash memory resets KEYSTART when the corresponding operation has been completed.

Application must set either KEYPROG or KEYERASE bit when setting KEYSTART. If application sets both KEYPROG or KEYERASE bits when setting KEYSTART the hardware immediately clears KEYSTART and triggers an option byte key error (OBKERRF).

Bit 14 **KEYPROG**: Key program

Set this bit with KEYSTART to write a new option byte keys. Keep this bit and KEYERASE bit cleared to read the key instead.

0: Read key. Result of the operation is stored in FLASH_OBKDRx registers, if applicable.

1: Write key stored in FLASH_OBKDRx registers.

Bit 13 **KEYERASE**: Key erase

Set this bit with KEYSTART to erase keys based on FLASH_OBKCLR information (see *Section 5.9.31* for details). The embedded flash memory resets KEYERASE when the erase operation has been completed.

0: No action.

1: Erase keys.

Bits 12:10 Reserved, must be kept at reset value.

Bits 9:8 **NEXTKL[1:0]**: Next key level

0x0: OBKINDEX represents the index of the option byte key stored for the hide protection level indicated in SBS_HDPLSR.

0x1: OBKINDEX represents the index of the option byte key stored for the hide protection level indicated in SBS_HDPLSR plus one (for example if HDPL =1 in SBS_HDPLR the key of level 2 is selected).

0x2 or 0x3: reserved

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **OBKINDEX[4:0]**: Option byte key index

This bitfield represents the index of the option byte key in a given hide protection level. Up to 32 keys can be provisioned per hide protection level (0, 1 or 2).

5.9.31 FLASH option byte key clear register (FLASH_OBKCLR)

Address offset: 0x234

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EKEY31	EKEY30	EKEY29	EKEY28	EKEY27	EKEY26	EKEY25	EKEY24	EKEY23	EKEY22	EKEY21	EKEY20	EKEY19	EKEY18	EKEY17	EKEY16
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EKEY15	EKEY14	EKEY13	EKEY12	EKEY11	EKEY10	EKEY9	EKEY8	EKEY7	EKEY6	EKEY5	EKEY4	EKEY3	EKEY2	EKEY1	EKEY0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **EKEY{i}**: Erase key {i}

Set this bit to request the erasing of option byte key of index OBKINDEX[4:0] = {i}. Key is also referenced by the HDP level defined in SBS_HDPLSR plus the bitfield NEXTKL[1:0].

The key is actually erased after the next option byte key programming sequence triggered by the setting of KEYERASE and KEYSTART bits. Clearing a key is mandatory when its value must be modified.

After a successful programming this register is cleared.

5.9.32 FLASH option bytes key data register x (FLASH_OBKDRx)

Address offset: 0x240 + 0x4 * x (x = 0 to 3)

Reset value: 0x0000 0000

Writes are ignored until the KEYSTART bit is cleared in FLASH_OBKCR, or when OBKERRF is set in FLASH_OPTISR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OBKDATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OBKDATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OBKDATA[31:0]**: option byte key data, bits [31+x:0+x]

Data register used in conjunction with FLASH_OBKCR register.

Reading this register (read value once), or incrementing HDPL value in SBS peripheral automatically clears OBKDATA to 0x0.

5.9.33 FLASH option byte word 1 status register (FLASH_OBW1SR)

Address offset: 0x260

Reset value: 0xXXXX XXXX (see *Table 30: Option byte user words organization*)

This register reflects the current values of the corresponding option bits.

Bit 31 **SWAP_BANK**: Bank swapping
This bit is set when a swapping of physical bank is requested on the device. Effect of swapping on registers is summarized on *Table 28* and *Table 29* in *Section 5.3.14*.
By default physical bank 1 is allocated to the bank A.
0: Following a system or power-on-reset both SWAP_BANK bits are cleared in FLASH_xSR registers (see *Section 5.9.5*).
1: Following a system or power-on-reset both SWAP_BANK bits are set in FLASH_xSR registers (see *Section 5.9.5*).

Bit 30 Reserved, must be kept at reset value.

Bit 29 **VDDIO_HSLV**: I/O high-speed at low-voltage
This bit indicates that the product operates below 2.5 V.
0: Product working in the full voltage range, I/O speed optimization at low-voltage disabled
1: Product operating below 2.5 V, I/O speed optimization at low-voltage feature allowed

Bits 28:19 Reserved, must be kept at reset value.

Bit 18 **IWDG_FZ_STBY**: IWDG standby mode freeze
When set the independent watchdog IWDG is frozen in system Standby mode.
0: Independent watchdog frozen in Standby mode
1: Independent watchdog keep running in Standby mode

Bit 17 **IWDG_FZ_STOP**: IWDG stop mode freeze
When set the independent watchdog IWDG is frozen in system Stop mode.
0: Independent watchdog frozen in Stop mode
1: Independent watchdog keep running in Stop mode

Bits 16:11 Reserved, must be kept at reset value.

Bit 10 **ECC_ON_SRAM**: ECC on SRAM
0: ECC on SRAM option disabled (default)
1: ECC on SRAM option enabled

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **NRST_STBY**: Reset on standby mode
0: Independent WDG generates a reset if STANDBY mode is requested
1: Independent WDG does not generate a reset if STANDBY mode is requested (default)

Bit 6 **NRST_STOP**: Reset on stop mode
0: Independent WDG generates a reset if STOP mode is requested
1: Independent WDG does not generate a reset if STOP mode is requested (default)

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IWDG_HW**: Independent watchdog HW Control
1: IWDG watchdog is controlled by software (default)
0: IWDG watchdog is controller by hardware

Bits 3:2 **BOR_LEV[1:0]**: Brownout level
These bits reflects the power level that generates a system reset.
0x0: BOR OFF, POR/PDR reset threshold level is applied (default)
0x1: BOR Level 1, the threshold level is low (around 2.1 V)
0x2: BOR Level 2, the threshold level is medium (around 2.4 V)
0x3: BOR Level 3, the threshold level is high (around 2.7 V)

Bits 1:0 Reserved, must be kept at reset value.

5.9.34 FLASH option byte word 1 status register programming (FLASH_OBW1SRP)

Address offset: 0x264

Reset value: 0xXXXX XXXX (same as for FLASH_OBW1SR)

Application must not write to this register when BUSY and IS_OPTCHANGE bits are set in FLASH_xSR.

					rw			rw	rw		rw	rw	rw		

Bit 31 **SWAP_BANK**: Bank swapping programming
Write to change corresponding bit in FLASH_OBW1SR register.
Writes to this bit are ignored when BOOT_LOCK is set in FLASH_ROTSR, or when hide protection level in SBS_HDPLSR register is 3.

Bit 30 Reserved, must be kept at reset value.

Bit 29 **VDDIO_HSLV**: I/O high-speed at low-voltage programming
Write to change corresponding bit in FLASH_OBW1SR register.

Bits 28:19 Reserved, must be kept at reset value.

Bit 18 **IWDG_FZ_STBY**: IWDG standby mode freeze programming
Write to change corresponding bit in FLASH_OBW1SR register.

Bit 17 **IWDG_FZ_STOP**: IWDG stop mode freeze
Write to change corresponding bit in FLASH_OBW1SR register.

Bits 16:11 Reserved, must be kept at reset value.

Bit 10 **ECC_ON_SRAM**: ECC on SRAM
Write to change corresponding bit in FLASH_OBW1SR register.

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **NRST_STBY**: Reset on standby mode programming
Write to change corresponding bit in FLASH_OBW1SR register.

Bit 6 **NRST_STOP**: Reset on stop mode programming
Write to change corresponding bit in FLASH_OBW1SR register.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IWDG_HW**: Independent watchdog HW Control
Write to change corresponding bit in FLASH_OBW1SR register.

Bits 3:2 **BOR_LEV[1:0]**: Brownout level
Write to change corresponding bits in FLASH_OBW1SR register.

Bits 1:0 Reserved, must be kept at reset value.

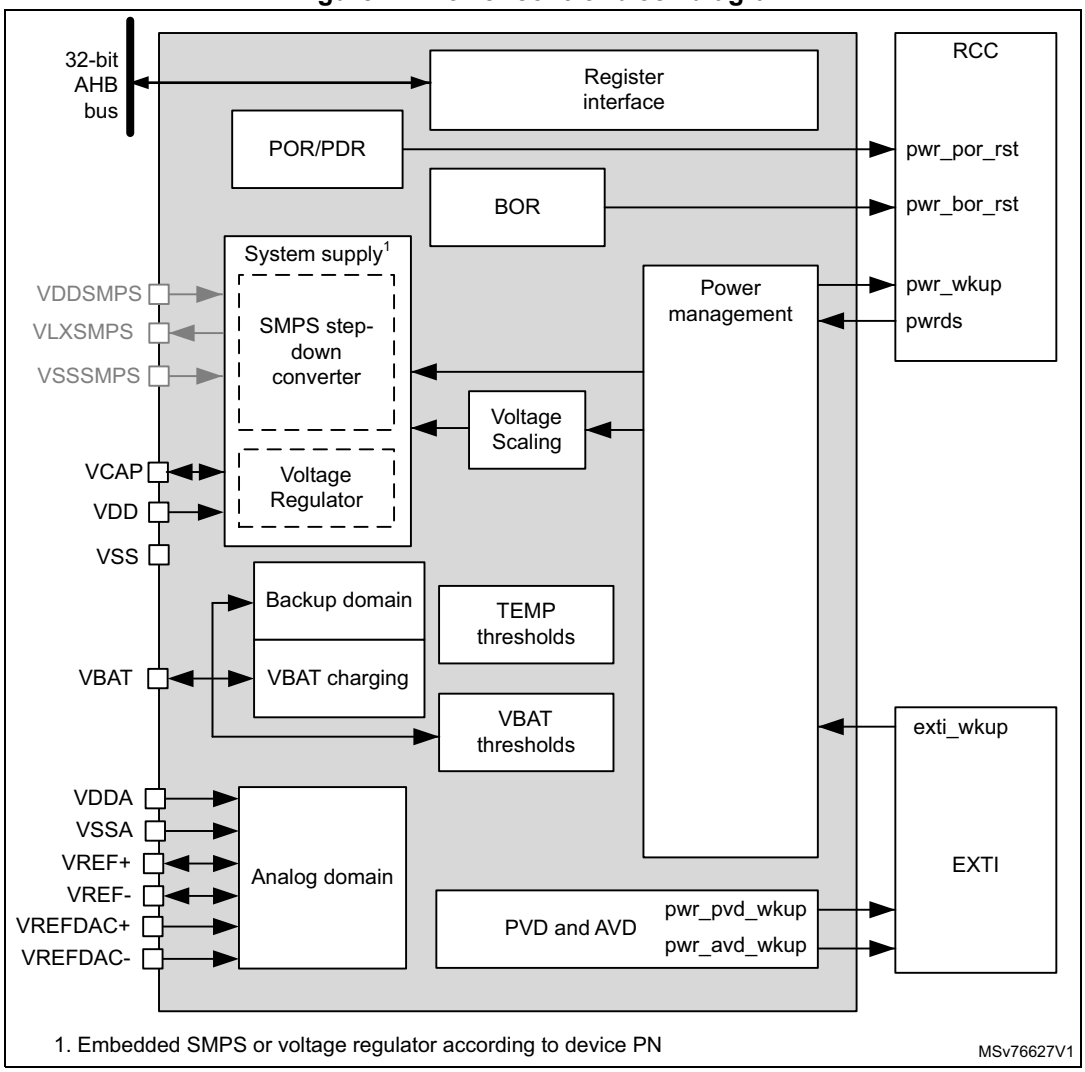
6 Power control (PWR)

6.1 Introduction

The power control section (PWR) provides an overview of the supply architecture for the different power domains and of the supply configuration controller.



It also describes the features of the power supply supervisors and explains how the V_{CORE} supply domain is configured depending on the operating modes, the selected performance (clock frequency) and the voltage scaling.

6.2 PWR main features

- Power supplies and supply domains
  - Core domains (V_{CORE})
  - V_{DD} domain
  - Backup domain (V_{SW}, V_{BKP})
  - Analog domain (V_{DDA})
- System supply voltage regulation
  - Integrated switched-mode power supply power-efficient voltage down-converter (SMPS step-down converter) or voltage regulator (LDO)
- Power supply supervision
  - POR/PDR monitor
  - BOR monitor
  - PVD monitor
  - AVD monitor
  - V_{BAT} thresholds
  - Temperature thresholds
- Power management
  - V_{BAT} battery charging
  - Operating modes
  - Voltage scaling control
  - Low-power modes

6.3 PWR block diagram

Figure 17. Power control block diagram

6.3.1 PWR pins and internal signals

Table 38 lists the PWR inputs and output signals connected to package pins or balls, while *Table 39* shows the internal PWR signals.

Table 38. PWR input/output signals connected to package pins or balls

Pin name	Signal type	Description
VDD	Supply input	Main I/O and V_{DD} domain supply input
VDDA	Supply input	External analog power supply for analog peripherals
VSSA	Supply	Analog peripherals ground
VREFDAC+, VREFDAC-	Supply input	External reference voltage for DACs

Table 38. PWR input/output signals connected to package pins or balls (continued)

Pin name	Signal type	Description
VREF+,VREF-	Supply input/output	External reference voltage for ADCs
VBAT	Supply input/output	Backup battery supply input
VDDSMPS	Supply input	Step-down converter supply input(1)
VLXSMPS	Supply output	Step-down converter supply output(1)
VSSSMPS	Supply input	Step-down converter ground(1)
VCAP	Supply Input/Outputs	Digital core domain supply
VSS	Supply	Main ground
WKUPx	Input	Wakeup pins

1. If embedded SMPS option

Table 39. PWR internal input/output signals

Signal name	Signal type	Description
AHB	Input/output	AHB register interface
pwr_pvd_wkup	Output	Programmable voltage detector output
pwr_avd_wkup	Output	Analog voltage detector output
pwr_por_rst	Output	Power-on reset
pwr_bor_rst	Output	Brownout reset
exti_wkup	Input	Wakeup request
pwr_wkup	Output	Bus matrix clock wakeup request

6.4 Power supplies

The device uses the following power supply pins:

- V_{DD}: external power supply for I/Os and system analog blocks such as reset, power management and oscillators, as well as the backup domain if no battery is present. VDD also supplies the integrated voltage regulator when enabled.
- V_{BAT}: optional external power supply for backup domain when V_{DD} is not present (V_{BAT} mode).

  This power supply must be connected to VDD when no battery is used.
- V_{DDSMPS} (SMPS option): external power supply for the SMPS step-down converter.

  VDDSMPS must be connected to VDD or tied to VSS when the SMPS is not used.
- V_{LXSMPS} (SMPS option): step-down converter supply output.
- V_{SSSMPS} (SMPS option): separate step-down converter ground.
- V_{CAP}: digital core domain (V_{CORE}) supply

  This power supply is independent from all the other power supplies:
  - (LDO option) When the embedded voltage regulator is enabled, V_{CORE} is delivered by the internal voltage regulator. An external decoupling capacitor can be connected to the VCAP pin.
  - (SMPS option) V_{CORE} is delivered from the SMPS step-down converter through the VCAP pin.
  - (LDO or SMPS bypass) V_{CORE} is delivered from an external power supply through the VCAP pin.
- V_{DDA}: external analog power supply for ADCs and voltage reference buffers.

  This power supply is independent from all the other power supplies.
- V_{REF+}: external reference voltage for ADC.
  - When the voltage reference buffer is enabled, V_{REF+} and V_{REF-} are delivered by the internal voltage reference buffer.
  - When the voltage reference buffer is disabled, V_{REF+} is delivered by an independent external reference supply.
- V_{SSA}: separate analog and reference voltage ground.
- V_{SS}: common ground for all supplies except for step-down converter and analog peripherals.

Note: Depending on the operating power supply range, some peripherals might be used with limited features and performance. For more details, refer to section "General operating conditions" of the device datasheets.

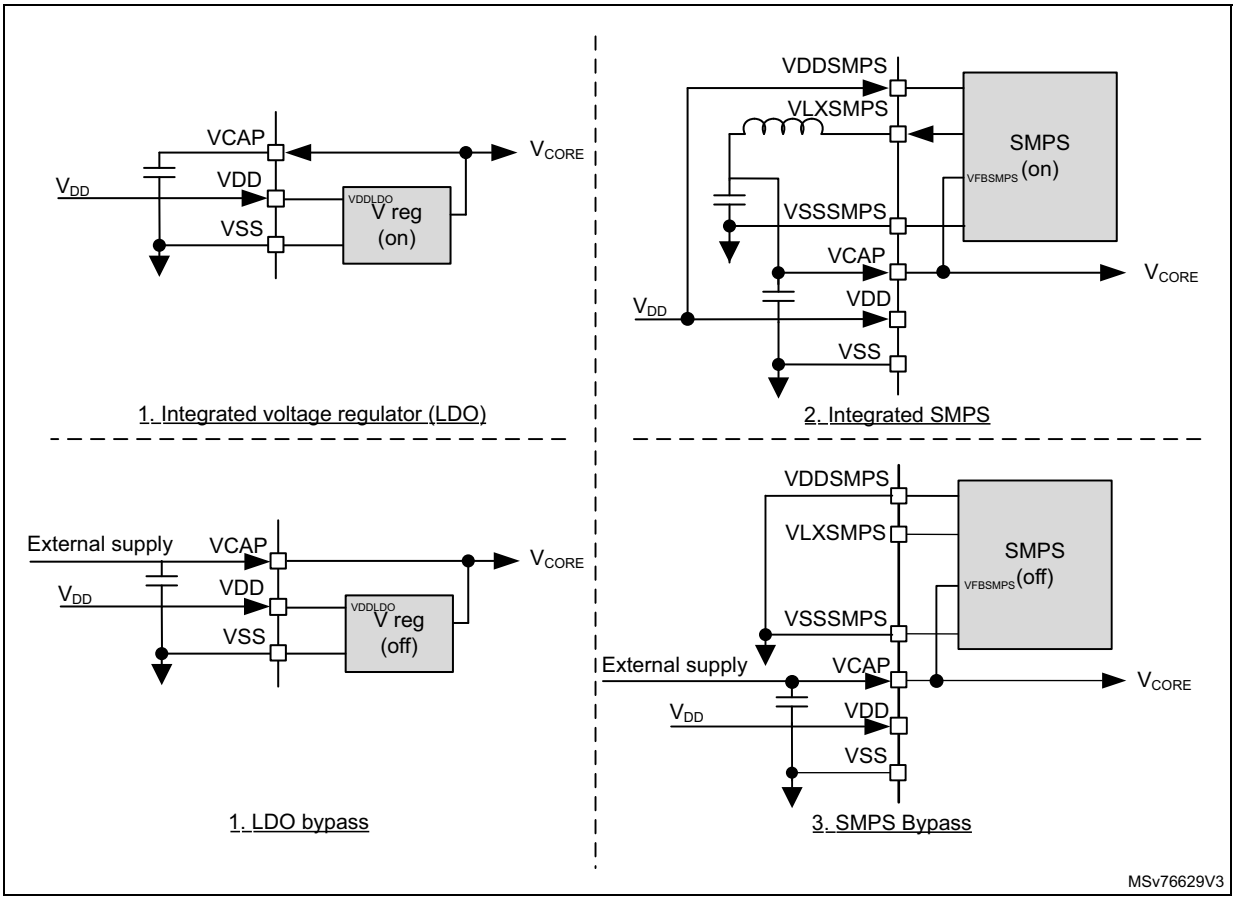


Figure 18. Power supply overview

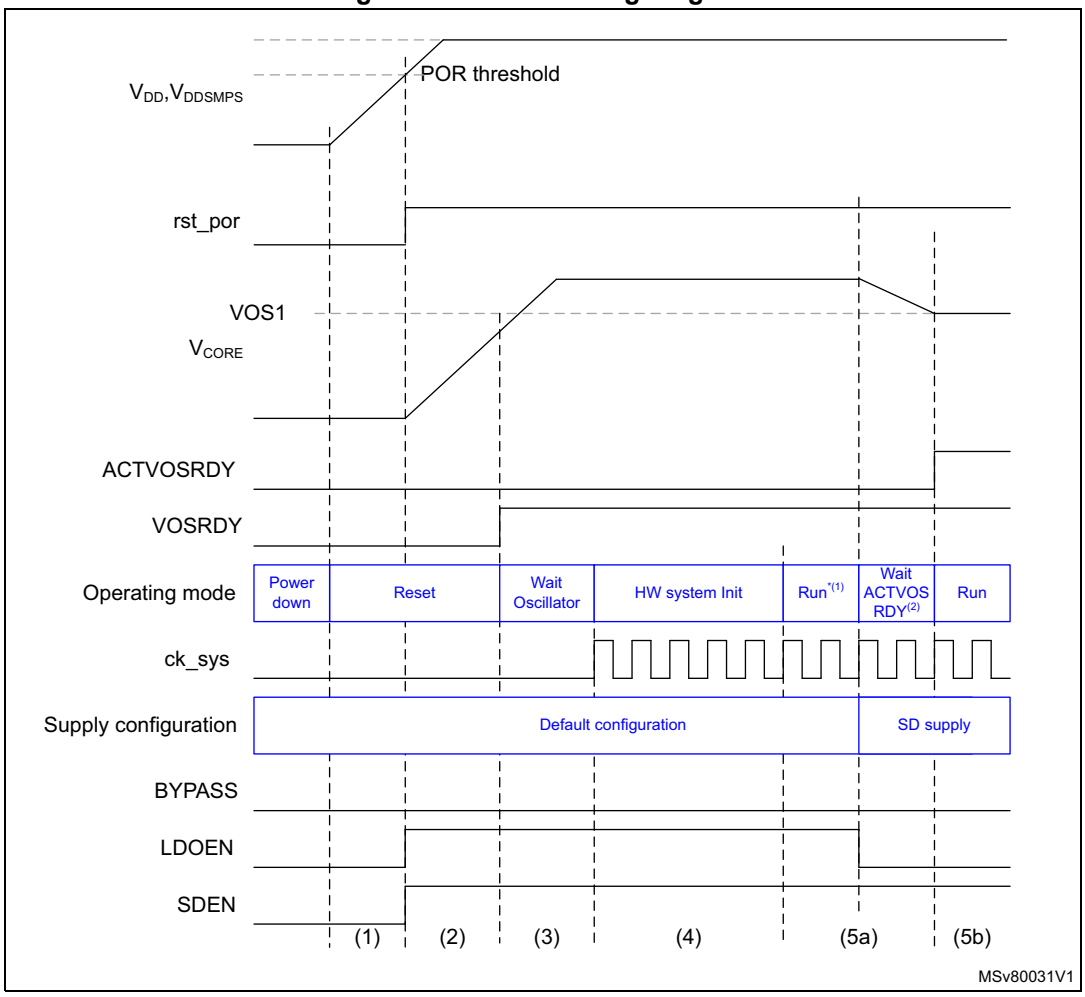
Depending on the selected product option there are four possible configurations for supplying V_{CORE} illustrated in *Figure 19*.

1. (LDO option) Integrated voltage regulator is used to supply the core voltage (low cost solution in terms of external components).
2. (LDO option) Integrated voltage regulator not used (bypassed). The core voltage comes from an external source.
3. (SMPS option) Integrated SMPS step down converter is used to directly supply the core voltage (high efficiency solution).
4. (SMPS option) Integrated SMPS not used (bypassed). The core voltage comes from an external source.

Figure 19. Supply configurations[a]

6.4.1 System supply startup

The system startup sequence from power-on in different supply configurations is the following (see *Figure 20*):



a. Refer to application note ANxxxx (TBD) “Getting started hardware with STM32H7Pxxx MCUs" for the possible power scheme and connected capacitors.

1. When the system is powered on, the POR monitors V_{DD} supply. Once V_{DD} is above the POR threshold level, the integrated SMPS step-down converter or voltage regulator is enabled in the default supply configuration.
2. The system is kept in reset as long as V_{CORE} is not stable.
3. Once V_{CORE} is stable, the system is taken out of reset and the HSI oscillator is enabled.
4. Once the oscillator is stable, the system is initialized: flash memory is ready, option bytes are loaded and the CPU starts in limited run mode (Run*).
5. The software must program the BYPASS bit in the PWR control status register 2 (PWR_CSR2) to indicate whether an external power supply is connected (bypass mode). If an external power supply is connected, the internal power supply (LDO or SMPS) is disabled.
   The software must then poll the ACTVOSRDY bit in the *PWR status register 1 (PWR_SR1)* to guarantee valid voltage levels:
   a) As long as ACTVOSRDY indicates that voltage levels are invalid, the system is in Run* mode, write accesses to the RAMs are not permitted and VOS must not be changed.
   b) Once ACTVOSRDY indicates that voltage levels are valid, the system is in normal Run mode, write accesses to RAMs are allowed and VOS can be changed.

V_{CORE} supplied from the integrated voltage regulator or SMPS step-down converter

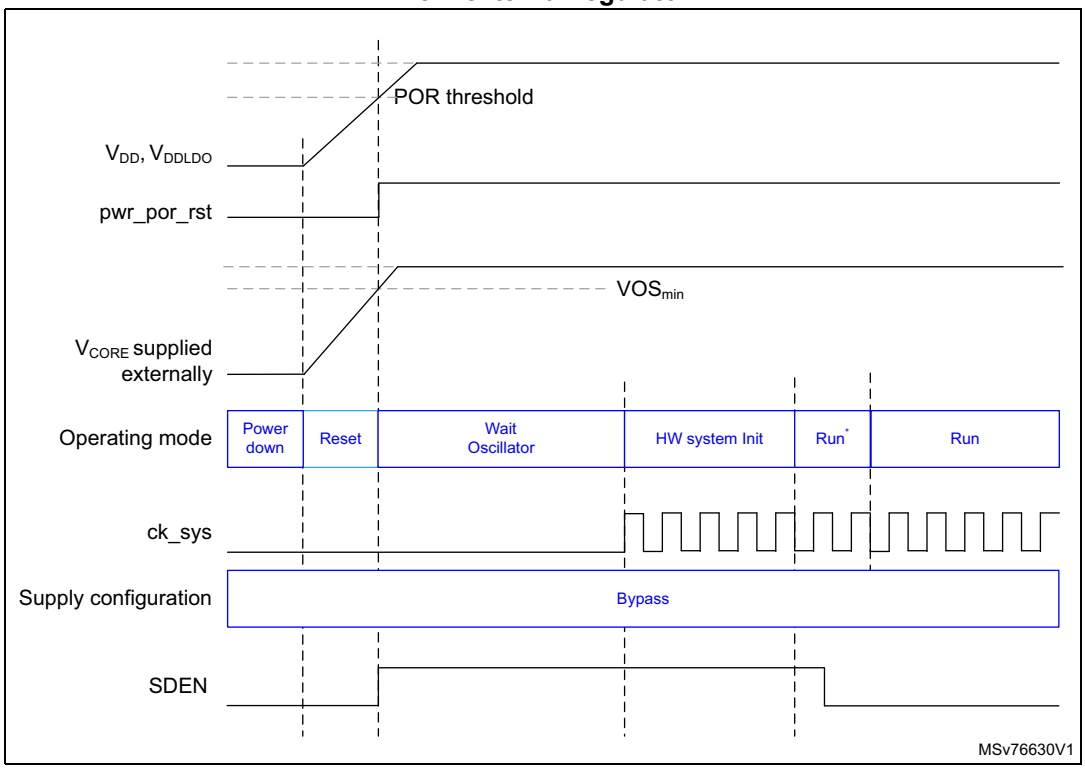
When V_{CORE} is supplied from the integrated voltage regulator or SMPS step-down converter, the V_{CORE} voltage first settles at V_{CORE} default level (VOS1).

Figure 20. Device startup with V_{CORE} supplied from integrated SMPS or voltage regulator

1. In Run* mode, write operations to RAM are not allowed.
2. Write operations to RAM are allowed and VOS can be changed only when ACTVOSRDY is valid.

When exiting from Standby mode, the software must wait for the ACTVOSRDY bit to be set in *PWR status register 1 (PWR_SR1)* to indicate V_{CORE} voltage levels are valid, before performing write accesses to RAM or changing VOS.

V_{CORE} supplied in Bypass mode (internal regulator OFF)



The external V_{CORE} voltage can be adjusted according to the user application needs (refer to section *General operating conditions* of the datasheet for details on V_{CORE} level versus the maximum operating frequency).

Caution: When supplying V_{CORE} from an external supply, care must be taken to respect the start-up sequence shown in *Figure 21*. In particular failure to respect the following constraints may cause damage to the device:

- $V_{CORE} \leq V_{DD}$ at all times.
- $V_{CORE} > VOS_{min}$ when $V_{DD} >$ POR threshold

Once the device has entered Run* mode, the software must disable the internal supply by setting BYPASS = 0 in *PWR control status register 2 (PWR_CSR2)*.

Figure 21. Device startup sequence with V_{CORE} supplied in Bypass mode from external regulator

6.4.2 Core domain

The V_{CORE} core domain supply can be provided by the integrated SMPS step-down converter or LDO voltage regulator, depending on the part number, or by an external supply (VCAP). V_{CORE} supplies all the digital circuitries except for the backup domain and the Standby circuitry.

LDO voltage regulator

The embedded voltage regulator (LDO) requires external capacitors to be connected to VCAP pins.

The voltage regulator provides three different operating modes: high power (HP), low power (LP) or Off. These modes are used depending on the system operating modes (Run, Stop and Standby).

- Run modes

  The LDO regulator operates in high-power mode and delivers full power to the V_{CORE} domain (core, memories and digital peripherals). The regulator output voltage can be scaled by software to different voltage levels (VOS0, VOS1 and VOS2) that are configured through the VOS bitfield in the *PWR control status register 4 (PWR_CSR4)*. The VOS voltage scaling allows optimization of the power consumption when the system is clocked below the maximum frequency. By default VOS1 is selected after system reset. VOS can be changed on-the-fly to adapt to the required system performance.

- Stop mode

  The LDO regulator operates in LP mode and supplies the V_{CORE} domain to retain the content of registers and internal memories. In LP mode only SVOS low and SVOS high voltage levels are allowed. The voltage level is selected through the SVOS bit in the *PWR control register 1 (PWR_CR1)*, depending on whether peripheral clocks are active or not in STOP mode.

- Standby mode

  The voltage regulator is OFF and the V_{CORE} domains are powered down. The content of the registers and memories is lost except for the Standby circuitry and the backup domain.

For more details, refer to the voltage regulator section in the datasheets.

SMPS step-down converter regulator

The SMPS step-down converter requires:

- An external coil to connect between the dedicated VLXSMPS pin and VCAP
- An external capacitor to connect between VCAP and VSSSMPS

The SMPS step-down converter works in three different power modes: high power (HP), low power (LP) or Off.

When the SMPS step-down converter is used in internal supply mode, the converter operating modes depend on the system modes (Run, Stop, Standby) and are configured through the associated VOS and SVOS levels:

- Run mode

  The SMPS step-down converter operates in HP mode and provides full power to the V_{CORE} domain (core, memories and digital peripherals). The regulator output voltage can be scaled by software to different voltage levels (VOS0, VOS1 and VOS2) that are configured through the VOS bitfield in the *PWR control status register 4 (PWR_CSR4)*. The VOS voltage scaling allows optimization of the power consumption when the system is clocked below the maximum frequency. By default VOS1 is selected after system reset. VOS can be changed on-the-fly to adapt to the required system performance.

- Stop mode

  The SMPS step-down converter operates in LP mode and supplies the V_{CORE} domain to retain the content of registers and internal memories. In LP mode only SVOS low and SVOS high voltage levels are allowed. The voltage level is selected through the SVOS bit in the *PWR control register 1 (PWR_CR1)*, depending on whether peripheral clocks are active or not in STOP mode.

- Standby mode

  The SMPS step-down converter is OFF and the V_{CORE} domains are powered down. The content of the registers and memories are lost except for the Standby circuitry and the backup domain.

External supply

When V_{CORE} is supplied from an external source (Bypass mode), different operating modes can be used depending on the system operating modes (Run, Stop or Standby):

- In Run modes

  The external source supplies full power to the V_{CORE} domain (core, memories and digital peripherals). The external source output voltage is scalable through different voltage levels (VOS0 and VOS1 - VOS2 is not available in Bypass mode). The externally applied voltage level must be reflected in the VOS bit of *PWR control status register 4 (PWR_CSR4)* register. The RAMs must only be accessed for write operations when the external applied voltage level matches VOS settings.

- In Stop mode

  The external V_{CORE} supply should be maintained higher than VOS_{min} to ensure proper internal wakeup.

- In Standby mode

  The wake mechanism should be monitored externally. Refer to the datasheet for the proper V_{CORE} ramp time.

6.4.3 Backup domain

To retain the content of the backup domain (RTC, backup registers and backup RAM) when V_{DD} is turned off, VBAT pin can be connected to an optional voltage which is supplied from a battery or from another source.

The switching to V_{BAT} is controlled by the power-down reset embedded in the Reset block that monitors the V_{DD} supply.

Warning: **During $t_{RSTTEMPO}$ (time delay at V_{DD} startup) or after a PDR is detected, the power switch between V_{BAT} and V_{DD} remains connected to V_{BAT}.**
During the startup phase, if V_{DD} is established in less than $t_{RSTTEMPO}$ (see the datasheet for the value of $t_{RSTTEMPO}$) and $V_{DD} > V_{BAT} + 0.6$ V, a current may be injected into V_{BAT} through an internal diode connected between V_{DD} and the power switch (V_{BAT}).
If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

When the V_{DD} supply is present, the backup domain is supplied from V_{DD}. This allows saving V_{BAT} power supply battery life time.

If no external battery is used in the application, it is recommended to connect VBAT externally to VDD, and add a 100 nF external ceramic capacitor between VBAT and VSS.

When the V_{DD} supply is present and higher than the PDR threshold, the backup domain is supplied by V_{DD} and the following functions are available:

- PC14 and PC15 can be used either as GPIO or as LSE pins.
- PC13 can be used either as GPIO or as RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 pin assuming they have been configured by the RTC or the TAMPER registers (see *Section 42.3.3: GPIOs controlled by the RTC*).

Note: Since the switch only sinks a limited amount of current, the use of PC13, PC14 and PC15 GPIOs is restricted: only one I/O can be used as an output at a time. These I/Os must not be used as current sources (for example to drive an LED). Refer to the product datasheet.

In V_{BAT} mode, when the V_{DD} supply is absent and a supply is present on V_{BAT}, the backup domain is supplied by V_{BAT} and the following functions are available:

- PC14 and PC15 can be used as LSE pins only.
- PC13 can be used as RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 pin assuming they have been configured by the RTC or the TAMPER registers (see *Section 42.3.3: GPIOs controlled by the RTC*).

Accessing the backup domain

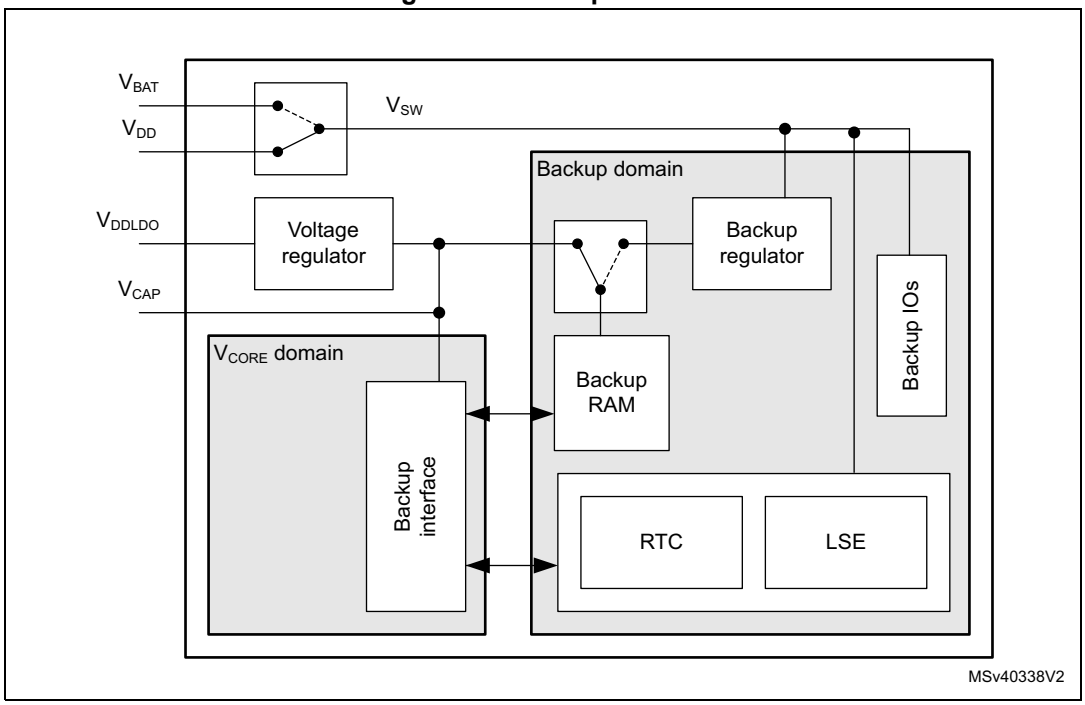
After reset, the backup domain (RTC registers and RTC backup registers) is protected against possible unwanted write accesses. To enable access to the backup domain, set the DBP bit in the *PWR control register 1 (PWR_CR1)*.

For more detail on RTC and backup RAM access, refer to *Section 7: Reset and clock control (RCC)*.

Backup RAM

The backup domain includes 4 Kbytes of backup RAM accessible in 32-bit, 16-bit or 8-bit data mode. The backup RAM is supplied from the backup regulator in the backup domain. When the backup regulator is enabled through BREN bit in the *PWR control status register 1 (PWR_CSR1)*, the backup RAM content is retained even in Standby and/or V_{BAT} mode (it can be considered as an internal EEPROM if V_{BAT} is always present.)

The backup regulator can be ON or OFF depending whether the application needs the backup RAM function in Standby or V_{BAT} modes.



After a tamper event, if the RTC flag is set, the backup RAM cannot be used until an erase is explicitly requested. When a tamper event is generated, reading the backup RAM returns 0x0, and any write different from 0 is not effective. The backup RAM can be erased:

- Through the flash memory interface when a regression from nvstate closed to nvstate open is requested. See also *Section 4: System security (TBD)*.

  or

- By performing a simple dummy write with zero as data to any address of the backup RAM (this action resets the whole backup RAM when it is performed after a tamper event).

Figure 22. Backup domain

6.4.4 V_{BAT} battery charging

When V_{DD} is present, the external battery connected to VBAT can be charged through an internal resistance.

V_{BAT} charging can be performed either through a 5 kΩ resistor or through a 1.5 kΩ resistor, depending on the VBRS bit value in *PWR control status register 2 (PWR_CSR2)*.

The battery charging is enabled by setting the VBE bit in the *PWR control status register 2 (PWR_CSR2)*. It is automatically disabled in V_{BAT} mode.

6.4.5 Analog supply

Separate V_{DDA} analog supply

The analog domain is supplied by dedicated V_{DDA} and V_{SSA} pins that allow the supply to be filtered and shielded from noise on the PCB, thus improving ADC conversion accuracy:

- The analog supply voltage input is on a separate VDDA pin.
- An isolated supply ground connection is provided on the VSSA pin.

Analog reference voltage V_{REF+}/V_{REF-}

V_{REF+} defines the upper limit of the ADC input voltage, represented by the full-scale value. V_{REF-} defines the lower limit, represented by the value 0.

When enabled by ENVR bit in the VREFBUF control and status register (see *Section 28: Voltage reference buffer (VREFBUF)*), V_{REF+} is provided by the internal voltage reference buffer and output on the VREF+ pin. V_{REF-} (connected to V_{SSA}) is output on VREF-.

When the internal voltage reference buffer is disabled by ENVR, the voltage reference can be provided by an external reference connected between the VREF+ and VREF- pins.

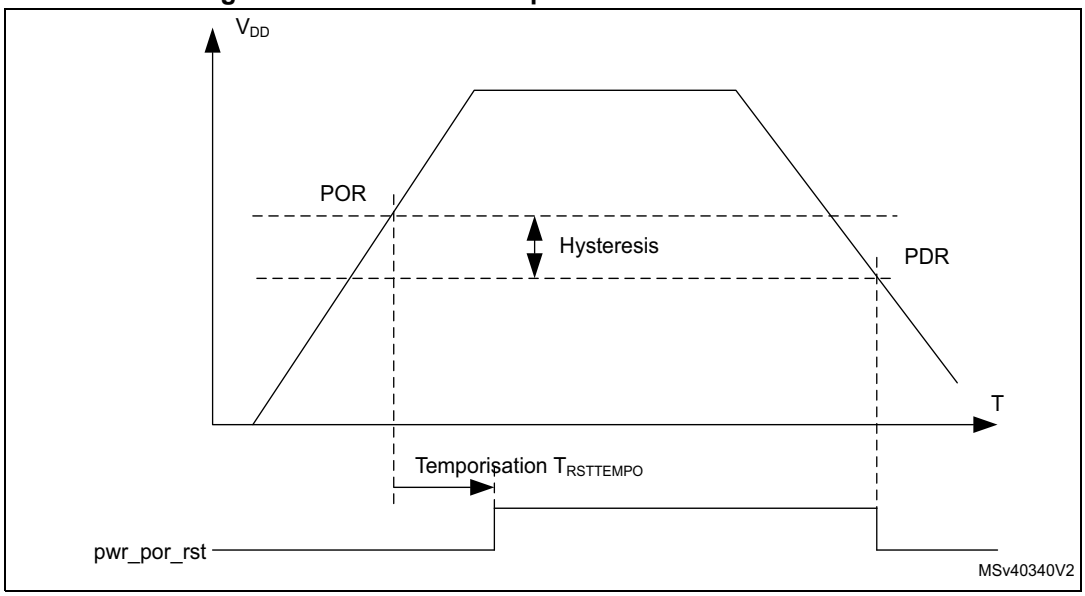
*Note: VREF+ and VREF- pins are not available on all packages (in this case they are connected internally respectively to VDDA and VSSA). **Do not** enable the internal voltage reference buffer when an external reference is connected.*

DAC reference voltage $DACV_{REF+}$/$DACV_{REF-}$

The DACs have a dedicated reference voltage. $DACV_{REF+}$ defines the upper limit (full scale) DAC output voltage and $DACV_{REF-}$ defines the lower limit (0 value). The DAC reference is supplied from an external reference connected between the DACVREF+ and DACVREF- pins. If the internal voltage reference buffer (VREFBUF) is enabled, it can be used to supply the DAC reference by connecting VREF+ to DACVREF+ and VREF- to DACVREF- externally. In this case, the DAC and ADC clocks should be synchronized, to avoid polluting the ADC with noise injected by the DAC, or vice versa.

6.5 Power supply supervision

Power supply level monitoring is available on the following supplies:



- V_{DD} (V_{DDSMPS}) can be monitored via POR/PDR (see *Section 6.5.1*), BOR (see *Section 6.5.2*) and PVD monitor (see *Section 6.5.3*)
- V_{DDA} can be monitored via AVD monitor (see *Section 6.5.4*)
- V_{BAT} can be monitored via V_{BAT} threshold (see *Section 6.5.5*)
- V_{SW} can be monitored via rst_vsw, which keeps the V_{SW} domain in Reset mode as long as the level is not OK.
- V_{BKP} can be monitored via a BRRDY bit in the *PWR control status register 1 (PWR_CSR1)*.
- V_{FBSMPS} (V_{CORE}) can be monitored via an SDRDY bit in the *PWR control status register 2 (PWR_CSR2)*.

6.5.1 Power-on reset (POR)/power-down reset (PDR)

The system has an integrated POR/PDR circuitry that ensures proper startup operation.

The system remains in Reset mode when V_{DD} is below a specified V_{POR} threshold, without the need for an external reset circuit. Once the V_{DD} supply level is above the V_{POR} threshold, the system is taken out of reset (see *Figure 23*). For more details concerning the power-on/power-down reset threshold, refer to the electrical characteristics section of the datasheets.

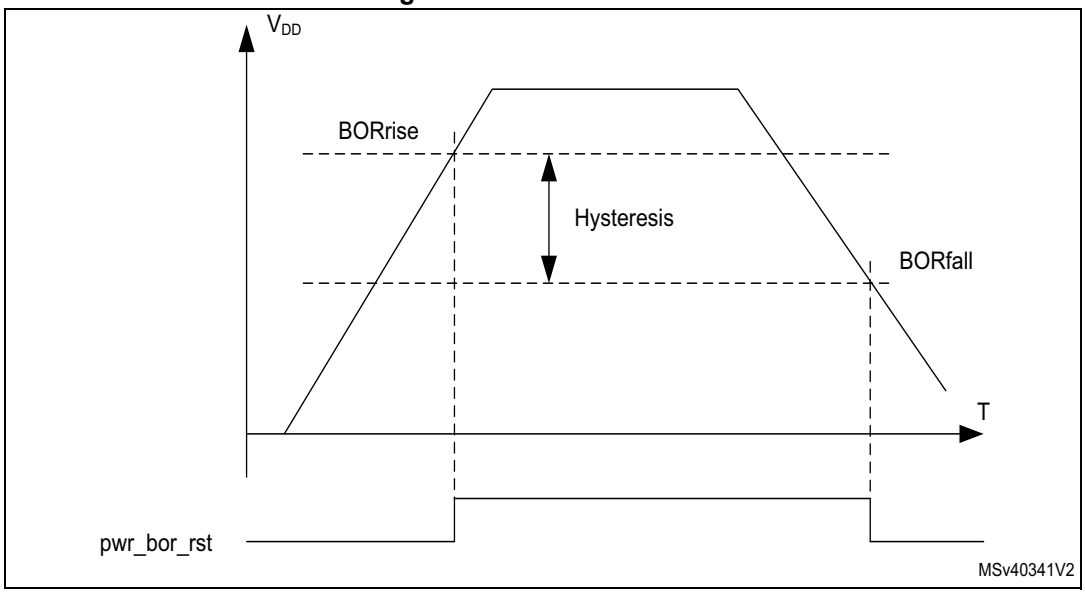
Figure 23. Power-on reset/power-down reset waveform

1. For thresholds and hysteresis values, refer to the datasheets.

6.5.2 Brownout reset (BOR)

During power-on, the Brownout reset (BOR) keeps the system under reset until the V_{DD} supply voltage reaches the specified V_{BOR} threshold.

The V_{BOR} threshold is configured through system option bytes. By default, BOR is OFF. The following programmable V_{BOR} thresholds can be selected:



- BOR OFF (V_{BOR0})
- BOR Level 1 (V_{BOR1})
- BOR Level 2 (V_{BOR2})
- BOR Level 3 (V_{BOR3})

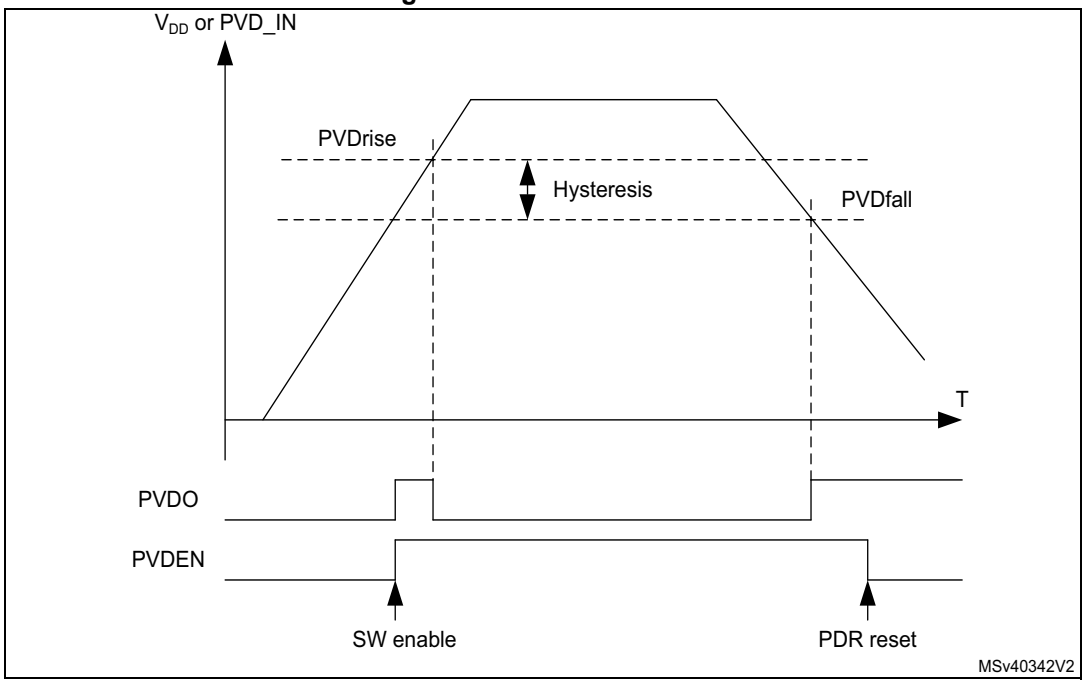
For more details on the brown-out reset thresholds, refer to the section “Electrical characteristics” of the product datasheet.

A system reset is generated when the BOR is enabled and the V_{DD} supply voltage drops below the selected V_{BOR} threshold.

BOR can be disabled by programming the system option bytes. To disable the BOR function, V_{DD} must have been higher than V_{BOR0} to start the system option byte programming sequence. The power-down is then monitored by the PDR (see *Section 6.5.1*).

Figure 24. BOR thresholds

1. For thresholds and hysteresis values, refer to the datasheets.



6.5.3 Programmable voltage detector (PVD)

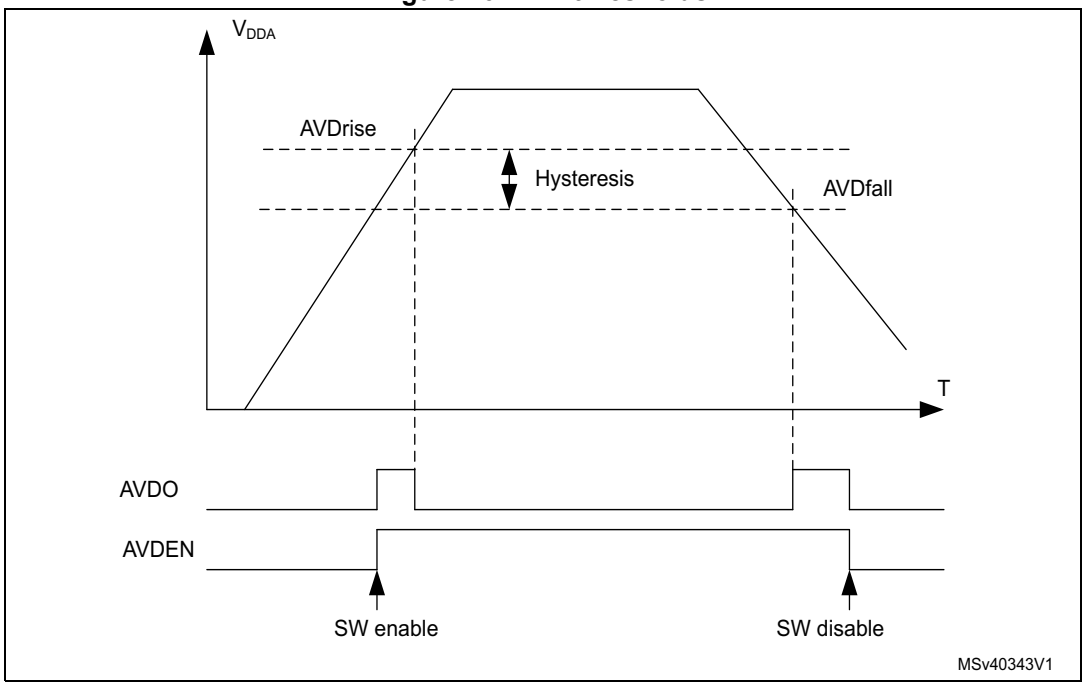
The PVD can be used to monitor the V_{DD} power supply by comparing it to a threshold selected by the PLS[2:0] bits in the *PWR control register 1 (PWR_CR1)*. The PVD can also be used to monitor a voltage level on the PVD_IN pin. In this case the PVD_IN voltage is compared to the internal V_{REFINT} level.

The PVD is enabled by setting the PVDE bit in the *PWR control register 1 (PWR_CR1)*.

A PVDO flag is available in the *PWR status register 1 (PWR_SR1)* to indicate if the V_{DD} or PVD_IN voltage is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt, assuming it has been enabled through the EXTI registers. The PVDO output interrupt can be generated when V_{DD} or PVD_IN voltage drops below the PVD threshold and/or when V_{DD} or PVD_IN voltage rises above the PVD threshold depending on EXTI rising/falling edge configuration. As an example the service routine could perform emergency shutdown tasks.

Figure 25. PVD thresholds

1. For thresholds and hysteresis values, refer to the datasheets.



6.5.4 Analog voltage detector (AVD)

The AVD can be used to monitor the V_{DDA} supply by comparing it to a threshold selected by the ALS[1:0] bits in the *PWR control register 1 (PWR_CR1)*.

The AVD is enabled by setting the AVDEN bit in the *PWR control register 1 (PWR_CR1)*.

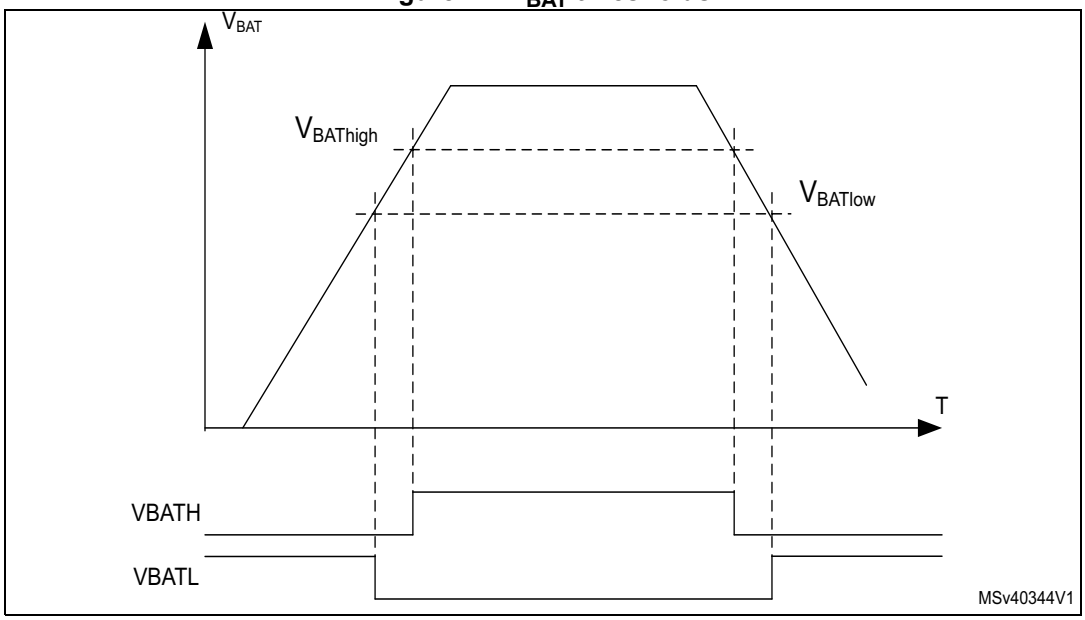
An AVDO flag is available in the *PWR status register 1 (PWR_SR1)* to indicate whether V_{DDA} is higher or lower than the AVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers. The AVDO interrupt can be generated when V_{DDA} drops below the AVD threshold and/or when V_{DDA} rises above the AVD threshold depending on the EXTI rising/falling edge configuration. As an example the service routine could indicate when the V_{DDA} supply drops below a minimum level.

Figure 26. AVD thresholds

1. For thresholds and hysteresis values, refer to the datasheets.

6.5.5 Battery voltage thresholds

The battery voltage supply monitors the backup domain V_{SW} level. V_{SW} is monitored by comparing it with two threshold levels: $V_{BAThigh}$ and V_{BATlow}. VBATH and VBATL flags in the *PWR control status register 1 (PWR_CSR1)*, indicate if V_{SW} is higher or lower than the threshold.



The V_{BAT} supply monitoring can be enabled/disabled via the MONEN bit in the *PWR control status register 1 (PWR_CSR1)*. When it is enabled, the battery voltage thresholds increase power consumption. As an example the V_{SW} levels monitoring could be used to trigger a tamper event for an over or under voltage of the RTC power supply domain (available in V_{BAT} mode).

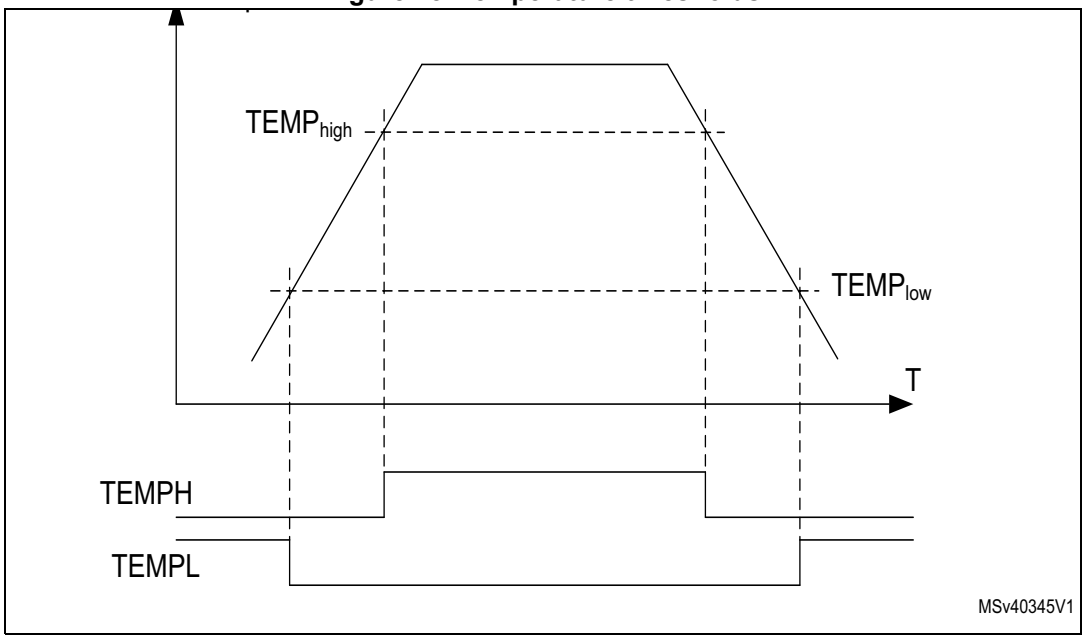
VBATH and VBATL are connected to RTC tamper signals (see *Section 42: Real-time clock (RTC)*).

Note: Battery voltage monitoring is only available when the backup regulator is enabled (BREN bit set in the PWR control status register 1 (PWR_CSR1)).

When the device does not operate in V_{BAT} mode, the battery voltage monitoring checks the V_{DD} level. When V_{DD} is available, V_{SW} is connected to V_{DD} through the internal power switch (see Section 6.4.3: Backup domain).

Figure 27. V_{BAT} thresholds

1. For thresholds and hysteresis values, refer to the datasheets.



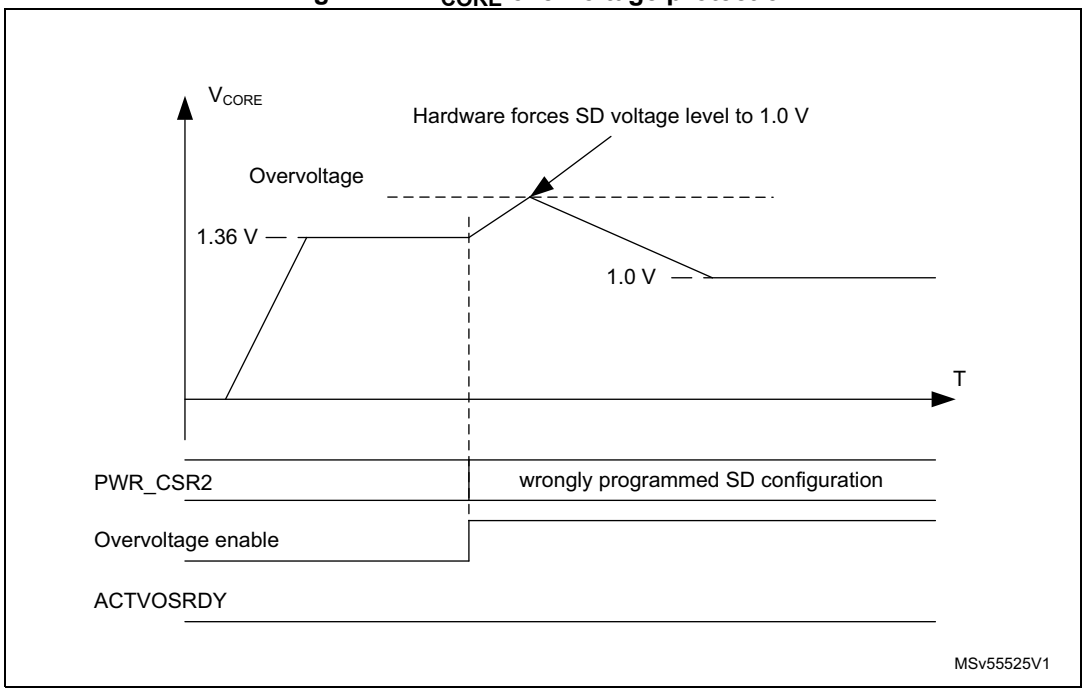
6.5.6 Temperature thresholds

The junction temperature can be monitored by comparing it with two threshold levels, $TEMP_{high}$ and $TEMP_{low}$. TEMPH and TEMPL flags, in the *PWR control status register 1 (PWR_CSR1)*, indicate whether the device temperature is higher or lower than the threshold. The temperature monitoring can be enabled/disabled via the MONEN bit in the *PWR control status register 1 (PWR_CSR1)*. When enabled, the temperature thresholds increase power consumption. As an example the levels could be used to trigger a routine to perform temperature control tasks.

The temperature thresholds are available only when the backup regulator is enabled (BREN bit set in the PWR_CSR1 register).

TEMPH and TEMPL wakeup interrupts are available on the RTC tamper signals (see *Section 42: Real-time clock (RTC)*).

Figure 28. Temperature thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

6.5.7 V_{CORE} maximum voltage level detector

V_{CORE} is protected against too high voltages in the direct SMPS step-down converter supply configuration. V_{CORE} overvoltage protection is enabled at startup by hardware once the SMPS step-down converter configuration has been programmed into *PWR control status register 2 (PWR_CSR2)*:

- V_{CORE} voltage level stays within range:
  - ACTVOSRDY bit in the *PWR status register 1 (PWR_SR1)* indicate valid voltage levels.
  - The system operates normally and V_{CORE} overvoltage protection is disabled.
- V_{CORE} overvoltage (due to a wrongly programmed SMPS step-down converter configuration):
  - The hardware forces the SMPS step-down converter voltage level to 1.0 V.
  - The ACTVOSRDY goes on indicating invalid voltage levels. In this case the software must be corrected and re-loaded to program a correct SMPS step-down converter configuration that matches the application supply connections. The system must then be power cycled.

Figure 29. V_{CORE} overvoltage protection

6.6 Power management

The power management block controls the V_{CORE} supply in accordance with the system operation modes (see *Section 6.6.1*).

The device power domains can operate in one of the following operating modes:

- Run (power ON, clock ON)
- Sleep (power ON, core clock stopped, peripherals keep running)
- Stop (power ON, clock OFF)
- Standby (power OFF, clock OFF).

The V_{CORE} supply level follows the system operating mode (Run, Stop, Standby).

The following voltage scaling features allow controlling the power with respect to the required system performance (see *Section 6.6.2: Voltage scaling*):

- To obtain a given system performance, the corresponding voltage scaling must be set in accordance with the system clock frequency. To do this, configure the VOS bits to the Run mode voltage scaling.
- To obtain the best trade-off between power consumption and exit-from-Stop mode latency, configure the SVOS bit to Stop mode voltage scaling.

6.6.1 Operating modes

Several system operating modes are available to tune the system according to the performance required, that is, when the CPU does not need to execute code and are waiting for an external event. It is up to the user to select the operating mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

The operating modes allow controlling the clock distribution to the different system blocks and powering them.

In Run mode, power consumption can be reduced by one of the following means:

- Lowering the system performance by slowing down the system clocks and reducing the V_{CORE} supply level through VOS voltage scaling bit.
- Gating the clocks to the APBx and AHBx peripherals when they are not used, through PERxEN bits.

Table 40. Operating mode summary

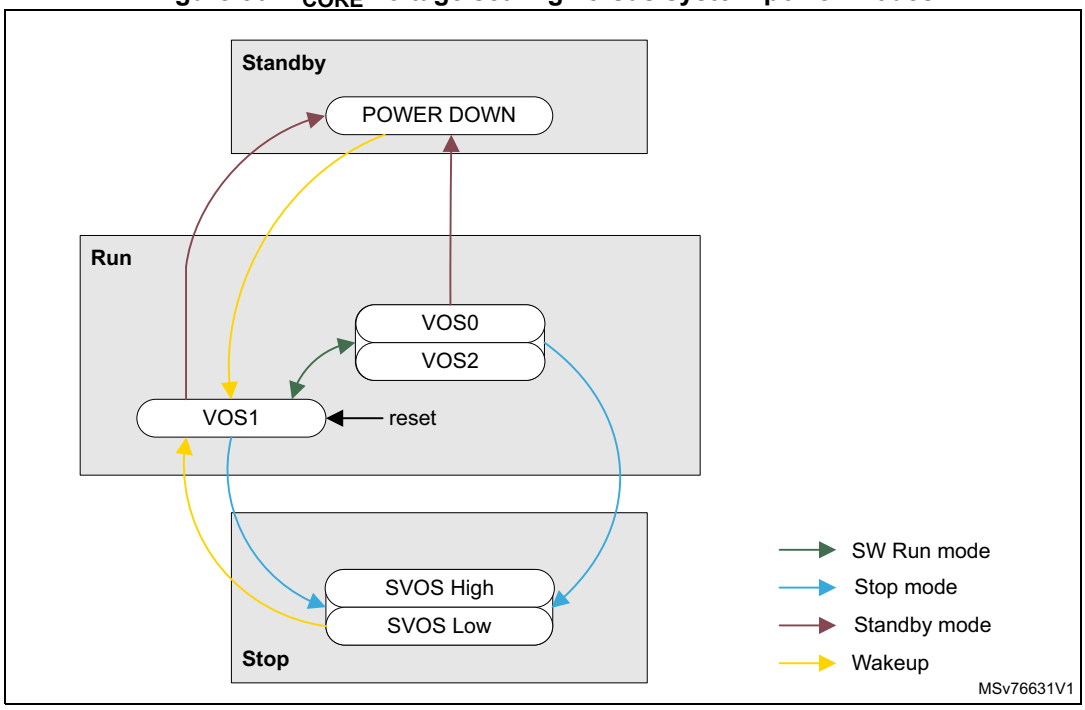
System	Entry	Wakeup	System oscillator	System clock	Peripheral clock	CPU clock	Voltage regulator
Run	-	-	ON	ON	ON	ON	ON (VOS)
Sleep	WFI or return from ISR or WFE	Any interrupt or event			ON/OFF(1)	OFF	
Stop	SLEEPDEEP bit + WFI or return from ISR or WFE or Wakeup source cleared(2)	Any EXTI interrupt or event	ON/OFF(3)	OFF			ON (SVOS)
Standby	PDDS bit + SLEEPDEEP bit + WFI or return from ISR or WFE or Wakeup source cleared(2)	WKUP pins rising or falling edge, RTC alarm (Alarm A or Alarm B), RTC Wakeup event, RTC tamper events, RTC time stamp event, external reset in NRST pin, IWDG reset	OFF		OFF		OFF

1. The CPU subsystem peripherals that have a PERxLPEN bit operate accordingly.
2. When the CPU is in Stop the last EXTI Wakeup source should be cleared by SW.
3. When the system oscillator HSI or CSI is used, the state is controlled by HSIKERON and CSIKERON, otherwise the system oscillator is OFF.

6.6.2 Voltage scaling

The V_{CORE} domain is supplied from a single voltage regulator supporting voltage scaling with the following features:

- Run mode voltage scaling
  - VOS2
  - VOS1
  - VOS0
- Stop mode voltage scaling
  - SVOS low
  - SVOS high



For more details on voltage scaling values, refer to the product datasheet.

After reset, the system starts up at the default Run mode voltage scaling (VOS1). The voltage scaling can then be changed on-the-fly by software by programming the VOS bit field in the *PWR control status register 4 (PWR_CSR4)* according to the required system performance. When exiting from Stop mode or Standby mode, the Run mode voltage scaling is reset to the default VOS1 value.

Before entering Stop mode, the software can preselect the SVOS level in *PWR control register 1 (PWR_CR1)*. The Stop mode voltage scaling for SVOS low and SVOS high also sets the voltage regulator in Low-power (LP) mode to further reduce power consumption.

In Standby mode the VCORE supply is switched off.

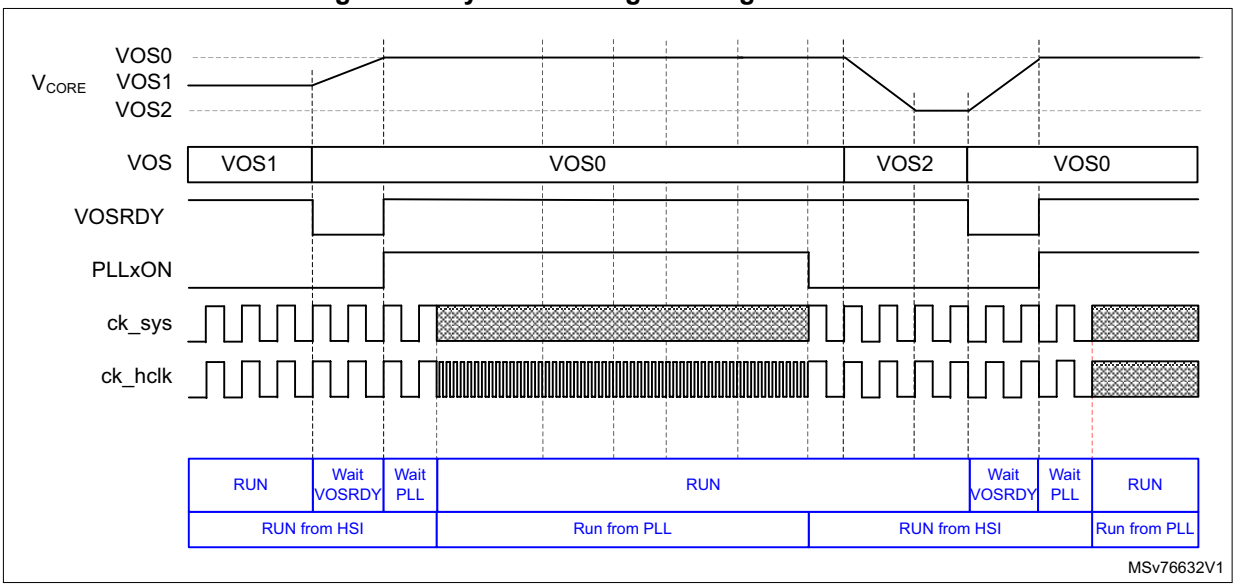
Figure 30. V_{CORE} voltage scaling versus system power modes

6.6.3 Power management examples

- *Figure 31* shows V_{CORE} voltage scaling behavior in Run mode.
- *Figure 32* shows V_{CORE} voltage scaling behavior in Stop mode.
- *Figure 33* shows V_{CORE} voltage regulator and voltage scaling behavior in Standby mode.

Example of V_{CORE} voltage scaling behavior in Run mode

Figure 31 illustrates the following system operation sequence example:



1. After reset, the system starts from HSI with VOS1.
2. The system performance is then increased to a high-speed clock from the PLL with voltage scaling VOS0. To do this:
   a) Program the voltage scaling to VOS0.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.
3. The next step is to reduce the system performance to HSI clock with voltage scaling VOS2. To do this:
   a) Switch the clock to HSI.
   b) Disable the PLL.

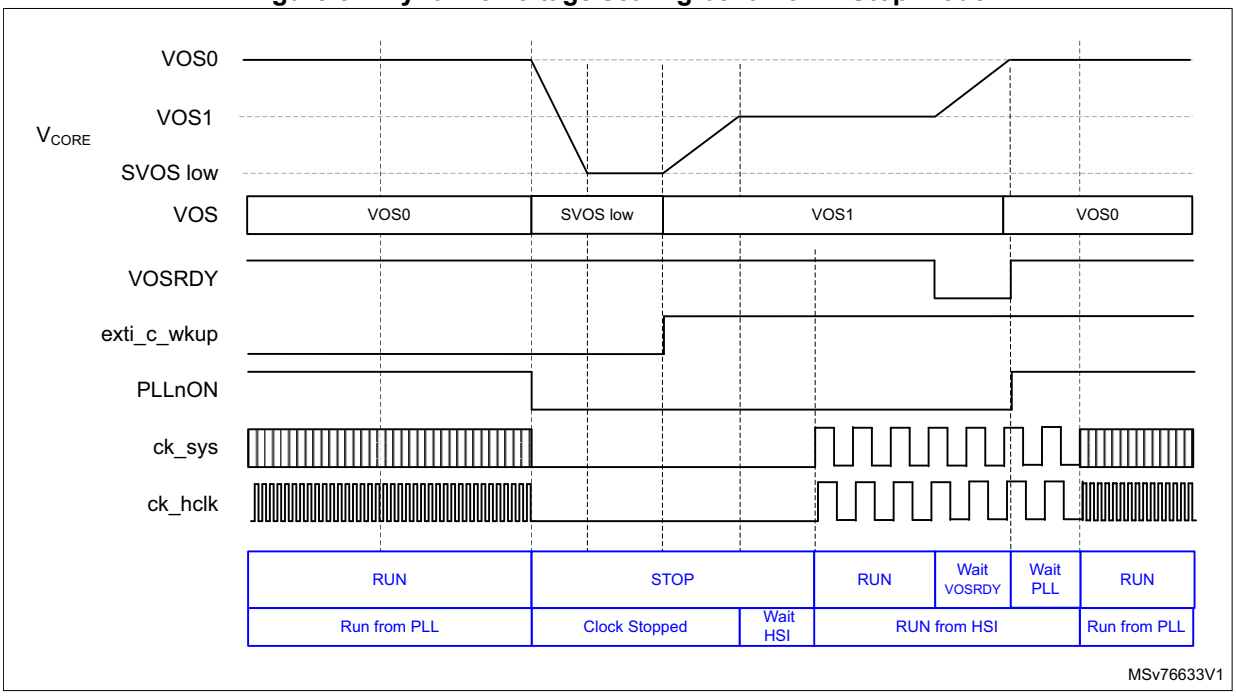
c) Decrease the voltage scaling to VOS2.

4. The system performance can then be increased to high-speed clock from the PLL. To do this:
   a) Program the voltage scaling to VOS0.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.

When the system performance (clock frequency) is changed, VOS must be set accordingly. Otherwise the system might be unreliable.

Figure 31. Dynamic voltage scaling in Run mode

1. The status of the register bits at each step is shown in blue.



Example of V_{CORE} voltage scaling behavior in Stop mode

Figure 32 illustrates the following system operation sequence example:

1. The system is running from the PLL in high-performance mode (VOS0 voltage scaling).
2. First the CPU subsystem deallocates all the peripheral, in a second step, the CPU subsystem enters Stop mode and the system enters Stop mode. The system clock is stopped and the hardware lowers the voltage scaling to the software preselected SVOS low.

3. The CPU subsystem is then woken up. The system exits from Stop mode and the CPU subsystem exits from Stop mode. The hardware always sets the voltage scaling to VOS1 after exiting from Stop mode and waits for the requested supply level to be reached before enabling the HSI clock. Once the HSI clock is stable, the system clock is enabled and switch in run mode under HSI clock.
4. The system performance could then be increased. To do this:
   a) The software first sets the voltage scaling to VOS0.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, the clock frequency can be increased by enabling the PLL.
   c) Once the PLL is locked, the system clock can be switched.

Figure 32. Dynamic voltage scaling behavior in Stop mode

1. The status of the register bits at each step is shown in blue.

Example of V_{CORE} voltage regulator and voltage scaling behavior in Standby mode

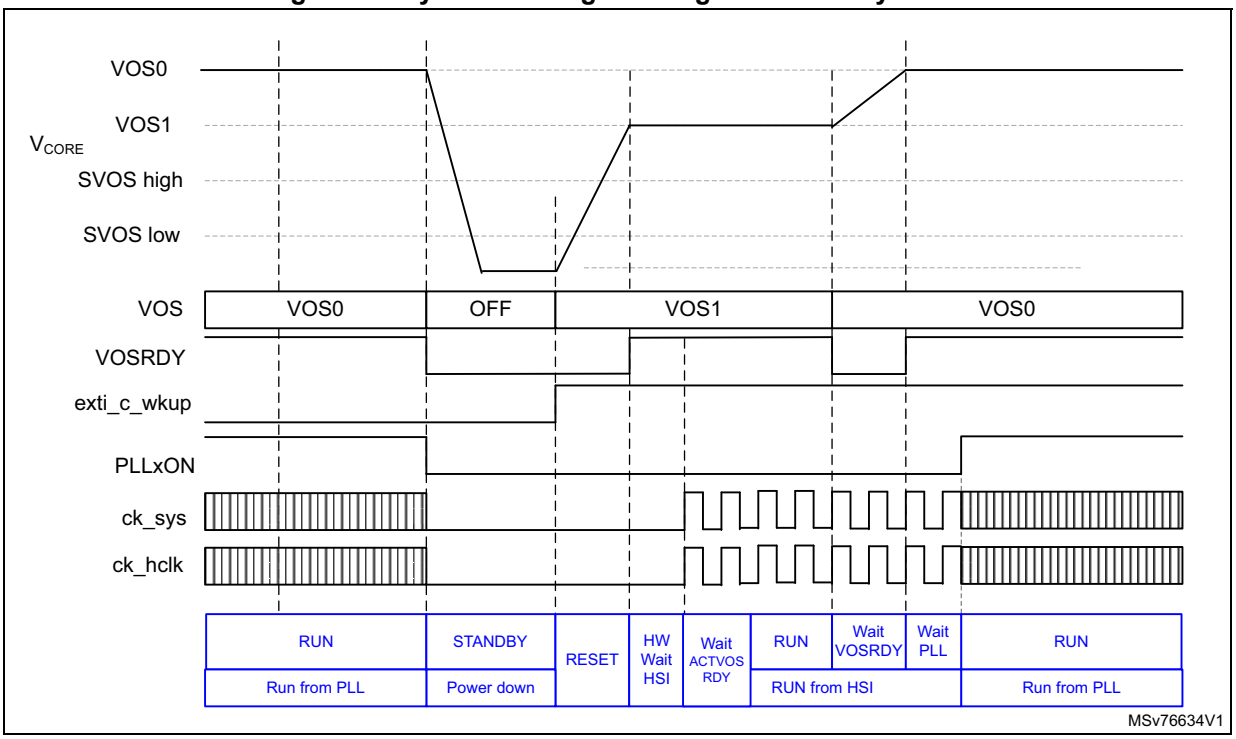


Figure 33 illustrates the following system operation sequence example:

1. The system is running from the PLL in high-performance mode (VOS0 voltage scaling).
2. The CPU subsystem deallocates all the peripherals and the power is switched off. The system enters in standby mode.
3. The system is then woken up by a wakeup source. The system exits from Standby mode. The hardware sets the voltage scaling to the default VOS1 and waits for the requested supply level to be reached before enabling the default HSI oscillator. Once

the HSI clock is stable, the system clock is enabled. The software must then check the ACTVOSRDY is valid before changing the system performance.

4. In a next step, increase the system performance. To do this:
   a) The software first increases the voltage scaling to VOS0.
   b) Before enabling the PLL, it waits for the requested supply level to be reached by monitoring VOSRDY bit.
   c) Once the PLL is locked, the system clock can be switched.

Figure 33. Dynamic voltage scaling from Standby mode

1. The status of the register bits at each step is shown in blue.

6.7 Low-power modes

Several low-power modes are available to save power when the CPU does not need to execute code (i.e. when waiting for an external event). It is up to the user application to select the mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources:

- Slowing down system clocks (see *Section 7.5.6: System clock (sys_ck)*)
- Controlling individual peripheral clocks (see *Section 7.5.12: Peripheral clock gating control*)
- Low-power modes
  - Sleep (CPU clock stopped and still in Run mode)
  - Stop (System clock stopped)
  - Standby (System powered down)

6.7.1 Slowing down system clocks

In Run mode, the speed of the system clock sys_ck can be reduced. For more details refer to *Section 7.5.6: System clock (sys_ck)*.

6.7.2 Controlling peripheral clocks

In Run mode, the HCLKx and PCLKx for individual peripherals can be stopped by configuring at any time PERxEN bit in RCC_xxxxENR to reduce power consumption.

To reduce power consumption in CSleep mode, the individual peripheral clocks can be disabled by configuring PERxLPEN bit in RCC_xxxxLPENR. For the peripherals still receiving a clock in Sleep mode, their clock can be slowed down before entering Sleep mode.

Example: for APB2 peripherals: the RCC register is named: RCC_APB2ENR, this register contains SPI4EN and so on.

6.7.3 Entering low-power modes

CPU subsystem Sleep and Stop low-power modes are entered by the MCU when executing the WFI (Wait For Interrupt) or WFE (wait for event) instructions, or when the SLEEPONEXIT bit in the Cortex®-M system control register is set on return from ISR.

The system can enter Stop or Standby low-power mode when all EXTI wakeup sources are cleared.

6.7.4 Exiting from low-power modes

The CPU subsystem exits from Sleep mode through any interrupt or event depending on how the low-power mode was entered:

- If the WFI instruction or return from ISR was used to enter to low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the system.
- If the WFE instruction is used to enter to low-power mode, the CPU exits from low-power mode as soon as an event occurs. The wakeup event can be generated either by:
  - An NVIC IRQ interrupt.

    When SEVONPEND = 0 in the Cortex®-M7 system control register, the interrupt must be enabled in the peripheral control register and in the NVIC.

    When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit in the NVIC interrupt clear pending register have to be cleared. Only NVIC interrupts with sufficient priority wake up and interrupts the MCU.

    When SEVONPEND = 1 in the Cortex®-M7 system control register, the interrupt must be enabled in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and, when

enabled, the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

All NVIC interrupts wakeup the MCU, even the disabled ones.

Only enabled NVIC interrupts with sufficient priority wakeup and interrupt the MCU.

– An event

An EXTI line must be configured in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It might be necessary to clear the interrupt flag in the peripheral.

The CPU subsystem exits from Stop modes by enabling an EXTI interrupt or event depending on how the low-power mode was entered (see above).

The CPU subsystem exits from Standby mode by enabling an EXTI interrupt or event. Program execution restarts from CPU local reset (such as a reset vector fetched from the system configuration boot and security block (SBS).

The CPU subsystem exits from Standby mode by enabling an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or an RTC event. Program execution restarts in the same way as after a system reset (such as boot pin sampling, option bytes loading or reset vector fetched).

6.7.5 Sleep mode

The Sleep mode applies only to the CPU subsystem. In Sleep mode, the CPU clock is stopped. The CPU subsystem peripheral clocks operate according to the values of PERxLPEN bits in RCC_xxxxENR.

Entering Sleep mode

The Sleep mode is entered according to *Section 6.7.3: Entering low-power modes*, when the SLEEPDEEP bit in the Cortex®-M System Control register is cleared.

Refer to *Table 41* for details on how to enter to Sleep mode.

Exiting from Sleep mode

The Sleep mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

Refer to *Table 41* for more details on how to exit from Sleep mode.

Table 41. Sleep mode

Sleep mode	Description
Mode entry	WFI (Wait for Interrupt) or WFE (Wait for Event) while: – SLEEPDEEP = 0 (refer to the Cortex®-M System Control register.) – CPU NVIC interrupts and events cleared.
	On return from ISR while: – SLEEPDEEP = 0 and – SLEEPONEXIT = 1 (refer to the Cortex®-M System Control register.) – CPU NVIC interrupts and events cleared.
Mode exit	If WFI or return from ISR was used for entry: – Any Interrupt enabled in NVIC: Refer to *Table 110: NVIC* If WFE was used for entry and SEVONPEND = 0: – Any event: Refer to *Section 16.5.3: EXTI CPU wake-up procedure* If WFE was used for entry and SEVONPEND = 1: – Any Interrupt even when disabled in NVIC: refer to *Table 110: NVIC* or any event: refer to *Section 16.5.3: EXTI CPU wake-up procedure*
Wakeup latency	None

6.7.6 Stop mode

The Stop mode applies to the MCU. In Stop mode, the CPU clock is stopped. All CPU subsystem peripheral clocks are stopped too.

In Stop mode, CPU subsystem peripherals having a kernel clock request can still request their kernel clock.

The flash memory can enter low-power Stop mode when it is enabled through FLPS in PWR_CR1 register. This allows a trade-off between domain Stop restart time and low-power consumption.

The HSI or CSI can remain enabled in system Stop mode (HSIKERON and CSIKERON set in RCC_CR register). After exiting Stop mode, the clock is quickly available as kernel clock

for peripherals. Other system oscillator sources are stopped in Stop mode and require a starting time after exiting Stop mode.

In Stop mode and SVOS high, peripherals using the LSI or LSE clock and peripherals having a kernel clock request are still able to operate.

In system Stop mode, the following features can be selected to remain active by programming individual control bits:

- Independent watchdog (IWDG)

  The IWDG is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 40.4* in *Section 40: Independent watchdog (IWDG)*.
- Real-time clock (RTC)

  This is configured via the RTCEN bit in the *RCC Backup domain control register (RCC_BDCR)*.
- Internal RC oscillator (LSI RC)

  This is configured via the LSION bit in the *RCC clock control and status register (RCC_CSR)*.
- External 32.768 kHz oscillator (LSE OSC)

  This is configured via the LSEON bit in the *RCC Backup domain control register (RCC_BDCR)*.
- Peripherals capable of running on the LSI or LSE clock.
- Peripherals having a kernel clock request.
- Internal RC oscillators (HSI and CSI)

  This is configured via the HSIKERON and CSIKERON bits in the *RCC source control register (RCC_CR)*.
- The ADC can also consume power during Stop mode, unless it is disabled before entering this mode. To disable them, the ADON bit in the ADC_CR2 register must be written to 0.

The selected SVOS low levels add an additional startup delay when exiting from system Stop mode (see *Table 42*).

Table 42. Stop mode operation

SVOS	Stop mode Voltage regulator operation	Wake-up Latency
SVOS high	**LP**	Voltage regulator wakeup time from SVOS high LP mode to VOS low
SVOS low	**LP**	Voltage regulator wakeup time from SVOS low LP mode to VOS low

Entering Stop mode

The Stop mode is entered according to *Section 6.7.3: Entering low-power modes*, when the SLEEPDEEP bit in the Cortex®-M system control register is set.

If flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the domain bus matrix is ongoing, the Stop mode entry is delayed until the domain bus matrix access is complete.

See *Table 43* below for details on how to enter to Stop mode.

Table 43. Stop mode

Stop mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP = 1 (refer to the Cortex®-M System control register.) – CPU NVIC interrupts and events cleared. – All CPU EXTI wakeup sources are cleared.
	On return from ISR while: – SLEEPDEEP = 1 and – SLEEPONEXIT = 1 (refer to the Cortex®-M system control register.) – CPU NVIC interrupts and events cleared. – All CPU EXTI wakeup sources are cleared.
Mode exit	If WFI or return from ISR was used for entry: – EXTI interrupt enabled in NVIC: refer to *Table 110: NVIC*, for peripheral which are not stopped or powered down. If WFE was used for entry and SEVONPEND = 0: – EXTI event: refer to *Section 16.5.3: EXTI CPU wake-up procedure*, for peripheral which are not stopped or powered down. If WFE was used for entry and SEVONPEND = 1: – EXTI interrupt even when disabled in NVIC: refer to *Table 110: NVIC* or EXTI event: refer to *Section 16.5.3: EXTI CPU wake-up procedure*, for peripheral which are not stopped or powered down.
Wakeup latency	EXTI and RCC wakeup synchronization (see *Section 7.4.11: Power-on and wakeup sequences*)

To allow peripherals having a kernel clock request to operate in Stop mode, the system must use SVOS high.

Note: Use a DSB instruction to ensure that outstanding memory transactions complete before entering stop mode.

Exiting from Stop mode

The Stop mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

Refer to *Table 43: Stop mode* for more details on how to exit from Stop mode.

When exiting from Stop mode, the system clock, bus matrix clocks and voltage scaling are reset.

STOPF status flag in the *PWR CPU control status register 3 (PWR_CSR3)* indicates that the system has exited from Stop mode.

I/O states in Stop mode

I/O pin configuration remains unchanged in Stop mode.

6.7.7 Standby mode

The Standby mode allows achieving the lowest power consumption. Like Stop mode, it is based on CPU subsystem Stop mode. However the V_{CORE} supply regulator is powered off.

When the system enters in Standby mode, the voltage regulator is disabled. The complete V_{CORE} domain is consequently powered off. The PLLs, HSI oscillator, CSI oscillator, HSI48 and the HSE oscillator are also switched off. SRAM and register contents are lost except for backup domain registers (RTC registers, RTC backup register and backup RAM), and Standby circuitry (see *Section 6.4.3: Backup domain*).

In system Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG)

  The IWDG is started by programming its key register or by hardware option. Once started, it cannot be stopped except by a reset (see *Section 40.4* in *Section 40: Independent watchdog (IWDG)*.
- Real-time clock (RTC)

  This is configured via the RTCEN bit in the backup domain control register (RCC_BDCR).
- Internal RC oscillator (LSI RC)

  This is configured by the LSION bit in the RCC clock control and status register (RCC_CSR).
- External 32.768 kHz oscillator (LSE OSC)

  This is configured by the LSEON bit in the backup domain control register (RCC_BDCR).

Entering Standby mode

The Standby mode is entered according to *Section 6.7.3: Entering low-power modes*, when the PDDS bits in the *PWR CPU control status register 3 (PWR_CSR3)* are set to one.

If flash memory programming is ongoing, the Standby mode entry is delayed until the memory access is finished.

Refer to *Table 45* for more details on how to enter to Standby mode.

Exiting from Standby mode

The Standby mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

The system exits from Standby mode when an external reset (NRST pin), an IWDG reset, a WKUP pin event, an RTC alarm, a tamper event, or a time stamp event is detected. All registers are reset after waking up from Standby except for power control and status registers (*PWR control status register 2 (PWR_CSR2)*, *PWR CPU control status register 3 (PWR_CSR3)*), SBF bit in the *PWR CPU control status register 3 (PWR_CSR3)*, *PWR wakeup flag register (PWR_WKUPFR)*, and *PWR wakeup enable and polarity register (PWR_WKUPEPR)*.

After waking up from Standby mode, the program execution restarts in the same way as after a system reset (boot option sampling, boot vector reset fetched, etc.). The SBF status flags in the *PWR CPU control status register 3 (PWR_CSR3)* registers indicate from which mode the system has exited (refer to *Table 45*).

Table 44. Standby and Stop flags

SBF	STOPF	Description
0	1	System has been in Stop
1	0	System has been in Standby

Table 45. Standby mode

Standby mode	Description
Mode entry	– The CPU subsystem is in Stop mode, and there is no active EXTI wakeup source. – PDDS bit for select Standby. – All WKUPF bits in the PWR wakeup flag register (PWR_WKUPFR) are cleared.
Mode exit	– WKUP pins rising or falling edge, RTC alarm (Alarm A and Alarm B), RTC wakeup, tamper event, time stamp event, external reset in NRST pin, IWDG reset.
Wakeup latency	System reset phase (see *Section 7.4.2: The system and application resets (sys_rst and nreset)*)

I/O states in Standby mode

In Standby mode, all I/O pins are high impedance without pull, except for:

- Reset pad (still available)
- RTC_AF1 pin if configured for tamper, time stamp, RTC Alarm out, or RTC clock calibration out
- WKUP pins (if enabled). The WKUP pin pull configuration can be defined through WKUPPUPD register bits in the *PWR wakeup enable and polarity register (PWR_WKUPEPR)*
- I3C pin pull-up as configured in *PWR I3C pull-up control register (PWR_I3CPUCR)*, if enabled by the APC bit in *PWR apply pull register (PWR_APCR)*.
- XSPI control pin pull-up/down as configured in *PWR XSPI pull-up control register (PWR_XSPIPUCR)*, and *PWR XSPI pull-down control register (PWR_XSPIPDCR)*, if enabled by the APC bit in *PWR apply pull register (PWR_APCR)*

6.7.8 Monitoring low-power modes

The devices feature state monitoring pins to monitor the state transition to low-power mode (refer to *Table 46* for the list of pins and their description). The GPIO pin corresponding to each monitoring signal has to be programmed in alternate function mode.

This feature is not available in Standby mode since these I/O pins are switched to high impedance.

Table 46. Low-power modes monitoring pin overview

Power state monitoring pins	Description
PWR_CSLEEP (CSLEEP)	Sleeping CPU state
PWR_CSTOP (CDSLEEP)	Deepsleep CPU state

The values of the monitoring pins reflect the state of the CPU and domains. Refer to *Table 47* for the GPIO state depending on CPU and domain state.

Table 47. GPIO state according to CPU and domain state

CPU		CPU power state	Power mode
CSLEEP	CDSLEEP		
0	0	CPU in Run mode	Run mode
1	0	CPU in Sleep mode	
0	1	CPU in Run mode	
1	1	CPU in Deepsleep mode	Stop mode
-	-	-(1)	Standby mode

1. The CPU is powered off.

6.8 PWR registers

The PWR registers can be accessed in word, half-word and byte format, unless otherwise specified.

6.8.1 PWR control register 1 (PWR_CR1)

Address offset: 0x000

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALS[1:0]		AVDEN	AVDREADY	BOOSTE	Res.	FLPS	DBP	PLS[2:0]			PVDE	Res.	Res.	Res.	SVOS
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw				rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **ALS[1:0]**: Analog voltage detector level selection

These bits select the voltage threshold detected by the AVD.

00: AVD level 1

01: AVD level 2

10: AVD level 3

11: AVD level 4

Note: Refer to Section "Electrical characteristics" of the product datasheet for more details.

Bit 13 **AVDEN**: Peripheral voltage monitor on V_{DDA} enable

0: Peripheral voltage monitor on V_{DDA} disabled

1: Peripheral voltage monitor on V_{DDA} enabled

Bit 12 **AVDREADY**: Analog voltage ready

This bit is only used when the analog switch boost needs to be enabled (see BOOSTE bit).

It must be set by software when the expected $_{VDD}$A analog supply level is available.

The correct analog supply level is indicated by the AVDO bit (PWR_CSR1 register) after setting the AVDEN bit and selecting the supply level to be monitored (ALS bits).

0: peripheral analog voltage V_{DDA} not ready (default)

1: peripheral analog voltage V_{DDA} ready

Bit 11 **BOOSTE**: Analog switch VBoost control

This bit enables the booster to guarantee the analog switch AC performance when the V_{DD} supply voltage is below 2.7 V (reduction of the total harmonic distortion to have the same switch performance over the full supply voltage range).

The V_{DD} supply voltage can be monitored through the PVD and the PLS bits.

0: booster disabled (default)

1: booster enabled if analog voltage ready (AVD_READY = 1)

Bit 10 Reserved, must be kept at reset value.

Bit 9 **FLPS**: Flash low-power mode in Stop mode

This bit allows to obtain the best trade-off between low-power consumption and restart time when exiting from Stop mode.

When it is set, the flash memory enters low-power mode when device is in Stop mode.

0: Flash memory remains in normal mode when device enters Stop (quick restart time).

1: Flash memory enters low-power mode when device enters Stop mode (low-power consumption).

Bit 8 **DBP**: Disable backup domain write protection

In reset state, the RCC_BDCR register, the RTC registers (including the backup registers), the backup SRAM, and the BREN and MONEN bits in the PWR_CSR1 register, are protected against parasitic write access.

This bit must be set to enable access to these registers.

0: Read and write access to RTC and RTC backup registers disabled and backup SRAM write access disabled

1: Read and write access to RTC, RTC backup registers and backup SRAM enabled

Bits 7:5 **PLS[2:0]**: Programmable voltage detector level selection

These bits selects the condition below which the PVD output (PVDO bit in *PWR status register 1 (PWR_SR1)*) goes high:

000: V_{DD} < PVD level 1

001: V_{DD} < PVD level 2

010: V_{DD} < PVD level 3

011: V_{DD} < PVD level 4

100: V_{DD} < PVD level 5

101: V_{DD} < PVD level 6

110: V_{DD} < PVD level 7

111: PVD_IN < VREFINT

Note: Refer to Section "Electrical characteristics" of the product datasheet for more details.

Bit 4 **PVDE**: Programmable voltage detector enable

0: Programmable voltage detector disabled.

1: Programmable voltage detector enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **SVOS**: System Stop mode voltage scaling selection

0: SVOS low

1: SVOS high (default)

6.8.2 PWR status register 1 (PWR_SR1)

Address offset: 0x004

Reset value: 0x0000 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	AVDO	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDO	Res.	ACTVOSRDY	ACTVOS[1:0]	
		r									r		r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **AVDO**: Analog voltage detector output on V_{DDA}

This bit is set and cleared by hardware. It is valid only if AVD on V_{DDA} is enabled by the AVDEN bit.

0: V_{DDA} is equal or higher than the AVD threshold selected with the ALS[1:0] bits.

1: V_{DDA} is lower than the AVD threshold selected with the ALS[1:0] bits

Note: Since the AVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the AVDEN bit is set

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **PVDO**: Programmable voltage detect output

This bit is set and cleared by hardware. It is valid only if the PVD has been enabled by the PVDE bit.

0: V_{DD} or PVD_IN voltage is equal or higher than the PVD threshold selected through the PLS[2:0] bits.

1: V_{DD} or PVD_IN voltage is lower than the PVD threshold selected through the PLS[2:0] bits.

Note: Since the PVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the PVDE bit is set.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **ACTVOSRDY**: Voltage levels ready bit for currently used ACTVOS

This bit is set to 1 by hardware when the voltage regulator and the SMPS step-down converter are both disabled and Bypass mode is selected in PWR control register 2 (PWR_CSR2).

0: Voltage level invalid, above or below current ACTVOS selected levels.

1: Voltage level valid, at current ACTVOS selected levels.

Bits 1:0 **ACTVOS[1:0]**: VOS currently applied for V_{CORE} voltage scaling selection

These bit reflect the last VOS value applied to the PMU.

00: Reserved

01: VOS2

10: VOS1

11: VOS0

6.8.3 PWR control status register 1 (PWR_CSR1)

Address offset: 0x008

Reset value: 0x0000 0000

This register is not reset by wakeup from Standby mode, RESET signal and V_{DD} POR. It is only reset by V_{SW} POR and VSWRST reset.

This register must not be accessed when the VSWRST bit in the RCC_BDCR register resets the V_{SW} domain.

After reset, the PWR_CSR1 register is write-protected. Prior to modifying its content, the DBP bit in the PWR_CR1 register must be set to disable the write protection.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TEMPH	TEMPL	VBATH	VBATL	Res.	Res.	Res.	BRRDY
								r	r	r	r				r

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MONEN	Res.	Res.	Res.	BREN
											rw				rw

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TEMPH**: Temperature level monitoring versus high threshold
0: Temperature below high threshold level.
1: Temperature equal or above high threshold level.

Bit 22 **TEMPL**: Temperature level monitoring versus low threshold
0: Temperature above low threshold level.
1: Temperature equal or below low threshold level.

Bit 21 **VBATH**: V_{BAT} level monitoring versus high threshold
0: V_{BAT} level below high threshold level.
1: V_{BAT} level equal or above high threshold level.

Bit 20 **VBATL**: V_{BAT} level monitoring versus low threshold
0: V_{BAT} level above low threshold level.
1: V_{BAT} level equal or below low threshold level.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **BRRDY**: Backup regulator ready
This bit is set by hardware to indicate that the backup regulator is ready.
0: Backup regulator not ready.
1: Backup regulator ready.

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **MONEN:** V_{BAT} and temperature monitoring enable
When set, the V_{BAT} supply and temperature monitoring is enabled.
0: V_{BAT} and temperature monitoring disabled.
1: V_{BAT} and temperature monitoring enabled.
Note: V_{BAT} and temperature monitoring are only available when the backup regulator is enabled (BREN bit set to 1).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **BREN:** Backup regulator enable
When set, the backup regulator (used to maintain the backup RAM content in Standby and V_{BAT} modes) is enabled.
If BREN is reset, the backup regulator is switched off. The backup RAM can still be used in Run and Stop modes. However, its content is lost in Standby and V_{BAT} modes.
If BREN is set, the application must wait till the backup regulator ready flag (BRRDY) is set to indicate that the data written into the SRAM is maintained in Standby and V_{BAT} modes.
0: Backup regulator disabled.
1: Backup regulator enabled.

6.8.4 PWR control status register 2 (PWR_CSR2)

Address offset: 0x00C

Reset value: 0x0000 0006

This register is reset only by a power-on reset (POR). It is not reset by a wakeup from Standby mode or RESET signal.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	VBRS	VBE	Res.	Res.	Res.	Res.	Res.	SMPSEN	LDOEN	BYPASS
						rw	rw						r	r	rwo

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SDRDY**: Integrated SMPS step-down converter supply ready
This bit is set by hardware to indicate that the supply from the SMPS step-down converter is ready.
0: SMPS supply not ready.
1: SMPS supply ready.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **VBRS**: V_{BAT} charging resistor selection
0: Charge V_{BAT} through a 5 kΩ resistor.
1: Charge V_{BAT} through a 1.5 kΩ resistor.

Bit 8 **VBE**: V_{BAT} charging enable
0: V_{BAT} battery charging disabled.
1: V_{BAT} battery charging enabled.

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SMPSEN**: Integrated SMPS step-down converter enable (read only)
This bit is valid only when BYPASS has been programmed once after power-up.
0: SMPS step-down converter disabled
1: SMPS step-down converter enabled

Bit 1 **LDOEN**: Integrated low drop-out regulator enable (read only)
This bit is valid only when BYPASS has been programmed once after power-up.
0: Low drop-out regulator disabled
1: Low drop-out regulator enabled

Bit 0 **BYPASS**: Power management unit bypass
This bit must be programmed after power-up to select the V_{CORE} supply configuration (internal or external). After programming it can not be changed without a power down reset.
0: Internal supply (LDO or SMPS)
1: External supply.

6.8.5 PWR CPU control status register 3 (PWR_CSR3)

This register allows controlling the CPU power.

Address offset: 0x010

Reset value: 0x0000 0000

After Standby Reset value: 0x0000 0200

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	SBF	STOPF	Res.	Res.	Res.	Res.	Res.	Res.	CSSF	PDDS
						r	r							rc_w1	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **SBF**: System Standby flag
This bit is set by hardware and cleared only by a POR (power-on reset) or by setting the CPU CSSF bit.
0: System has not been in Standby mode
1: System has been in Standby mode

Bit 8 **STOPF**: Stop flag
This bit is set by hardware and cleared only by any reset or by setting the CPU CSSF bit.
0: System has not been in Stop mode
1: System has been in Stop mode

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CSSF**: Clear Standby and Stop flags (always read as 0)
This bit is cleared to 0 by hardware.
0: No effect.
1: flags (STOPF, SBF) are cleared.

Bit 0 **PDDS**: Power-down Deepsleep.
This bit allows CPU to define the Deepsleep mode
0: Stop mode when device enters Deepsleep.
1: Standby mode when device enters Deepsleep.

6.8.6 PWR control status register 4 (PWR_CSR4)

Address offset: 0x014

Reset value: 0x0000 0006

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VOSRDY	VOS[1:0]	
													r	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **VOSRDY**: VOS ready bit for V_{CORE} voltage scaling output selection.
When an internal regulator is used, this bit indicates that all the features allowed by the selected VOS can be used.
Note: When Bypass mode is selected in the PWR control register (PWR_CSR2), VOSRDY bit is set to 1 by hardware whatever the V_{CORE} level.
0: Not ready, voltage level below VOS selected level.
1: Ready, voltage level at or above VOS selected level.

Bits 1:0 **VOS[1:0]**: Voltage scaling selection according to performance
When an internal regulator is used, these bits control the V_{CORE} voltage level to obtain the best trade-off between power consumption and performance:
- When increasing the performance, the voltage scaling must be changed before increasing the system frequency.
- When decreasing performance, the system frequency must first be decreased before changing the voltage scaling.

00: Reserved
01: VOS2 (lowest power)
10: VOS1 (default)
11: VOS0 (highest frequency)
Note: Refer to section "Electrical characteristics" of the product datasheet for more details.
Note: When Bypass mode is selected in the PWR control register (PWR_CSR2), these bits have no effect

6.8.7 PWR wakeup clear register (PWR_WKUPCR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

								rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **WKUPC8**: Clear wakeup pin flag for WKUP8
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF8 flag (bit is cleared to 0 by hardware)

Bit 6 **WKUPC7**: Clear wakeup pin flag for WKUP7
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF7 flag (bit is cleared to 0 by hardware)

Bit 5 **WKUPC6**: Clear wakeup pin flag for WKUP6
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF6 flag (bit is cleared to 0 by hardware)

Bit 4 **WKUPC5**: Clear wakeup pin flag for WKUP5
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF5 flag (bit is cleared to 0 by hardware)

Bit 3 **WKUPC4**: Clear wakeup pin flag for WKUP4
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF4 flag (bit is cleared to 0 by hardware)

Bit 2 **WKUPC3**: Clear wakeup pin flag for WKUP3
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF3 flag (bit is cleared to 0 by hardware)

Bit 1 **WKUPC2**: Clear wakeup pin flag for WKUP2
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF2 flag (bit is cleared to 0 by hardware)

Bit 0 **WKUPC1**: Clear wakeup pin flag for WKUP1
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF1 flag (bit is cleared to 0 by hardware)

6.8.8 PWR wakeup flag register (PWR_WKUPFR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WKUPF8	WKUPF7	WKUPF6	WKUPF5	WKUPF4	WKUPF3	WKUPF2	WKUPF1
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **WKUPF8**: Wakeup pin WKUP8 flag

This bit is set by hardware and cleared only by a reset pin or by setting the WKUPC8 bit in the PWR wakeup clear register (PWR_WKUPCR).

0: No wakeup event occurred

1: A wakeup event was received from WKUP8 pin

Bit 6 **WKUPF7**: Wakeup pin WKUP7 flag

This bit is set by hardware and cleared only by a reset pin or by setting the WKUPC7 bit in the PWR wakeup clear register (PWR_WKUPCR).

0: No wakeup event occurred

1: A wakeup event was received from WKUP7 pin

Bit 5 **WKUPF6**: Wakeup pin WKUP6 flag

This bit is set by hardware and cleared only by a reset pin or by setting the WKUPC6 bit in the PWR wakeup clear register (PWR_WKUPCR).

0: No wakeup event occurred

1: A wakeup event was received from WKUP6 pin

Bit 4 **WKUPF5**: Wakeup pin WKUP5 flag

This bit is set by hardware and cleared only by a reset pin or by setting the WKUPC5 bit in the PWR wakeup clear register (PWR_WKUPCR).

0: No wakeup event occurred

1: A wakeup event was received from WKUP5 pin

Bit 3 **WKUPF4**: Wakeup pin WKUP4 flag

This bit is set by hardware and cleared only by a reset pin or by setting the WKUPC4 bit in the PWR wakeup clear register (PWR_WKUPCR).

0: No wakeup event occurred

1: A wakeup event was received from WKUP4 pin

Bit 2 **WKUPF3**: Wakeup pin WKUP3 flag

This bit is set by hardware and cleared only by a reset pin or by setting the WKUPC3 bit in the PWR wakeup clear register (PWR_WKUPCR).

0: No wakeup event occurred

1: A wakeup event was received from WKUP3 pin

Bit 1 **WKUPF2**: Wakeup pin WKUP2 flag

This bit is set by hardware and cleared only by a reset pin or by setting the WKUPC2 bit in the PWR wakeup clear register (PWR_WKUPCR).

0: No wakeup event occurred

1: A wakeup event was received from WKUP2 pin

Bit 0 **WKUPF1**: Wakeup pin WKUP1 flag

This bit is set by hardware and cleared only by a reset pin or by setting the WKUPC1 bit in the PWR wakeup clear register (PWR_WKUPCR).

0: No wakeup event occurred

1: A wakeup event was received from WKUP1 pin

6.8.9 PWR wakeup enable and polarity register (PWR_WKUPEPR)

Address offset: 0x028

Reset value: 0x0000 0000 (reset value after Standby: the value of the register is kept in Standby mode.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WKUPPUPD8[1:0]		WKUPPUPD7[1:0]		WKUPPUPD6[1:0]		WKUPPUPD5[1:0]		WKUPPUPD4[1:0]		WKUPPUPD3[1:0]		WKUPPUPD2[1:0]		WKUPPUPD1[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WKUP P8	WKUP P7	WKUP P6	WKUP P5	WKUP P4	WKUP P3	WKUP P2	WKUP P1	WKUP EN8	WKUP EN7	WKUP EN6	WKUP EN5	WKUP EN4	WKUP EN3	WKUP EN2	WKUP EN1
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **WKUPPUPDn[1:0]**: Wakeup pin pull configuration for WKUPn (n = 8 to 1)

These bits define the I/O pad pull configuration used when WKUPENn = 1. The associated GPIO port pull configuration must be set to the same value or to 00.

The Wakeup pin pull configuration is kept in Standby mode.

00: No pull

01: Pull-up

10: Pull-down

11: Reserved

Bits 15:8 **WKUPPn**: Wakeup pin polarity bit for WKUPn (n = 8 to 1)

These bits define the polarity used for event detection on WKUPn external wakeup pin.

0: Detection on high level (rising edge)

1: Detection on low level (falling edge)

Bits 7:0 **WKUPENn**: Enable wakeup pin WKUPn (n = 8 to 1)

Each bit is set and cleared by software.

0: An event on WKUPn pin does not wakeup the system from Standby mode.

1: A rising or falling edge on WKUPn pin wakes-up the system from Standby mode.

Note: Note: An additional wakeup event is detected if WKUPn pin is enabled (by setting the WKUPENn bit) when WKUPn pin level is already high when WKUPPn selects rising edge, or low when WKUPPn selects falling edge.

6.8.10 PWR USB Type-C and power delivery register (PWR_UCPDR)

Address offset: 0x02C

Reset value: 0x0000 0002 (reset value after Standby: the value of the register is kept in Standby mode.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UCPD_STBY	UCPD_DBDIS
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **UCPD_STBY**: UCPD Standby mode

When set, this bit is used to memorize the UCPD configuration in Standby mode.
This bit must be written to 1 just before entering Standby mode when using UCPD.
It must be written to 0 after exiting the Standby mode and before writing any UCPD registers.

Bit 0 **UCPD_DBDIS**: UCPD dead battery disable

After exiting reset, the USB Type-C “dead battery” behavior is enabled, which may have a pull-down effect on CC1 and CC2 pins. It is recommended to disable it in all cases, either to stop this pull-down or to handover control to the UCPD (the UCPD must be initialized before doing the disable).
0: UCPD dead battery pull-down behavior enabled on UCPDx_CC1 and UCPDx_CC2 pins
1: UCPD dead battery pull-down behavior disabled on UCPDx_CC1 and UCPDx_CC2 pins

6.8.11 PWR apply pull register (PWR_APCR)

Address offset: 0x030

Reset value: 0x0000 0000

(Reset value after Standby: the value of the register is kept in Standby mode.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	APC
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **APC**: Apply pull-up and pull-down configuration

0: The I/O pull-up and configurations defined in the I3C_PUCR and XSPI_PUCR/PDCR registers are not applied. The I/Os are set to the default mode in Standby (analog/Hi-Z)
1: The I/O pull-up and pull-down configurations defined in the I3C_PUCR and XSPI_PUCR/PDCR registers are applied in Standby mode and after wakeup until this bit is reset to 0.

6.8.12 PWR I3C pull-up control register (PWR_I3CPUCR)

Address offset: 0x034

Reset value: 0x0000 0000 (reset value after Standby: the value of the register is kept in Standby mode.)

rw	rw	rw	rw	rw	rw										

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **I3CPI2_PU**: Port PI2 I3C pull-up bit

When I3C is configured on PI2, this bit controls the pull-up on I3C1_SCL (PI2) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 28 **I3CPH12_PU**: Port PH12 I3C pull-up bit

When I3C is configured on PH12, this bit controls the pull-up on I3C1_SDA (PH12) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 27 **I3CPH11_PU**: Port PH11 I3C pull-up bit

When I3C is configured on PH11, this bit controls the pull-up on I3C1_SCL (PH11) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 26 **I3CPG14_PU**: Port PG14 I3C pull-up bit.

When I3C is configured on PD6, this bit controls the pull-up on I3C1_SCL (PG14) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 25 **I3CPG13_PU**: Port PG13 I3C pull-up bit

When I3C is configured on PG13, this bit controls the pull-up on I3C1_SDA (PG13) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bits 24:23 Reserved, must be kept at reset value.

Bit 22 **I3CPE6_PU**: Port PE6 I3C pull-up bit

When I3C is configured on PE6, this bit controls the pull-up on I3C1_SDA (PE6) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 21 **I3CPE5_PU**: Port PE5 I3C pull-up bit

When I3C is configured on PE5, this bit controls the pull-up on I3C1_SCL (PE5) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 20 **I3CPD7_PU**: Port PD7 I3C pull-up bit

When I3C is configured on PD7, this bit controls the pull-up on I3C1_SDA (PD7) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 19 **I3CPD6_PU**: Port PD6 I3C pull-up bit

When I3C is configured on PD6, this bit controls the pull-up on I3C1_SCL (PD6) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 18 **I3CPD1_PU**: Port PD1 I3C pull-up bit

When I3C is configured on PD1, this bit controls the pull-up on I3C1_SDA (PD1) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 17 **I3CPD0_PU**: Port PD0 I3C pull-up bit

When I3C is configured on PD0, this bit controls the pull-up on I3C1_SCL (PD0) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 16 **I3CPC9_PU**: Port PC9 I3C pull-up bit

When I3C is configured on PC9, this bit controls the pull-up on I3C1_SDA (PC9) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 15 **I3CPC8_PU**: Port PC8 I3C pull-up bit

When I3C is configured on PC8, this bit controls the pull-up on I3C1_SCL (PC8) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 14 **I3CPB9_PU**: Port PB9 I3C pull-up bit

When I3C is configured on PB9, this bit controls the pull-up on I3C1_SDA (PB9) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 13 **I3CPB8_PU**: Port PB8 I3C pull-up bit

When I3C is configured on PB8, this bit controls the pull-up on I3C1_SDA (PB8) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 12 **I3CPB4_PU**: Port PB4 I3C pull-up bit

When I3C is configured on PB4, this bit controls the pull-up on I3C1_SCL (PB4) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 11 **I3CPB3_PU**: Port PB3 I3C pull-up bit

When I3C is configured on PB3, this bit controls the pull-up on I3C1_SDA (PB3) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 10 **I3CPA15_PU**: Port PA15 I3C pull-up bit

When I3C is configured on PA15, this bit controls the pull-up on I3C1_SCL (PA15) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bits 9:0 Reserved, must be kept at reset value.

6.8.13 PWR XSPI pull-up control register (PWR_XSPIPUCR)

Address offset: 0x038

Reset value: 0x0000 0000 (POR and System Reset) (reset value after Standby: the value of the register is kept in Standby mode.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **XSPIPH0_PU**: Port PH0 XSPI pull-up bit

When XSPI is configured on PH0, this bit controls the pull-up on XSPI DQS0 (PH0) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 30 **XSPIPH1_PU**: Port PH1 XSPI pull-up bit

When XSPI is configured on PH1, this bit controls the pull-up on XSPI NCS2 (PH1) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 29 **XSPIPF2_PU**: Port PF2 XSPI pull-up bit

When XSPI is configured on PF2, this bit controls the pull-up on XSPI NCLK (PF2) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 28 **XSPIPA0_PU**: Port PA0 XSPI pull-up bit

When XSPI is configured on PA0, this bit controls the pull-up on XSPI CLK (PA0) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 27 **XSPIPA2_PU**: Port PA2 XSPI pull-up bit

When XSPI is configured on PA2, this bit controls the pull-up on XSPI NCS1 (PA2) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 26 **XSPIPA3_PU**: Port PA3 XSPI pull-up bit

When XSPI is configured on PA3, this bit controls the pull-up on XSPI DQS0 (PA3) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 25 **XSPIPA4_PU**: Port PA4 XSPI pull-up bit

When XSPI is configured on PA4, this bit controls the pull-up on XSPI NCS2 (PA4) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 24 **XSPIPA5_PU**: Port PA5 XSPI pull-up bit

When XSPI is configured on PA5, this bit controls the pull-up on XSPI NCS1 (PA5) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 23 **XSPIPB1_PU**: Port PB1 XSPI pull-up bit

When XSPI is configured on PB1, this bit controls the pull-up on XSPI CLK (PB1) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 22 **XSPIPB2_PU**: Port PB2 XSPI pull-up bit

When XSPI is configured on PB2, this bit controls the pull-up on XSPI NCLK (PB2) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 21 **XSPIPD0_PU**: Port PD0 XSPI pull-up bit

When XSPI is configured on PD0, this bit controls the pull-up on XSPI DQS0 (PD0) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 20 **XSPIPD1_PU**: Port PD1 XSPI pull-up bit

When XSPI is configured on PD1, this bit controls the pull-up on XSPI NCS2 (PD1) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 19 **XSPIPD2_PU**: Port PD2 XSPI pull-up bit

When XSPI is configured on PD2, this bit controls the pull-up on XSPI CLK (PD2) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 18 **XSPIPD3_PU**: Port PD3 XSPI pull-up bit

When XSPI is configured on PD3, this bit controls the pull-up on XSPI NCLK (PD3) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 17 **XSPIPG10_PU**: Port PG10 XSPI pull-up bit

When XSPI is configured on PG10, this bit controls the pull-up on XSPI NCS1 (PG10) in standby mode.

0: Pull-up is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-up is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bits 16:0 Reserved, must be kept at reset value.

6.8.14 PWR XSPI pull-down control register (PWR_XSPIPDCR)

Address offset: 0x03C

Reset value: 0x0000 0000 (reset value after Standby: the value of the register is kept in Standby mode.)

Bit 31 **XSPIPH0_PD:** Port PH0 XSPI pull-down bit

When XSPI is configured on PH0, this bit controls the pull-down on XSPI DQS0 (PH0) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 30 **XSPIPH1_PD:** Port PH1 XSPI pull-down bit

When XSPI is configured on PH1, this bit controls the pull-down on XSPI NCS2 (PH1) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 29 **XSPIPF2_PD:** Port PF2 XSPI pull-down bit

When XSPI is configured on PF2, this bit controls the pull-down on XSPI NCLK (PF2) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 28 **XSPIPA0_PD:** Port PA0 XSPI pull-down bit

When XSPI is configured on PA0, this bit controls the pull-down on XSPI CLK (PA0) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 27 **XSPIPA2_PD:** Port PA2 XSPI pull-down bit

When XSPI is configured on PA2, this bit controls the pull-down on XSPI NCS1 (PA2) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 26 **XSPIPA3_PD:** Port PA3 XSPI pull-down bit

When XSPI is configured on PA3, this bit controls the pull-down on XSPI DQS0 (PA3) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 25 **XSPIPA4_PD:** Port PA4 XSPI pull-down bit

When XSPI is configured on PA4, this bit controls the pull-down on XSPI NCS2 (PA4) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 24 **XSPIPA5_PD:** Port PA5 XSPI pull-down bit

When XSPI is configured on PA5, this bit controls the pull-down on XSPI NCS1 (PA5) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 23 **XSPIPB1_PD:** Port PB1 XSPI pull-down bit

When XSPI is configured on PB1, this bit controls the pull-down on XSPI CLK (PB1) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 22 **XSPIPB2_PD:** Port PB2 XSPI pull-down bit

When XSPI is configured on PB2, this bit controls the pull-down on XSPI NCLK (PB2) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 21 **XSPIPD0_PD:** Port PD0 XSPI pull-down bit

When XSPI is configured on PD0, this bit controls the pull-down on XSPI DQS0 (PD0) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 20 **XSPIPD1_PD:** Port PD1 XSPI pull-down bit

When XSPI is configured on PD1, this bit controls the pull-down on XSPI NCS2 (PD1) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 19 **XSPIPD2_PD:** Port PD2 XSPI pull-down bit

When XSPI is configured on PD2, this bit controls the pull-down on XSPI CLK (PD2) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 18 **XSPIPD3_PD:** Port PD3 XSPI pull-down bit

When XSPI is configured on PD3, this bit controls the pull-down on XSPI NCLK (PD3) in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bit 17 **XSPIPG10_PD:** Port PG10 XSPI pull-down bit

When XSPI is configured on PG10, this bit controls the pull-down on XSPI NCS1(PG10 in standby mode.

0: Pull-down is disabled in standby mode

1: If PWR_APCR. APC = 1, pull-down is active in standby mode and after wakeup until PWR_APCR. APC is reset to 0.

Bits 16:0 Reserved, must be kept at reset value.

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

7 Reset and clock control (RCC)

The RCC block manages the clock and reset generation for the whole microcontroller.

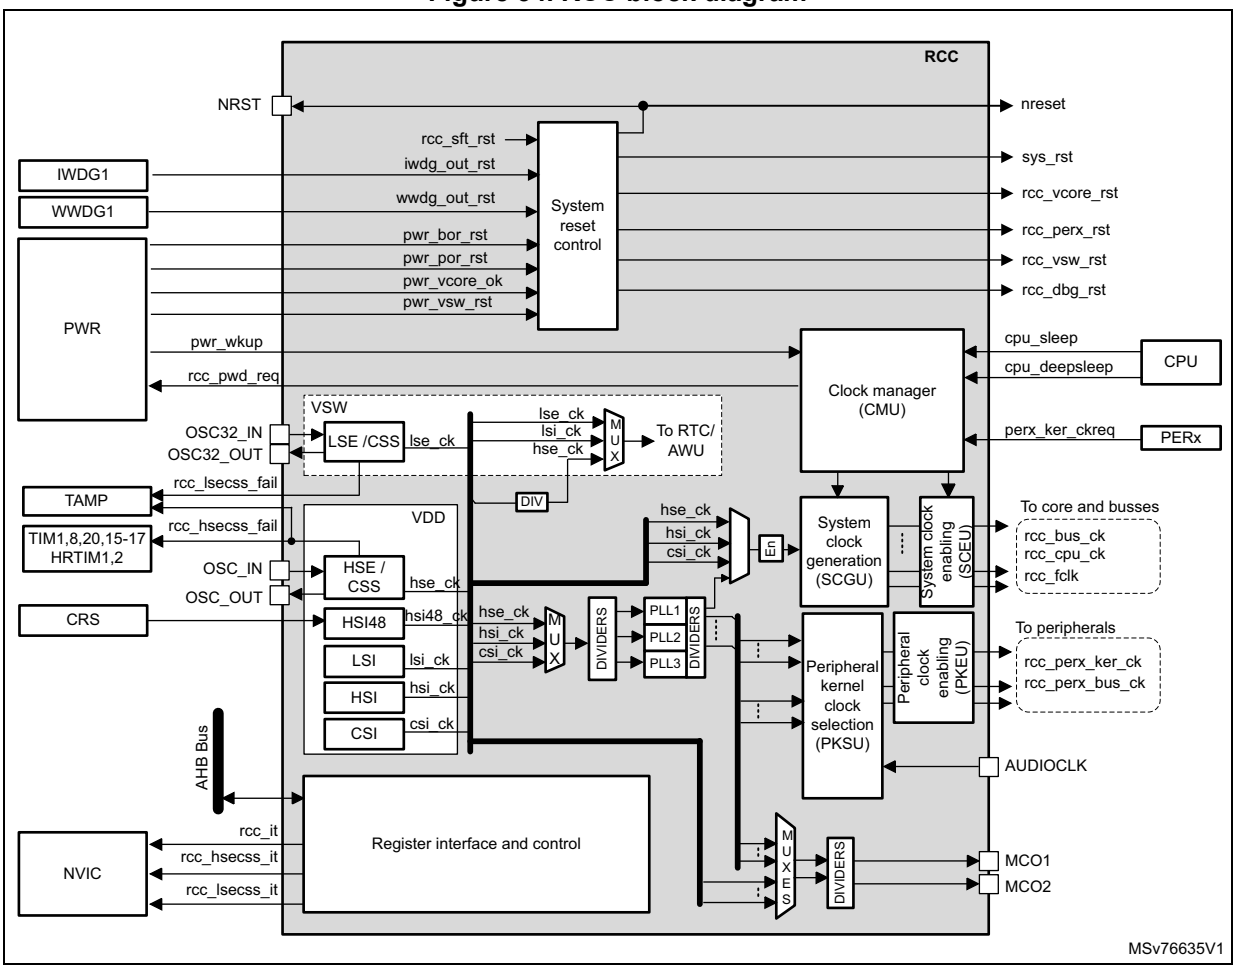
The operating modes to which this section refers are defined in *Section 6.6.1: Operating modes* of the PWR block.

7.1 RCC main features

AHB-Lite bus interface

Reset block:

- Generation of local and system reset
- Bidirectional pin reset allowing to reset the microcontroller or external devices
- WWDG and IWDG reset supported
- Power-on (POR) and Brownout (BOR) resets initiated by the power control (PWR)



Clock generation block:

- Generation and dispatching of clocks for the complete device
- 3 separate PLLs using integer or fractional ratios
- Possibility of changing the PLL fractional ratios on-the-fly
- Smart clock gating to reduce power dissipation
- System clock protection
- 2 external oscillators:
  - High-speed external oscillator (HSE) supporting a wide range of crystals from 4 to 50 MHz frequency
  - Low-speed external oscillator (LSE) for the 32 kHz crystals
- 4 internal oscillators
  - High-speed internal oscillator (HSI)
  - 48 MHz RC oscillator (HSI48)
  - Low-power internal oscillator (CSI)
  - Low-speed internal oscillator (LSI)
- Buffered clock outputs for external devices
- Generation of two types of interrupts lines:
  - Dedicated interrupt lines for clock security management
  - One general interrupt line for other events
- Clock generation handling in Stop and Standby mode

7.2 RCC block diagram

Figure 34 shows the RCC block diagram.

Figure 34. RCC block diagram

7.3 RCC pins and internal signals

Table 49 lists the RCC inputs and output signals connected to package pins or balls.

Table 49. RCC input/output signals connected to package pins or balls

Signal name	Signal type	Description
NRST	I/O	System reset, can be used to provide reset to external devices
OSC32_IN	I	32 kHz oscillator input
OSC32_OUT	O	32 kHz oscillator output
OSC_IN	I	System oscillator input
OSC_OUT	O	System oscillator output
MCO1	O	Output clock 1 for external devices
MCO2	O	Output clock 2 for external devices
AUDIOCLK	I	External kernel clock input for digital audio interfaces: SPI/I2S and ADF

The RCC exchanges a lot of internal signals with all components of the product. For that reason, *Table 50* only shows the most significant internal signals.

Table 50. RCC internal input/output signals

Signal name	Signal type	Description
rcc_it	O	General interrupt request line
rcc_hsecss_it	O	HSE clock security failure interrupt
rcc_lsecss_it	O	LSE clock security failure interrupt
rcc_hsecss_fail	O	Event indicating that a HSE clock security failure is detected. This signal is connected to TIMERS.
rcc_lsecss_fail	O	Event indicating that a LSE clock security failure is detected. This signal is connected to TAMP, EXTI and PWR
nreset	I/O	Application reset
sys_rst	I/O	System reset
iwdg_out_rst	I	Reset line driven by the IWDG, indicating that a timeout occurred
wwdg_out_rst	I	Reset line driven by the WWDG, indicating that a timeout occurred
pwr_bor_rst	I	Brownout reset generated by the PWR block
pwr_por_rst	I	Power-on reset generated by the PWR block
pwr_vsw_rst	I	Power-on reset of the V_{SW} domain generated by the PWR block
rcc_perx_rst	O	Reset generated by the RCC for the peripherals
pwr_wkup	I	Wakeup domain request generated by the PWR and used to restore the domain clocks
rcc_pwd_req	O	Low-power request generated by the RCC and used to set the circuit into low-power mode

Table 50. RCC internal input/output signals (continued)

Signal name	Signal type	Description
cpu_sleep	I	Signals generated by the CPU, indicating if the CPU is in CRun, Sleep or CStop
cpu_deepsleep	I	
perx_ker_ckreq	I	Signal generated by some peripherals in order to request the activation of their kernel clock
rcc_perx_ker_ck	O	Kernel clock signals generated by the RCC, for some peripherals
rcc_perx_bus_ck	O	Bus interface clock signals generated by the RCC for peripherals
rcc_bus_ck	O	Clocks for APB, AHB and AXI bridges generated by the RCC
rcc_cpu_ck	O	Clocks for the CPU, generated by the RCC
rcc_fclk	O	

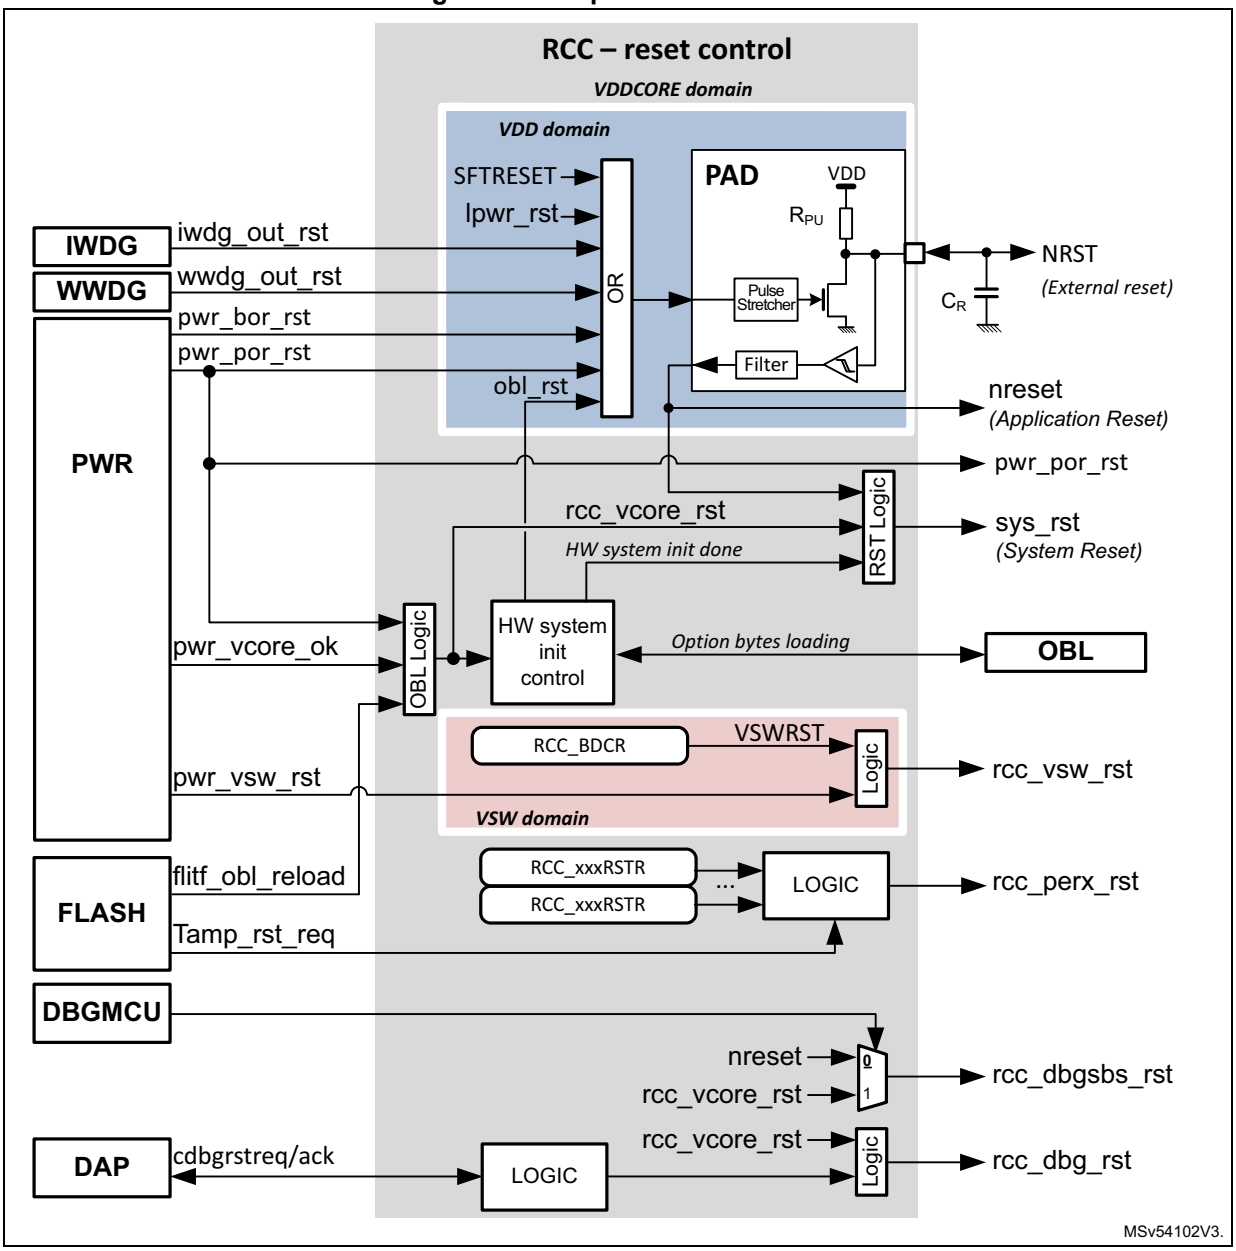
7.4 RCC reset block functional description

The RCC handles the reset generation for the complete product, using events coming from different sources:

- Assertion of the NRST pin from an external device
- A failure on the supply voltage applied to VDD, VBAT
- An exit from Standby
- A watchdog timeout
- A software command

The reset scope depends on the source that generates the reset.

7.4.1 Reset from PWR block



The PWR block provides several reset signals to the RCC:

- The power-on/off reset signal (**pwr_por_rst**), which is asserted when the VDD supply is lower than the VPOR threshold.
- The brown-out reset signal (**pwr_bor_rst**), which is asserted when the VDD supply is lower than the VBOR threshold.
- The core reset signal (**pwr_vcore_ok**), which is asserted when the VDDCORE supply is not valid or available. Note that the V_{DDCORE} voltage is switched off when the product is in Standby. So when the system exits from Standby mode, the **pwr_vcore_ok** signal is asserted as long the V_{DDCORE} voltage provided by the internal regulator is not valid. Note that when the V_{DD} supply is not valid, **pwr_vcore_ok** is asserted as well.
- The V_{SW} domain reset signal (**pwr_vsw_rst**), which is asserted when the VSW supply is lower than the expected threshold.

*Note: The **rcc_vcore_rst** is generated from the **pwr_vcore_ok** signal, the main difference between these two signals is that **rcc_vcore_rst** remains asserted until the option byte loading operation is completed.*

Refer to *Table 51: Reset coverage summary* for details.

Figure 35. Simplified reset circuit

7.4.2 The system and application resets (sys_rst and nreset)

A system reset (**sys_rst)** resets most of the registers to their default values unless otherwise specified in the register description.

A system reset can be generated from one of the following sources:

- An assertion of the NRST pin (external reset)
- A reset from the power-on/off reset block (**pwr_por_rst**)
- A reset from the brownout reset block (**pwr_bor_rst**)

  Refer to *Section 6.5.2: Brownout reset (BOR)* for a detailed description of the BOR function.
- A reset from the independent watchdogs (**iwdg_out_rst**)
- An exit from Standby (**rcc_vcore_rst**).
- A reset from the window watchdogs depending on WWDG configuration (**wwdg_out_rst**)
- A software reset from the Cortex®-M7 core

  It is generated via the SYSRESETREQ signal issued by the Cortex®-M7 core. This signal is also named SFTRESET in this document.
- A reset from the low-power mode security reset, depending on option byte configuration (**lpwr_rst**).
- An option byte reload request from the flash interface (**obl_rst**)

The application reset (**nreset**) is similar to the system reset, but it is not asserted when the system exits from Standby.

Note: The SYSRESETREQ bit in Cortex®-M7 must be set through the FPU application interrupt and reset control register to force a software reset on the device. Refer to the Cortex®-M7 with FPU technical reference manual for more details (see http://infocenter.arm.com).

7.4.3 The NRST reset

The NRST is active low. A pulse stretcher guarantees a minimum reset pulse duration of 20 µs (Refer to datasheet for details). In addition it is possible to extend the NRST assertion thanks to C_R capacitor. It is not recommended to let the NRST pin unconnected.

When it is not used, connect this pin to the ground via a 10 to 100 nF capacitor (C_R in *Figure 35*). As shown in *Figure 35*, a filter is also present in order to suppress spurs coming from NRST PAD.

7.4.4 Low-power mode security reset (lpwr_rst)

To prevent critical applications from mistakenly enter a low-power mode, two low-power mode security resets are available. When enabled through nRST_STOP and nRST_STANDBY option bytes, a system reset is generated if the following conditions are met:

- The CPU accidentally enters Stop mode.
  This type of reset is enabled by resetting nRST_STOP user option byte. In this case, whenever the Stop mode entry sequence is successfully executed, a system reset is generated.
- The system accidentally enters Standby mode.
  This type of reset is enabled by resetting nRST_STANDBY user option byte. In this

case, whenever a Standby mode entry sequence is successfully executed, a system reset is generated.
When the Standby mode is entered, a flag is also set in the power controller.

LPWRRSTF bit in the *RCC Reset status register (RCC_RSR)* indicates that a low-power mode security reset occurred (see line #7 in *Table 52*).

lpwr_rst is activated when a low-power mode security reset due to CPU occurred.

Refer to *Section 5.4: FLASH option bytes* for additional information.

Refer to *Section 6: Power control (PWR)* for additional information and *Table 40: Operating mode summary* for the overview of the existing power modes.

7.4.5 Backup domain reset

A backup domain reset (**pwr_vsw_rst**) is generated when one of the following events occurs:

- Software reset (triggered by setting the VSWRST bit in the *RCC Backup domain control register (RCC_BDCR)*). All RTC registers and the RCC_BDCR register are set to their reset values, with the exception of LSEDRV, which is not changed if LSEON=1. The BKPSRAM is not affected.
- When the V_{SW} voltage is outside the operating range. All RTC registers and the RCC_BDCR register are set to their reset values. In this case the content of the BKPSRAM is no longer valid.

Refer to *Section 6.4.3: Backup domain* section of PWR block and to section “System security” for additional information.

7.4.6 Coresight debug reset

The coresight debug components can be reset in different ways:

- Over the DAP by setting to 1 the bit CDBGRSTREQ of the control/status register of the debug port. This action asserts the debug reset request signal cdbgrstreq connected to the RCC. Then the RCC activates the debug reset (**rcc_dbg_rst**), a handshake signal cdbgrstack is provided to the DAP request. The debug reset remains as long as the cdbgrstreq is to 1, refer to *Figure 35* for details.
- When V_{DDCORE} power-on reset occurs (**rcc_vcore_rst**). This reset is activated after a power-on reset, or when the product exits from Standby.

Refer to Section 1.7.1: CoreSight Debug Reset for details(TBD xref to Debug section?).

7.4.7 Option bytes loading

As shown in *Figure 35*, the option bytes loading (OBL) sequence is triggered under the following conditions:

- After a power-on, or
- When the system exits from Standby
- When the flash interface requested a reload of option bytes

The system reset (**sys_rst**) can be released only when the option byte loading (OBL) is completed.

7.4.8 Peripheral resets

The application can individually reset any peripheral whenever requested. This can be done via the RCC_xxxxRSTR registers where “xxxx” is the name of the bus to which the peripheral is connected.

In order to reset a peripheral, the corresponding reset bit must be set to 1, and then set back to 0. There is no need to enable the peripheral clock in order to reset a peripheral.

Note also that the CRYP, SAES and HASH blocks can be reset in the case of a tamper event.

7.4.9 Reset coverage summary

Table 51: Reset coverage summary gives a detailed view of the reset coverage of the most important reset sources.

Note: When V_{DD} is not valid, V_{DDCORE} is also not valid.

Table 51. Reset coverage summary(1)

Functions that are reset		Main reset lines						
		pwr_por_rst (2)	rcc_vcore_rst	sys_rst	nreset (4)	rcc_dbg_rst	rcc_perx_rst	rcc_vsw_rst
V_{DD} domain		x	-	-	-	-	-	-
MCU		x	x	x	-	-	-	-
WWDG		x	x	x	-	-	-	-
IWDG		x	-	-	x	-	-	-
AXI/AHB Interconnections.		x	x	x	-	-	-	-
Debug components, including DBGMCU Reset all the debug parts except the SWJ-DP function. The SWJ-DP is reset by the NJTRST or rcc_vcore_rst resets. The bit DCRT on DBGMCU_CR is reset with pwr_por_rst.		x	x	-	-	x	-	-
Hardware system init. It includes the reload of the option bytes.		x	x	-	-	-	-	-
RCC	*RCC Reset status register (RCC_RSR)*	x	-	-	-	-	-	-
	RCC clock control and status register (RCC_CSR)	x	-	-	-	-	-	-
	RCC Backup domain control register (RCC_BDCR)	-	-	-	-	-	-	x
	Other RCC registers	x	x	x	-	-	-	-
PWR	PWR_CSR1	-	-	-	-	-	-	x
	PWR_CSR2	x	-	-	-	-	-	-
	PWR_CSR3 Individual bits of this register do not have the same reset condition, refer to the PWR section for details.	x	x	x	-	-	-	-
	PWR_WKUPCR, PWR_WKUPFR, PWR_WKUPEPR	x	-	-	x	-	-	-
	Other registers	x	x	x	-	-	-	-
RTC		-	-	-	-	-	-	x
BKPSRAM After a reset of the V_{SW} domain, the backup regulator of the BKPSRAM is disabled, this function is controlled via the PWR block, BREN bit. If the rcc_vsw_rst reset is due to a too low V_{SW} voltage, the content of BKPSRAM is lost.		-	-	-	-	-	-	x
SBS	SBS_RSSCMDR	x	-	-	-	-	-	-
Other Peripherals		x	x	x	-	-	x	-

1. The ‘x’ means that the function is reset by the corresponding reset line, the ‘-’ means that the function is not reset by the corresponding reset line.
2. The pwr_por_rst is asserted when the voltage applied to VDD is not valid.
When pwr_por_rst is asserted, the rcc_vcore_rst, NRST, the sys_rst and the nreset, are asserted as well.

3. The rcc_vcore_rst is asserted when the voltage applied to VDD is not valid, or when the system exits from Standby (because V_{DDCORE} was switched off).
   When rcc_vcore_rst is asserted, the sys_rst, and the pwr_dbg_rst are asserted as well.
4. When nreset is asserted, the sys_rst is also asserted.

7.4.10 Reset source identification

The CPU can identify the reset source by checking the reset flags in the RCC_RSR register.

The CPU can reset the flags by setting the RMVF bit.

Table 52 shows how the status bits of the RCC_RSR register behave according to the situation that generated the reset. For example, when an IWDG timeout occurs (line #6), if the CPU is reading the RCC_RSR register during the boot phase, both PINRSTF and IWDGRSTF bits are set, indicating that the IWDG also generated a pin reset.

Table 52. Reset source identification (RCC_RSR)(1)

#	Situations generating a reset	SBF (2)	LPWRRSTF	WWDGRSTF	IWDGRSTF	SFTRSTF	PORRSTF	PINRSTF	BORRSTF	OBLRSTF
1	Power-on reset (**pwr_por_rst**)	0	0	0	0	0	1	1	1	0
2	Pin reset (NRST)	0	0	0	0	0	0	1	0	0
3	Brownout reset (**pwr_bor_rst**)	0	0	0	0	0	0	1	1	0
4	System reset generated by CPU (SFTRESET)	0	0	0	0	1	0	1	0	0
5	WWDG reset (**wwdg_out_rst**)	0	0	1	0	0	0	1	0	0
6	IWDG reset (**iwdg_out_rst**)	0	0	0	1	0	0	1	0	0
7	CPU erroneously enters Stop or Standby mode	0	1	0	0	0	0	1	0	0
8	The flash interface requested a reload of option bytes	0	0	0	0	0	0	1	0	1
9	The product exits from Standby	1	0	0	0	0	0	1	0	0

1. Grayed cells highlight the register bits that are set.
2. The SBF bit is located into the PWR_CSR3 register of the PWR block

7.4.11 Power-on and wakeup sequences

For detailed diagrams refer to *Section 6.4.1: System supply startup* in the PWR section.

The time interval between the event that exits the product from low power and the moment where the CPU is able to execute code, depends on the system state and on its configuration. *Figure 36* shows the most usual examples.

Power-on wakeup sequence

The power-on wakeup sequence shown in *Figure 36* gives the most significant phases of the power-on sequence. It is the longest sequence since the circuit was not powered. Note that this sequence remains unchanged, whatever V_{BAT} was present or not.

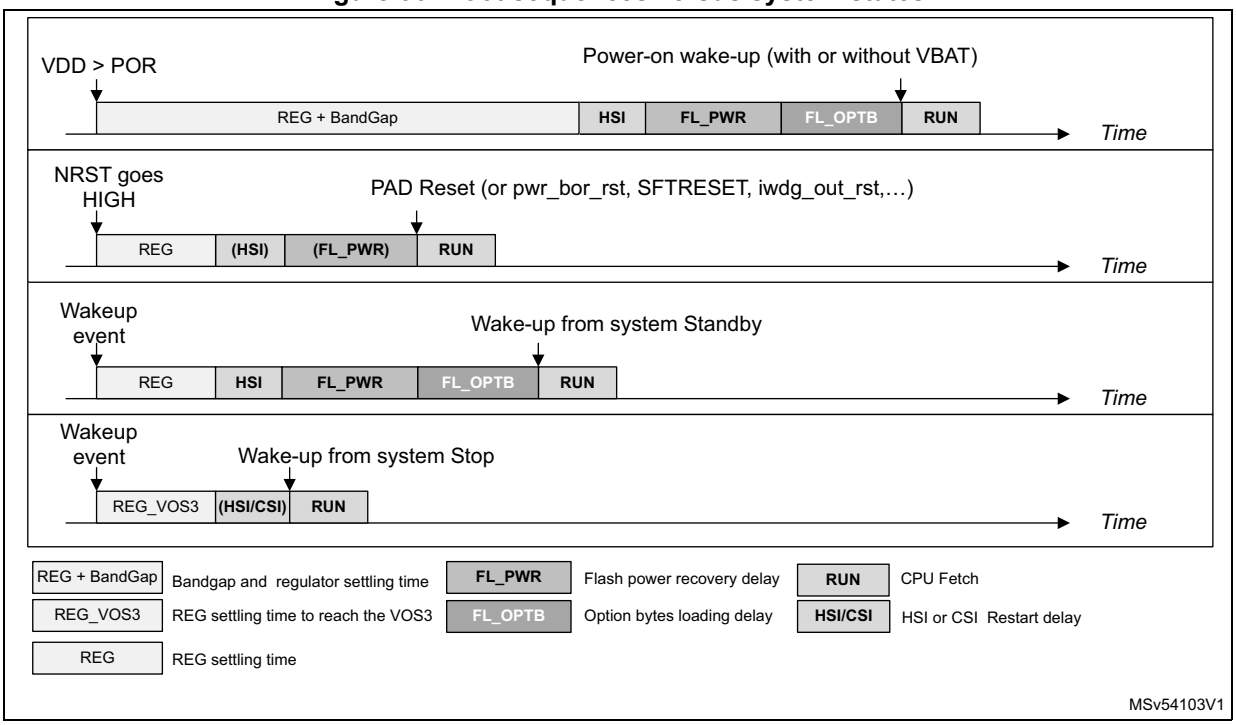
Boot from pin reset

When a pin reset occurs, V_{DD} is still present. As a result:

- The regulator settling time is faster since the reference voltage is already stable.
- The HSI restart delay may be needed if the HSI was not enabled when the NRST occurred, otherwise this restart delay phase is skipped.
- The flash memory power recovery delay can also be skipped if the flash memory was enabled when the NRST occurred.

Note: The boot sequence is similar for pwr_bor_rst, lpwr_rst, STFRESET, iwdg_out_rst and wwdg_out_rst.

Boot from system Standby



When waking up from system Standby, the reference voltage is stable since V_{DD} has not been removed. As a result, the regulator settling time is fast. Since V_{CORE} was not present, the restart delay for the HSI, the flash memory power recovery and the option byte reloading cannot be skipped.

Restart from system Stop

When restarting from Stop, V_{DD} is still present. As a result, the sequence is mainly composed of two steps:

1. Regulator settling time to reach VOS LOW (default voltage).
2. HSI/CSI restart delay. This step can be skipped if the HSIKERON or CSIKERON bit is set to 1 in the *RCC register map*.

Figure 36. Boot sequences versus system states

7.5 RCC clock block functional description

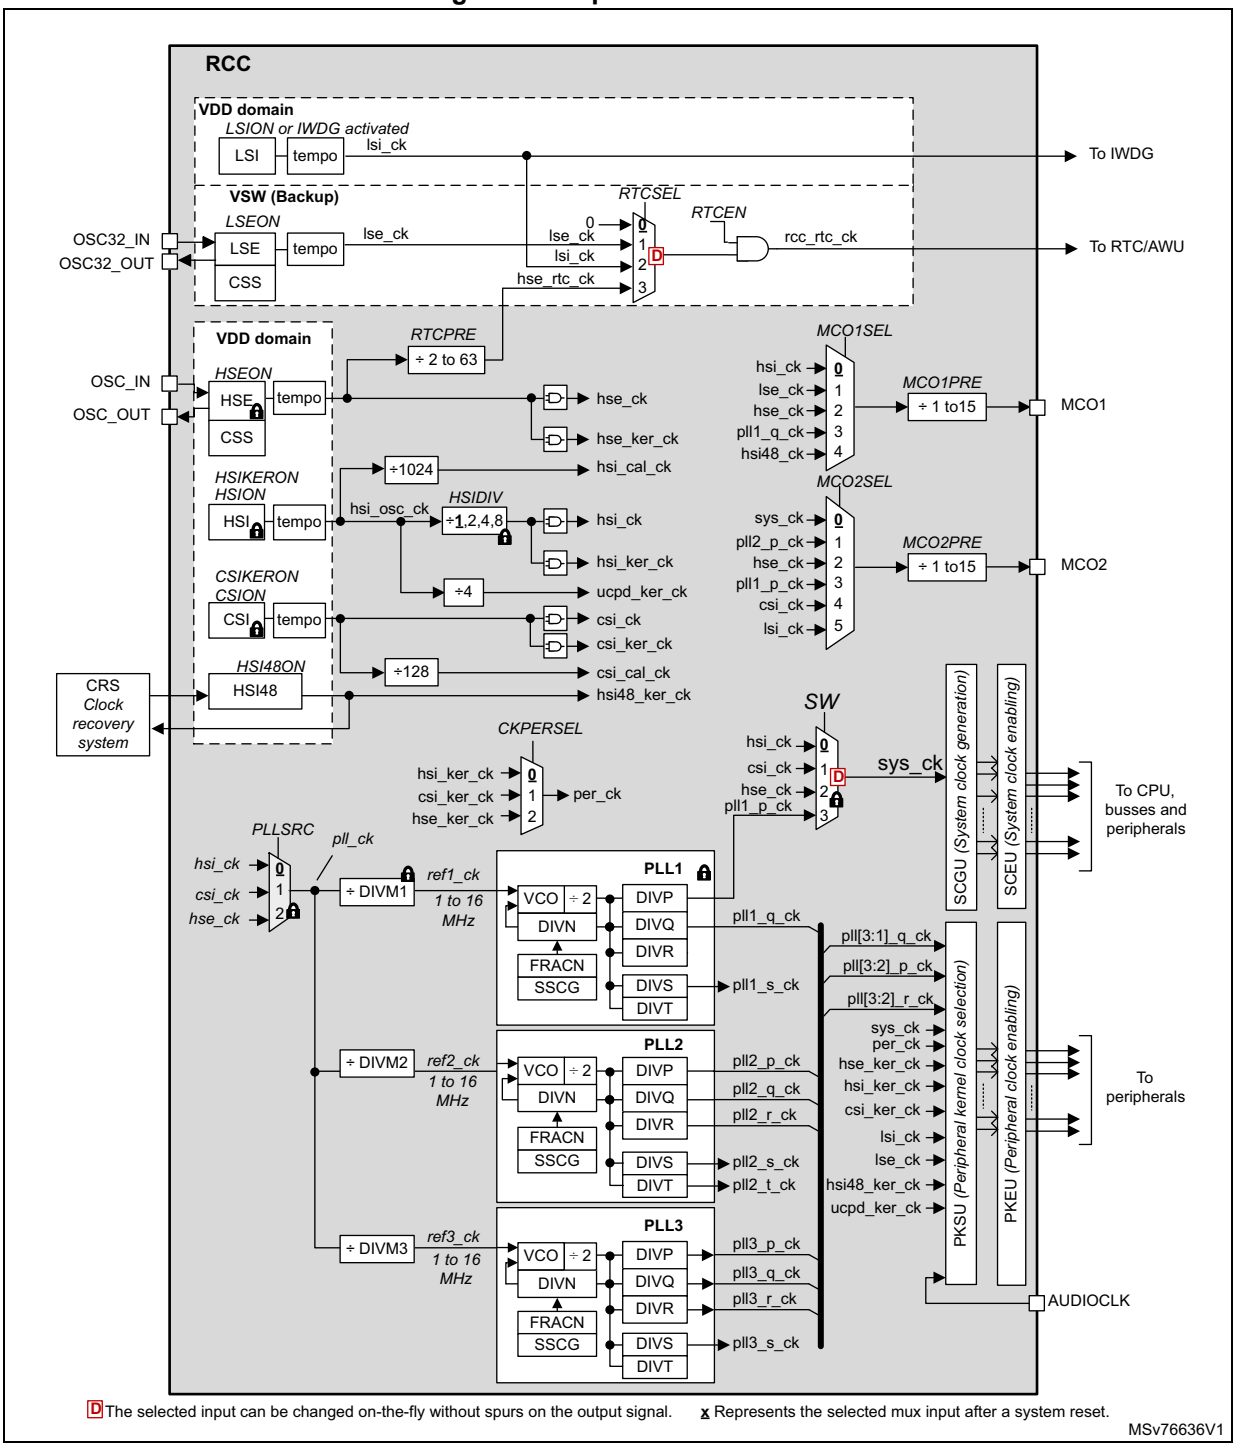
The RCC provides a wide choice of clock generators:

- HSI (high-speed internal oscillator) clock: ~8, 16, 32 or 64 MHz
- HSE (high-speed external oscillator) clock: 4 to 50 MHz
- LSE (low-speed external oscillator) clock: 32 kHz
- LSI (low-speed internal oscillator) clock: ~32 kHz
- CSI (low-power internal oscillator) clock: ~4 MHz
- HSI48 (high-speed internal oscillator) clock: ~48 MHz

The RCC offers a high flexibility for the application to select the appropriate clock for CPU and peripherals, in particular for peripherals that require a specific clock such as SPI/I2S and ADF.

To optimize the power consumption, each clock source can be switched ON or OFF independently.

The RCC provides up to 3 PLLs; each of them can be configured in integer, with or without SSCG, or fractional mode.



As shown in the *Figure 37*, the RCC offers two clock outputs (MCO1 and MCO2), with a great flexibility in the clock selection and frequency adjustment.

The SCGU block (system clock generation unit) contains several prescalers used to configure the CPU and bus matrix clock frequencies.

The PKSU block (peripheral kernel clock selection unit) provides several dynamic switches allowing a large choice of kernel clock distribution to peripherals.

The PKEU (peripheral kernel clock enable unit) and SCEU (system clock enable unit) blocks perform the peripheral kernel clock gating, and the bus interface/cores/bus matrix clock gating, respectively.

Figure 37. Top-level clock tree

7.5.1 Clock naming convention

The RCC provides clocks to the complete circuit. To avoid misunderstanding, the following terms are used in this document:

- **Peripheral clocks**

  The peripheral clocks are the clocks provided by the RCC to the peripherals. Two kinds of clock are available:

  – Bus interface clocks

  – Kernel clocks

  A peripheral receives from the RCC a bus interface clock in order to access its registers, and thus control the peripheral operation. This clock is generally the AHB, APB or AXI clock depending on which bus the peripheral is connected to. Some peripherals only need a bus interface clock (such as RNG, TIMx).

  Some peripherals also require a dedicated clock to handle the interface function. This clock is named kernel clock. As an example, peripherals such as I2S must generate specific and accurate master clock frequencies, which require dedicated kernel clock frequencies. Another advantage of decoupling the bus interface clock from the specific interface needs, is that the bus clock can be changed without reprogramming the peripheral.

- **CPU clock**

  The CPU clock is the clock provided to the CPU. It is derived from the system clock (**sys_ck**).

- **Bus matrix clocks**

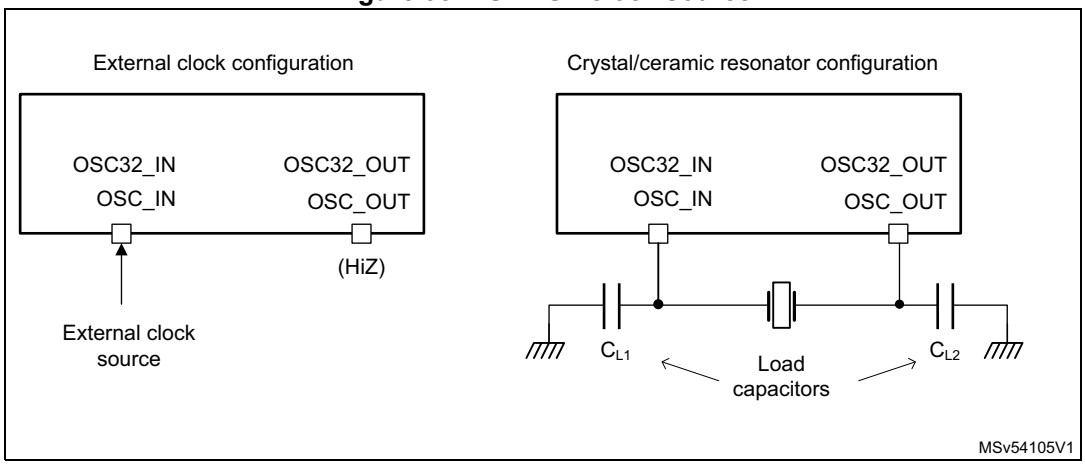
  The bus matrix clocks are the clocks provided to the different bridges (APB, AHB or AXI). These clocks are derived from the system clock (**sys_ck**).

7.5.2 Oscillators description

The table hereafter shows the oscillator states versus system modes, when the oscillators are enabled via registers. The term “available” means that the resource can be used if activated via registers.

Table 53. Oscillator states versus system modes

System modes	V_{DD} domain					V_{SW} domain
	HSE	HSI	HSI48	CSI	LSI	LSE
Exit from system reset	OFF	ON	OFF	OFF	Available	Available
Exit from system Stop	OFF	ON (1)	OFF	ON (2)	Available	Available
In Run/Sleep	Available	Available	Available	Available	Available	Available
In Stop	OFF	Available (3)	OFF	Available (4)	Available	Available
In Standby	OFF	OFF	OFF	OFF	Available	Available
In VBAT	OFF	OFF	OFF	OFF	OFF	Available



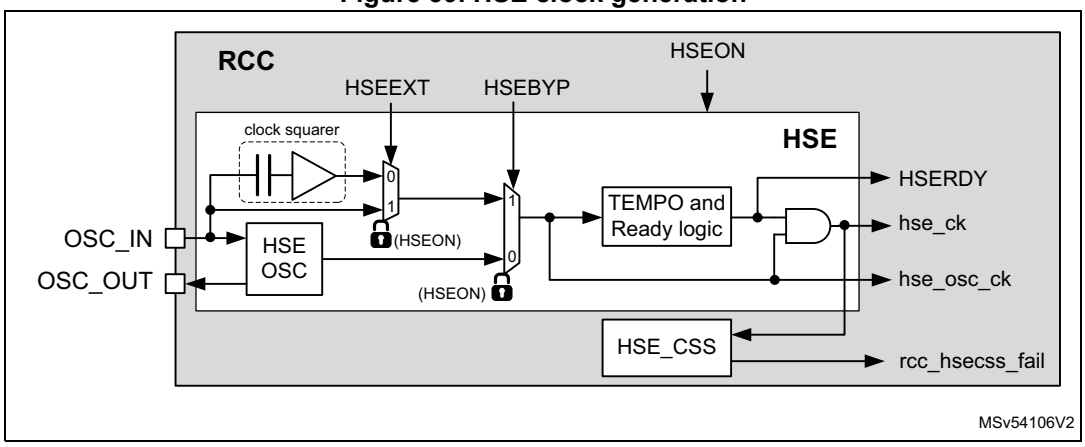
1. If STOPWUCK = 0 or STOPKERWUCK = 0.
2. If STOPWUCK = 1 or STOPKERWUCK = 1.
3. HSI can remain activated in Stop if HSIKERON = 1, or if a peripheral selecting HSI, generates a kernel clock request.
4. CSI can remain activated in Stop if CSIKERON = 1, or if the peripheral selecting CSI, generates a kernel clock request.

HSE oscillator

The HSE block allows the application to provide a very accurate high-speed clock for the product. The HSE can generate an internal clock from two possible sources:

- External clock source
- External crystal/ceramic resonator

Figure 38. HSE/LSE clock source



External clock source (HSE bypass)

In this mode the oscillator is not used, and an external clock source must be provided to OSC_IN pin. The external clock can be low swing (analog) or digital. The OSC_OUT pin must be left high-Z (see *Figure 38*).

The external clock signal can be digital or analog (square, sinus or triangle). An analog clock signal with a reduced amplitude is supported thanks to an internal clock squarer. The input signal must have a duty cycle close to 50%. Refer to the datasheet for additional information.

This mode is selected when HSEBYP = 1, and HSEON = 1. In case of an analog clock input (low swing) the HSEEXT must be set to 0, for a digital clock input, HSEEXT bits must be set to 1.

Figure 39. HSE clock generation

External crystal/ceramic resonator

A crystal/resonator can be connected as shown in *Figure 38*: the crystal/resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The oscillator mode is enabled by setting the HSEBYP bit to 0 and HSEON bit to 1.

HSE ready logic

The HSERDY flag indicates when a valid clock is available at HSE output (**hse_ck**). When the HSE is enabled (HSEON set to '1'), the HSERDY flag goes to 1 when 256 valid cycles of HSE have been detected. The **hse_ck** clock is not released until HSERDY goes to 1.

An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.

HSE controls

The HSE can be switched ON and OFF through the HSEON bit.

The hardware does not allow modifying HSEON bit if one of the following conditions is met:

- The HSE is used directly (via SW switch) as system clock.
- The HSE is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via SW switch).
- The bit XSPICKP is set to 1.
- The bit FMCCKP is set to 1.

The hardware does not allow changing the values of HSEBYP and HSEEXT when HSEON = 1. Bits HSEBYP, HSEEXT and HSEON are located into the *RCC register map*.

The HSE is automatically disabled by hardware when the system enters Stop or Standby mode (See *Table 53: Oscillator states versus system modes*).

In addition, the HSE clock can be driven to the MCO1 and MCO2 outputs and used as clock source for other application components.

Programming sequence

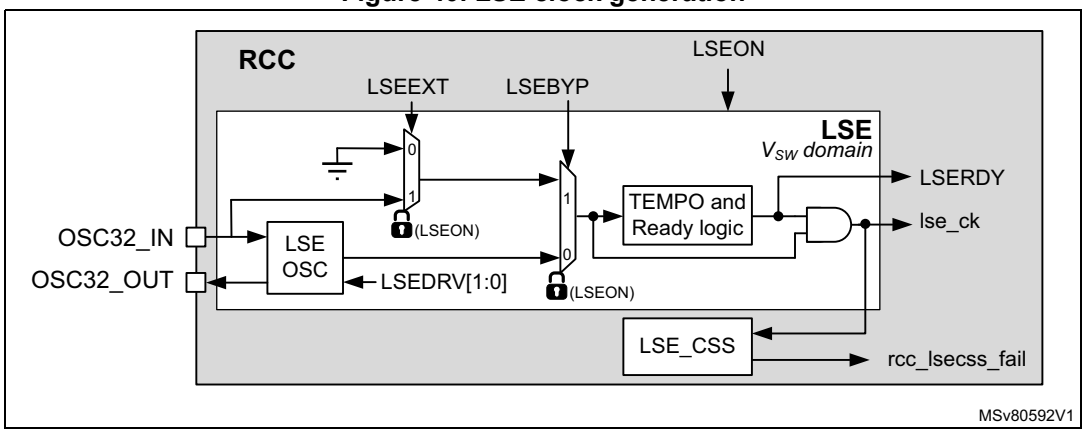
In order to initialize the HSE, the application must follow the sequence hereafter:

- Make sure the HSE is not directly or indirectly used as system clock, if it is the case, use HSI or CSI as clock source for system clock.
- Make sure that XSPICKP and FMCCKP are set to 0
- Disable the HSE by writing to 0 the HSEON bit,
- Check that the HSE is disabled by waiting that the bit HSERDY is set to 0,
- If the oscillator mode is needed:
  - Select the oscillator mode by setting HSEBYP to 0,
- If an external clock is connected to OSC_IN:
  - Select the bypass mode by setting HSEBYP to 1,
  - If the input clock is a full-swing digital signal, set HSEEXT to 1
  - If the input clock is a low-swing signal, set HSEEXT to 0
- Enable again the HSE by writing the HSEON bit to 1,
- Wait for HSERDY = 1, then the HSE is ready for use.

LSE oscillator

The LSE block allows the application to provide a very accurate low-frequency clock for the product. The LSE can generate an internal clock from two possible sources:

- External user clock
- External crystal/ceramic resonator



External clock source (LSE bypass)

In this mode, the oscillator is not used, and an external clock source must be provided to OSC32_IN pin. The OSC32_OUT pin must be left high-Z (see *Figure 38*).

The external clock signal can have a frequency up to 1 MHz. The signal must comply with the GPIO digital input requirements.

This mode is selected by setting the LSEBYP, LSEEXT, and LSEON bits to 1.

Figure 40. LSE clock generation

External crystal/ceramic resonator source (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It has the advantage to provide a low-power highly accurate clock source to the real-time clock (RTC)

for clock/calendar or other timing functions. A crystal/resonator can be connected as shown in *Figure 38*: the crystal/resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The oscillator mode is selected by setting LSEBYP bit to 0 and LSEON bit to 1.

The LSE also offers a programmable driving capability (LSEDRV[1:0]) that can be used to modulate the amplifier driving capability. This driving capability is chosen according to the external crystal/ceramic component requirement to insure a stable oscillation.

The driving capability must be set before enabling the LSE oscillator.

Warning: It is not allowed to change the driving capability when the LSE is enabled. The LSE behavior is not guaranteed in that case.

LSE ready logic

The LSE offers an LSERDY flag which indicates whether the LSE clock is available or not. When the LSE is enabled (LSEON set to 1) the LSERDY flag goes to 1 when a certain amount of valid cycles of LSE clock have been detected. The **lse_ck** clock is not released until LSERDY goes to 1.

When LSEBYP = 0, the RCC waits 4096 clocks cycles before activating the LSERDY flag, when LSEBYP = 1, the RCC waits 8 clocks cycles.

An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.

LSERDY bit is located into the *RCC Backup domain control register (RCC_BDCR)*.

LSE controls

The LSE control bits LSEBYP, LSEEXT, LSEDRV[1:0] and LSEON are located in the *RCC Backup domain control register (RCC_BDCR)*. This register is write-protected by DBP bit of PWR_CR1 register. In order to modify the RCC_BDCR register, the bit DBP must be set 1.

The LSE oscillator is switched ON and OFF using the LSEON bit.

The LSE remains enabled when the system enters Stop, Standby or VBAT mode (See *Table 53: Oscillator states versus system modes*).

The hardware does not allow changing the values of LSEBYP and LSEEXT when LSEON = 1.

In addition, the LSE clock can be driven to the MCO1 output and used as a clock source for external components.

LSE Programming sequence

In order to initialize the LSE, the application must follow the sequence hereafter:

- Set the DBP bit of PWR_CR1 to 1 in order to allow write accesses to the RCC_BDCR register.
- Disable the LSE by writing to 0 the LSEON bit,
- Check that the LSE is disabled by waiting until the bit LSERDY is set to 0,
- If the oscillator mode is needed:
  - Select the oscillator mode by setting LSEBYP to 0,
  - Configure LSEDRV[1:0],
- If an external clock is connected to OSC32_IN:
  - Select the bypass mode by setting LSEBYP to 1,
  - Set LSEEXT to 1
- Enable again the LSE by writing the LSEON bit to 1,
- Wait for LSERDY = 1, then the LSE is ready for use.
- If RCC_BDCR register no longer needs to be changed, set the DBP bit of PWR_CR1 to 0 in order to write-protect accesses.

Caution: If LSE bypass is used in V_{BAT} mode, the input clock signal must meet the required input levels relative to the V_{BAT} voltage. Refer to the device datasheet.

HSI oscillator

The HSI block provides the default clock to the product.

The HSI is a high-speed internal RC oscillator that can be used directly as system clock, peripheral clock, or as PLL input. A predivider allows the application to select an HSI output frequency of 8, 16, 32 or 64 MHz. This predivider is controlled by the HSIDIV.

The HSI advantages are the following:

- Low-cost clock source since no external crystal is required
- Faster startup time than HSE (a few microseconds)

The HSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

HSI controls

The HSI can be switched ON and OFF using the HSION bit.

The hardware does not allow modifying HSION bit if one of the following conditions is met:

- The HSI is used directly (via software mux) as the system clock.
- The HSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).
- The bit XSPICKP is set to 1.
- The bit FMCCKP is set to 1.

Note that the HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to 1). In that case the hardware does not update the HSIDIV with the new value. However it is possible to change the HSIDIV if the HSI is used directly as system clock.

The HSIRDY flag indicates if the HSI is stable or not. At startup, the HSI output clock is not released until this bit is set by the hardware.

The HSI clock can also be used as a backup source (auxiliary clock) if the HSE fails (refer to *Section : CSS on HSE*).

The HSI can be disabled or not when the system enters Stop mode (See *Table 53: Oscillator states versus system modes*).

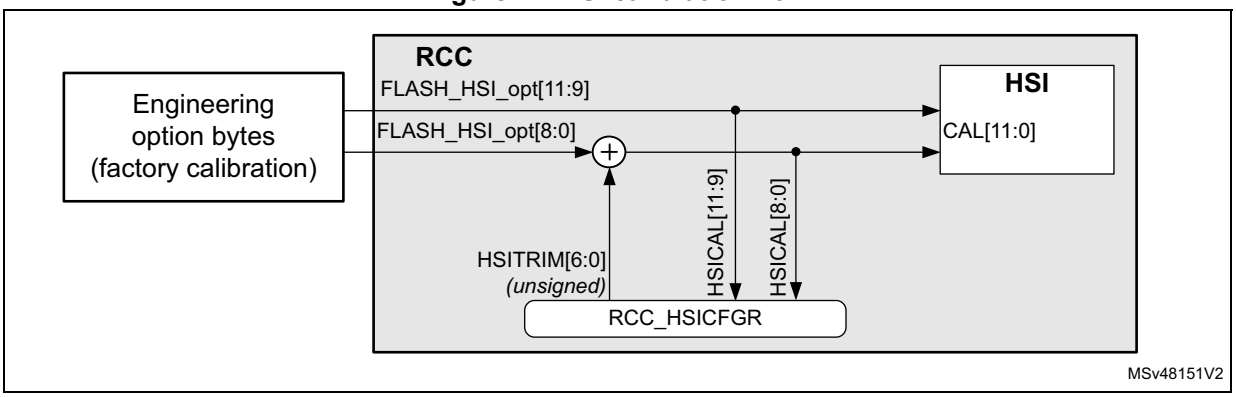
In addition, the HSI clock can be driven to the MCO1 output and used as clock source for other application components.

Care must be taken when the HSI is used as kernel clock for communication peripherals, the application must take into account the following parameters:

- The time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- The frequency accuracy.

HSION, HSIRDY and HSIDIV bits are located in the *RCC register map*.

HSI calibration



RC oscillator frequencies can vary from one chip to another due to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACC_{HSI} (refer to the product datasheet for more information).

After a power-on reset, or at the exit of Standby mode, the factory calibration value is loaded in the HSICAL[11:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the HSI frequency using the HSITRIM[6:0] bits.

Note: HSICAL[11:0] and HSITRIM[6:0] bits are located in the RCC HSI calibration register (RCC_HSICFGR).

Figure 41. HSI calibration flow

CSI oscillator

The CSI is a low-power RC oscillator that can be used directly as system clock, peripheral clock, or PLL input.

The CSI advantages are the following:

- Low-cost clock source since no external crystal is required
- Faster startup time than HSE (a few microseconds)
- Very low-power consumption.

The CSI provides a clock frequency of about 4 MHz, while the HSI is able to provide a clock up to 64 MHz.

CSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

CSI controls

The CSI can be switched ON and OFF through the CSION bit. The CSIRDY flag indicates whether the CSI is stable or not. At startup, the CSI output clock is not released until this bit is set by the hardware.

The hardware does not allow modifying CSION bit if one of the conditions is met:

- The CSI is used directly (via software mux) as system clock.
- The CSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).
- The bit XSPICKP is set to 1.
- The bit FMCCKP is set to 1.

The CSI can be disabled or not when the system enters Stop mode (See *Table 53: Oscillator states versus system modes*).

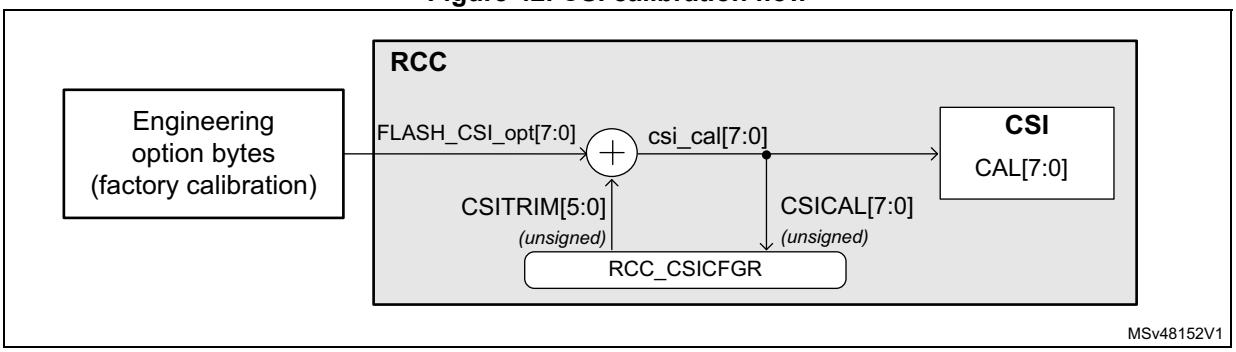
In addition, the CSI clock can be driven to the MCO2 output and used as clock source for other application components.

Even if the CSI settling time is faster than the HSI, care must be taken when the CSI is used as kernel clock for communication peripherals: the application must take into account the following parameters:

- The time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- The frequency precision.

Note: CSION and CSIRDY bits are located in the RCC register map.

CSI calibration



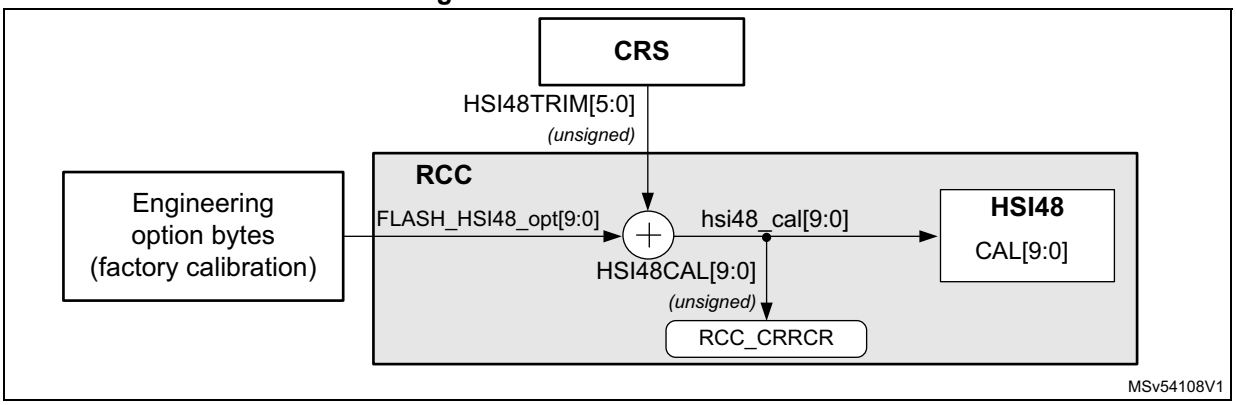
RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by STMicroelectronics to achieve accuracy of ACC_{CSI} (refer to the product datasheet for more information).

After a power-on reset, or at the exit of Standby mode, the factory calibration value is loaded in the CSICAL[7:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the CSI frequency using the CSITRIM[5:0] bits.

Note: Bits CSICAL[7:0] and CSITRIM[5:0] are located into the RCC CSI calibration register (RCC_CSICFGR)

Figure 42. CSI calibration flow



HSI48 oscillator

The HSI48 is an RC oscillator delivering a 48 MHz clock that can be used directly as kernel clock for some peripherals.

The HSI48 oscillator mainly aims at providing an accurate clock to the USB Full-Speed peripherals by means of a special clock recovery system (CRS) circuitry. The CRS can use the USB SOF signal, the LSE or an external signal to automatically adjust the oscillator frequency on-the-fly, with a very small granularity. It is possible to read the calibration value provided to the HSI48 via *RCC clock recovery RC register (RCC_CRRCR)*. The HSI48TRIM value can be adjusted through the CRS block, for more details, refer to *Section 8: Clock recovery system (CRS)*.

Figure 43. HSI48 calibration flow

The HSI48 oscillator is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, this oscillator is free-running and thus subject to manufacturing process variations. This is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACC_{HSI48} (refer to the product datasheet for more information).

The HSI48RDY flag indicates whether the HSI48 oscillator is stable or not. At startup, the HSI48 output clock is not released until this bit is set by the hardware.

After a power-on reset, or at the exit of Standby mode, the factory calibration value is loaded into the HSI48.

The HSI48 can be switched ON and OFF using the HSI48ON bit.

The HSI48 clock can also be driven to the MCO1 multiplexer and used as clock source for other application components.

Note: HSI48ON and HSI48RDY bits are located in the RCC register map.

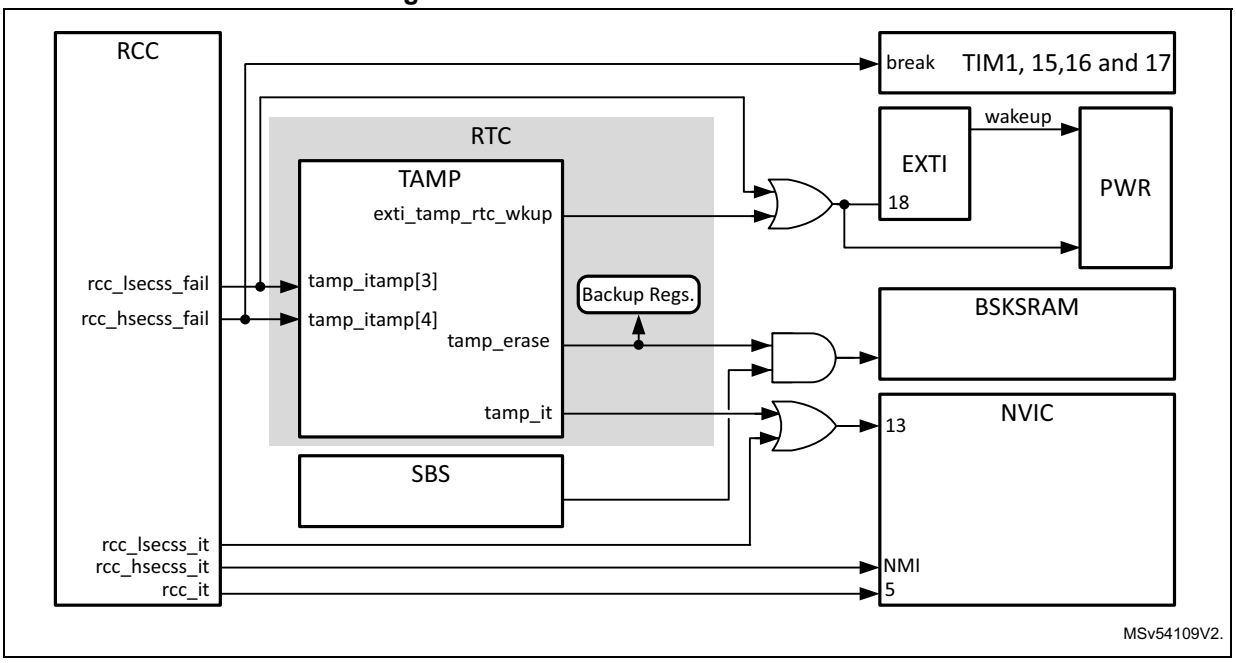
LSI oscillator

The LSI acts as a very-low-power clock source that can be kept running when the system is in Stop or Standby mode for the independent watchdog (IWDG) and auto-wakeup unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheet.

The LSI can be switched ON and OFF using the LSION bit. The LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started either by hardware or software, the LSI is forced ON and cannot be disabled.

The LSI remains enabled when the system enters Stop or Standby mode (See *Table 53: Oscillator states versus system modes*).

At LSI startup, the clock is not provided until the hardware sets the LSIRDY bit. An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.



In addition, the LSI clock can be driven to the MCO2 output and used as a clock source for other application components.

Note: Bits LSION and LSIRDY bits are located into the RCC clock control and status register (RCC_CSR).

7.5.3 Clock security system (CSS)

The RCC offers a clock security system for the HSE and LSE oscillators. The clock security systems are capable of detecting a failure on HSE and LSE oscillators. The figure hereafter shows how this function interacts with other blocks.

Figure 44. LSE and HSE CSS function

CSS on HSE

The clock security system can be enabled by software via the HSECSSON bit. The HSECSSON bit can be enabled even when the HSEON is set to 0.

The CSS on HSE is activated when the HSE is enabled and ready, and the software sets the HSECSSON bit to 1. The CSS on HSE is no longer working when the HSE is disabled. For example, this function does not work when the system is in Stop mode.

It is not possible to clear directly the HSECSSON bit by software. The HSECSSON bit is cleared by hardware when a system reset occurs or when the system enters Standby mode (see *Section 7.4.2: The system and application resets (sys_rst and nreset)*).

When the CSS on HSE is enabled, the following actions are done by the RCC if a failure is detected:

- The signal **rcc_hsecss_fail** is asserted.
- If the STOPWUCK = 0, the HSI clock is enabled and the SW switch automatically selects HSI as system clock.
- If the STOPWUCK = 1, the CSI clock is enabled and the SW switch automatically selects CSI as system clock.
- The HSE is then automatically disabled.
- If the HSE output was used as clock source for PLLs, the PLLs are also disabled.
- The XSPISEL switch goes to recovery position.
- The FMCSEL switch goes to recovery position:
  - If PLL1 has been disabled and FMCSEL is in position 1.
  - If PLL2 has been disabled and FMCSEL is in position 2.

  See details on *Section : Clock distribution for SDMMC, FMC, and XSPI*.
- The clock failure event (**rcc_hsecss_fail**) is also sent to the break inputs of advanced-control timers (TIM1, TIM 8, TIM15, TIM16, TIM17 and TIM20) and high-resolution timers (HRTIM1, HRTIM2).
- An NMI interrupt is generated to inform the software about the failure (CSS interrupt: ***rcc_hsecss_it***), thus allowing the MCU to perform rescue operations. The CSS interrupt is asserted until the HSECSSF bit is cleared. The HSECSSF flag can be cleared by setting the HSECSSC bit in the *RCC clock source interrupt clear register (RCC_CICR)*.
- A tamper event can also be triggered, in order to clear content of the backup registers, and backup RAM.

CSS on LSE

A clock security system on the LSE oscillator can be enabled by software by programming the LSECSSON bit in the *RCC Backup domain control register (RCC_BDCR)*.

This bit is disabled by hardware if one of the following conditions is met:

- After a V_{SW} hardware reset (**pwr_vsw_rst),**
- After a V_{SW} software reset via VSWRST bit

The software can also disable the clock security system after an LSE failure detection.

The CSS on LSE works in all modes (Run, Stop and Standby) including VBAT.

The LSECSS provides a re-arm feature, offering to the software the possibility to re-arm the LSECSS and re-enable the LSE clock when a failure has been detected. This feature allows the application to decide if the LSE is to be provided again to the RTC even if a failure occurred, or if another action must be performed. For example the application can decide to reset the V_{SW} domain only if a certain number of consecutive LSE failures occurred, within a time window.

The LSECSS offers two flag signals:

- The LSECSSD, capable of retaining an LSE failures even in V_{BAT} mode.
- The LSECSSF is used to generate interrupt in case of LSE failure. This flag is not affected by a failure detected when the product is in V_{BAT} mode

The sequence hereafter describes the LSE enabling sequence with the clock security system enabled.

- Follow the LSE enable procedure given is the section *LSE Programming sequence*, except the last step
- Select the LSE clock via RTCSEL[1:0]
- Set the LSECSSON bit to 1
- If the RCC_BDCR register no longer needs to be changed, set the DBP bit of PWR_CR1 to 0 in order to write-protect accesses.

Note: The LSECSSON bit must be enabled after the LSE is enabled (LSEON bit set by software) and ready (LSERDY set by hardware), and after the RTC clock has been selected through the RTCSEL bit.

If a failure is detected on the LSE, the hardware does the following:

- The LSE clock is no more delivered to the RTC.
- The values of RTCSEL, LSECSSON and LSEON bits are not changed by the hardware.
- A failure event is generated (**rcc_lsecss_fail**). This event allows the system to wake up from Standby, but also to protect the backup registers and BKPSRAM via TAMP block. This event is also generated in VBAT mode.
- The interrupt flag LSECSSF is activated (except in V_{BAT} mode) in order to generate an interrupt (**rcc_lsecss_it**).
- The LSECSSD flag is activated as well, retaining the first LSE failure even in V_{BAT} mode.

In the software side, different actions can be taken according to the application requirements. Three different cases are described hereafter in order to illustrate the hardware behavior, they can also be combined. The application can also decide to handle LSE failure differently.

Case A:

The application no longer wants to use LSE when a failure is detected:

- Unlock the RCC_BDCR register by setting the DBP bit of PWR_CR1 to 1
- Disable the CSS function (this step is mandatory)
  - Clear the LSECSSF bit, if interrupt was enabled for this event
  - Set the LSECSSON bit to 0
  - Set the LSEON bit to 0, in order to disable the LSE
- Change the clock source for the RTC if needed:
  - Set the RTCEN bit to 0 to disable the RTC clock
  - Enable the new clock source for the RTC
  - Select the proper clock source via RTCSEL
  - Set the RTCEN bit to 1 to enable the RTC clock
- The application must perform specific actions consecutive to TAMPER events if enabled
- Lock the RCC_BDCR register by setting the DBP bit of PWR_CR1 to 0

Case B:

The application wants to re-initialize the V_{SW} domain:

- Unlock the RCC_BDCR register by setting the DBP bit of PWR_CR1 to 1
- Perform a V_{SW} reset by setting the VSWRST bit to 1, then back to 0 (it is in reality a pulse of one period of sys_ck)
- The application must perform specific actions consecutive to TAMPER events if enabled
- Re-initialize all components of the V_{SW} domain.
- Lock the RCC_BDCR register by setting the DBP bit of PWR_CR1 to 0

Case C:

The application tries to re-use LSE when a failure is detected:

- If the number of failures in a given time window is higher than a given threshold then go to case A or B. Otherwise continue to the next step.
- Unlock the RCC_BDCR register by setting the DBP bit of PWR_CR1 to 1
- Clear the LSECSSF bit if interrupt was enabled for this event.
- The application must perform specific actions consecutive to TAMPER events if enabled
- Set the LSECSSON bit to 0.
- Re-arm the LSECSS function by writing the LSECSSRA bit to 1, then back to 0.
- Wait for LSERDY set 1. The LSERDY flag must go to 1 after the oscillator settling time delay plus, 4096 periods of LSE clock. If this is not the case, it probably means that the LSE failure is permanent. It is not possible to set LSECSSON to 1, it is recommended to execute case A or B.
- Set the LSECSSON bit to 1.
- When LSECSSON is seen to 1, the LSE is enabled, and protected by LSECSS.
- Lock the RCC_BDCR register by setting the DBP bit of PWR_CR1 to 0

All bits used in these sequences (except DBP) are located into *RCC Backup domain control register (RCC_BDCR)*.

7.5.4 Clock output generation (MCO1/MCO2)

Two microcontroller clock output pins MCO1 and MCO2, are available. A clock source can be selected for each output. The selected clock can be divided thanks to a configurable prescaler (refer to *Figure 37* for additional information on signal selection).

MCO1 and MCO2 outputs are controlled via MCO1PRE[3:0], MCO1SEL[2:0], MCO2PRE[3:0] and MCO2SEL[2:0] located in the *RCC clock configuration register (RCC_CFGR)*.

The GPIO port corresponding to each MCO pin must be programmed in alternate function mode.

The dividers MCO1PRE and MCO2PRE, provide a clock with a duty cycle of 50% for even divisions values. More generally the duty cycle is given by the following formula:

$$DC(\%) = \frac{\text{FLOOR}\left(\frac{\text{MCOxPRE}}{2}\right)}{\text{MCOxPRE}} \times 100$$

For MCOxPRE = 2 to 15.

Note that the MCO1 and MCO2 outputs are available in Run and Stop modes.

Caution: The clock provided to the MCOs outputs must not exceed the maximum PAD speed, refer to the product datasheet for information about the supported PAD speed.

The table hereafter shows the signals available on each MCO output.

Table 54. Oscillator states versus system modes

MCO1SEL		MCO2SEL	
Pos.	**Clock source**	**Pos.**	**Clock source**
0	hsi_ck	0	sys_ck
1	lse_ck	1	pll2_p_ck
2	hse_ck	2	hse_ck
3	pll1_q_ck	3	pll1_p_ck
4	hsi48_ck	4	csi_ck
-	-	5	lsi_ck

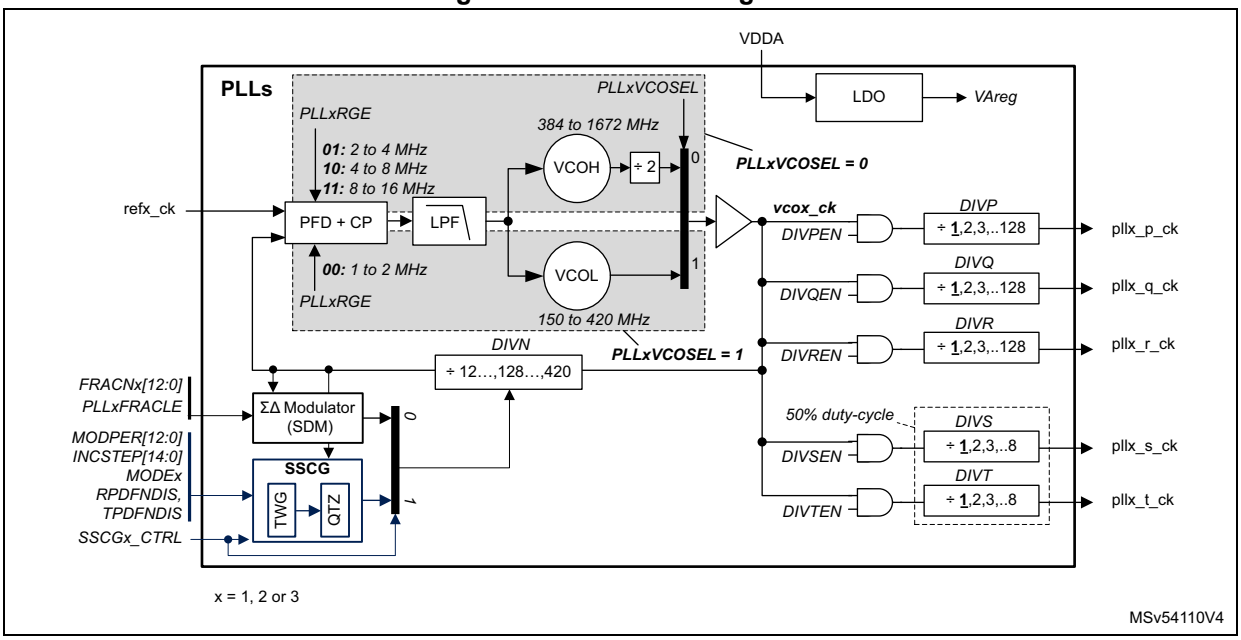
7.5.5 PLL description

The RCC features three PLLs:

- PLL1, generally used to provide clocks to the CPU, busses, and some peripherals
- PLL2, generally used to provide clocks to XSPI and SDMMC, and some peripherals
- PLL3, dedicated to the kernel clock generation for peripherals

The PLLs integrated into the RCC are completely independent. They offer the following features:

- A VCO supporting two modes:
  - A wide-range
  - A low-range used for instance in audio application cases
- Input frequency range:
  - 2 to 16 MHz for the VCO in wide-range mode
  - 1 to 2 MHz for the VCO in low-range mode
- VCO frequency range:
  - 384 to 1672 MHz for the VCO in high-range mode (VCOH), before the divider.
  - 150 to 420 MHz for the VCO in low-range mode (VCOL)
- Capability to work either in integer with or without SSGC, or in fractional mode
- 13-bit sigma-delta modulator, allowing to fine-tune the VCO frequency by steps of 10 to 0.3 ppm
- The sigma-delta modulator can be updated on-the-fly without generating frequency overshoots on PLLs outputs.
- PLLs offer up to 5 outputs with post-dividers.



For better flexibility, all PLLs offer two VCOs (VCOH and VCOL), the application can select the wanted VCO via PLLxVCOSEL bit.

The frequency of the reference clock provided to the PLLs (**refx_ck**) must range from 1 to 16 MHz. The DIVMx dividers of the *RCC PLLs clock source selection register (RCC_PLLCKSELR)* must be properly programmed in order to match this condition. In addition, the PLLxRGE[1:0] field of the *RCC PLLs configuration register (RCC_PLLCFGR)* must be set according to the reference input frequency to guarantee an optimal performance of the PLL.

The user application can then configure the proper VCO. VCOL must be chosen when the reference clock frequency is lower than 2 MHz.

To reduce the power consumption, it is recommended to configure the VCO output to the smaller range.

Figure 45. PLL block diagram

The PLLs can be enabled by setting PLLxON to 1. The PLLxRDY bits indicate that the PLL is ready (means locked).

The DIVN loop divider must be programmed to achieve the expected frequency at VCO output. The VCO output range must be respected.

PLLs have a divider-by-2, at VCOH output, insuring that the clock provided to the post-dividers has a duty-cycle of 50%.

The frequency of the clocks provided by the PLLs can also be adjusted thanks to post-divider DIVP, DIVQ, DIVR, DIVS and DIVT. The post-divider values can be changed without disabling the PLLs, if their respective enable bits are set to 0.

The post-dividers provide clocks with a 50% duty-cycle in the following conditions:

- When the post-dividers are dividing the clock by an even value.
- When VCOH is used and post-dividers are bypassed.
- When VCOH is selected and post-dividers DIVS and DIVT are used.

PLL programming recommendations

This section is providing a list of recommendations to follow in order to guarantee a good usage of the PLLs. Note that programming examples are given in *Section 7.7.1: PLL programming procedure*.

- Before enabling the PLLs, the user must ensure that the reference frequency (**refx_ck**) provided to the PLL is stable and in the good range.
- When one or several PLL outputs are not used, the application must set the corresponding enable bit DIV[y]ENx and the divider value DIV[y]x to 0 (with x = 1, 2 or 3, and y = P, Q, R, S or T).
- In order to ensure the good behavior of the PLL, the bits PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN and PLLxTEN must be set to 0 before disabling the corresponding PLL. In the same way, the bits PLLxPEN, PLLxQEN, PLLxREN,

PLLxSEN and PLLxTEN can be set to 1 only if the corresponding bit PLLON is already set to 1 and the PLL is ready.

Refer to section *Section 7.7.1: PLL programming procedure* for additional information.

PLL protections

- The RCC hardware does not allow changing DIVMx, DIVN, PLLxRGE, PLLxVCOSEL when the corresponding PLLx is ON and it is also not possible to change PLLSRC when one of the PLL is ON.
- The hardware prevents writing PLL1ON or PLL1PEN to 0 if the PLL1 is currently used to deliver the system clock. There are other hardware protections on the clock generators (refer to *Section 7.5.7: Clock protection*).

The PLLs are disabled by hardware when the system enters Stop or Standby mode.

PLLs using HSE as reference clock are also disabled by hardware if an HSE failure is detected.

Note: The refx_ck clock is provided to the PLLx when the corresponding PLLON bit is set to 1.

The PLLs can work in 3 different modes:

- In integer mode
- In fractional mode
- In spread spectrum mode

Using the PLLs in integer mode

The PLL is working in integer mode when the sigma-delta modulator (SDM) is loaded with a 0, and the bit PLLxSSCGEN = 0.

In order to load 0 into the SDM, the user has to perform the following sequence:

– Write PLLxFRACLE of *RCC PLLs configuration register (RCC_PLLCFGR)* to 0
– Write FRACN[12:0] to 0,
– Write PLLxFRACLE to 1
– Wait at least 5 µs

The bits FRACN[12:0] are located in the RCC_PLLxFRACR registers.

The VCO frequency (F_{VCO}) and output frequencies expressions are given by the following table:

Table 55. VCO frequency and output frequency in integer mode

PLLxVCOSEL = 0	PLLxVCOSEL = 1
$F_{VCO} = 2 \times F_{ref_ck} \times (DIVN + 1)$	$F_{VCO} = F_{ref_ck} \times (DIVN + 1)$
$F_{pll_y_ck} = \frac{F_{VCO}}{2 \times (DIVy + 1)}$ with y = P, Q, R, S or T	$F_{pll_y_ck} = \frac{F_{VCO}}{(DIVy + 1)}$ with y = P, Q, R, S or T

Refer to section *Section 7.7.1: PLL programming procedure* for additional information.

Using the PLLs in fractional mode

The fractional mode is activated when the value loaded into the SDM is different from 0, and the bit PLLxSSCGEN = 0.

The SDM value can be updated at any time by the application by executing the following sequence:

- Write PLLxFRACLE bit to 0
- Wait at least three reference clock cycles
- Write into FRACN[12:0] the new fractional value,
- Write PLLxFRACLE to 1.
  The new FRACN value is applied after maximum three reference clock periods

The sigma delta modulator is designed in order to minimize the jitter impact while allowing very small frequency steps.

When the PLL is used in fractional mode, the DIVN divider must be initialized before enabling the PLL.

This feature can be used either to generate a specific frequency, with a good accuracy from any crystal value, or to perform a fine-tuning of the frequency on-the-fly.

The VCO frequency (F_{VCO}) and output frequencies expressions are given by the following table:

Table 56. VCO frequency and output frequency in fractional mode

PLLxVCOSEL = 0	PLLxVCOSEL = 1
$F_{VCO} = 2 \times F_{ref_ck} \times \left(DIVN + 1 + \frac{FRACN}{2^{13}} \right)$	$F_{VCO} = F_{ref_ck} \times \left(DIVN + 1 + \frac{FRACN}{2^{13}} \right)$
$F_{pll_y_ck} = \frac{F_{VCO}}{2 \times (DIVy + 1)}$ with y = P, Q, R, S or T	$F_{pll_y_ck} = \frac{F_{VCO}}{(DIVy + 1)}$ with y = P, Q, R, S or T

Refer to section *Section 7.7.1: PLL programming procedure* for additional information.

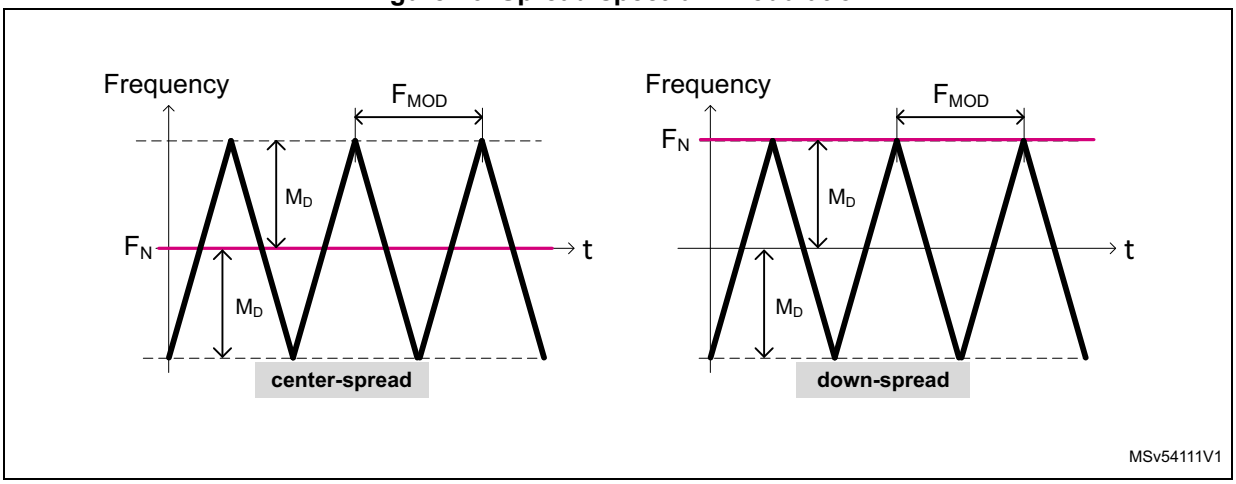
Using the PLLs in spread spectrum mode

The spread spectrum mode is activated when the SDM is loaded with 0, and the bit PLLxSSCGEN = 1. This feature is available on all PLLs.

The VCOH must be selected when the spread spectrum mode is activated. VCOH is selected by setting PLLxVCOSEL to 0. PLLxVCOSEL are located into the *RCC clock configuration register (RCC_CFGR)*.

The spread spectrum technique consists of modulating the VCO frequency with a low-frequency signal (in our case a triangular signal), in order to spread the clock energy into a wider frequency band. As a consequence, the number of emitted EMI peaks is reduced.

The parameters of the spread spectrum modulation are adjusted via the following fields:



- MODPER[12:0]: used to adjust the modulation frequency
- INCSTEP[14:0]: used to adjust the modulation depth (or modulation index)
- SPREADSEL: used to define if the modulation is centered around the VCO frequency (center-spread) or if it is lowered with respect to VCO frequency (down-spread).

The bits MODPER[12:0], INCSTEP[14:0] and SPREADSEL are located into the RCC_PLLxSSCGR registers with x=1, 2 or 3.

Figure 46 shows the signal modulating the nominal frequency (F_N), when SPREADSEL = 0 (center-spread) and SPREADSEL = 1 (down-spread). The nominal frequency is the frequency output by the PLL in integer mode, when no clock spreading is applied.

Setting the SPREADSEL bit to 1 (down-spread) guarantees that the PLL output frequency does not exceed the programmed frequency value when the SSCG is enabled.

Figure 46. Spread-spectrum modulation

The peak modulation depth (in percentage) is given by the following formula:

$$M_D\,(\%) = \frac{\text{MODPER} \times \text{INCSTEP} \times 100 \times 5}{(2^{15} - 1) \times (\text{DIVN} + 1)}$$

Note that MODPER x INCSTEP must not exceed (2^{15}-1).

The modulation frequency (F_{mod}) is given by:

$$F_{mod} = \frac{F_{ck_ref}}{4 \times \text{MODPER}}$$

Note: Refer to the datasheet of the product for the recommended modulation frequency range.

In order to use the spread spectrum feature, the user has to do the following:

- Program the PLL as explained in *Section : Using the PLLs in integer mode* in order to adjust the nominal frequency (F_N) according to the targeted by the application.
- Compute the MODPER value according to the wanted modulation frequency (F_{mod}):

$$MODPER = ROUND\left(\frac{F_{ck_ref}}{4 \times F_{mod}}\right)$$

- Compute the INCSTEP value according to the wanted modulation depth (M_D):

$$INCSTEP = ROUND\left(\frac{(2^{15} - 1) \times M_D \times (DIVN + 1)}{100 \times 5 \times MODPER}\right)$$

  Check that MODPER x INCSTEP does not exceed (2^{15}-1).
- Then DIVP, Q, R, S or T can be adjusted, and the bit PLLxSSCGEN can be set to 1, and the PLL enabled.

The user can check F_{MIN}, F_{MAX} and F_C as follows:

- If SSCG_MODE = 0 (centered-spread)

  F_C is given by the formula of the *Section : Using the PLLs in integer mode*

  $F_{MIN} = F_C$ x (1 - M_D/100)

  $F_{MAX} = F_C$ x (1 + M_D/100)
- If SSCG_MODE = 1 (down-spread)

  F_{MAX} is given by the formula of the *Section : Using the PLLs in integer mode*

  $F_{MIN} = F_{MAX}$ x (1 - 2 x M_D/100)

  $F_C = F_{MAX}$ x (1 - M_D/100)

Figure 47 shows the digital signal generated by Triangular Waveform Generator (TWG block), and the way of MODPER and INCSTEP are changing the triangular waveform.

Figure 47. Triangular waveform generator

Refer to section *Section 7.7.1: PLL programming procedure* for additional information.

7.5.6 System clock (sys_ck)

System clock selection

After a system reset, the HSI is selected as system clock and all PLLs are switched OFF. When a clock source is used for the system clock, it is not possible for the software to disable the selected source via the xxxON bits.

Of course, the system clock can be stopped by the hardware when the system enters Stop or Standby mode.

When the system is running, the user application can select the system clock (**sys_ck**) among the 4 following sources:

- HSE
- HSI
- CSI
- pll1_p_ck

This function is controlled by programming the *RCC clock configuration register (RCC_CFGR)*. A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready.

The SWS status bits in the *RCC clock configuration register (RCC_CFGR)* indicate which clock is currently used as system clock. The other status bits in the RCC_CR register indicate which clock(s) is (are) ready.

System clock generation

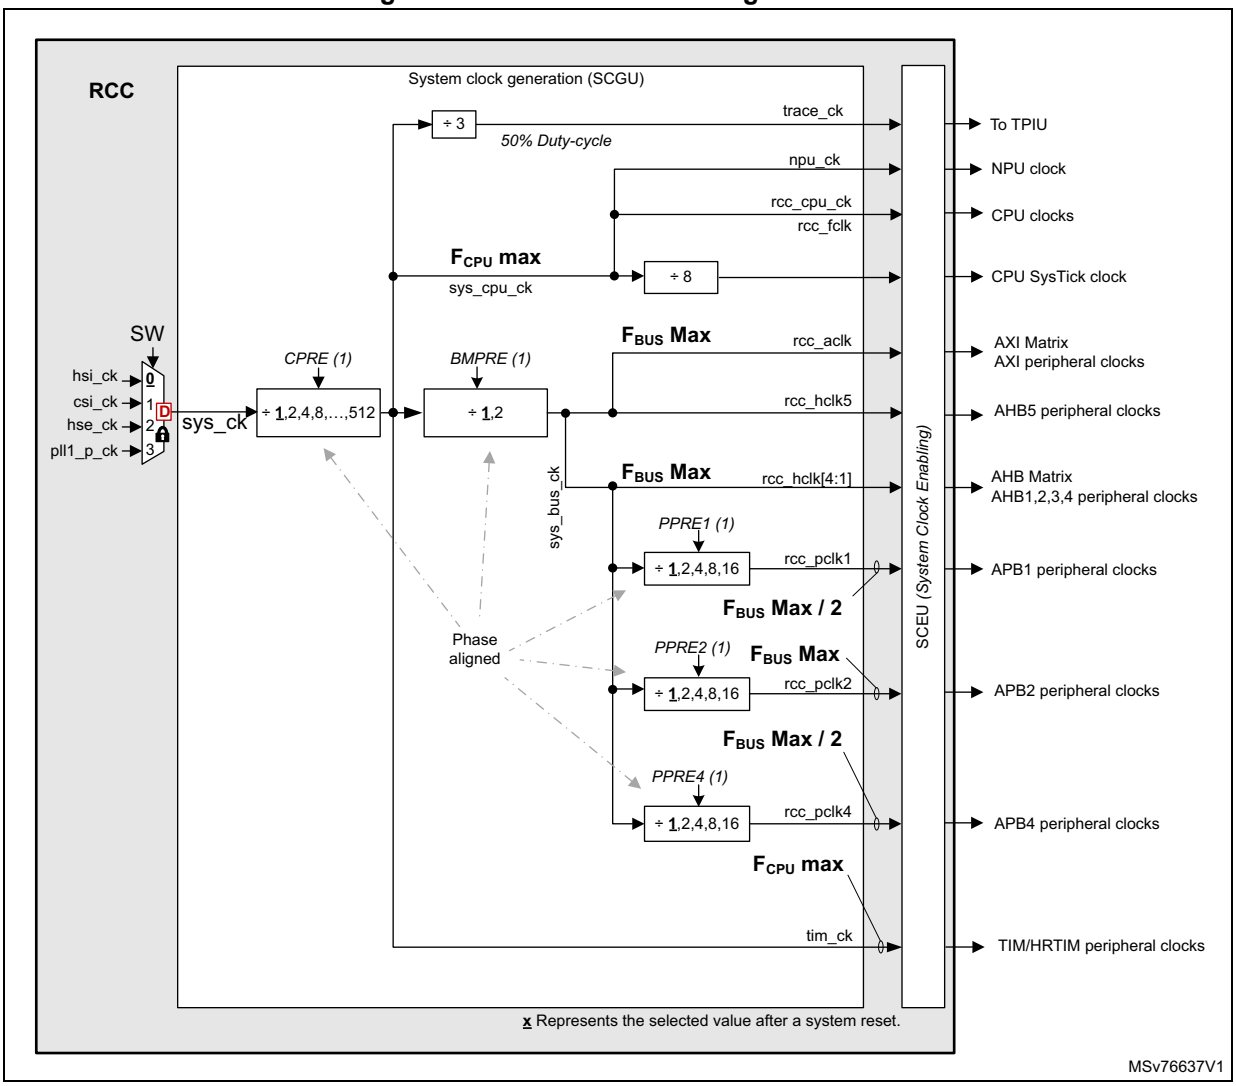


Figure 48 shows a simplified view of the clock distribution for the CPU and buses. All the dividers shown in the block diagram can be changed on-the-fly without generating timing violations. This feature is a very simple solution to adapt the bus frequencies to the application needs, thus optimizing the power consumption.

The CPRE divider can be used to adjust the CPU clock. However this also impacts the clock frequency of all bus matrix. CPRE is controlled via the RCC_CDCFGR register.

In the same way, BMPRE divider can be used to adjust the clock for the bus matrix (AHB and AXI), but this also impacts the clock frequency of APB buses. BMPRE is controlled via the RCC_BMCFGR register.

Most of the prescalers are controlled via RCC_CDCFGR and RCC_SRDCFGR registers.

Figure 48. Core and bus clock generation

1. Divider values can be changed on-the-fly. All dividers have 50% duty cycles.

Note that the application must respect the maximum allowed frequencies: F_{CPU} Max and F_{BUS} Max. F_{BUS} represents the maximum allowed frequency for the AHB and AXI buses. Refer to the product datasheet for maximum values.

*Note: The trace clock (**trace_ck**) is generated from **sys_cpu_ck** clock, divided by 3. For additional information refer to Section : Clock distribution for Debug and Trace.*

7.5.7 Clock protection

The RCC does not allow the system clock (**sys_ck**) to be disabled. Several protective measures are implemented to prevent accidentally disabling the system clock.

In addition, protection bits are provided to prevent accidental disabling of FMC and XSPI block activities.

The protection consists in ignoring invalid write operations. It is recommended to read back registers having protection to insure that the clock configuration expected by the software is accepted by the RCC.

The table hereafter shows the protections handled by the RCC.

Table 57. Clock protection summary

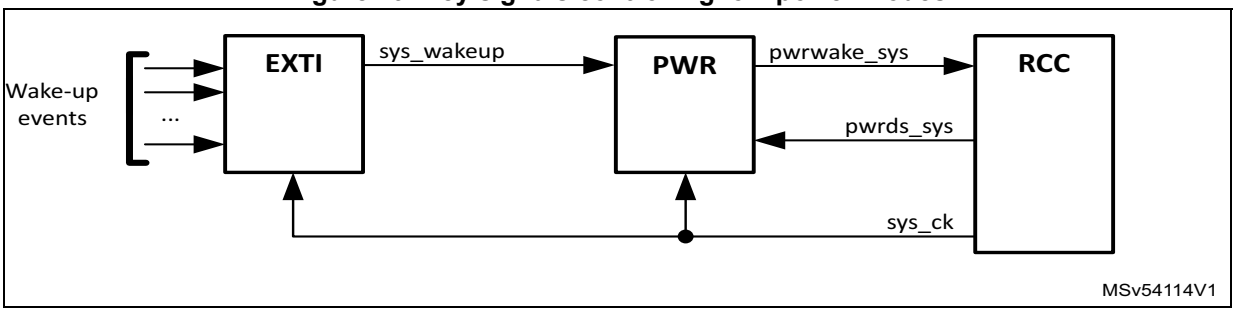
Protected fields	Conditions checked by the RCC
SW[2:0]	Changing SW value is allowed only if the targeted clock is enabled and ready.
PLLSRC[1:0]	Changing PLLSRC value is allowed if: - The targetted clock is enabled and ready, and, - All PLL disabled
HSEON, HSION or CSION	Changing these fields is allowed if: - The oscillator is not used directly or indirectly (via PLL1) as system clock, and - FMCCKP = XSPICKP = 0.
DIVMx[5:0], PLLxRGE[1:0], PLLxVCOSEL, DIVN[8:0]	Changing these fields is allowed only if the corresponding PLL is disabled (PLLxON=0)
DIVP[6:0], DIVQ[6:0], DIVR[6:0], DIVS[2:0], DIVT[2:0]	Changing these fields is allowed only if the corresponding DIVyEN bit is equal to 0 (y = P, Q, R, S or T)
PLL1ON	Changing this field is allowed if: - SW switch is not selecting the PLL1, and - FMCCKP = 0.
PLL1PEN	Disabling the DIVP output of PLL1 is allowed if the SW switch is not selecting PLL1
PLL2ON	Changing this field is allowed only if FMCCKP = XSPICKP = 0.
PLL2SEN, PLL2TEN, XSPI1EN, XSPI1LPEN XSPI1RST	Changing these fields is allowed only if XSPICKP = 0.
PLL1QEN, PLL2REN, FMCEN, FMCLPEN, FMCRST	Changing these fields is allowed only if FMCCKP = 0.
HSEBYP, HSEEXT	Changing these fields is allowed only if HSEON = 0.
LSEBYP, LSEEXT	Changing these fields is allowed only if LSEON = 0.

There is also a clock protection mechanism in case of HSE failure, refer to *Section : CSS on HSE*.

7.5.8 Clock generation in Stop and Standby modes

When the whole system enters Stop mode, all the clocks (system and kernel clocks) are stopped and the following clock sources are disabled as well:

- CSI, HSI (depending on HSIKERON, and CSIKERON bits)
- HSE
- PLL1, PLL2 and PLL3
- HSI48



The content of the RCC registers is not altered except for PLL1ON, PLL2ON, PLL3ON HSEON and HSI48ON that are set to 0.

HSION and CSION bits are also affected depending on STOPWUCK and STOPKERWUCK bits (see *Table 58*).

When the CPU requests to go into Stop mode, the RCC first stops all the requested clocks, and informs the PWR that all clocks have been properly stopped. As shown in *Figure 49*, three main signals are used to control power transitions:

- The **rcc_pwrds** is used to indicate to the PWR that the RCC has stopped all the clocks, and thus the PWR can go to Stop or Standby.
- The **pwr_wkup** is used to indicate to the RCC to re-enable the clocks.
- The **exti_wkup** is used to indicate to the PWR that an event requests the system to exit from Stop mode.

Figure 49. Key signals controlling low-power modes

Exiting Stop mode

When the microcontroller exits system Stop mode via a wakeup event, the application can select which oscillator (HSI and/or CSI) is used to restart. The STOPWUCK bit selects the oscillator used as system clock. The STOPKERWUCK bit selects the oscillator used as kernel clock for peripherals. The STOPKERWUCK bit is useful if after a system Stop, a peripheral needs a kernel clock generated by an oscillator different from the one used for the system clock.

All these bits belong to the *RCC clock configuration register (RCC_CFGR)*.

Table 58 gives a detailed description of their behavior.

Table 58. STOPWUCK and STOPKERWUCK description

STOPWUCK	STOPKERWUCK	-	Activated oscillator when system exits Stop mode	Distributed clocks when system exits Stop mode	
				System clock	Kernel clock
0	0	→	HSI	HSI	HSI
	1	→	HSI and CSI		HSI and/or CSI
1	0	→		CSI	
	1	→	CSI		CSI

During Stop mode

There are two specific cases where the HSI or CSI can be enabled during system Stop mode:

- When a dedicated peripheral requests the kernel clock
  The peripheral receives the HSI or CSI according to the kernel clock source selected for this peripheral (via PERxSRC).
- When the HSIKERON or CSIKERON bits are set the HSI and CSI are kept running during Stop mode but the outputs are gated. The clock is then available immediately when the system exits Stop mode or when a peripheral requests the kernel clock (see *Table 59* for details).

HSIKERON and CSIKERON bits belong to *RCC register map*. *Table 59* gives a detailed description of their behavior.

Table 59. HSIKERON and CSIKERON behavior

HSIKERON (CSIKERON)	-	HSI (CSI) state during Stop mode	HSI (CSI) setting time
0	→	OFF	$t_{su(HSI)}$ ($t_{su(CSI)}$) (1)
1	→	Running and gated	Immediate

1. $t_{su(HSI)}$ and $t_{su(CSI)}$ are the startup times of the HSI and CSI oscillators (refer to the product datasheet for values of these parameters).

When the microcontroller exits Standby mode, the HSI is selected as system and kernel clock. The RCC registers are reset to their initial values except for the RCC_RSR and RCC_BDCR registers.

Note that the HSI and CSI outputs provide two clock paths (see *Figure 37*):

- One path for the system clock (**hsi_ck** or **csi_ck**)
- One path for the peripheral kernel clock (**hsi_ker_ck** or **csi_ker_ck**).

When a peripheral requests the kernel clock in system Stop mode, only the path providing the **hsi_ker_ck** or **csi_ker_ck** is activated.

Caution: The CPU does not automatically get the same clock frequencies when leaving Stop mode: it is up to the application to restore the previous clock settings if needed.

7.5.9 Peripheral clock distribution

Some peripherals are designed to work with two different clock domains that operate asynchronously:

- A clock domain synchronous with the register and bus interface (**ckg_bus_perx** clock)
- A clock domain generally synchronous with the peripheral (kernel clock)

The benefit of having peripherals supporting these two clock domains is that the user application has more freedom to choose an optimized clock frequency for the CPU, bus matrix and for the kernel part of the peripheral.

As a consequence, the user application can change the bus frequency without reprogramming the peripherals. As an example an ongoing transfer with UART is not disturbed if its APB clock is changed on-the-fly.

Table 60 shows the clocks the RCC delivers to the peripherals. Note as well that the clock named per_ck, is the output of a mux which allows the application to select:

- hsi_ker_ck, or
- csi_ker_ck, or
- hse_ker_ck

Table 60. Peripheral clock distribution summary

Peripherals	Clock types	Clock sources	Kernel clock MUX		Max Kernel clock freq. [MHz] (1)	Type (2)(3)
			Pos.	Control field		
UCPD	Kernel	ucpd_ker_ck	-	-	25	A
	Bus	pclk1	-	-	F_{MAX} / 4	-
VREFBUF	Bus	pclk4	-	-	F_{MAX} / 4	-
WWDG1	Bus	pclk1	-	-	F_{MAX} / 4	-

1. The F_{MAX} value depends on the device reference and can be found on the datasheet of the product.
2. 'A' Means that the kernel clock is asynchronous with respect to the bus interface clock.
3. 'S' Means that the kernel clock is synchronous with respect to the bus interface clock.
4. Reset value
5. NPU bus clocks are in reality clock enable signals, which indicate the NPU core (kernel) clock cycle on which the bus is valid
6. The RTC switch is in the V_{SW} voltage domain

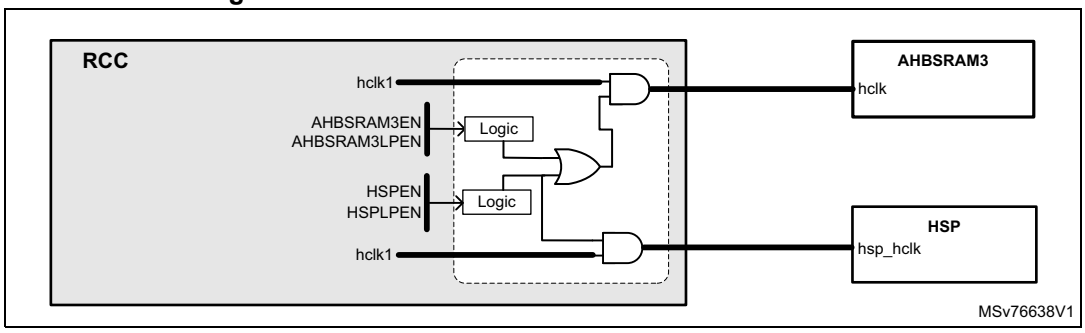

Figure 50 to *Figure 65* provide a more detailed description of kernel clock distribution. Refer to *Section 7.5.12: Peripheral clock gating control* for more details.

To reduce the number of switches, some peripherals share the same kernel clock source. Nevertheless, all peripherals have their dedicated enable signal.

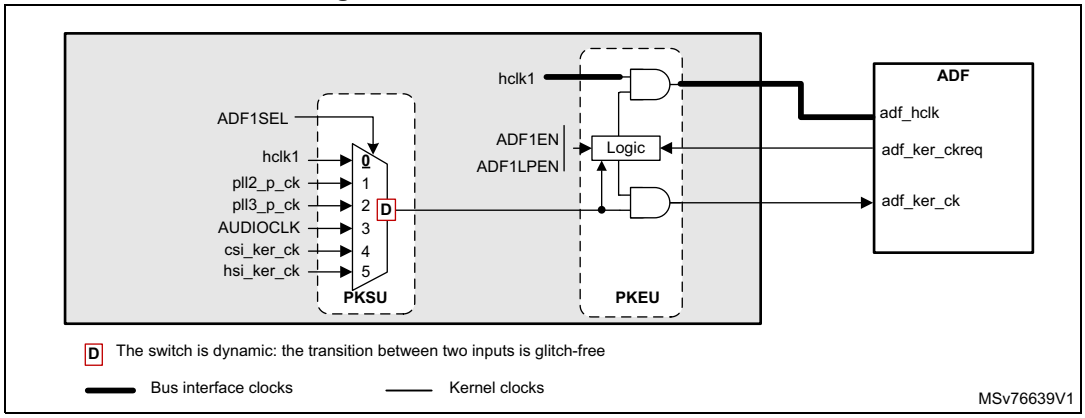
Clock distribution for HSP

The HSP is clocked by the AHB1 peripheral clock, as shown in *Figure 50*.

Figure 50. Clock distribution for HSP and AHBSRAM3

The HSP can operate in Sleep mode, when the HSPLPEN bit is set to 1, but not in Stop mode. The HSP uses AHBSRAM3, so whenever the HSP clock is enabled, the AHBSRAM3 clock is also enabled.

Clock distribution for ADF



The audio peripherals generally need specific accurate frequencies. As shown in *Figure 51*, the kernel clock of the ADF can be generated by:

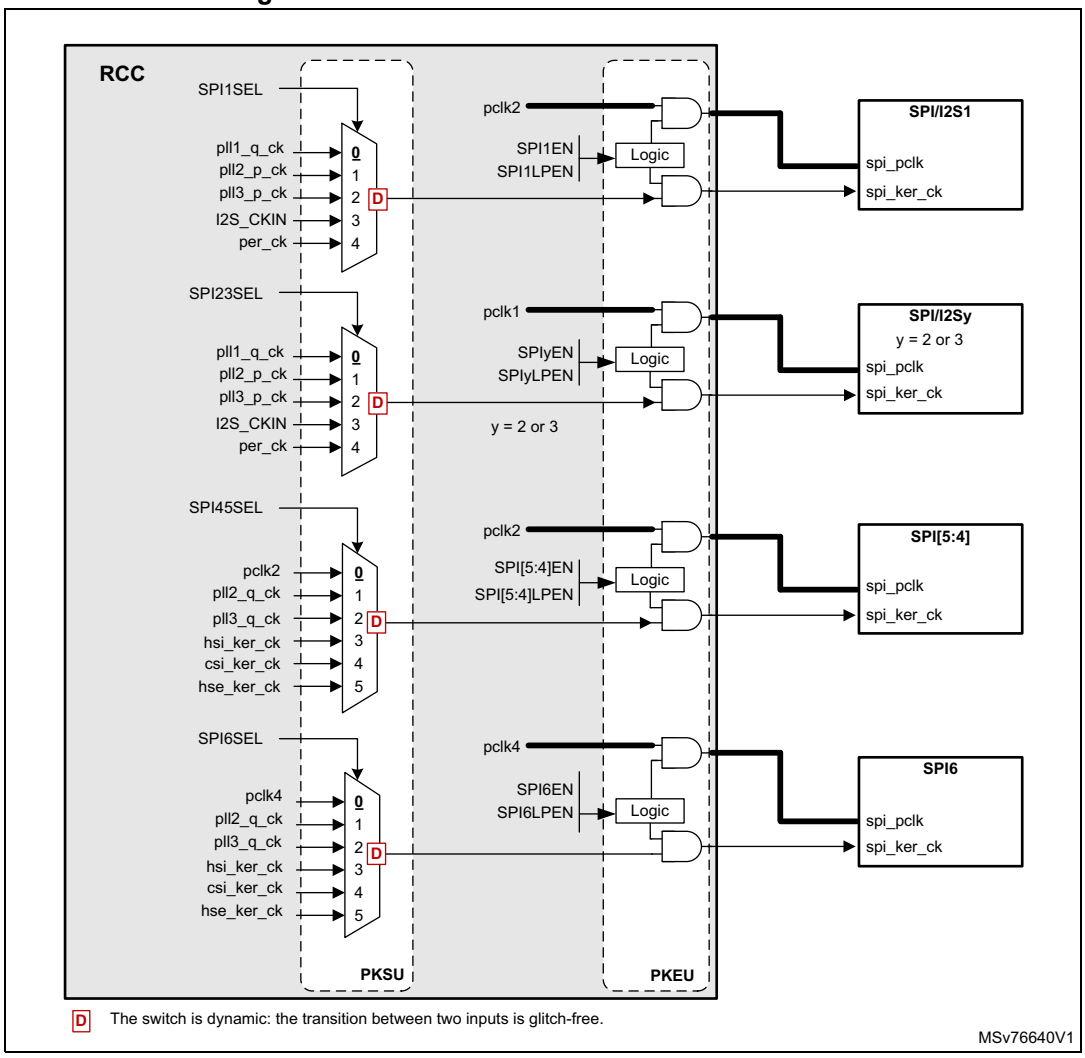
- AHB peripheral clock
- PLL2 or 3 for optimal flexibility in frequency generation
- HSI or CSI for use-cases where the current consumption is critical
- AUDIOCLK when an external clock reference needs to be used

The ADF can work even in Stop mode as long as the bus clock is not requested. Working in Stop mode is possible only if the application selected csi_ker_ck or hsi_ker_ck as kernel clock sources. The ADF asserts the adf_ker_ckreq when the kernel clock is requested.

The kernel clock mechanism works only if the kernel clock source is provided by an RC oscillator (**hsi_ker_ck** or **csi_ker_ck**).

Figure 51. Clock distribution for ADF

1. **X** represents the selected mux input after a system reset.



Clock distribution for SPIs, SPI/I2Ss

SPI peripherals do not need an accurate kernel clock frequency but a clock fast enough for the serial interface. The SPI/I2S peripherals may request an accurate kernel clock frequency when using the I2S function. For that purpose the source can be selected among the following ones:

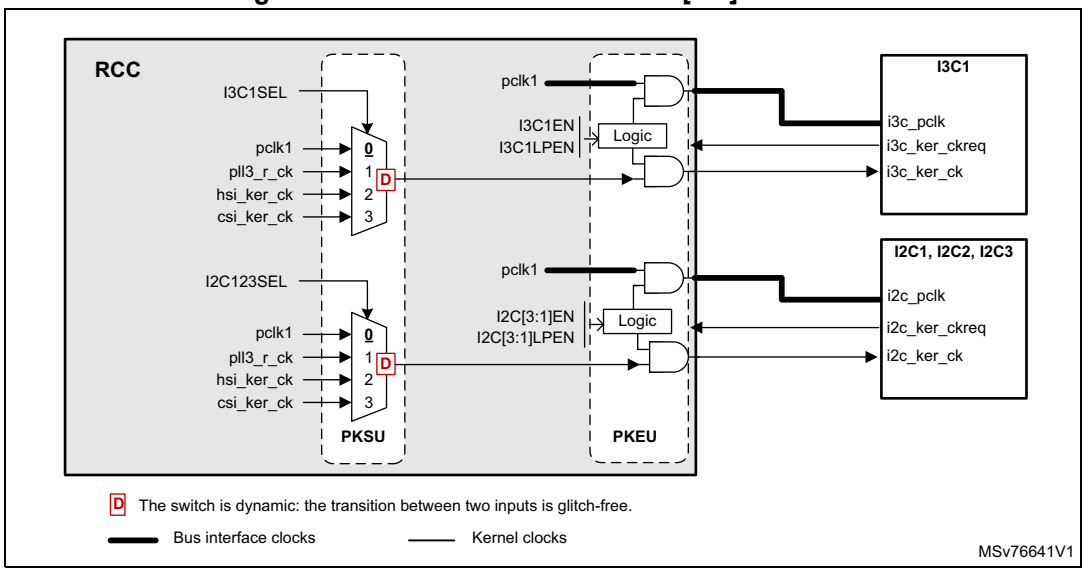
- The bus clock (for SPIs)
- PLL1 when the number of active PLLs must be reduced
- PLL2 or PLL3 if better flexibility is required. As an example, this solution allows changing the frequency bus via PLL1 without affecting the speed of some serial interfaces.
- HSI or CSI or per_ck for low-power use-cases.

The SPI/I2S also have common kernel clocks with the ADF in order to ease data exchange.

Figure 52. Clock distribution for SPIs and SPI/I2S

1. **X** represents the selected switch input after a system reset.

Clock distribution for I2C[3:1], and I3C1



I2C and I3C peripherals do not need an accurate kernel clock frequency but a clock fast enough to properly handle the serial interface. The following kernel clock sources are proposed:

- The bus clock
- PLL3 in the case where the bus clock cannot be used
- HSI or CSI for low-power use-cases

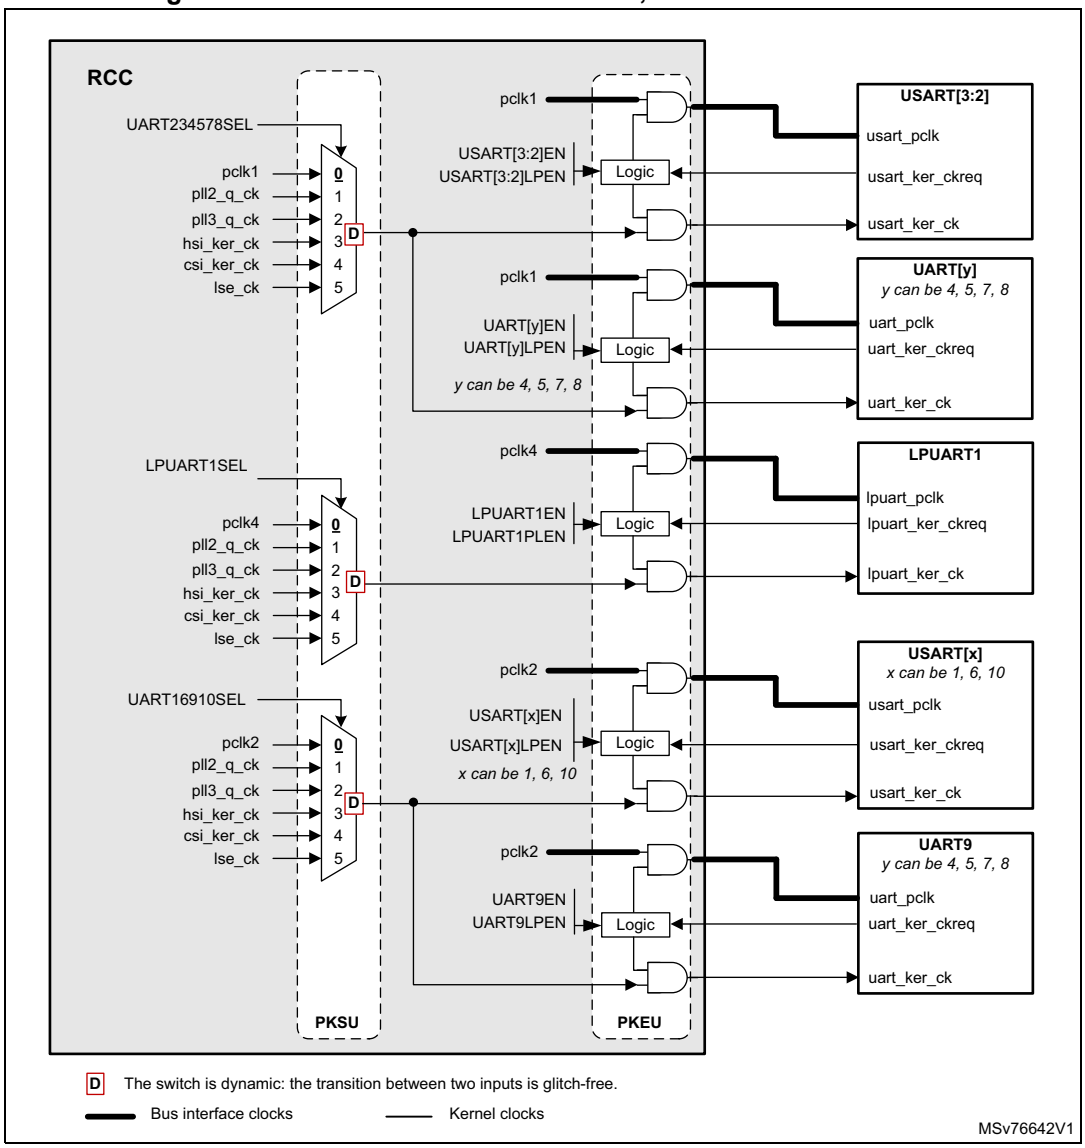
The I2Cs and I3C1 can work even in Stop mode as long as the bus clock is not requested. Working in Stop mode is possible only if the application selected **csi_ker_ck** or **hsi_ker_ck** as kernel clock sources. The I2Cs and I3C1 assert the **i2c_ker_ckreq** or **i3c_ker_ckreq** signals, when the kernel clock is requested.

The kernel clock mechanism works only if the kernel clock source is provided by an RC oscillator (**hsi_ker_ck** or **csi_ker_ck**).

Figure 53. Clock distribution for I2C[3:1] and I3C1

1. **X** represents the selected switch input after a system reset

Clock distribution for UARTs and USARTs



UARTs need a kernel clock frequency allowing the adjustment of the baud rate with an acceptable accuracy (generally less than ±2%). For that purpose the source can be selected among the following ones:

- The bus clock
- PLL3 in the case where the bus clock cannot be used
- HSI, CSI or LSE for low-power use-cases

The UARTs can work even in Stop mode as long as the bus clock is not requested. Working in Stop mode is possible only if the application selected csi_ker_ck or hsi_ker_ck as kernel clock sources. The UARTs assert the **uartx_ker_ckreq** signal, when the kernel clock is requested. The kernel clock mechanism works only if the kernel clock source is provided by an RC oscillator (**hsi_ker_ck** or **csi_ker_ck**).

UARTs can also work in Stop mode using the LSE clock when high baud rates are not required.

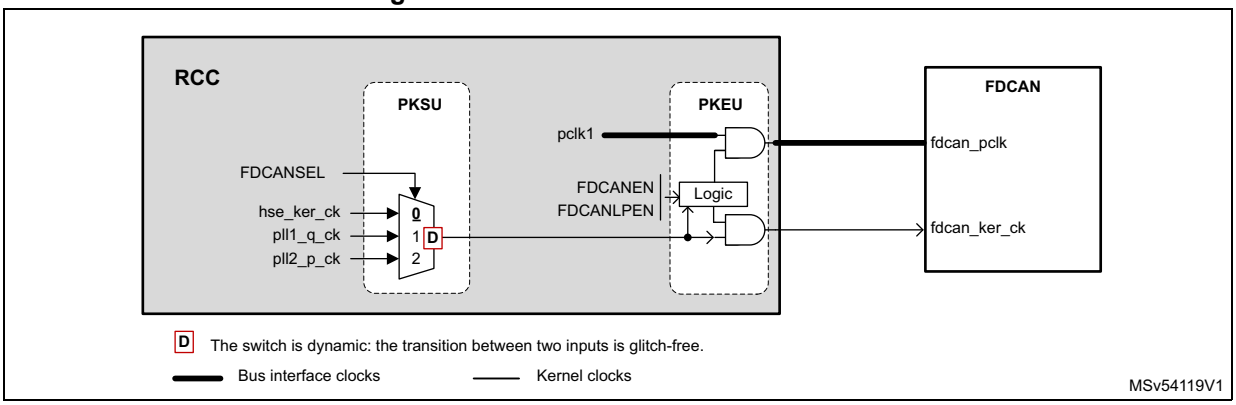


Figure 54. Clock distribution for UARTs, LPUART1 and USARTs

1. **X** represents the selected switch input after a system reset.

Clock distribution for FDCAN

Figure 55. Clock distribution for FDCAN

1. **X** represents the selected switch input after a system reset.

Clock distribution for SDMMC, FMC, and XSPI

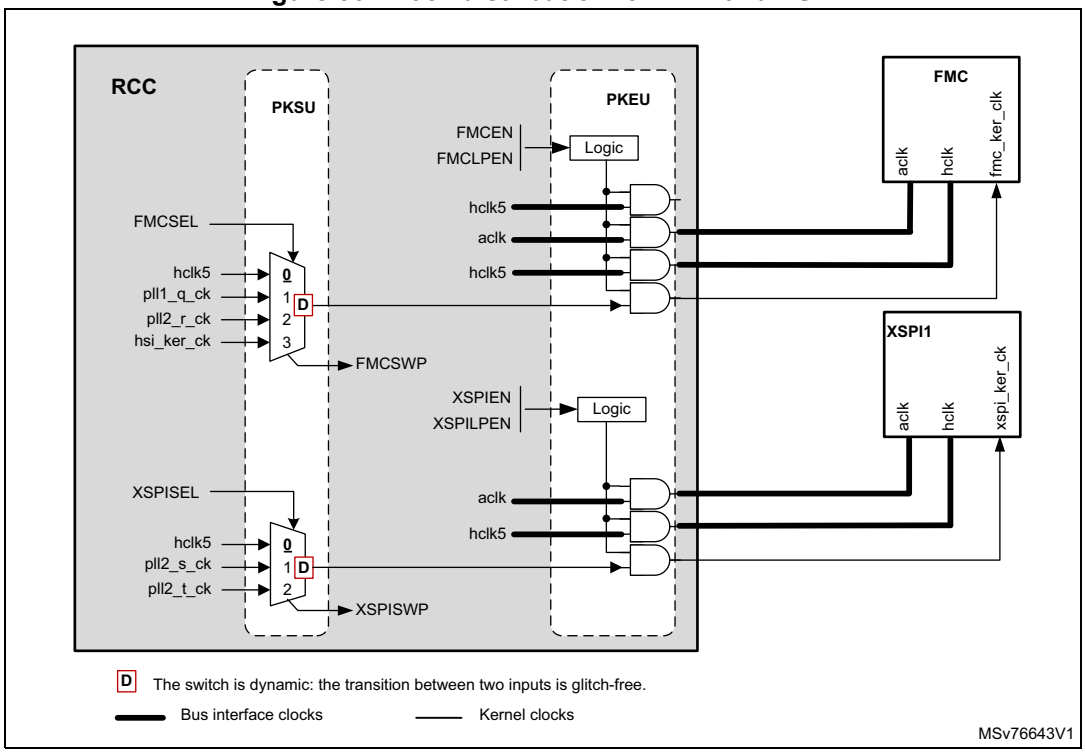
The FMC kernel clock can be chosen between four different sources, giving good flexibility.

For XSPI, a clock switch allows selection between three different sources, giving good flexibility.

The switches FMCSEL, XSPISEL, also embeds several protections:

- In case of HSE failure detected by the HSECSS function, the XSPISEL switch and the FMCSEL switch go to recovery position in order to provide a default clock.
- A protection bit: FMCCKP prevents the application to accidentally change the FMCSEL value. Refer to *Section 7.5.7: Clock protection* for details.
- A protection bit: XSPICKP prevents the application to accidentally change the XSPISEL value. Refer to *Section 7.5.7: Clock protection* for details.
- Status fields (FMCSWP, XSPISWP) located in the *RCC clock protection register (RCC_CKPROTR)* allow the application to check the effective position of the switches.
- If one of the switches is selecting an input with an invalid clock, the switch outputs a recovery clock preventing a memory crash and allowing the application to log or correct the issue. The RCC provides **hclk5**/4 as recovery clock. In order to work fine, the application must ensure that the recovery clock frequency is supported by the external device.
- For the XSPISEL switches:
  - Going to position 1 is allowed if PLL2ON = PLL2SEN = 1. If the application switches to position 1 when these conditions are not met, the switch generates the recovery clock.
  - Going to position 2 is allowed if PLL2ON = PLL2TEN = 1. If the application switches to position 2 when these conditions are not met, the switch generates the recovery clock.
- For the FMCSEL switch:
  - Going to position 1 is allowed if PLL1ON = PLL1QEN = 1. If the application switches to position 1 when these conditions are not met, the switch generates the recovery clock.
  - Going to position 2 is allowed if PLL2ON = PLL2REN = 1. If the application switches to position 2 when these conditions are not met, the switch generates the

recovery clock.



– Going to position 3 is allowed if HSION = 1. If the application switches to position 3 when this condition is not met, the switch generates the recovery clock.

How to handle XSPI switches properly:

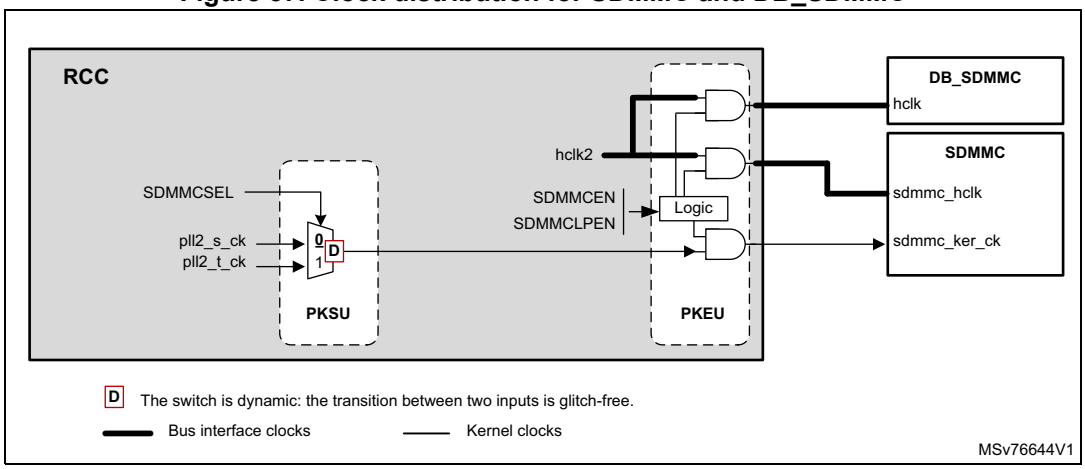
- Switch on the wanted clock source,
- Ensure the clock source is ready, and the conditions described above are met,
- Set XSPISEL to the wanted position,
- Enable the XSPI clock (XSPIEN = 1),
- Read XSPISWP field from RCC_CKPROTR register,
- If the position given by XSPISWP is the same as the wanted, it means that the XSPI kernel clock is as expected.
- If the position given by XSPISWP is 000, it means that there is no clock present at the selected input.

The XSPI must provide a clock to the external memory, with a duty cycle distortion generally lower than 5%. In order to reach this requirement, the kernel clock provided to the XSPI has a typical duty cycle of 50%. In addition, the XSPI embeds a prescaler allowing clock division by even ratios.

Figure 56. Clock distribution for FMC and XSPI

1. **X** represents the selected switch input after a system reset.

The SDMMC1 and SDMMC2 share the same kernel clock. A clock switch allows the selection between two different sources. It is possible to enable independently each SDMMC block. Note that when one of the SDMMC is enabled via its SDMMC[2:1]EN bit, the associated delay block is enabled as well.



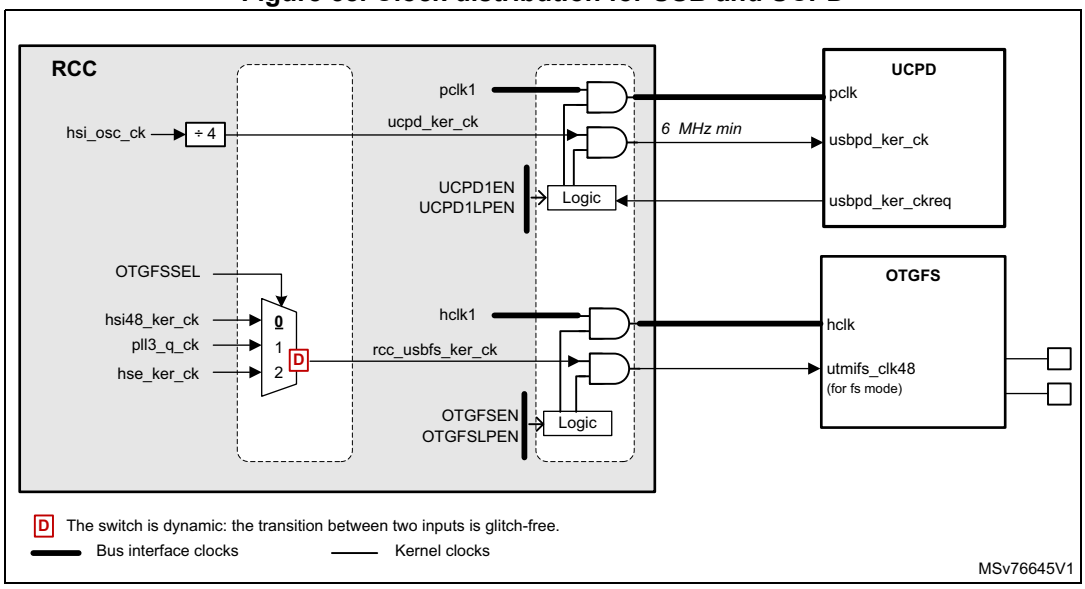
The application must take care about the duty-cycle of the kernel clock provided to the SDMMC blocks.

Table 61. SDMMC interface clock constraints

SDMMC mode	Mode name	Interface clock frequency	Duty cycle constraint
SDIO	SDR12	25 MHz or less	30 - 70%
	SDR25	50 MHz or less	30 - 70%
	DDR50	50 MHz or less	45 - 55%
	SDR50	100 MHz or less	30 - 70%
e.MMC	Backward compatible	26 MHz or less	30 - 70%
	High Speed SDR	52 MHz or less	30 - 70%
	High Speed DDR	52 MHz or less	45 - 55%

For example, if the SDMMC works in SDR50, then a kernel clock of 50 MHz, with a duty cycle better than 30-70% is enough. If the SDMMC works in DDR50, then it is recommended to provide a kernel clock of 100 MHz, and divide the frequency of the kernel clock by two, using the SDMMC divider in order to insure a duty-cycle very close to 50% for the SDMMC_CK.

Figure 57. Clock distribution for SDMMC and DB_SDMMC



1. **X** represents the selected switch input after a system reset.

Clock distribution for OTGFS and UCPD

Figure 58 shows the clock distribution for the USB blocks.

- The USB type-C power delivery block (UCPD), uses ucpd_ker_ck as kernel clock. The ucpd_ker_ck is directly generated from the HSI output divided by 4.
- The OTGFS receives a 48 MHz clock. The application can select:
  - The hsi48_ker_ck for crystal-less applications
  - hse_ker_ck or
  - pll3_q_ck

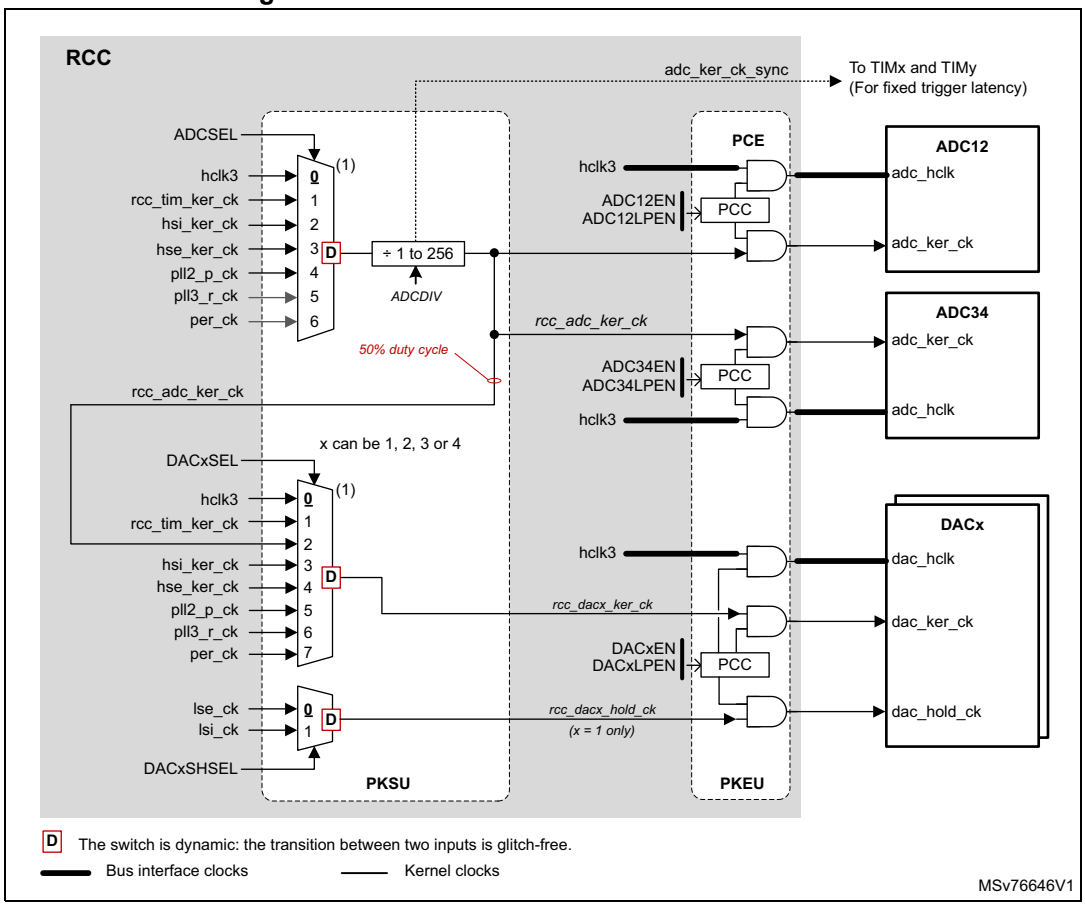


Figure 58. Clock distribution for USB and UCPD

1. **X** represents the selected switch input after a system reset.

Clock distribution for ADCs and DACs

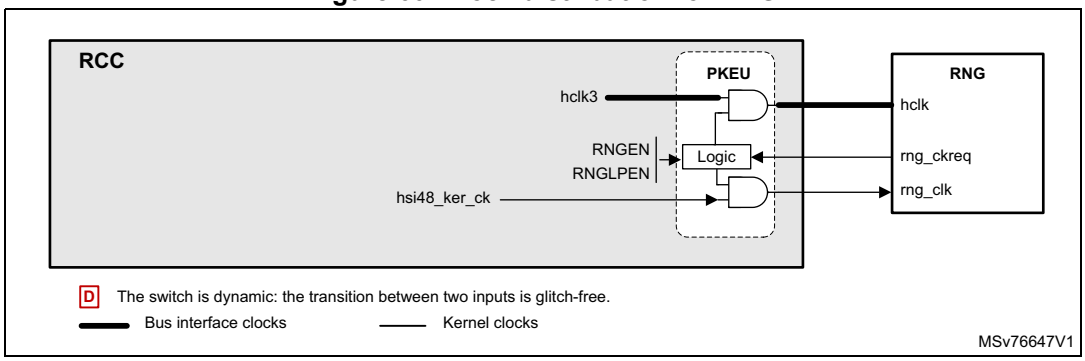
Figure 59. Clock distribution for ADCs and DACs

1. **X** represents the selected switch input after a system reset.

Every ADC receives the same kernel clock, rcc_adc_ker_ck, to minimize interference. The ADC kernel clock can be selected from a variety of sources:

- The bus clock (hclk3) - can be set to Fcpu or Fcpu/2
- The timers kernel clock (rcc_tim_ker_ck) - Fcpu only
- The HSI or HSE oscillator clocks
- The PLL2 P divider or PLL3 R divider outputs
- The peripheral clock (per_ck)

To synchronize the ADCs with the Timers, select hclk3 or rcc_tim_ker_ck as the ADC kernel clock.



Similarly, the DACs all receive the same kernel clock, rcc_dac_ker_ck. The same choice of sources is available for the DAC kernel clock. In addition, the ADC kernel clock can be selected for the DACs as well. This can help reduce interference between DAC and ADC.

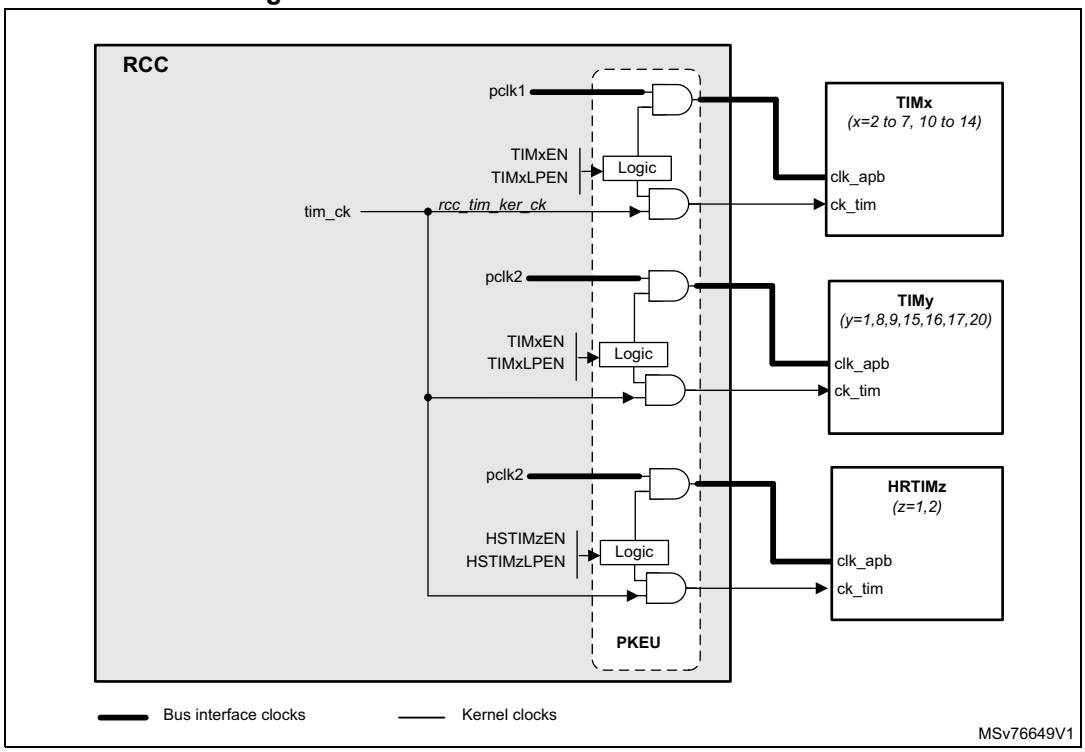
If the bus clock, hclk3, is selected as the DAC kernel clock, the DACs are automatically switched to synchronous mode, which reduces the conversion delay.

The DAC sample and hold clock (rcc_dacx_hold_ck) is used to refresh the DAC output voltage if there is a slow sample rate (< 32 kHz). It can be selected from either the LSE (lse_ck) or the LSI (lsi_ck) outputs. This only applies to buffered DACs (that is DAC1).

Clock distribution for RNG

Figure 60. Clock distribution for RNG

1. **X** represents the selected switch input after a system reset.



The RNG block uses the hsi48_ker_ck as kernel clock. The logic handling controlling the clock of the RNG is different from standard peripherals. When enabled, the RNG has to assert its kernel clock request in order to get a kernel clock. Refer to *Section 7.5.12: Peripheral clock gating control* for details.

Clock distribution for HRTIM, TIM and LPTIM

The timers use kernel clocks (tim_ck) phase aligned with the bus interface clock.

The working frequency of the timers clock is equal to the CPU clock frequency.

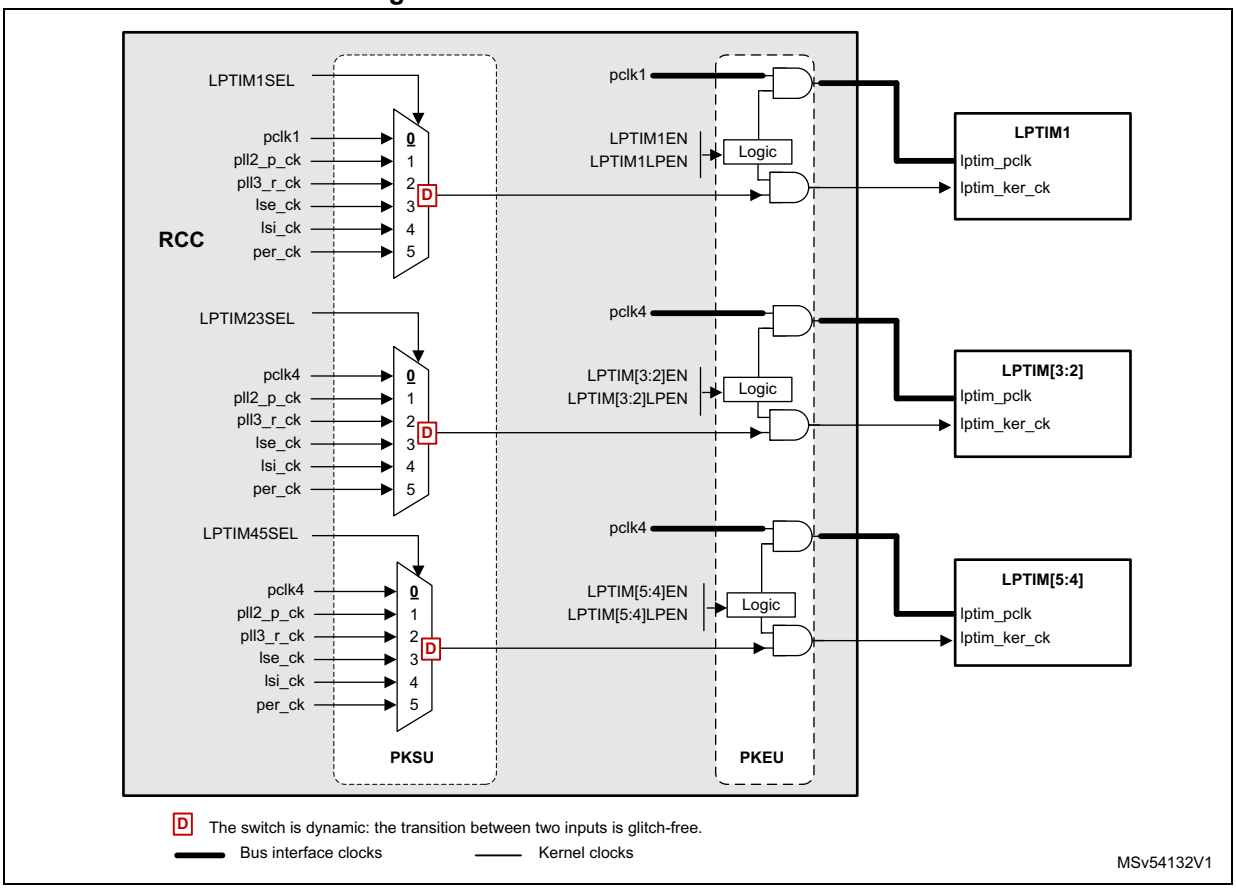


Figure 61. Clock distribution for TIM and HRTIM

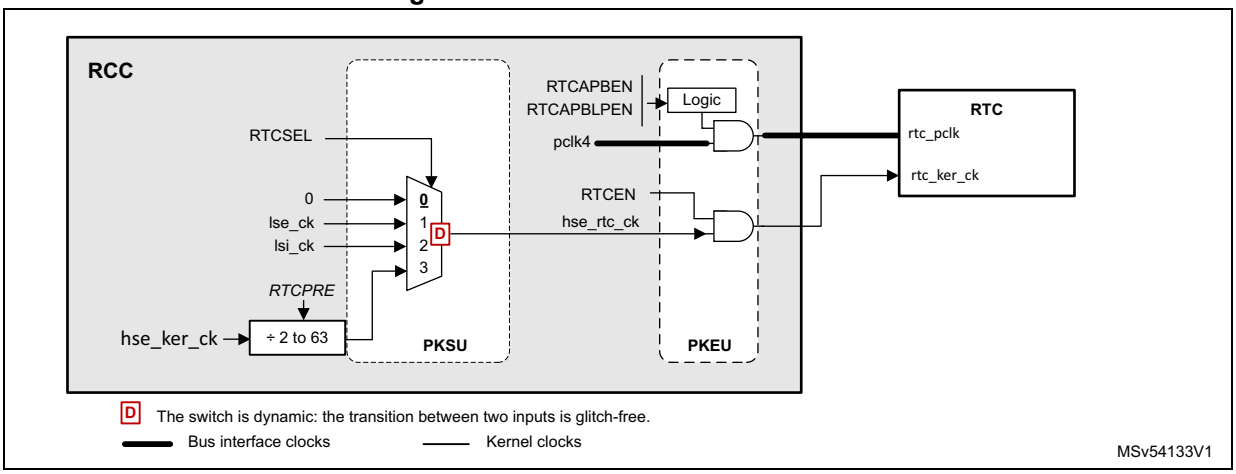
The LPTIM timers have a kernel clock fully asynchronous with respect to their bus interface clock. The kernel clock can be selected among up to six clock sources.

The LPTIMs also use lse_ck and lsi_ck as kernel clock, allowing them to work even when the system is in Stop mode.

Figure 62. Clock distribution for LPTIMs

1. **X** represents the selected switch input after a system reset

Clock distribution for RTC/AWU clock



The **rtc_ck** clock source can be one of the following:

- The **hse_rtc_ck** (**hse_ker_ck** divided by a programmable prescaler)
- The **lse_ck**
- The **lsi_ck** clock

The source clock is selected by programming the RTCSEL[1:0] bits in the *RCC Backup domain control register (RCC_BDCR)* and the RTCPRE[5:0] bits in the *RCC clock configuration register (RCC_CFGR)*.

This selection cannot be modified without resetting the Backup domain.

Figure 63. Clock distribution for RTC

1. **X** represents the selected switch input after a system reset

If the LSE is selected as RTC clock, the RTC works normally even if the backup or the V_{DD} supply disappears.

The LSE clock is in the Backup domain, whereas the other oscillators are not. As a consequence:

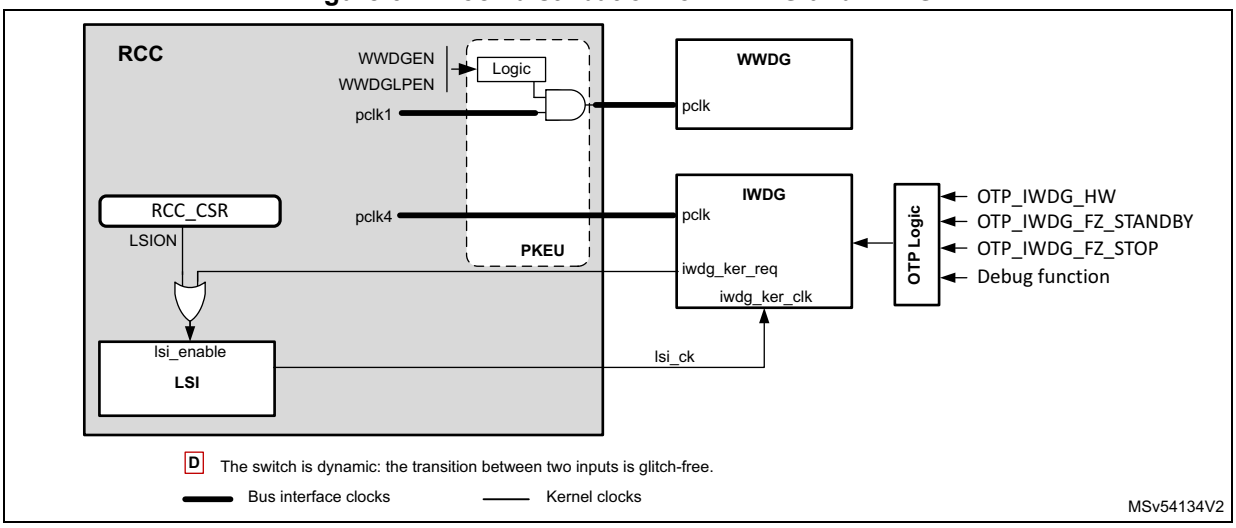
- If LSE is selected as RTC clock, the RTC continues working even if the V_{DD} supply is switched OFF, provided the V_{BAT} supply is maintained.
- If LSI is selected as the RTC clock, the AWU state is not guaranteed if the V_{DD} supply is powered off.
- If the HSE clock is used as RTC clock, the RTC state is not guaranteed if the V_{DD} supply is powered off or if the V_{CORE} supply is powered off. In addition the HSE is not available if the system goes to Stop.

The **rtc_ck** clock is enabled through the RTCEN bit located in the *RCC Backup domain control register (RCC_BDCR)*.

The RTC bus interface clock (APB clock) is enabled through RTCAPBEN and RTCAPBLPEN bits located in RCC_APB4ENR/LPENR registers.

Note: To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency ($F_{APB} < 7 \times F_{RTCLCK}$), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC_TR gives the same result than the first one. Otherwise a third read access must be performed.

Clock distribution for watchdog



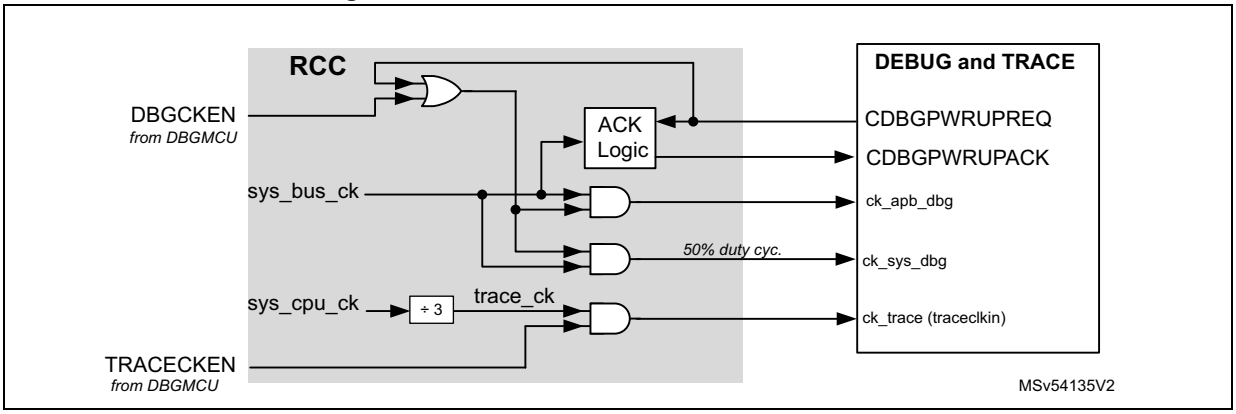
The RCC provides the clock for the two watchdog blocks available on the circuit. The independent watchdog (IWDG) is connected to the LSI. The window watchdog (WWDG) is connected to the APB clock.

If an independent watchdog is started by either hardware option or software access, the LSI is forced ON and cannot be disabled. After the LSI oscillator setup delay, the clock is provided to the IWDG.

The window watchdog clock (pclk1) can be enabled by setting the WWDGEN bit in the RCC_APB1ENR register. The software cannot stop WWDG down-counting by setting the WWDGEN bit to 0.

The WWDG block is frozen when the MCU goes to Stop mode.

Figure 64. Clock distribution for WWDG and IWDG



1. **X** represents the selected switch input after a system reset

Clock distribution for Debug and Trace

The clock generation for the trace and debug is controlled by the DBGMCU block. The DBGCKEN bit allows the application to provide a clock to the debug components. It is also possible to enable this clock via the Debug Access Port.

The trace clock generation is controlled via TRACECKEN bit.

Figure 65. Clock distribution for DBG and trace

1. **X** represents the selected switch input after a system reset

Clock frequency measurement using TIMx

Most of the clock source generator frequencies can be measured by means of the input capture of TIMx.

- Calibrating the HSI or CSI with the LSE:

  The primary purpose of having the LSE connected to a TIMx input capture is to be able to accurately measure the HSI or CSI. This requires to use the HSI or CSI as system clock source either directly or via PLL1. The number of system clock counts between

consecutive edges of the LSE signal gives a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio). The precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio is, the more accurate the measurement is.

The HSI and CSI oscillators have dedicated user-accessible calibration bits for this purpose (see *RCC CSI calibration register (RCC_CSICFGR)*). When HSI or CSI is used via the PLLx, the system clock can also be fine-tuned by using the fractional divider of the PLLs.

- Calibrating the LSI with the HSI:

  The LSI frequency can also be measured: this is useful for applications that do not have a crystal. The ultra-low-power LSI oscillator has a large manufacturing process deviation. The LSI clock frequency can be measured using the more precise HSI clock source. Using this measurement, a more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy can be obtained.

7.5.10 General clock concept overview

The RCC handles the distribution of the CPU, bus interface and peripheral clocks for the system, according to the CPU operating mode (refer to *Section 7.5.1: Clock naming convention* for details on clock definitions).

For each peripheral, the application can control the activation/deactivation of its kernel and bus interface clock. Prior to using a peripheral, the CPU must enable it (by setting PERxEN to 1), and define if this peripheral remains active in Sleep mode (by setting PERxLPEN to 1). This is called ‘allocation’ of a peripheral by the CPU (refer to *Section 7.5.11: Peripheral allocation* for more details).

The peripheral allocation is used:

- By the RCC to automatically control the clock gating according to the CPU modes, and
- By the PWR to control the supply voltages of VCORE.

Memory handling

The CPU can access all the memory areas available in the product:

- AXISRAM1, AXISRAM2, AXISRAM3, AXISRAM4, ITCM, DTCM1, DTCM2 and FLASH
- AHBSRAM1, AHBSRAM2 and AHBSRAM3
- BKPRAM

The BKPRAM, AHBSRAM1, AHBSRAM2 and AHBSRAM3 have dedicated enable bits in order to gate the bus interface clock. These enable bits are set to 1 by default, and can be programmed with 0 by software to reduce power consumption if the memories are not actively being used.

The AHBSRAM3 is also enabled when the HSP enable bit is set.

Note: The memory interface clocks (flash memory and RAM interfaces) can be stopped by software during Sleep mode (via the respective LPEN bits).

Refer to *Section 7.5.12: Peripheral clock gating control* and *Section 7.5.13: CPU and bus matrix clock gating control* sections for details on clock enabling.

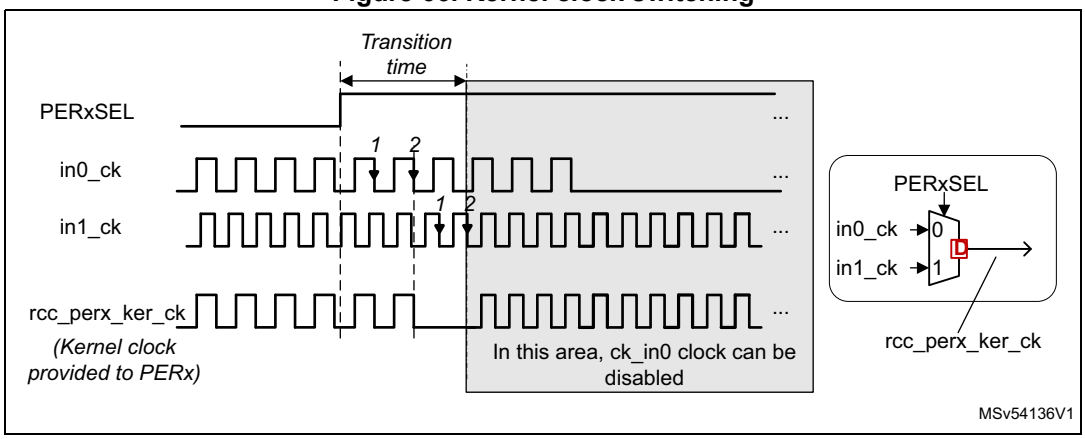
7.5.11 Peripheral allocation

The CPU can allocate a peripheral and hence control its kernel and bus interface clock.

The CPU can allocate a peripheral by setting the dedicated PERxEN bit to 1.

The CPU can control the peripheral clock gating when it is in Sleep mode via the PERxLPEN bits.

The peripheral allocation bits (PERxEN bits) are used by the hardware to provide the kernel and bus interface clocks to the peripherals. However they are also used to link peripherals to the CPU. In this way, the hardware is able to safely gate the peripheral clocks and bus matrix clocks according to CPU states.



Clock switches and gating

- Clock switching delays

  The input selected by the clock switches can be changed dynamically without generating spurs or timing violation. For example, if PERxSEL (In *Figure 66*) goes from 0 to 1, the switch first disables the clock output using the currently selected clock (in0_ck), and enables again the clock output using the new selected clock (in1_ck). The disable and enable commands are re-synchronized to their respective clocks. If one of the two clocks is not present, the sequence cannot be completed, and no clock is output. To recover from this situation, the user must either provide a valid clock to in1_ck input or set back PERxSEL to 0.

  During the transition from one input to another, the kernel clock provided to the peripheral is gated, in the worst case, during 2 or 3 clock cycles of the new selected clock. As shown in *Figure 66*, both input clocks must be present during transition time.

Figure 66. Kernel clock switching

- Clock enabling delays

  In the same way, the clock gating logic synchronizes the enable command (coming generally from a kernel clock request or PERxEN bits) with the selected clock, in order to avoid generation of spurs.

  – A maximum delay of two periods of the enabled clock may occur between the enable command and the first rising edge of the clock. The enable command can be the rising edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request asserted by a peripheral.

  – A maximum delay of 1.5 periods of the disabled clock may occur between the disable command and the last falling edge of the clock. The disable command can

be the falling edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request released by a peripheral.

Note: Both the kernel and bus interface clocks are affected by this re-synchronization delay.

7.5.12 Peripheral clock gating control

As mentioned previously, each peripheral requires one or several bus interface clocks, named **rcc_perx_bus_ck** (for peripheral x). These clocks can be an APB, AHB or AXI clock, according to which bus, or buses, the peripheral is connected.

The clocks used as bus interface for peripherals, can be **aclk**, **hclk[5:1]**, **pclk[~~5:~~4], or pclk[2:1],** depending on the bus connected to each peripheral.

Some peripherals also require dedicated clocks for their communication interface. These clocks are generally asynchronous with respect to the bus interface clock. They are named kernel clocks (**perx_ker_ck**). Both bus interface and kernel clocks can be gated according to several conditions detailed hereafter.

As shown in *Figure 67*, enabling the kernel and bus interface clocks of each peripheral depends on several input signals:

- PERxEN and PERxLPEN bits,

  PERxEN represents the peripheral enable (allocation) bit for the CPU. The CPU can write these bits to 1 via the RCC_xxxxENR registers.
- CPU state (**cpu_sleep** and **cpu_deepsleep** signals)
- Kernel clock request (**perx_ker_ckreq**) of the peripheral itself, when the feature is available

Refer to *Section 7.5.11: Peripheral allocation* for more details.

Figure 67. Peripheral kernel clock enable logic details

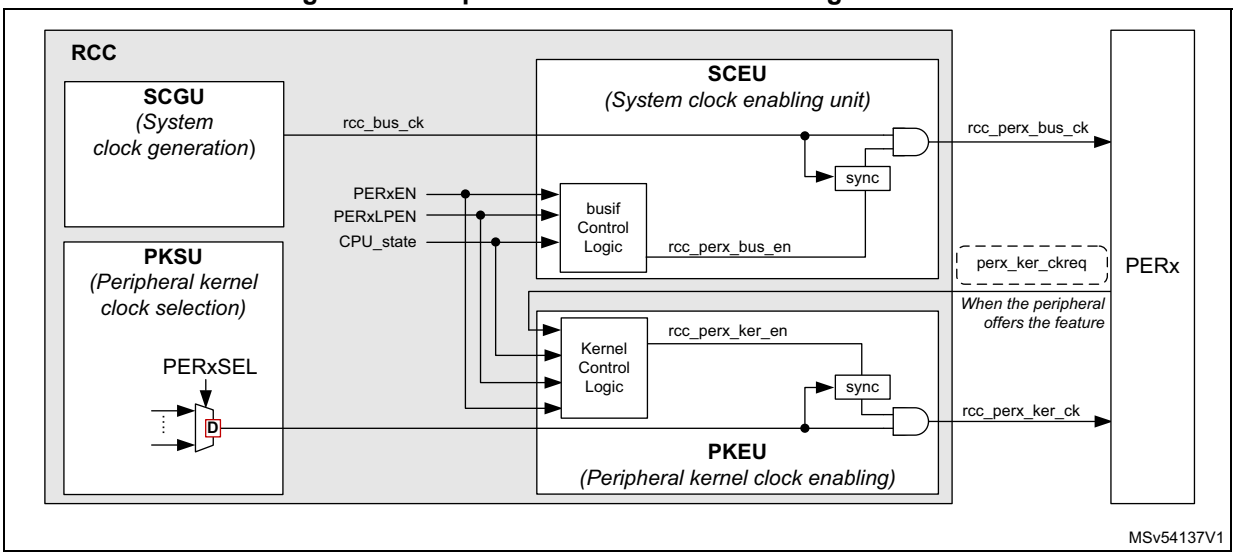


Table 62 gives a detailed description of the enabling logic of the peripheral clocks for peripherals located in the CPU domain and allocated by the CPU.

Table 62. Peripheral clock enabling

PERxEN	PERxLPEN	PERxSEL	perx_ker_ckreq	CPU state	rcc_perx_ker_ck	rcc_perx_bus_ck	Comments
0	X	X	X	X	-	-	No clock provided to the peripheral, because PERxEN=0
1	X	X	X	Run	CK	CK	Kernel and bus interface clocks are provided to the peripheral, because the CPU is in Run, and PERxEN = 1.
1	0	X	X	Sleep	-	-	No clock provided to the peripheral, because the CPU is in Sleep and PERxLPEN = 0
1	1				CK	CK	Kernel and bus interface clocks are provided to the peripheral, because CPU is in Sleep, and PERxLPEN = 1
1	0	X	X	Stop	-	-	No clock provided to the peripheral because the PERxLPEN bit is set to 0.
1	1	no lsi_ck and no lse_ck and no hsi_ker_ck and no csi_ker_ck	X		-	-	No clock provided to the peripheral because CPU is in Stop and **lse_ck** or **lsi_ck** or **hsi_ker_ck** or **csi_ker_ck** are not selected as kernel clock.
1	1	lsi_ck or lse_ck	X		CK	-	Kernel clock is provided to the peripheral because: PERxEN = PERxLPEN = 1 and **lsi_ck** or **lse_ck** are selected and enabled. The bus interface clock is not provided as the CPU is in Stop.
1	1	hsi_ker_ck or csi_ker_ck	1		CK	-	Kernel clock is provided to the peripheral because: **req_ker_perx** = 1, and PERxEN = PERxLPEN = 1 and **hsi_ker_ck** or **csi_ker_ck** are selected and enabled. The bus interface clock is not provided as the CPU is in Stop.
1	1	hsi_ker_ck or csi_ker_ck	0		-	-	No clock provided to the peripheral because CPU is in Stop, and no kernel clock request pending

As a summary, we can state that the kernel clock is provided to the peripherals when the following conditions are met:

1. The CPU is in Run mode, and the peripheral is enabled.
2. The CPU is in Sleep mode and the peripheral is enabled with PERxLPEN = 1.
3. The CPU is in Stop mode, the peripheral is enabled with PERxLPEN = 1, the peripheral generates a kernel clock request and the selected clock is **hsi_ker_ck** or **csi_ker_ck**.
4. The CPU is in Stop mode, the peripheral is enabled with PERxLPEN = 1 and the kernel source clock of the peripheral is **lse_ck** or **lsi_ck**.

The bus interface clock is provided to the peripherals only when conditions 1 or 2 are met.

The RNG block is not clocked as other peripherals, the table hereafter shows the way RNG is clocked.

Table 63. RNG clock enabling

RNGEN	RNGLPEN	rng_ker_ckreq	CPU state	hsi48_ker_ck	rcc_rng_hclk3	Comments
0	X	X	X	-	-	No clock provided to the peripheral, because RNGEN=0.
1	X	0	Run	-	CK	**hsi48_ker_ck** not provided because the kernel clock request is not asserted. hclk3 clock is provided.
1	X	1		CK	CK	Both **hsi48_ker_ck** and hclk3 are provided because the kernel clock request is asserted, and RNGEN = 1.
1	0	X	Sleep	-	-	No clock provided, because the CPU is in Sleep and RNGLPEN = 0.
1	1	0		-	CK	**hsi48_ker_ck** not provided because the kernel clock request is not asserted. hclk3 clock is provided.
1	1	1		CK	CK	Both **hsi48_ker_ck** and hclk3 are provided because the kernel clock request is asserted, RNGEN = 1 and RNGLPEN = 1.
1	X	X	Stop	-	-	No clock provided because the CPU is in Stop mode.

7.5.13 CPU and bus matrix clock gating control

The clocks of the CPU, AHB and AXI bridges and APB buses are enabled according to the rules hereafter:

- The CPU clock (**rcc_cpu_ck**) is enabled when the CPU is in Run or Sleep mode.
- The AXI bridge clock is enabled when the CPU is in Run or Sleep mode.
- Each AXI master and slave has an independent clock gating activated by default, to further reduce the power consumption. When activated the clock is automatically enabled on bus transaction request. The *RCC AXI clocks gating disable register (RCC_CKGDISR)* allows the application to control this behavior.
- The AHB bus matrix clock is enabled if one of the following conditions is met:
  - The CPU is in Run mode.
  - The CPU is in Sleep mode, and at least one peripheral connected to this bridge have both its PERxEN and PERxLPEN set to 1.
  - The CPU is in Sleep mode, and either AHB1, AHB2, AHB3, AHB4 or AHB5 has its clock enabled.
- The clocks of the bridges AHB1, 2, 3, 4, 5 are enabled when one of the following conditions is met:
  - The CPU is in Run mode.
  - The CPU is in Sleep mode with at least one peripheral connected to this bus having both its PERxEN and PERxLPEN set to 1.
  - The CPU is in Sleep mode and the APB bus connected to the AHB bridge has its clock enabled.
- The APB1, 2, 4 clock buses are enabled when one of the following conditions is met:
  - The CPU is in Run mode.
  - When the CPU is in Sleep mode with at least one peripheral connected to this bus having both its PERxEN and PERxLPEN set to 1.

7.5.14 Low-power emulation modes

In order to ease the debugging of the circuit, the RCC is able to handle an emulation mode for Stop and Standby modes.

Sleep emulation mode

The Sleep emulation mode is controlled by the DBG_SLEEP bit of the DBGMCU_CR register. When the processor goes to Sleep with DBG_SLEEP = 1, then the processor clock, the clocks of all enabled peripherals, debug parts, and interconnect are maintained active.

Stop emulation mode

The Stop emulation mode is controlled by the DBG_STOP bit of the DBGMCU_CR register. When the processor goes to Stop with DBG_STOP = 1, then:

- The PWR and the RCC remain active.
- The V_{DDCORE} voltage is set to the minimum VOS value.
- The RCC selects HSI or CSI as system clock, depending on the STOPWUCK bit.
- The processor clock is gated (rcc_cpu_ck, see *Figure 48*).
- The free-running clock is generated (rcc_fclk, see *Figure 48*), and all the debug parts remain clocked.
- All peripheral clocks are gated. Peripherals can still receive a kernel clock if they request it, and if the kernel clock source is an RC oscillator. They also receive the kernel clock if the kernel clock source is LSI or LSE.
- The interconnect clocks are gated.

When a wakeup event occurs:

- The V_{DDCORE} voltage remains to the minimum VOS value.
- The peripheral that wakes up the system sends the interrupt to the NVIC via the EXTI.
- The CPU exits from STOP and the RCC provides the processor clock and interconnect clocks.

Standby emulation mode

The Standby emulation mode is controlled by the DBG_STANDBY bit of the DBGMCU_CR register.

When the system goes to Standby with DBG_STANDBY = 1, then:

- The V_{DDCORE} voltage is not switched-off, but remains to the minimum VOS value.
- All the V_{DDCORE} domain is under reset except the debug part.
- The debug part is clocked.
- Peripherals on V_{BAT} or V_{DD} domains are not reset.

When the system exits from Standby, then:

- Option bytes are reloaded.
- The reset of the V_{DDCORE} domain is released.
- The Standby flag is updated as well.

7.6 RCC interrupts

The RCC provides three interrupt lines:

- **rcc_it**: general interrupt line providing events when the PLLs are ready or when the oscillators are ready
- **rcc_hsecss_it**: interrupt line dedicated to the failure detection of the HSE CSS (clock security system)
- **rcc_lsecss_it**: interrupt line dedicated to the failure detection of the LSE CSS

The interrupt enable is controlled by *RCC clock source interrupt enable register (RCC_CIER)*, except for the HSE CSS failure. When the HSE CSS feature is enabled, it is not possible to mask the interrupt generation.

The interrupt flags can be checked via *RCC clock source interrupt flag register (RCC_CIFR)*, and these flags can be cleared via *RCC clock source interrupt clear register (RCC_CICR)*.

Note: The interrupt flags are not relevant if the corresponding interrupt enable bit is not set.

Table 64 gives a summary of the interrupt sources and the way to control them.

Table 64. Interrupt sources and control

Interrupt source	Description	Interrupt enable	Action to clear interrupt	Interrupt line
LSIRDYF	LSI ready	LSIRDYIE	Set LSIRDYC to 1	rcc_it
LSERDYF	LSE ready	LSERDYIE	Set LSERDYC to 1	
HSIDRYF	HSI ready	HSIDRYIE	Set HSIRDYC to 1	
HSERDYF	HSE ready	HSERDYIE	Set HSERDYC to 1	
CSIRDYF	CSI ready	CSIRDYIE	Set CSIRDYC to 1	
HSI48RDYF	HSI48 ready	HSI48RDYIE	Set HSI48RDYC to 1	
PLL1RDYF	PLL1 ready	PLL1RDYIE	Set PLL1RDYC to 1	
PLL2RDYF	PLL2 ready	PLL2RDYIE	Set PLL2RDYC to 1	
PLL3RDYF	PLL3 ready	PLL3RDYIE	Set PLL3RDYC to 1	
LSECSSF	LSE CSS failure	LSECSSFIE (1)	Set LSECSSC to 1	rcc_lsecss_it
HSECSSF	HSE CSS failure	- (2)	Set HSECSSC to 1	rcc_hsecss_it

1. The security system feature must also be enabled (LSECSSON = 1), in order to generate interrupts.
2. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = 1).

7.7 RCC Programming examples

7.7.1 PLL programming procedure

PLL initialization procedure

The recommended initialization sequence of the PLLs for the integer and fractional mode is given hereafter:

- The PLL is supposed to be disabled: PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN, PLLxTEN, PLLxON, and PLLxRDY set to 0, if it is not the case, refer to *PLL disabling procedure*.
- Enable the wanted clock source (HSE, HSI, or CSI) and wait for the ready flag.
- Select the clock source via PLLSCR into *RCC PLLs clock source selection register (RCC_PLLCKSELR)*.
- Initialize the pre-dividers (DIVMx) in order to provide a valid reference clock to the PLL. DIVMx are located into *RCC PLLs clock source selection register (RCC_PLLCKSELR)*.
- Configure the PLL:
  - In integer or clock spreading mode the application must ensure that a 0 is loaded into the SDM. This can be done as follows:
    - Set PLLxFRACLE to 0
    - Write FRACN to 0
    - Set PLLxFRACLE to 1
    - Write FRACN to 0
    - Wait at least 5 µs
  - In fractional mode, the application must load the SDM with the wanted value (FracInitValue) by executing a sequence similar to the integer mode, but with FRACN = FracInitValue.
  - Program the fields PLLxRGE, PLLxVCOSEL, SSCG_CTRL, DIVxN, DIVxP, DIVxQ, DIVxR, DIV2S and DIV2T.
  - If the clock spreading mode is used, also program the MODPER, INCSTEP, SPREADSEL, TPDFNDIS, RPDFNDIS fields, and set PLLxSSCGEN to 1.
  - If the clock spreading mode is not used, set PLLxSSCGEN to 0.
- Enable the PLL:
  - Set the corresponding PLLxON bit to 1, and wait for PLLxRDY bit set to 1,
  - If the PLL is in fractional mode, the FRACLE bit must not be set back to 0 as long as PLLxRDY = 0.
- When the PLLxRDY bit is equal to 1, the application can enable the wanted outputs by setting PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN, PLLxTEN to 1.
- If the application intends to tune the PLL frequency on-the-fly (only possible in fractional mode), then:
  - Set PLLxFRACLE to 0,
    When FRACLE = 0, the sigma delta modulator is still operating with the current value,
  - Write the new value into FRACN[12:0] (FracValue(n)),
  - Set PLLxFRACLE to 1, in order to latch the content of FRACN[12:0] into the SDM.
  - Wait at least 5 µs.

Note: When the PLLxRDY goes to 1, it means that the PLLx output frequency is within 2% of its target value.

Reprogramming post-dividers

When the PLLs are enabled, it is possible to change the values of post-dividers (DIVP, DIVQ, DIVR, DIVS or DIVT) without disabling the corresponding PLLx, by performing the following sequence:

- Disable the wanted output by setting the bit PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN or PLLxTEN to 0,
- Change the value of the corresponding post-divider (DIVP, DIVQ, DIVR, DIVS or DIVT),
- Re-enable this output by setting the bit PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN or PLLxTEN to 1.

PLL disabling procedure

The recommended disabling sequence is given hereafter:

- Disable all the post-dividers by setting PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN and PLLxTEN bits of PLLx to 0,
- Disable the PLL: set PLLxON bit of PLLx to 0,
- Wait for PLLxRDY = 0.

Using the SSCG block

For example, if an application needs to generate with the PLL2, a clock signal having the following characteristics:

- A frequency at DIVS output (**FpII2_s_ck**) of 200 MHz Max,
- With a modulation depth of 0.5% peak (M_D),
- With a frequency modulation of 28 kHz (F_{MOD}).

The assumption is that the crystal oscillator is 8 MHz (F_{hse_ck}).

DIVM2 is programmed to 0 in order to provide a reference clock of 8 MHz to the PLL2 (F_{ref2_ck}). The VCOH must be selected when SSCG is used.

From an 8 MHz reference clock, it is possible to generate 200 MHz, by programming the PLL2 as follows: (DIVN+1) = 50, (Fvco = 800 MHz), (DIVS+1) = 4.

The application has to compute the following parameters:

Computing MODPER:

$$MODPER = ROUND\left(\frac{F_{ref_ck}}{4 \times F_{MOD}}\right) = ROUND\left(\frac{8 \times 10^6}{4 \times 28 \times 10^3}\right) = 71$$

Computing INCSTEP:

$$INCSTEP = ROUND\left(\frac{(2^{15} - 1) \times M_D \times (DIVN + 1)}{100 \times 5 \times MODPER}\right) = ROUND\left(\frac{32767 \times 0.5 \times (49 + 1)}{100 \times 5 \times 71}\right) = 23$$

Check that MODPER x INCSTEP is lower than (2^{15}-1)

In the example, MODPER x INCSTEP = 1633 ==> OK

Due to rounding operations, the modulation period and the modulation depth do not completely match the target. The real modulation depth is:

$$M_D\,(\%) = \frac{MODPER \times INCSTEP \times 100 \times 5}{(2^{15} - 1) \times (DIVN + 1)} = \frac{71 \times 23 \times 100 \times 5}{(2^{15} - 1) \times (49 + 1)} = 0.498\ \%$$

And the modulation frequency (Fmod) is:

$$F_{mod} = \frac{F_{ck_ref}}{4 \times MODPER} = \frac{8 \times 10^6}{4 \times 80} = 28.2\ \text{kHz}$$

The down-spread modulation must be used (SPREADSEL = 1) to keep the maximum frequency to a value lower than 200 MHz.

7.7.2 Frequency configuration examples

This section gives various frequency settings for CPU and XSPI interfaces, combined with audio constraints. The case without audio constraints is not shown as it is obvious that PLL1 and PLL2 can provide the expected frequency. If audio applications are required, several options are offered to the user:

- Generate the kernel clock with PLL1, PLL2 or PLL3
- Use the external audio clock input (AUDIOCLK)
- Use oscillators

In this section, we explore the cases where PLL1 or PLL2 are used for audio.

Note as well that PLL2 is also used for XSPIs, if it is shared for audio application, it is not recommended to activate the SSCG.

The configurations listed in the tables hereafter are not exhaustive, many other settings are available. For example if the clock provided to the I2S must be shared with FDCAN, then the application would like to generate a clock around 100 MHz to insure good working conditions for FDCAN. These considerations are not taken into account in these tables.

Note also that in order to get the best clock quality at PLL output, F_{REF} must be as close as possible to 16 MHz. This is not always easy to do for PLLs in integer mode, but can be done easily when the PLLs are in fractional mode (as shown in the tables).

Table 65. Clock configuration examples with PLLs in integer mode

Configuration	HSE (MHz)	DIVM+1	F_{REF} (MHz) (1)	PLLxRGE	DIVN+1	FRACV	F_{VCO} (MHz) (2)	DIVP+1	DIVQ+1	DIVS/T+1	F_{CPU} (MHz)(3)	F_{XSPI} (MHz)(4)	F_{AUDIO} (MHz)(5)	F_{CPU} accuracy (%)	F_{XSPI} accuracy (%)	F_{AUDIO} accuracy (ppm)
PLL1 CPU: 500 MHz Audio: 48 kHz	16	7	2.286	1	215	0	982.9	1	4		491.4	-	122.86	-1.7	-	-186
	24	11	2.182	1	214	0	933.8	1	19		466.9	-	24.574	-6.6	-	-75
PLL1 CPU: 500 MHz Audio: 44.1 kHz	16	3	5.333	2	91	0	970.7	1	43		485.3	-	11.287	-3	-	-246
	24	10	2.400	1	207	0	993.6	1	4		496.8	-	124.2	-0.6	-	116
PLL1 CPU: 550 MHz Audio: 48 kHz	16	5	3.200	1	169	0	1081.6	1	11		540.8	-	49.164	-1.7	-	237
	24	2	12.000	3	43	0	1032.0	1	6		516.0	-	86.00	-6.2	-	-186
PLL1 CPU: 550 MHz Audio: 44.1 kHz	16	8	2.000	1	271	0	1084.0	1	6		542.0	-	90.333	-1.5	-	183
	24	12	2.000	1	271	0	1084.0	1	6		542.0	-	90.333	-1.5	-	183
PLL1 CPU: 400 MHz Audio: 48 kHz	16	7	2.286	1	172	0	786.2	1	4		393.1	-	98.290	-1.7	-	-186
	24	7	3.429	1	223	0	1597.7	2	13		399.4	-	61.451	-0.2	-	-172
PLL1 CPU: 400 MHz Audio: 44.1 kHz	24	11	2.182	1	357	0	1557.8	2	23		389.5	-	33.866	-2.6	-	-94

1. F_{REF} is the reference frequency at PLL1 or PLL2 inputs.
2. F_{VCO} is the clock frequency at VCO output of PLL1 or PLL2.
3. F_{CPU} is the clock frequency provided to the CPU (rcc_cpu_ck).
4. $F_{XSPI:}$ is the kernel clock frequency provided to the XSPI1 or XSPI2 (xspi_ker_ck).
5. F_{AUDIO} is the kernel clock frequency provided to the audio blocks such as ADF, SPI/I2Sx.
   For a 48 kHz stream, the expected kernel clock is 48 kHz x 256 x k, with k integer.
   For a 44.1 kHz stream, the expected kernel clock is 44.1 kHz x 256 x k, with k integer.

Table 66. Clock configuration examples with PLLs in fractional mode(1)

Configuration	HSE (MHz)	DIVM+1	F_{REF} (MHz) (2)	DIVN+1	FRACV	F_{VCO} (MHz) (3)	DIVP+1	DIVQ+1	DIVS/T+1	F_{CPU} (MHz)(4)	F_{XSPI} (MHz)(5)	F_{AUDIO} (MHz)(6)	F_{CPU} accuracy (%)	F_{XSPI} accuracy (%)	F_{AUDIO} accuracy (ppm)
PLL1 CPU: 500 MHz Audio: 48 kHz	16	1	16.0	30	5898	983.0	1	4	-	491.5	-	122.88	-1.7	-	-1
	24	2	12.0	40	7864										
PLL1 CPU: 500 MHz Audio: 44.1 kHz	16	1	16.0	31	380	993.5	1	4		496.7		124.2	-0.6		-0.4
	24	2	12.0	41	3237										-1.4
PLL1 CPU: 550 MHz Audio: 48 kHz	16	1	16.0	33	6488	1081.3	1	11	-	540.7	-	49.15	-1.7	-	0.2
	24	2	12.0	45	459										0.7
PLL1 CPU: 550 MHz Audio: 44.1 kHz	16	1	16.0	33	7117	1083.8	1	6		541.9		90.32	-1.5		-0.7
	24	2	12.0	45	1298										1.0
PLL1 CPU: 400 MHz Audio: 48 kHz	16	1	16.0	49	1245	1572.9	2	8	-	393.2	-	98.30	-1.7	-	0.5
	24	2	12.0	65	4391										0.1
PLL1 CPU: 400 MHz Audio: 44.1 kHz	16	1	16.0	49	3212	1580.5	2	70		395.1		112.90	1.2		-1.8
	24	2	12.0	65	7012										-0.7

1. Note that for all these configurations, PLLxRGE is always equal to 3.
2. F_{REF} is the reference frequency at PLL1 or PLL2 inputs.
3. F_{VCO} is the clock frequency at VCO output of PLL1 or PLL2.
4. F_{CPU} is the clock frequency provided to the CPU (rcc_cpu_ck).
5. F_{XSPI} is the kernel clock frequency provided to the XSPI1 or XSPI2 (xspi_ker_ck).
6. F_{AUDIO} is the kernel clock frequency provided to the SPI/I2Sx.
   For a 48 kHz stream, the expected kernel clock is 48 kHz x 256 x k, with k integer.
   For a 44.1 kHz stream, the expected kernel clock is 44.1 kHz x 256 x k, with k integer.

7.8 RCC registers

7.8.1 RCC source control register (RCC_CR)

Address offset: 0x000

Reset value: 0x0000 0025

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	PLL3RDY	PLL3ON	PLL2RDY	PLL2ON	PLL1RDY	PLL1ON	Res.	Res.	Res.	HSECSSON	HSEEXT	HSEBYP	HSERDY	HSEON
		r	rw	r	rw	r	rw				rw	rw	rw	r	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	HSI48RDY	HSI48ON	Res.	Res.	CSIKERON	CSIRDY	CSION	Res.	HSIDIVF	HSIDIV[1:0]		HSIRDY	HSIKERON	HSION
		r	rw			rw	r	rw		r	rw	rw	r	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **PLL3RDY**: PLL3 clock ready flag
Set by hardware to indicate that the PLL3 is locked.
0: PLL3 unlocked (default after reset)
1: PLL3 locked

Bit 28 **PLL3ON**: PLL3 enable
Set and cleared by software to enable PLL3.
Cleared by hardware when entering Stop or Standby mode.
0: PLL3 OFF (default after reset)
1: PLL3 ON

Bit 27 **PLL2RDY**: PLL2 clock ready flag
Set by hardware to indicate that the PLL2 is locked.
0: PLL2 unlocked (default after reset)
1: PLL2 locked

Bit 26 **PLL2ON**: PLL2 enable
Set and cleared by software to enable PLL2.
Cleared by hardware when entering Stop or Standby mode. Note that the hardware prevents writing this bit to 0, if FMCCKP = 1, or XSPICKP = 1.
0: PLL2 OFF (default after reset)
1: PLL2 ON

Bit 25 **PLL1RDY**: PLL1 clock ready flag
Set by hardware to indicate that the PLL1 is locked.
0: PLL1 unlocked (default after reset)
1: PLL1 locked

Bit 24 **PLL1ON**: PLL1 enable
Set and cleared by software to enable PLL1.
Cleared by hardware when entering Stop or Standby mode. Note that the hardware prevents writing this bit to 0, if the PLL1 output is used as the system clock (SW=3) or if FMCCKP = 1, or if XSPICKP = 1.
0: PLL1 OFF (default after reset)
1: PLL1 ON

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **HSECSSON**: HSE clock security system enable

Set by software to enable clock security system (CSS) on HSE.

Clearing this bit has no effect, the CSS is disabled by a system reset or when the system enters in Standby mode.

When HSECSSON is set, the clock detector is enabled by hardware when the HSE is ready and disabled by hardware if an oscillator failure is detected.

0: CSS on HSE OFF (clock detector OFF) (default after reset)

1: CSS on HSE ON (clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 19 **HSEEXT**: external high speed clock type in Bypass mode

Set and reset by software to select the external clock type (analog or digital).

The external clock must be enabled with the HSEON bit to be used by the device.

The HSEEXT bit can be written only if the HSE oscillator is disabled.

0: HSE in analog mode (default after reset)

1: HSE in digital mode

Bit 18 **HSEBYP**: HSE clock bypass

Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit to be used by the device.

The HSEBYP bit can be written only if the HSE oscillator is disabled.

0: HSE oscillator not bypassed (default after reset)

1: HSE oscillator bypassed with an external clock

Bit 17 **HSERDY**: HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable.

0: HSE clock is not ready (default after reset)

1: HSE clock is ready

Bit 16 **HSEON**: HSE clock enable

Set and cleared by software.

Cleared by hardware to stop the HSE when entering Stop or Standby mode.

This bit cannot be cleared if the HSE is used directly (via SW mux) as system clock, or if the HSE is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1) or if FMCCKP = 1, or if XSPICKP = 1.

0: HSE is OFF (default after reset)

1: HSE is ON

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **HSI48RDY**: HSI48 clock ready flag

Set by hardware to indicate that the HSI48 oscillator is stable.

0: HSI48 clock is not ready (default after reset)

1: HSI48 clock is ready

Bit 12 **HSI48ON**: HSI48 clock enable

Set by software and cleared by software or by the hardware when the system enters to Stop or Standby mode.

0: HSI48 is OFF (default after reset)

1: HSI48 is ON

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **CSIKERON**: CSI clock enable in Stop mode

Set and reset by software to force the CSI to ON, even in Stop mode, in order to be quickly available as kernel clock for some peripherals. This bit has no effect on the value of CSION.

0: No effect on CSI (default after reset)

1: CSI is forced to ON even in Stop mode

Bit 8 **CSIRDY**: CSI clock ready flag

Set by hardware to indicate that the CSI oscillator is stable. This bit is activated only if the RC is enabled by CSION (it is not activated if the CSI is enabled by CSIKERON or by a peripheral request).

0: CSI clock is not ready (default after reset)

1: CSI clock is ready

Bit 7 **CSION**: CSI clock enable

Set and reset by software to enable/disable CSI clock for system and/or peripheral.

Set by hardware to force the CSI to ON when the system leaves Stop mode, if STOPWUCK = 1 or STOPKERWUCK = 1.

This bit cannot be cleared if the CSI is used directly (via SW mux) as system clock, or if the CSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1) or if FMCCKP = 1, or if XSPICKP = 1.

0: CSI is OFF (default after reset)

1: CSI is ON

Bit 6 Reserved, must be kept at reset value.

Bit 5 **HSIDIVF**: HSI divider flag

Set and reset by hardware.

As a write operation to HSIDIV has not an immediate effect on the frequency, this flag indicates the current status of the HSI divider. HSIDIVF goes immediately to 0 when HSIDIV value is changed, and is set back to 1 when the output frequency matches the value programmed into HSIDIV.

0: New division ratio not yet propagated to **hsi(_ker)_ck** (default after reset)

1: **hsi(_ker)_ck** clock frequency reflects the new HSIDIV value (default register value when the clock setting is completed)

Bits 4:3 **HSIDIV[1:0]**: HSI clock divider

Set and reset by software.

These bits allow selecting a division ratio in order to configure the wanted HSI clock frequency. The HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to 1). In that case, the new HSIDIV value is ignored.

00: Division by 1, **hsi(_ker)_ck** = 64 MHz (default after reset)

01: Division by 2, **hsi(_ker)_ck** = 32 MHz

10: Division by 4, **hsi(_ker)_ck** = 16 MHz

11: Division by 8, **hsi(_ker)_ck** = 8 MHz

Bit 2 **HSIRDY**: HSI clock ready flag

Set by hardware to indicate that the HSI oscillator is stable.

0: HSI clock is not ready (default after reset)

1: HSI clock is ready

Bit 1 **HSIKERON**: HSI clock enable in Stop mode

Set and reset by software to force the HSI to ON, even in Stop mode, in order to be quickly available as kernel clock for peripherals. This bit has no effect on the value of HSION.

0: No effect on HSI (default after reset)

1: HSI is forced to ON even in Stop mode

Bit 0 **HSION**: HSI clock enable

Set and cleared by software.

Set by hardware to force the HSI to ON when the product leaves Stop mode, if STOPWUCK = 0 or STOPKERWUCK = 0.

Set by hardware to force the HSI to ON when the product leaves Standby mode or in case of a failure of the HSE which is used as the system clock source.

This bit cannot be cleared if the HSI is used directly (via SW switch) as system clock, or if the HSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1) or if FMCCKP = 1, or if XSPICKP = 1.

0: HSI is OFF

1: HSI is ON (default after reset)

7.8.2 RCC clock protection register (RCC_CKPROTR)

Address offset: 0x100

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	FMCSWP[2:0]			Res.	Res.	Res.	Res.	Res.	XSPISWP[2:0]			Res.	Res.	FMCCKP	XSPICKP
	r	r	r						r	r	r			rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:12 **FMCSWP[2:0]**: FMC kernel clock switch position

Set by hardware.

This field can be used to verify the real position of FMC kernel switch selector.

000: The switch is in neutral mode and output clock is gated (default after reset)

001: The switch is selecting hclk5

010: The switch is selecting pll1_q_ck

011: The switch is selecting pll2_r_ck

100: The switch is selecting hsi_ker_ck

101: The switch is in recovery position (hclk5/4)

Bits 11:7 Reserved, must be kept at reset value.

Bits 6:4 **XSPISWP[2:0]**: XSPI kernel clock switch position
Set by hardware.
This field can be used to verify the real position of XSPI kernel switch selector.
000: The switch is in neutral mode and output clock is gated (default after reset)
001: The switch is selecting hclk5
010: The switch is selecting pll2_s_ck
011: The switch is selecting pll2_t_ck
100: The switch is in recovery position (hclk5/4)

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **FMCCKP**: FMC clock protection
Set and cleared by software.
When set to 1, this bit prevents disabling accidentally the FMC. The following fields cannot be modified when this bit is set to 1:
PLL1ON, PLL2ON, PLL1QEN, PLL2REN, HSEON, HSION, CSION, FMCEN, FMCLPEN, FMCRST.
0: Clock protection is disabled (default after reset)
1: Clock protection is enabled

Bit 0 **XSPICKP**: XSPI clock protection
Set and cleared by software.
When set to 1, this bit prevents disabling accidentally the XSPIs. The following fields cannot be modified when this bit is set to 1:
PLL2ON, PLL2SEN, PLL2TEN, HSEON, HSION, CSION, XSPIEN, XSPILPEN, XSPIRST.
0: Clock protection is disabled (default after reset)
1: Clock protection is enabled

7.8.3 RCC HSI calibration register (RCC_HSICFGR)

Address offset: 0x004

Reset value: 0x4000 0XXX

The reset value depends on the flash option bytes setting.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	HSITRIM[6:0]							Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSICAL[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **HSITRIM[6:0]**: HSI clock trimming
Set by software to adjust calibration.
HSITRIM field is added to the engineering option bytes loaded during reset phase (FLASH_HSI_opt) in order to form the calibration trimming value.
HSICAL = HSITRIM + FLASH_HSI_opt.
Note: The reset value of the field is 0x40.

Bits 23:12 Reserved, must be kept at reset value.

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration
Set by hardware by option byte loading.
Adjusted by software through trimming bits HSITRIM.
This field represents the sum of engineering option byte calibration value and HSITRIM bits value.

7.8.4 RCC clock recovery RC register (RCC_CRRCR)

Address offset: 0x008

Reset value: 0x0000 0XXX

The reset value depends on the flash option bytes setting.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	HSI48CAL[9:0]									
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **HSI48CAL[9:0]**: Internal RC 48 MHz clock calibration
Set by hardware by option byte loading.
Read-only.

7.8.5 RCC CSI calibration register (RCC_CSICFGR)

Address offset: 0x00C

Reset value: 0x2000 00XX

The reset value depends on the flash option bytes setting.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	CSITRIM[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
		rw	rw	rw	rw	rw	rw								

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSICAL[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:24 **CSITRIM[5:0]**: CSI clock trimming
Set by software to adjust calibration.
CSITRIM field is added to the engineering option bytes loaded during reset phase (FLASH_CSI_opt) in order to form the calibration trimming value.
CSICAL = CSITRIM + FLASH_CSI_opt.
Note: The reset value of the field is 0x20.

Bits 23:8 Reserved, must be kept at reset value.

Bits 7:0 **CSICAL[7:0]**: CSI clock calibration
Set by hardware by option byte loading.
Adjusted by software through trimming bits CSITRIM.
This field represents the sum of engineering option byte calibration value and CSITRIM bits value.

7.8.6 RCC clock configuration register (RCC_CFGR)

Address offset: 0x010

Reset value: 0x0000 0000

Access: Word, half-word only

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MCO2SEL[2:0]			MCO2PRE[3:0]				MCO1SEL[2:0]			MCO1PRE[3:0]				Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	RTCPRE[5:0]						STOPKERWUCK	STOPWUCK	Res.	SWS[1:0]		Res.	SW[1:0]	
		rw	rw	rw	rw	rw	rw	rw	rw		r	r		rw	rw

Bits 31:29 **MCO2SEL[2:0]**: microcontroller clock output 2
Set and cleared by software. Clock source selection may generate glitches on MCO2.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: System clock selected (**sys_ck**) (default after reset)
001: PLL2 oscillator clock selected (**pll2_p_ck**)
010: HSE clock selected (**hse_ck**)
011: PLL1 clock selected (**pll1_p_ck**)
100: CSI clock selected (**csi_ck**)
101: LSI clock selected (**lsi_ck**)
Others: Reserved

Bits 28:25 **MCO2PRE[3:0]**: MCO2 prescaler

Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.

0000: Prescaler disabled (default after reset)
0001: Division by 1 (bypass)
0010: Division by 2
0011: Division by 3
0100: Division by 4
...
1111: Division by 15

Bits 24:22 **MCO1SEL[2:0]**: Microcontroller clock output 1

Set and cleared by software. Clock source selection may generate glitches on MCO1.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.

000: HSI clock selected (**hsi_ck**) (default after reset)
001: LSE oscillator clock selected (**lse_ck**)
010: HSE clock selected (**hse_ck**)
011: PLL1 clock selected (**pll1_q_ck**)
100: HSI48 clock selected (**hsi48_ck**)
Others: Reserved

Bits 21:18 **MCO1PRE[3:0]**: MCO1 prescaler

Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.

0000: Prescaler disabled (default after reset)
0001: Division by 1 (bypass)
0010: Division by 2
0011: Division by 3
0100: Division by 4
...
1111: Division by 15

Bits 17:14 Reserved, must be kept at reset value.

Bits 13:8 **RTCPRE[5:0]**: HSE division factor for RTC clock

Set and cleared by software to divide the HSE to generate a clock for RTC.
Caution: The software must set these bits correctly to ensure that the clock supplied to the RTC is lower than 1 MHz. These bits must be configured if needed before selecting the RTC clock source.

000000: No clock (default after reset)
000001: No clock
000010: HSE/2
000011: HSE/3
000100: HSE/4
...
111110: HSE/62
111111: HSE/63

Bit 7 **STOPKERWUCK**: kernel clock selection after a wake up from system Stop

Set and reset by software to select the kernel wakeup clock from system Stop.

0: HSI selected as wake up clock from system Stop (default after reset)
1: CSI selected as wake up clock from system Stop

See *Section 7.5.8: Clock generation in Stop and Standby modes* for details.

Bit 6 **STOPWUCK**: system clock selection after a wake up from system Stop
Set and reset by software to select the system wakeup clock from system Stop.
The selected clock is also used as emergency clock for the clock security system (CSS) on HSE.
0: HSI selected as wake up clock from system Stop (default after reset)
1: CSI selected as wake up clock from system Stop
See *Section 7.5.8: Clock generation in Stop and Standby modes* for details.

Caution: STOPWUCK must not be modified when CSS is enabled (by HSECSSON bit) and the system clock is HSE (SWS = 10) or a switch on HSE is requested (SW =10).

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **SWS[1:0]**: system clock switch status
Set and reset by hardware to indicate which clock source is used as system clock.
00: HSI used as system clock (**hsi_ck**) (default after reset)
01: CSI used as system clock (**csi_ck**)
10: HSE used as system clock (**hse_ck**)
11: PLL1 used as system clock (**pll1_p_ck**)

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SW[1:0]**: system clock switch
Set and reset by software to select system clock source (**sys_ck**).
Set by hardware in order to force the selection of the HSI or CSI (depending on STOPWUCK selection) when leaving a system Stop mode or in case of failure of the HSE when used directly or indirectly as system clock.
00: HSI selected as system clock (**hsi_ck**) (default after reset)
01: CSI selected as system clock (**csi_ck**)
10: HSE selected as system clock (**hse_ck**)
11: PLL1 selected as system clock (**pll1_p_ck**)

7.8.7 RCC CPU domain clock configuration register (RCC_CDCFGR)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPRE[3:0]			
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **CPRE[3:0]**: CPU domain core prescaler

Set and reset by software to control the CPU clock division factor.
Changing this division ratio has an impact on the frequency of the CPU clock and all bus matrix clocks.
After changing this prescaler value, it takes up to 16 periods of the slowest APB clock before the new division ratio is taken into account. The application can check if the new division factor is taken into account by reading back this register.
0000 - 0111: **sys_ck** not divided (default after reset)
1000: **sys_ck** divided by 2
1001: **sys_ck** divided by 4
1010: **sys_ck** divided by 8
1011: **sys_ck** divided by 16
1100: **sys_ck** divided by 64
1101: **sys_ck** divided by 128
1110: **sys_ck** divided by 256
1111: **sys_ck** divided by 512

Caution: Care must be taken when using the voltage scaling. Due to the propagation delay of the new division factor, after a prescaler factor change and before lowering the V_{CORE} voltage, this register must be read in order to check that the new prescaler value has been taken into account.

Depending on the clock source frequency and the voltage range, the software application must program a correct value in BMPRE to make sure that the system frequency does not exceed the maximum frequency.

7.8.8 RCC AHB clock configuration register (RCC_BMCFGR)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BMPRE[3:0]			
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **BMPRE[3:0]**: Bus matrix clock prescaler

Set and reset by software to control the division factor of **rcc_hclk[5:1]** and **rcc_aclk**. This group of clocks is also named **sys_bus_ck**. Changing this division ratio has an impact on the frequency of all bus matrix clocks.
0000 - 0111: **sys_bus_ck= sys_cpu_ck** (default after reset)
1000 - 1111: **sys_bus_ck** = **sys_cpu_ck** / 2

*Note: The new prescaler factor takes effect from 1 to 16 periods of the slowest APB clock among **rcc_pclk1,2,4** following an update of BMPRE.*

*Note: Note also that frequency of **rcc_hclk[5:1]** = **rcc_aclk = sys_bus_ck**.*

7.8.9 RCC APB clocks configuration register (RCC_APBCFGR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rw	rw	rw		rw	rw	rw		rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **PPRE4[2:0]**: CPU domain APB4 prescaler

Set and reset by software to control the division factor of **rcc_pclk4**.
The clock is divided by the new prescaler factor from 1 to 16 cycles of **sys_bus_ck** after PPRE4 write.
000 - 011: **rcc_pclk4** = **sys_bus_ck** (default after reset)
100: **rcc_pclk4** = **sys_bus_ck** / 2
101: **rcc_pclk4** = **sys_bus_ck** / 4
110: **rcc_pclk4** = **sys_bus_ck** / 8
111: **rcc_pclk4** = **sys_bus_ck** / 16

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE2[2:0]**: CPU domain APB2 prescaler

Set and reset by software to control the division factor of **rcc_pclk2**.
The clock is divided by the new prescaler factor from 1 to 16 cycles of **sys_bus_ck** after PPRE2 write.
000 - 011: **rcc_pclk2** = **sys_bus_ck** (default after reset)
100: **rcc_pclk2** = **sys_bus_ck** / 2
101: **rcc_pclk2** = **sys_bus_ck** / 4
110: **rcc_pclk2** = **sys_bus_ck** / 8
111: **rcc_pclk2** = **sys_bus_ck** / 16

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **PPRE1[2:0]**: CPU domain APB1 prescaler

Set and reset by software to control the division factor of **rcc_pclk1**.
The clock is divided by the new prescaler factor from 1 to 16 cycles of **sys_bus_ck** after PPRE1 write.
000 - 011: **rcc_pclk1** = **sys_bus_ck** (default after reset)
100: **rcc_pclk1** = **sys_bus_ck** / 2
101: **rcc_pclk1** = **sys_bus_ck** / 4
110: **rcc_pclk1** = **sys_bus_ck** / 8
111: **rcc_pclk1** = **sys_bus_ck** / 16

7.8.10 RCC PLLs clock source selection register (RCC_PLLCKSELR)

Address offset: 0x028

Reset value: 0x0202 0200

Access: Word only

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **DIVM3[5:0]:** prescaler for PLL3

Set and cleared by software to configure the prescaler of the PLL3.
The hardware does not allow any modification of this prescaler when PLL3 is enabled (PLL3ON = 1).
In order to save power when PLL3 is not used, the value of DIVM3 must be set to 0.
000000: Prescaler disabled
000001: Division by 1 (bypass)
000010: Division by 2
000011: Division by 3
...
100000: Division by 32 (default after reset)
...
111111: Division by 63

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:12 **DIVM2[5:0]**: prescaler for PLL2

Set and cleared by software to configure the prescaler of the PLL2.
The hardware does not allow any modification of this prescaler when PLL2 is enabled (PLL2ON = 1).
In order to save power when PLL2 is not used, the value of DIVM2 must be set to 0.
000000: Prescaler disabled
000001: Division by 1 (bypass)
000010: Division by 2
000011: Division by 3
...
100000: Division by 32 (default after reset)
...
111111: Division by 63

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:4 **DIVM1[5:0]**: prescaler for PLL1

Set and cleared by software to configure the prescaler of the PLL1.
The hardware does not allow any modification of this prescaler when PLL1 is enabled (PLL1ON = 1).
In order to save power when PLL1 is not used, the value of DIVM1 must be set to 0.
000000: Prescaler disabled
000001: Division by 1 (bypass)
000010: Division by 2
000011: Division by 3
...
100000: Division by 32 (default after reset)
...
111111: Division by 63

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **PLLSRC[1:0]:** DIVMx and PLLs clock source selection

Set and reset by software to select the PLL clock source.
These bits can be written only when all PLLs are disabled.
In order to save power, when no PLL is used, PLLSRC must be set to 11.
00: HSI selected as PLL clock (**hsi_ck**) (default after reset)
01: CSI selected as PLL clock (**csi_ck**)
10: HSE selected as PLL clock (**hse_ck**)
11: No clock send to DIVMx divider and PLLs

7.8.11 RCC PLLs configuration register (RCC_PLLCFGR)

Address offset: 0x02C

Reset value: 0x0000 0000

rw	rw	rw	rw	rw			rw		rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **PLL3SEN**: PLL3 DIVS divider output enable

Set and reset by software to enable the **pll3_s_ck** output of the PLL3.
To save power, PLL3SEN must be set to 0 when the **pll3_s_ck** is not used.
0: **pll3_s_ck** output disabled (default after reset)
1: **pll3_s_ck** output enabled

Bit 29 **PLL3REN**: PLL3 DIVR divider output enable

Set and reset by software to enable the **pll3_r_ck** output of the PLL3.
To save power, PLL3REN and DIVR bits must be set to 0 when the **pll3_r_ck** is not used.
0: **pll3_r_ck** output disabled (default after reset)
1: **pll3_r_ck** output enabled

Bit 28 **PLL3QEN**: PLL3 DIVQ divider output enable
Set and reset by software to enable the **pll3_q_ck** output of the PLL3.
To save power, PLL3REN and DIVR bits must be set to 0 when the **pll3_q_ck** is not used.
0: **pll3_q_ck** output disabled (default after reset)
1: **pll3_q_ck** output enabled

Bit 27 **PLL3PEN**: PLL3 DIVP divider output enable
Set and reset by software to enable the **pll3_p_ck** output of the PLL3.
To save power, PLL3REN and DIVR bits must be set to 0 when the **pll3_p_ck** is not used.
0: **pll3_p_ck** output disabled (default after reset)
1: **pll3_p_ck** output enabled

Bits 26:25 **PLL3RGE[1:0]**: PLL3 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL3.
These bits can only be modified if PLL3ON = 0 in *RCC source control register (RCC_CR)*.
00: PLL3 input (**ref3_ck**) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL3 input (**ref3_ck**) clock range frequency between 2 and 4 MHz
10: PLL3 input (**ref3_ck**) clock range frequency between 4 and 8 MHz
11: PLL3 input (**ref3_ck**) clock range frequency between 8 and 16 MHz

Bit 24 **PLL3SSCGEN**: PLL3 SSCG enable
Set and reset by software to enable the spread spectrum clock generator of PLL3, in order to reduce the number of EMI peaks.
0: SSCG disabled (default after reset)
1: SSCG enabled

Bit 23 **PLL3VCOSEL**: PLL3 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL3.
This bit can only be modified if PLL3ON = 0 in *RCC source control register (RCC_CR)*. It allows the application to select the VCO range:
– VCOH: working from 384 to 1672 MHz (F_{ref2_ck} must be between 2 and 16 MHz)
– VCOL: working from 150 to 420 MHz (F_{ref2_ck} must be between 1 and 2 MHz)
0: VCOH selected (default after reset)
1: VCOL selected

Bit 22 **PLL3FRACEN**: PLL3 fractional latch enable
Set and reset by software to latch the content of FRACN into the sigma-delta modulator.
In order to latch the FRACN value into the sigma-delta modulator, PLL3FRACEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN into the modulator.
Refer to *PLL initialization procedure on page 385* for additional information.
PLL3FRACEN must remain at 0 for at least 5 µs.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **PLL2TEN**: PLL2 DIVT divider output enable
Set and reset by software to enable the **pll2_t_ck** output of the PLL2.
To save power, PLL2TEN must be set to 0 when the **pll2_t_ck** is not used.
The hardware prevents writing this bit if XSPICKP = 1.
0: **pll2_t_ck** output disabled (default after reset)
1: **pll2_t_ck** output enabled

Bit 19 **PLL2SEN**: PLL2 DIVS divider output enable
Set and reset by software to enable the **pll2_s_ck** output of the PLL2.
To save power, PLL2SEN must be set to 0 when the **pll2_s_ck** is not used.
The hardware prevents writing this bit if XSPICKP = 1.
0: **pll2_s_ck** output disabled (default after reset)
1: **pll2_s_ck** output enabled

Bit 18 **PLL2REN**: PLL2 DIVR divider output enable
Set and reset by software to enable the **pll2_r_ck** output of the PLL2.
The hardware prevents writing this bit if FMCCKP = 1.
To save power, PLL3REN and DIVR bits must be set to 0 when the **pll3_r_ck** is not used.
0: **pll2_r_ck** output disabled (default after reset)
1: **pll2_r_ck** output enabled

Bit 17 **PLL2QEN**: PLL2 DIVQ divider output enable
Set and reset by software to enable the **pll2_q_ck** output of the PLL2.
To save power, PLL3QEN and DIVQ bits must be set to 0 when the **pll2_q_ck** is not used.
0: **pll2_q_ck** output disabled (default after reset)
1: **pll2_q_ck** output enabled

Bit 16 **PLL2PEN**: PLL2 DIVP divider output enable
Set and reset by software to enable the **pll2_p_ck** output of the PLL2.
To save power, PLL2PEN and DIVP bits must be set to 0 when the **pll2_p_ck** is not used.
0: **pll2_p_ck** output disabled (default after reset)
1: **pll2_p_ck** output enabled

Bits 15:14 **PLL2RGE[1:0]**: PLL2 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL2.
These bits can only be modified if PLL2ON = 0 in *RCC source control register (RCC_CR)*.
00: PLL3 input (**ref2_ck**) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL3 input (**ref2_ck**) clock range frequency between 2 and 4 MHz
10: PLL3 input (**ref2_ck**) clock range frequency between 4 and 8 MHz
11: PLL3 input (**ref2_ck**) clock range frequency between 8 and 16 MHz

Bit 13 **PLL2SSCGEN**: PLL2 SSCG enable
Set and reset by software to enable the Spread Spectrum Clock Generator of PLL2, in order to reduce the amount of EMI peaks.
0: SSCG disabled (default after reset)
1: SSCG enabled

Bit 12 **PLL2VCOSEL**: PLL2 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL2.
This bit can only be modified if PLL2ON = 0 in *RCC source control register (RCC_CR)*. It allows the application to select the VCO range:
– VCOH: working from 384 to 1672 MHz (F_{ref2_ck} must be between 2 and 16 MHz)
– VCOL: working from 150 to 420 MHz (F_{ref2_ck} must be between 1 and 2 MHz)
0: VCOH selected (default after reset)
1: VCOL selected

Bit 11 **PLL2FRACLEN**: PLL2 fractional latch enable
Set and reset by software to latch the content of FRACN into the sigma-delta modulator.
In order to latch the FRACN value into the sigma-delta modulator, PLL2FRACLEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN into the modulator.
Refer to *PLL initialization procedure on page 385* for additional information.
PLL2FRACLEN must remain at 0 for at least 5 µs.

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **PLL1SEN**: PLL1 DIVS divider output enable

Set and reset by software to enable the **pll1_s_ck** output of the PLL1.
To save power, PLL1SEN must be set to 0 when the **pll1_s_ck** is not used.
0: **pll1_s_ck** output disabled (default after reset)
1: **pll1_s_ck** output enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **PLL1QEN**: PLL1 DIVQ divider output enable

Set and reset by software to enable the **pll1_q_ck** output of the PLL1.
The hardware prevents writing this bit if FMCCKP = 1.
In order to save power, when the **pll1_q_ck** output of the PLL1 is not used, the **pll1_q_ck** must be disabled.
0: **pll1_q_ck** output disabled (default after reset)
1: **pll1_q_ck** output enabled

Bit 5 **PLL1PEN**: PLL1 DIVP divider output enable

Set and reset by software to enable the **pll1_p_ck** output of the PLL1.
The hardware prevents modifying this bit if the PLL1 output is used as the system clock (SW=3).
In order to save power, when the **pll1_p_ck** output of the PLL1 is not used, the **pll1_p_ck** must be disabled.
0: **pll1_p_ck** output disabled (default after reset)
1: **pll1_p_ck** output enabled

Bits 4:3 **PLL1RGE[1:0]**: PLL1 input frequency range

Set and reset by software to select the reference frequency range used for PLL1.
These bits can only be modified if PLL1ON = 0 in *RCC source control register (RCC_CR)*.
00: PLL1 input (**ref1_ck**) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL1 input (**ref1_ck**) clock range frequency between 2 and 4 MHz
10: PLL1 input (**ref1_ck**) clock range frequency between 4 and 8 MHz
11: PLL1 input (**ref1_ck**) clock range frequency between 8 and 16 MHz

Bit 2 **PLL1SSCGEN**: PLL1 SSCG enable

Set and reset by software to enable the Spread Spectrum Clock Generator of PLL1, in order to reduce the amount of EMI peaks.
0: SSCG disabled (default after reset)
1: SSCG enabled

Bit 1 **PLL1VCOSEL**: PLL1 VCO selection

Set and reset by software to select the VCO frequency range used for PLL1.
This bit can only be modified if PLL1ON = 0 in *RCC source control register (RCC_CR)*. It allows the application to select the VCO range:

- VCOH: working from 384 to 1672 MHz (F_{ref1_ck} must be between 2 and 16 MHz)
- VCOL: working from 150 to 420 MHz (F_{ref1_ck} must be between 1 and 2 MHz)

0: VCOH selected (default after reset)
1: VCOL selected

Bit 0 **PLL1FRACEN**: PLL1 fractional latch enable

Set and reset by software to latch the content of FRACN into the sigma-delta modulator.
In order to latch the FRACN value into the sigma-delta modulator, PLL1FRACEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN into the modulator.
Refer to *PLL initialization procedure on page 385* for additional information.
PLL1FRACEN must remain at 0 for at least 5 µs.

7.8.12 RCC PLL1 dividers configuration register 1 (RCC_PLL1DIVR1)

Address offset: 0x030

Reset value: 0x0101 0280

Access: Word and half-word only

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **DIVQ[6:0]**: PLL1 DIVQ division factor

Set and reset by software to control the frequency of the **pll1_q_ck** clock.

0000000: **pll1_q_ck** = **vco1_ck**

0000001: **pll1_q_ck** = **vco1_ck** / 2 (default after reset)

0000010: **pll1_q_ck** = **vco1_ck** / 3

0000011: **pll1_q_ck** = **vco1_ck** / 4

...

1111111: **pll1_q_ck** = **vco1_ck** / 128

Bits 15:9 **DIVP[6:0]**: PLL1 DIVP division factor

Set and reset by software to control the frequency of the **pll1_p_ck** clock.
0000000: **pll1_p_ck** = **vco1_ck**
0000001: **pll1_p_ck** = **vco1_ck** / 2 (default after reset)
0000010: Not allowed
0000011: **pll1_p_ck** = **vco1_ck** / 4
...
1111111: **pll1_p_ck** = **vco1_ck** / 128

Bits 8:0 **DIVN[8:0]**: multiplication factor for PLL1 VCO

Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL1ON = 0 in *RCC source control register (RCC_CR)*).
.....: Not used
0x006: Wrong configuration
0x007: DIVN = 8
...
0x080: DIVN = 129 (default after reset)
...
0x1A3: DIVN = 420
Others: Wrong configurations

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

– 128 to 544 MHz if PLL1VCOSEL = 0
– 150 to 420 MHz if PLL1VCOSEL = 1

VCO output frequency = F_{ref1_ck} x DIVN, when fractional value 0 has been loaded into FRACN, with:

– DIVN between 8 and 420
– The input frequency F_{ref1_ck} must be between 1 and 16 MHz.

7.8.13 RCC PLL1 dividers configuration register 2 (RCC_PLL1DIVR2)

Address offset: 0x0C0

Reset value: 0x0000 0101

													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **DIVS[2:0]**: PLL1 DIVS division factor

Set and reset by software to control the frequency of the **pll1_s_ck** clock.
This post-divider performs divisions with 50% duty-cycle.
The duty-cycle of 50% is guaranteed only in the following conditions:

– With VCOL, if (DIVS+1) is even,
– With VCOH, for all DIVS values

These bits can be written only when the PLL1SEN = 0.
000: **pll1_s_ck** = **vco1_ck**
001: **pll1_s_ck** = **vco1_ck** / 2 (default after reset)
010: **pll1_s_ck** = **vco1_ck** / 3
011: **pll1_s_ck** = **vco1_ck** / 4
100: **pll1_s_ck** = **vco1_ck** / 5
101: **pll1_s_ck** = **vco1_ck** / 6
110: **pll1_s_ck** = **vco1_ck** / 7
111: **pll1_s_ck** = **vco1_ck** / 8

7.8.14 RCC PLL1 fractional divider register (RCC_PLL1FRACR)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

FRACN[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **FRACN[12:0]**: fractional part of the multiplication factor for PLL1 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.
These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

– 128 to 544 MHz if PLL1VCOSEL = 0
– 150 to 420 MHz if PLL1VCOSEL = 1

VCO output frequency = F_{ref1_ck} x $\left(\text{DIVN} + (\text{FRACN} / 2^{13})\right)$, with

– DIVN between 8 and 420
– FRACN can be between 0 and 2^{13}- 1
– The input frequency F_{ref1_ck} must be between 1 and 16 MHz.

To change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

– Set the bit PLL1FRACEN to 0.
– Write the new fractional value into FRACN.
– Set the bit PLL1FRACEN to 1
– Wait at least 5 µs.

Bits 2:0 Reserved, must be kept at reset value.

7.8.15 RCC PLL1 Spread Spectrum Clock Generator register (RCC_PLL1SSCGR)

Address offset: 0x0CC

Reset value: 0x0000 0000

Access: Word and half-word only

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:16 **INCSTEP[14:0]**: Modulation Depth Adjustment for PLL1

Set and reset by software to adjust the modulation depth of the clock spreading generator.

Bit 15 **SPREADSEL**: Spread spectrum clock generator mode for PLL1

Set and reset by software to select the clock spreading mode.

0: Center-spread modulation selected (default after reset)

1: Down-spread modulation selected

Bit 14 **RPDFNDIS**: Dithering RPDF noise control for PLL1

Set and reset by software.

This bit is used to enable or disable the injection of a dithering noise into the SSCG modulator. This dithering noise is generated using a rectangular probability density function.

0: Dithering noise injection enabled (default after reset)

1: Dithering noise injection disabled

Bit 13 **TPDFNDIS**: Dithering TPDF noise control for PLL1

Set and reset by software.

This bit is used to enable or disable the injection of a dithering noise into the SSCG modulator. This dithering noise is generated using a triangular probability density function.

0: Dithering noise injection enabled (default after reset)

1: Dithering noise injection disabled

Bits 12:0 **MODPER[12:0]**: Modulation Period Adjustment for PLL1

Set and reset by software to adjust the modulation period of the clock spreading generator.

7.8.16 RCC PLL2 dividers configuration register 1 (RCC_PLL2DIVR1)

Address offset: 0x038

Reset value: 0x0101 0280

Access: Word and half-word only

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **DIVR[6:0]**: PLL2 DIVR division factor

Set and reset by software to control the frequency of the **pll2_r_ck** clock.
0000000: **pll2_r_ck** = **vco2_ck**
0000001: **pll2_r_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_r_ck** = **vco2_ck** / 3
0000011: **pll2_r_ck** = **vco2_ck** / 4
...
1111111: **pll2_r_ck** = **vco2_ck** / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **DIVQ[6:0]**: PLL2 DIVQ division factor

Set and reset by software to control the frequency of the **pll2_q_ck** clock.
0000000: **pll2_q_ck** = **vco2_ck**
0000001: **pll2_q_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_q_ck** = **vco2_ck** / 3
0000011: **pll2_q_ck** = **vco2_ck** / 4
...
1111111: **pll2_q_ck** = **vco2_ck** / 128

Bits 15:9 **DIVP[6:0]**: PLL2 DIVP division factor

Set and reset by software to control the frequency of the **pll2_p_ck** clock.
0000000: **pll2_p_ck** = **vco2_ck**
0000001: **pll2_p_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_p_ck** = **vco2_ck** / 3
0000011: **pll2_p_ck** = **vco2_ck** / 4
...
1111111: **pll2_p_ck** = **vco2_ck** / 128

Bits 8:0 **DIVN[8:0]**: multiplication factor for PLL2 VCO

Set and reset by software to control the multiplication factor of the VCO.

These bits can be written only when the PLL is disabled (PLL2ON = 0 in *RCC source control register (RCC_CR)*).

.....: Not used

0x006: wrong configuration

0x007: DIVN = 8

...

0x080: DIVN = 129 (default after reset)

...

0x1A3: DIVN = 420

Others: wrong configurations

Caution: The software must set correctly these bits to insure that the VCO output frequency is within its valid frequency range, that is:

– 128 to 544 MHz if PLL2VCOSEL = 0

– 150 to 420 MHz if PLL2VCOSEL = 1

VCO output frequency = F_{ref2_ck} x DIVN, when fractional value 0 has been loaded into FRACN, with

– DIVN between 8 and 420

– The input frequency F_{ref2_ck} must be between 1 and 16 MHz.

7.8.17 RCC PLL2 dividers configuration register 2 (RCC_PLL2DIVR2)

Address offset: 0x0C4

Reset value: 0x0000 0101

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **DIVT[2:0]**: PLL2 DIVT division factor

Set and reset by software to control the frequency of the **pll2_t_ck** clock.

This post-divider performs divisions with 50% duty-cycle.

The duty-cycle of 50% is guaranteed only in the following conditions:

– With VCOL, if (DIVT+1) is even,

– With VCOH, for all DIVT values

These bits can be written only when the PLL2TEN = 0.

000: **pll2_t_ck** = **vco2_ck**

001: **pll2_t_ck** = **vco2_ck** / 2 (default after reset)

010: **pll2_t_ck** = **vco2_ck** / 3

011: **pll2_t_ck** = **vco2_ck** / 4

100: **pll2_t_ck** = **vco2_ck** / 5

101: **pll2_t_ck** = **vco2_ck** / 6

110: **pll2_t_ck** = **vco2_ck** / 7

111: **pll2_t_ck** = **vco2_ck** / 8

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **DIVS[2:0]**: PLL2 DIVS division factor

Set and reset by software to control the frequency of the **pll2_s_ck** clock.
This post-divider performs divisions with 50% duty-cycle.
The duty-cycle of 50% is guaranteed only in the following conditions:

- With VCOL, if (DIVS+1) is even,
- With VCOH, for all DIVS values

These bits can be written only when the PLL2SEN = 0.
000: **pll2_s_ck** = **vco2_ck**
001: **pll2_s_ck** = **vco2_ck** / 2 (default after reset)
010: **pll2_s_ck** = **vco2_ck** / 3
011: **pll2_s_ck** = **vco2_ck** / 4
100: **pll2_s_ck** = **vco2_ck** / 5
101: **pll2_s_ck** = **vco2_ck** / 6
110: **pll2_s_ck** = **vco2_ck** / 7
111: **pll2_s_ck** = **vco2_ck** / 8

7.8.18 RCC PLL2 fractional divider register (RCC_PLL2FRACR)

Address offset: 0x03C

Reset value: 0x0000 0000

Access: Word and half-word only

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

FRACN[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **FRACN[12:0]**: fractional part of the multiplication factor for PLL2 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO. These bits can be written at any time, allowing dynamic fine-tuning of the PLL2 VCO.

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 128 to 544 MHz if PLL2VCOSEL = 0
- 150 to 420 MHz if PLL2VCOSEL = 1

VCO output frequency = F_{ref2_ck} x $\left(DIVN + (FRACN / 2^{13})\right)$, with

- DIVN between 8 and 420
- FRACN can be between 0 and 2^{13} - 1
- The input frequency F_{ref2_ck} must be between 1 and 16 MHz.

In order to change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL2FRACLEN to 0.
- Write the new fractional value into FRACN.
- Set the bit PLL2FRACLEN to 1.
- Wait at least 5 µs.

Bits 2:0 Reserved, must be kept at reset value.

7.8.19 RCC PLL2 spread spectrum clock generator register (RCC_PLL2SSCGR)

Address offset: 0x0D0

Reset value: 0x0000 0000

Access: Word and half-word only

Bits 1:0 **FMCSEL[1:0]**: FMC kernel clock source selection
Set and reset by software.
00: **hclk5** selected as kernel peripheral clock (default after reset)
01: **pll1_q_ck** selected as kernel peripheral clock
10: **pll2_r_ck** selected as kernel peripheral clock
11: **hsi_ker_ck** selected as kernel peripheral clock

7.8.25 RCC peripheral kernel clock selection register 2 (RCC_CCIPR2)

Address offset: 0x050

Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **FDCANSEL[1:0]**: FDCAN kernel clock source selection
00: **hse_ker_ck** selected as FDCAN kernel clock (default after reset)
01: **pll1_q_ck** selected as FDCAN kernel clock
10: **pll2_p_ck** selected as FDCAN kernel clock
11: Reserved, the kernel clock is disabled

Bits 21:19 Reserved, must be kept at reset value.

Bits 18:16 **LPTIM1SEL[2:0]**: LPTIM1 kernel clock source selection
Set and reset by software.
000: **pclk1** selected as kernel peripheral clock (default after reset)
001: **pll2_p_ck** selected as kernel peripheral clock
010: **pll3_r_ck** selected as kernel peripheral clock
011: **lse_ck** selected as kernel peripheral clock
100: **lsi_ck** selected as kernel peripheral clock
101: **per_ck** selected as kernel peripheral clock
Others: Reserved, the kernel clock is disabled

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **I3C1SEL[1:0]**: I3C1 kernel clock source selection
Set and reset by software.
00: **pclk1** selected as kernel peripheral clock (default after reset)
01: **pll3_r_ck** selected as kernel peripheral clock
10: **hsi_ker_ck** selected as kernel peripheral clock
11: **csi_ker_ck** selected as kernel peripheral clock

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **I2C123SEL[1:0]**: I2C1, I2C2, I2C3 kernel clock source selection
Set and reset by software.
00: **pclk1** selected as kernel clock (default after reset)
01: **pll3_r_ck** selected as kernel clock
10: **hsi_ker_ck** selected as kernel clock
11: **csi_ker_ck** selected as kernel clock

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **SPI23SEL[2:0]**: SPI/I2S2 and SPI/I2S3 kernel clock source selection
Set and reset by software.

Caution: If the selected clock is the external clock and this clock is stopped, it is not be possible to switch to another clock. Refer to *Clock switches and gating on page 378* for additional information.

000: **pll1_q_ck** selected as kernel clock (default after reset)
001: **pll2_p_ck** selected as kernel clock
010: **pll3_p_ck** selected as kernel clock
011: **AUDIOCLK** selected as kernel clock
100: **per_ck** selected as kernel clock
Others: Reserved, the kernel clock is disabled

Note: AUDIOCLK is an external clock taken from a pin.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **UART234578SEL[2:0]**: USART2,3, UART4,5,7,8 (APB1) kernel clock source selection
Set and reset by software.
000: **pclk1** selected as kernel clock (default after reset)
001: **pll2_q_ck** selected as kernel clock
010: **pll3_q_ck** selected as kernel clock
011: **hsi_ker_ck** selected as kernel clock
100: **csi_ker_ck** selected as kernel clock
101: **lse_ck** selected as kernel clock
Others: Reserved, the kernel clock is disabled

7.8.26 RCC peripheral kernel clock selection register 3 (RCC_CCIPR3)

Address offset: 0x054

Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **SPI1SEL[2:0]**: SPI/I2S1 kernel clock source selection

Set and reset by software.

Caution: If the selected clock is the external clock (AUDIOCLK) and this clock is stopped, it is not possible to switch to another clock. Refer to *Clock switches and gating on page 378* for additional information.

000: **pll1_q_ck** selected as SPI/I2S1 kernel clock (default after reset)
001: **pll2_p_ck** selected as SPI/I2S1 kernel clock
010: **pll3_p_ck** selected as SPI/I2S1 kernel clock
011: **AUDIOCLK** selected as SPI/I2S1 kernel clock
100: **per_ck** selected as SPI/I2S1 kernel clock
Others: Reserved, the kernel clock is disabled

Note: I2S_CKIN is an external clock taken from a pin.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **SPI45SEL[2:0]**: SPI4 and 5 kernel clock source selection

Set and reset by software.
000: **pclk2** selected as kernel clock (default after reset)
001: **pll2_q_ck** is selected as kernel clock
010: **pll3_q_ck** is selected as kernel clock
011: **hsi_ker_ck** is selected as kernel clock
100: **csi_ker_ck** is selected as kernel clock
101: **hse_ker_ck** is selected as kernel clock
Others: Reserved, the kernel clock is disabled

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **USART16910SEL[2:0]**: USART1, UARTS6, USART9 and USART10 kernel clock source selection

Set and reset by software.
000: **pclk2** selected as kernel clock (default after reset)
001: **pll2_q_ck** selected as kernel clock
010: **pll3_q_ck** selected as kernel clock
011: **hsi_ker_ck** selected as kernel clock
100: **csi_ker_ck** selected as kernel clock
101: **lse_ck** selected as kernel clock
Others: Reserved, the kernel clock is disabled

7.8.27 RCC peripheral kernel clock selection register 4 (RCC_CCIPR4)

Address offset: 0x058

Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are

present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **DAC4SEL[2:0]**: DAC4 kernel clock source selection
Set and reset by software.
000: **hclk3** selected as kernel peripheral clock - synchronous mode (default after reset)
001: **rcc_tim_ker_ck** selected as kernel peripheral clock
010: **rcc_adc_ker_ck** selected as kernel peripheral clock
011: **hsi_ker_ck** selected as kernel peripheral clock
100: **hse_ker_ck** selected as kernel peripheral clock
101: **pll2_p_ck** selected as kernel peripheral clock
110: **pll3_r_ck** selected as kernel peripheral clock
111: **per_ck** selected as kernel peripheral clock

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **DAC3SEL[2:0]**: DAC3 kernel clock source selection
Set and reset by software.
000: **hclk3** selected as kernel peripheral clock - synchronous mode (default after reset)
001: **rcc_tim_ker_ck** selected as kernel peripheral clock
010: **rcc_adc_ker_ck** selected as kernel peripheral clock
011: **hsi_ker_ck** selected as kernel peripheral clock
100: **hse_ker_ck** selected as kernel peripheral clock
101: **pll2_p_ck** selected as kernel peripheral clock
110: **pll3_r_ck** selected as kernel peripheral clock
111: **per_ck** selected as kernel peripheral clock

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **DAC2SEL[2:0]**: DAC2 kernel clock source selection
Set and reset by software.
000: **hclk3** selected as kernel peripheral clock - synchronous mode (default after reset)
001: **rcc_tim_ker_ck** selected as kernel peripheral clock
010: **rcc_adc_ker_ck** selected as kernel peripheral clock
011: **hsi_ker_ck** selected as kernel peripheral clock
100: **hse_ker_ck** selected as kernel peripheral clock
101: **pll2_p_ck** selected as kernel peripheral clock
110: **pll3_r_ck** selected as kernel peripheral clock
111: **per_ck** selected as kernel peripheral clock

Bit 19 **DAC1SHSEL**: DAC1 hold clock selection
Set and reset by software.
0: **lse_ck** selected as rcc_dac_hold_ck
1: **lsi_ck** selected as rcc_dac_hold_ck

Bits 18:16 **DAC1SEL[2:0]**: DAC1 kernel clock source selection
Set and reset by software.
000: **hclk3** selected as kernel peripheral clock - synchronous mode (default after reset)
001: **rcc_tim_ker_ck** selected as kernel peripheral clock
010: **rcc_adc_ker_ck** selected as kernel peripheral clock
011: **hsi_ker_ck** selected as kernel peripheral clock
100: **hse_ker_ck** selected as kernel peripheral clock
101: **pll2_p_ck** selected as kernel peripheral clock
110: **pll3_r_ck** selected as kernel peripheral clock
111: **per_ck** selected as kernel peripheral clock

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **LPTIM45SEL[2:0]**: LPTIM4, and LPTIM5 kernel clock source selection
Set and reset by software.
000: **pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_p_ck** selected as kernel peripheral clock
010: **pll3_r_ck** selected as kernel peripheral clock
011: **lse_ck** selected as kernel peripheral clock
100: **lsi_ck** selected as kernel peripheral clock
101: **per_ck** selected as kernel peripheral clock
Others: Reserved, the kernel clock is disabled

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **LPTIM23SEL[2:0]**: LPTIM2 and LPTIM3 kernel clock source selection
Set and reset by software.
000: **pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_p_ck** selected as kernel peripheral clock
010: **pll3_r_ck** selected as kernel peripheral clock
011: **lse_ck** selected as kernel peripheral clock
100: **lsi_ck** selected as kernel peripheral clock
101: **per_ck** selected as kernel peripheral clock
Others: Reserved, the kernel clock is disabled

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **SPI6SEL[2:0]**: SPI/I2S6 kernel clock source selection
Set and reset by software.
000: **pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_q_ck** selected as kernel peripheral clock
010: **pll3_q_ck** selected as kernel peripheral clock
011: **hsi_ker_ck** selected as kernel peripheral clock
100: **csi_ker_ck** selected as kernel peripheral clock
101: **hse_ker_ck** selected as kernel peripheral clock
Others: Reserved, the kernel clock is disabled

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **LPUART1SEL[2:0]**: LPUART1 kernel clock source selection
Set and reset by software.
000: **pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_q_ck** selected as kernel peripheral clock
010: **pll3_q_ck** selected as kernel peripheral clock
011: **hsi_ker_ck** selected as kernel peripheral clock
100: **csi_ker_ck** selected as kernel peripheral clock
101: **lse_ck** selected as kernel peripheral clock
Others: Reserved, the kernel clock is disabled

7.8.28 RCC clock source interrupt enable register (RCC_CIER)

Address offset: 0x060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **LSECSSIE**: LSE clock security system interrupt enable
Set and reset by software to enable/disable interrupt caused by the clock security system (CSS) on external 32 kHz oscillator.
0: LSE CSS interrupt disabled (default after reset)
1: LSE CSS interrupt enabled

Bit 8 **PLL3RDYIE**: PLL3 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by PLL3 lock.
0: PLL3 lock interrupt disabled (default after reset)
1: PLL3 lock interrupt enabled

Bit 7 **PLL2RDYIE**: PLL2 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by PLL2 lock.
0: PLL2 lock interrupt disabled (default after reset)
1: PLL2 lock interrupt enabled

Bit 6 **PLL1RDYIE**: PLL1 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by PLL1 lock.
0: PLL1 lock interrupt disabled (default after reset)
1: PLL1 lock interrupt enabled

Bit 5 **HSI48RDYIE**: HSI48 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSI48 oscillator stabilization.
0: HSI48 ready interrupt disabled (default after reset)
1: HSI48 ready interrupt enabled

Bit 4 **CSIRDYIE**: CSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the CSI oscillator stabilization.
0: CSI ready interrupt disabled (default after reset)
1: CSI ready interrupt enabled

Bit 3 **HSERDYIE**: HSE ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSE oscillator stabilization.
0: HSE ready interrupt disabled (default after reset)
1: HSE ready interrupt enabled

Bit 2 **HSIRDYIE**: HSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSI oscillator stabilization.
0: HSI ready interrupt disabled (default after reset)
1: HSI ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the LSE oscillator stabilization.
0: LSE ready interrupt disabled (default after reset)
1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the LSI oscillator stabilization.
0: LSI ready interrupt disabled (default after reset)
1: LSI ready interrupt enabled

7.8.29 RCC clock source interrupt flag register (RCC_CIFR)

Address offset: 0x64

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	HSECSSF	LSECSSF	PLL3RDYF	PLL2RDYF	PLL1RDYF	HSI48RDYF	CSIRDYF	HSERDYF	HSIRDYF	LSERDYF	LSIRDYF
					r	r	r	r	r	r	r	r	r	r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSF**: HSE clock security system interrupt flag
Reset by software by writing HSECSSC bit.
Set by hardware in case of HSE clock failure.
0: No clock security interrupt caused by HSE clock failure (default after reset)
1: Clock security interrupt caused by HSE clock failure

Bit 9 **LSECSSF**: LSE clock security system interrupt flag
Reset by software by writing LSECSSC bit.
Set by hardware when a failure is detected on the external 32 kHz oscillator and LSECSSIE is set.
0: No failure detected on the external 32 kHz oscillator (default after reset)
1: Failure detected on the external 32 kHz oscillator

Bit 8 **PLL3RDYF**: PLL3 ready interrupt flag
Reset by software by writing PLL3RDYC bit.
Set by hardware when the PLL3 locks and PLL3RDYIE is set.
0: No clock ready interrupt caused by PLL3 lock (default after reset)
1: Clock ready interrupt caused by PLL3 lock

Bit 7 **PLL2RDYF**: PLL2 ready interrupt flag
Reset by software by writing PLL2RDYC bit.
Set by hardware when the PLL2 locks and PLL2RDYIE is set.
0: No clock ready interrupt caused by PLL2 lock (default after reset)
1: Clock ready interrupt caused by PLL2 lock

Bit 6 **PLL1RDYF**: PLL1 ready interrupt flag
Reset by software by writing PLL1RDYC bit.
Set by hardware when the PLL1 locks and PLL1RDYIE is set.
0: No clock ready interrupt caused by PLL1 lock (default after reset)
1: Clock ready interrupt caused by PLL1 lock

Bit 5 **HSI48RDYF**: HSI48 ready interrupt flag
Reset by software by writing HSI48RDYC bit.
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set.
0: No clock ready interrupt caused by the HSI48 oscillator (default after reset)
1: Clock ready interrupt caused by the HSI48 oscillator

Bit 4 **CSIRDYF**: CSI ready interrupt flag
Reset by software by writing CSIRDYC bit.
Set by hardware when the CSI clock becomes stable and CSIRDYIE is set.
0: No clock ready interrupt caused by the CSI (default after reset)
1: Clock ready interrupt caused by the CSI

Bit 3 **HSERDYF**: HSE ready interrupt flag
Reset by software by writing HSERDYC bit.
Set by hardware when the HSE clock becomes stable and HSERDYIE is set.
0: No clock ready interrupt caused by the HSE (default after reset)
1: Clock ready interrupt caused by the HSE

Bit 2 **HSIRDYF**: HSI ready interrupt flag
Reset by software by writing HSIRDYC bit.
Set by hardware when the HSI clock becomes stable and HSIRDYIE is set.
0: No clock ready interrupt caused by the HSI (default after reset)
1: Clock ready interrupt caused by the HSI

Bit 1 **LSERDYF**: LSE ready interrupt flag
Reset by software by writing LSERDYC bit.
Set by hardware when the LSE clock becomes stable and LSERDYIE is set.
0: No clock ready interrupt caused by the LSE (default after reset)
1: Clock ready interrupt caused by the LSE

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Reset by software by writing LSIRDYC bit.
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.
0: No clock ready interrupt caused by the LSI (default after reset)
1: Clock ready interrupt caused by the LSI

7.8.30 RCC clock source interrupt clear register (RCC_CICR)

Address offset: 0x68

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	HSECSSC	LSECSSC	PLL3RDYC	PLL2RDYC	PLL1RDYC	HSI48RDYC	CSIRDYC	HSERDYC	HSIRDYC	LSERDYC	LSIRDYC
					w	w	w	w	w	w	w	w	w	w	w

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSC**: HSE clock security system interrupt clear
Set by software to clear HSECSSF.
Reset by hardware when clear done.
0: No effect
1: Clear HSECSSF

Bit 9 **LSECSSC**: LSE clock security system interrupt clear
Set by software to clear LSECSSF.
Reset by hardware when clear done.
0: No effect
1: Clear LSECSSF

Bit 8 **PLL3RDYC**: PLL3 ready interrupt clear
Set by software to clear PLL3RDYF.
Reset by hardware when clear done.
0: No effect
1: Clear PLL3RDYF

Bit 7 **PLL2RDYC**: PLL2 ready interrupt clear
Set by software to clear PLL2RDYF.
Reset by hardware when clear done.
0: No effect
1: Clear PLL2RDYF

Bit 6 **PLL1RDYC**: PLL1 ready interrupt clear
Set by software to clear PLL1RDYF.
Reset by hardware when clear done.
0: No effect
1: Clear PLL1RDYF

Bit 5 **HSI48RDYC**: HSI48 ready interrupt clear
Set by software to clear HSI48RDYF.
Reset by hardware when clear done.
0: No effect
1: Clear HSI48RDYF

Bit 4 **CSIRDYC**: CSI ready interrupt clear
Set by software to clear CSIRDYF.
Reset by hardware when clear done.
0: No effect
1: Clear CSIRDYF

Bit 3 **HSERDYC**: HSE ready interrupt clear
Set by software to clear HSERDYF.
Reset by hardware when clear done.
0: No effect
1: Clear HSERDYF

Bit 2 **HSIRDYC**: HSI ready interrupt clear
Set by software to clear HSIRDYF.
Reset by hardware when clear done.
0: No effect
1: Clear HSIRDYF

Bit 1 **LSERDYC**: LSE ready interrupt clear
Set by software to clear LSERDYF.
Reset by hardware when clear done.
0: No effect
1: Clear LSERDYF

Bit 0 **LSIRDYC**: LSI ready interrupt clear
Set by software to clear LSIRDYF.
Reset by hardware when clear done.
0: No effect
1: Clear LSIRDYF

7.8.31 RCC Backup domain control register (RCC_BDCR)

Address offset: 0x070

Reset value: 0x0000 0010

Reset by Backup domain reset.

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

After a system reset, the RCC_BDCR register is write-protected. To modify this register, the DBP bit in the *PWR control register 1 (PWR_CR1)* must be set to 1. RCC_BDCR bits are only reset after a Backup domain reset (see *Section 7.4.5: Backup domain reset*). Any other internal or external reset does not have any effect on these bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VSWRST
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTCEN	Res.	Res.	LSECSSRA	Res.	Res.	RTCSEL[1:0]		LSEEXT	LSECSSD	LSECSSON	LSEDRV[1:0]		LSEBYP	LSERDY	LSEON
rw			rw			rwo	rwo	rw	r	rw	rw	rw	rw	r	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **VSWRST:** VSwitch domain software reset

Set and reset by software.
To generate a V_{SW} reset, it is recommended to write this bit to 1, then back to 0.
0: Reset not activated (default after Backup domain reset)
1: Generates a reset pulse, resetting the entire V_{SW} domain.

Bit 15 **RTCEN**: RTC clock enable

Set and reset by software.
0: **rtc_ck** disabled (default after Backup domain reset)
1: **rtc_ck** enabled

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LSECSSRA**: Re-Arm the LSECSS function

Set by software.
After a LSE failure detection, the software application can re-enable the LSECSS by writing this bit to 1. Reading this bit returns the written value. Prior to set this bit to 1, LSECSSON must be set to 0. Refer to *Section : CSS on LSE* for details.
0: Writing 0 has no effect (default after Backup domain reset)
1: Writing 1 generates a re-arm pulse for the LSECSS function

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**:RTC clock source selection

Set by software to select the clock source for the RTC. These bits can be written only one time (except in case of failure detection on LSE). These bits must be written before LSECSSON is enabled. The VSWRST bit can be used to reset them, then it can be written one time again.

If HSE is selected as RTC clock, this clock is lost when the system is in Stop mode or in case of a pin reset (NRST).

00: No clock (default after Backup domain reset)

01: LSE selected as RTC clock

10: LSI selected as RTC clock

11: HSE divided by RTCPRE value selected as RTC clock

Bit 7 **LSEEXT**: low-speed external clock enable in Bypass mode

Set by software to enable the external clock when in BYPASS mode (LSEBYP = 1).

The LSEEXT bit can be written only if the LSE oscillator is disabled (LSEON = 0).

0: External LSE disabled (default after Backup domain reset)

1: External LSE enabled.

Bit 6 **LSECSSD**: LSE clock security system failure detection

Set by hardware to indicate when a failure has been detected by the clock security system on the external 32 kHz oscillator.

0: No failure detected on 32 kHz oscillator (default after Backup domain reset)

1: Failure detected on 32 kHz oscillator

Bit 5 **LSECSSON**: LSE clock security system enable

Set by software to enable the clock security system on 32 kHz oscillator.

LSECSSON must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware) and after RTCSEL is selected.

Once enabled, this bit can only be disabled following

- an LSE failure detection (LSECSSD = 1). In that case the software must disable LSECSSON.
- a back-up domain reset

0: CSS on 32 kHz oscillator OFF (default after Backup domain reset)

1: CSS on 32 kHz oscillator ON

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator driving capability

Set by software to select the driving capability of the LSE oscillator.

00: Lowest drive

01: Medium-low drive

10: Medium-high drive (default after backup domain reset)

11: Highest drive

Bit 2 **LSEBYP**: LSE oscillator bypass
Set and reset by software to bypass oscillator in debug mode. This bit can only be written when the LSE is disabled (LSEON = 0)
0: LSE oscillator not bypassed (default after Backup domain reset)
1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready
Set and reset by hardware to indicate when the LSE is stable. This bit goes low six cycles of **lse_ck** clock after LSEON has been set to 0.
0: LSE oscillator not ready (default after Backup domain reset)
1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enabled
Set and reset by software.
0: LSE oscillator OFF (default after Backup domain reset)
1: LSE oscillator ON

7.8.32 RCC clock control and status register (RCC_CSR)

Address offset: 0x074

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LSIRDY	LSION
														r	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: LSI oscillator ready
Set and reset by hardware to indicate when the low-speed internal RC oscillator is stable.
This bit needs 3 cycles of **lsi_ck** clock to fall down after LSION has been set to 0.
This bit can be set even when LSION is not enabled if there is a request for LSI clock by the clock security system on LSE or by the low-speed watchdog or by the RTC.
0: LSI clock is not ready (default after reset)
1: LSI clock is ready

Bit 0 **LSION**: LSI oscillator enable
Set and reset by software.
0: LSI is OFF (default after reset)
1: LSI is ON

7.8.33 RCC AHB1 peripheral reset register (RCC_AHB1RSTR)

Address offset: 0x080

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw			

Bit 31 **ADF1RST**: ADF block reset
Set and reset by software.
0: Does not reset ADF block (default after reset)
1: Resets ADF block

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 **OTGFSRST**: OTGFS block reset
Set and reset by software.
0: Does not reset OTGFS block (default after reset)
1: Resets OTGFS block

Bits 26:5 Reserved, must be kept at reset value.

Bit 4 **GPDMA1RST**: GPDMA1 blocks reset
Set and reset by software.
0: Does not reset GPDMA1 block (default after reset)
1: Resets GPDMA1 block

Bit 3 **HSP1RST**: HSP block reset
Set and reset by software.
0: Does not reset HSP block (default after reset)
1: Resets HSP block

Bits 2:0 Reserved, must be kept at reset value.

7.8.34 RCC AHB2 peripheral reset register (RCC_AHB2RSTR)

Address offset: 0x084

Reset value: 0x0000 0000

rw	rw														

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **FMAC1RST**: FMAC1 reset
Set and reset by software.
0: Does not reset FMAC1 block (default after reset)
1: Resets FMAC1 block

Bit 14 **CORDICRST**: CORDIC reset
Set and reset by software.
0: Does not reset CORDIC block (default after reset)
1: Resets CORDIC block

Bits 13:0 Reserved, must be kept at reset value.

7.8.35 RCC AHB3 peripheral reset register (RCC_AHB3RSTR)

Address offset: 0x0A4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rw	rw

Bit 31 **DAC4RST**: DAC4block reset
Set and reset by software.
0: Does not reset DAC4 block (default after reset)
1: Resets DAC4 block

Bit 30 **DAC3RST**: DAC3 block reset
Set and reset by software.
0: Does not reset DAC3 block (default after reset)
1: Resets DAC3 block

Bit 29 **DAC2RST**: DAC2 block reset
Set and reset by software.
0: Does not reset DAC2 block (default after reset)
1: Resets DAC2 block

Bit 28 **DAC1RST**: DAC1 block reset
Set and reset by software.
0: Does not reset DAC1 block (default after reset)
1: Resets DAC1 block

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **ADC34RST**: ADC34 block reset
Set and reset by software.
0: Does not reset ADC34 block (default after reset)
1: Resets ADC34 block

Bit 24 **ADC12RST**: ADC12 block reset
Set and reset by software.
0: Does not reset ADC12 block (default after reset)
1: Resets ADC12 block

Bits 23:2 Reserved, must be kept at reset value.

Bit 1 **HASHRST**: HASH block reset
Set and reset by software.
0: Does not reset HASH block (default after reset)
1: Resets HASH block

Bit 0 **RNGRST**: random number generator block reset
Set and reset by software.
0: Does not reset RNG block (default after reset)
1: Resets RNG block

7.8.36 RCC AHB4 peripheral reset register (RCC_AHB4RSTR)

Address offset: 0x088

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CRCRST**: CRC block reset
Set and reset by software.
0: Does not reset the CRC block (default after reset)
1: Resets the CRC block

Bits 18:9 Reserved, must be kept at reset value.

Bit 8 **GPIOIRST**: GPIOI block reset
Set and reset by software.
0: Does not reset the GPIOI block (default after reset)
1: Resets the GPIOI block

Bit 7 **GPIOHRST**: GPIOH block reset
Set and reset by software.
0: Does not reset the GPIOH block (default after reset)
1: Resets the GPIOH block

Bit 6 **GPIOGRST**: GPIOG block reset
Set and reset by software.
0: Does not reset the GPIOG block (default after reset)
1: Resets the GPIOG block

Bit 5 **GPIOFRST**: GPIOF block reset
Set and reset by software.
0: Does not reset the GPIOF block (default after reset)
1: Resets the GPIOF block

Bit 4 **GPIOERST**: GPIOE block reset
Set and reset by software.
0: Does not reset the GPIOE block (default after reset)
1: Resets the GPIOE block

Bit 3 **GPIODRST**: GPIOD block reset
Set and reset by software.
0: Does not reset the GPIOD block (default after reset)
1: Resets the GPIOD block

Bit 2 **GPIOCRST**: GPIOC block reset
Set and reset by software.
0: Does not reset the GPIOC block (default after reset)
1: Resets the GPIOC block

Bit 1 **GPIOBRST**: GPIOB block reset
Set and reset by software.
0: Does not reset the GPIOB block (default after reset)
1: Resets the GPIOB block

Bit 0 **GPIOARST**: GPIOA block reset
Set and reset by software.
0: Does not reset the GPIOA block (default after reset)
1: Resets the GPIOA block

7.8.37 RCC AHB5 peripheral reset register (RCC_AHB5RSTR)

Address offset: 0x07C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw			rw	rw				rw

Bit 31 **NPURST**: NPU block reset
Set and reset by software.
0: Reset is released (default after reset)
1: Reset is asserted

Bits 30:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1RST**: SDMMC1 and DB_SDMMC1 blocks reset
Set and reset by software.
0: Reset is released (default after reset)
1: Reset is asserted

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **XSPI1RST**: XSPI1 and MCE1 blocks reset
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: Reset is released (default after reset)
1: Reset is asserted

Bit 4 **FMCRST**: FMC and MCE3 blocks reset
Set and reset by software.
The hardware prevents writing this bit if FMCCKP = 1.
0: Reset is released (default after reset)
1: Reset is asserted

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **HPDMA1RST**: HPDMA1 block reset
Set and reset by software.
0: Reset is released (default after reset)
1: Reset is asserted

7.8.38 RCC APB1 peripheral reset register 1 (RCC_APB1RSTR1)

Address offset: 0x090

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **UART8RST**: UART8 block reset
Set and reset by software.
0: Does not reset the UART8 block (default after reset)
1: Resets the UART8 block

Bit 30 **UART7RST**: UART7 block reset
Set and reset by software.
0: Does not reset the UART7 block (default after reset)
1: Resets the UART7 block

Bits 29:25 Reserved, must be kept at reset value.

Bit 24 **I3C1RST**: I3C1 block reset
Set and reset by software.
0: Does not reset the I3C1 block (default after reset)
1: Resets the I3C1 block

Bit 23 **I2C3RST**: I2C3 block reset
Set and reset by software.
0: Does not reset the I2C3 block (default after reset)
1: Resets the I2C3 block

Bit 22 **I2C2RST**: I2C2 block reset
Set and reset by software.
0: Does not reset the I2C2 block (default after reset)
1: Resets the I2C2 block

Bit 21 **I2C1RST**: I2C1/I3C1 block reset
Set and reset by software.
0: Does not reset the I2C1/I3C1 block (default after reset)
1: Resets the I2C1/I3C1 block

Bit 20 **UART5RST**: UART5 block reset
Set and reset by software.
0: Does not reset the UART5 block (default after reset)
1: Resets the UART5 block

Bit 19 **UART4RST**: UART4 block reset
Set and reset by software.
0: Does not reset the UART4 block (default after reset)
1: Resets the UART4 block

Bit 18 **USART3RST**: USART3 block reset
Set and reset by software.
0: Does not reset the USART3 block (default after reset)
1: Resets the USART3 block

Bit 17 **USART2RST**: USART2 block reset
Set and reset by software.
0: Does not reset the USART2 block (default after reset)
1: Resets the USART2 block

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3RST**: SPI2S3 block reset
Set and reset by software.
0: Does not reset the SPI2S3 block (default after reset)
1: Resets the SPI2S3 block

Bit 14 **SPI2RST**: SPI2S2 block reset
Set and reset by software.
0: Does not reset the SPI2S2 block (default after reset)
1: Resets the SPI2S2 block

Bit 13 **TIM11RST**: TIM11 block reset
Set and reset by software.
0: Does not reset the TIM11 block (default after reset)
1: Resets the TIM11 block

Bit 12 **TIM10RST**: TIM10 block reset
Set and reset by software.
0: Does not reset the TIM10 block (default after reset)
1: Resets the TIM10 block

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1RST**: LPTIM1 block reset
Set and reset by software.
0: Does not reset the LPTIM1 block (default after reset)
1: Resets the LPTIM1 block

Bit 8 **TIM14RST**: TIM14 block reset
Set and reset by software.
0: Does not reset the TIM14 block (default after reset)
1: Resets the TIM14 block

Bit 7 **TIM13RST**: TIM13 block reset
Set and reset by software.
0: Does not reset the TIM13 block (default after reset)
1: Resets the TIM13 block

Bit 6 **TIM12RST**: TIM12 block reset
Set and reset by software.
0: Does not reset the TIM12 block (default after reset)
1: Resets the TIM12 block

Bit 5 **TIM7RST**: TIM7 block reset
Set and reset by software.
0: Does not reset the TIM7 block (default after reset)
1: Resets the TIM7 block

Bit 4 **TIM6RST**: TIM6 block reset
Set and reset by software.
0: Does not reset the TIM6 block (default after reset)
1: Resets the TIM6 block

Bit 3 **TIM5RST**: TIM5 block reset
Set and reset by software.
0: Does not reset the TIM5 block (default after reset)
1: Resets the TIM5 block

Bit 2 **TIM4RST**: TIM4 block reset
Set and reset by software.
0: Does not reset the TIM4 block (default after reset)
1: Resets the TIM4 block

Bit 1 **TIM3RST**: TIM3 block reset
Set and reset by software.
0: Does not reset the TIM3 block (default after reset)
1: Resets the TIM3 block

Bit 0 **TIM2RST**: TIM2 block reset
Set and reset by software.
0: Does not reset the TIM2 block (default after reset)
1: Resets the TIM2 block

7.8.39 RCC APB1 peripheral reset register 2 (RCC_APB1RSTR2)

Address offset: 0x094

Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **UCPD1RST**: UCPD block reset
Set and reset by software.
0: Does not reset the UCPD block (default after reset)
1: Resets the UCPD block

Bits 26:9 Reserved, must be kept at reset value.

Bit 8 **FDCANRST**: FDCAN block reset
Set and reset by software.
0: Does not reset the FDCAN block (default after reset)
1: Resets the FDCAN block

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CRSRST**: Clock recovery system reset
Set and reset by software.
0: Does not reset CRS (default after reset)
1: Resets CRS

Bit 0 Reserved, must be kept at reset value.

7.8.40 RCC APB2 peripheral reset register (RCC_APB2RSTR)

Address offset: 0x098

Reset value: 0x0000 0000

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **HRTIM2RST**: HRTIM2 block reset
Set and reset by software.
0: Does not reset the HRTIM2 block (default after reset)
1: Resets the HRTIM2 block

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **HRTIM1RST**: HRTIM1 block reset
Set and reset by software.
0: Does not reset the HRTIM1 block (default after reset)
1: Resets the HRTIM1 block

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **SPI5RST**: SPI5 block reset
Set and reset by software.
0: Does not reset the SPI5 block (default after reset)
1: Resets the SPI5 block

Bit 19 **TIM9RST**: TIM9 block reset
Set and reset by software.
0: Does not reset the TIM9 block (default after reset)
1: Resets the TIM9 block

Bit 18 **TIM17RST**: TIM17 block reset
Set and reset by software.
0: Does not reset the TIM17 block (default after reset)
1: Resets the TIM17 block

Bit 17 **TIM16RST**: TIM16 block reset
Set and reset by software.
0: Does not reset the TIM16 block (default after reset)
1: Resets the TIM16 block

Bit 16 **TIM15RST**: TIM15 block reset
Set and reset by software.
0: Does not reset the TIM15 block (default after reset)
1: Resets the TIM15 block

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4RST**: SPI4 block reset
Set and reset by software.
0: Does not reset the SPI4 block (default after reset)
1: Resets the SPI4 block

Bit 12 **SPI1RST**: SPI2S1 block reset
Set and reset by software.
0: Does not reset the SPI2S1 block (default after reset)
1: Resets the SPI2S1 block

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **USART10RST**: USART10 block reset
Set and reset by software.
0: Does not reset the USART10 block (default after reset)
1: Resets the USART10 block

Bit 6 **USART9RST**: USART9 block reset
Set and reset by software.
0: Does not reset the USART9 block (default after reset)
1: Resets the USART9 block

Bit 5 **USART6RST**: USART6 block reset
Set and reset by software.
0: Does not reset the USART6 block (default after reset)
1: Resets the USART6 block

Bit 4 **USART1RST**: USART1 block reset
Set and reset by software.
0: Does not reset the USART1 block (default after reset)
1: Resets the USART1 block

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TIM20RST**: TIM20 block reset
Set and reset by software.
0: Does not reset the TIM20 block (default after reset)
1: Resets the TIM20 block

Bit 1 **TIM8RST**: TIM8 block reset
Set and reset by software.
0: Does not reset the TIM8 block (default after reset)
1: Resets the TIM8 block

Bit 0 **TIM1RST**: TIM1 block reset
Set and reset by software.
0: Does not reset the TIM1 block (default after reset)
1: Resets the TIM1 block

7.8.41 RCC APB4 peripheral reset register (RCC_APB4RSTR)

Address offset: 0x09C

Reset value: 0x0000 0000

Bit 31 **COMP78RST**: COMP78 block reset
Set and reset by software.
0: Does not reset the COMP78 block (default after reset)
1: Resets the COMP78 block

Bit 30 **COMP56RST**: COMP56 block reset
Set and reset by software.
0: Does not reset the COMP56 block (default after reset)
1: Resets the COMP56 block

Bit 29 **COMP34RST**: COMP34 block reset
Set and reset by software.
0: Does not reset the COMP34 block (default after reset)
1: Resets the COMP34 block

Bit 28 **COMP12RST**: COMP512 block reset
Set and reset by software.
0: Does not reset the COMP12 block (default after reset)
1: Resets the COMP12 block

Bit 27 Reserved, must be kept at reset value.

Bit 26 **DTSRST**: DTS block reset
Set and reset by software.
0: Does not reset the DTS block (default after reset)
1: Resets the DTS block

Bits 25:16 Reserved, must be kept at reset value.

Bit 15 **VREFRST**: VREF block reset
Set and reset by software.
0: Does not reset the VREF block (default after reset)
1: Resets the VREF block

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5RST**: LPTIM5 block reset
Set and reset by software.
0: Does not reset the LPTIM5 block (default after reset)
1: Resets the LPTIM5 block

Bit 11 **LPTIM4RST**: LPTIM4 block reset
Set and reset by software.
0: Does not reset the LPTIM4 block (default after reset)
1: Resets the LPTIM4 block

Bit 10 **LPTIM3RST**: LPTIM3 block reset
Set and reset by software.
0: Does not reset the LPTIM3 block (default after reset)
1: Resets the LPTIM3 block

Bit 9 **LPTIM2RST**: LPTIM2 block reset
Set and reset by software.
0: Does not reset the LPTIM2 block (default after reset)
1: Resets the LPTIM2 block

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **SPI6RST**: SPI/I2S6 block reset
Set and reset by software.
0: Does not reset the SPI/I2S6 block (default after reset)
1: Resets the SPI/I2S6 block

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1RST**: LPUART1 block reset
Set and reset by software.
0: Does not reset the LPUART1 block (default after reset)
1: Resets the LPUART1 block

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SBSRST**: SBS block reset
Set and reset by software.
0: Does not reset the SBS block (default after reset)
1: Resets the SBS block

Bit 0 Reserved, must be kept at reset value.

7.8.42 RCC AXI clocks gating disable register (RCC_CKGDISR)

Address offset: 0x0B0

Reset value: 0x8000 0000

The dynamic power consumption can be optimized by enabling the functional clock gating.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JTAGCKG	EXTICKG	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FLASHCKG	AXISRAM1CKG	AXISRAM2CKG	AXISRAM3CKG	AXISRAM4CKG

rw	rw	rw	rw						rw	rw	rw	rw	rw	rw	rw

Bit 31 **JTAGCKG**: JTAG automatic clock gating disabling
This bit is set and reset by software.
0: The clock gating is enabled. The clock is disabled except if a JTAG connection has been detected
1: The clock gating is disabled. The clock is always enabled. (default after reset)

Bit 30 **EXTICKG**: EXTI clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock is enabled after an event detection and stopped again when the event flag is cleared. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bits 29:21 Reserved, must be kept at reset value.

Bit 20 **FLASHCKG**: Flash interface (FLIFT) AXI manager port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI manager port connected to the FLASH is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 19 **AXISRAM1CKG**: AXISRAM1 AXI manager port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI manager port connected to the AXISRAM1 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 18 **AXISRAM2CKG**: AXISRAM2 AXI manager port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI manager port connected to the AXISRAM2 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 17 **AXISRAM3CKG**: AXISRAM3 AXI manager port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI manager port connected to the AXISRAM3 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 16 **AXISRAM4CKG**: AXISRAM4 AXI manager port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI manager port connected to the AXISRAM4 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 15 **XSPI1CKG**: XSPI1 AXI manager port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI manager port connected to the XSPI1 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 14 **FMCCKG**: FMC AXI manager port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI manager port connected to the FMC is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 13 **AHBICCKG**: AHB interconnect AXI manager port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI manager port connected to the AHB interconnect is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled

Bit 12 **AHBSCKG**: AHBS AXI manager port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI manager port connected to the CPU AHBS bus is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled

Bits 11:7 Reserved, must be kept at reset value.

Bit 6 **NPU1CKG**: AXI NPU port 1 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the NPU is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 5 **NPU0CKG**: AXI NPU port 0 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the NPU is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 4 **CPUCKG**: AXI CPU port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the CPU is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 3 **HPDMA1CKG**: AXI HPDMA1 port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the HPDMA1 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled

Bit 2 **SDMMC1CKG**: AXI SDMMC1 port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to SDMMC1 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 1 **AHBMCKG**: AXI AHB matrix port clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the AHB interconnect is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 0 **AXICKG**: AXI interconnect matrix clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The AXI interconnect matrix clock is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled

7.8.43 RCC Reset status register (RCC_RSR)

Address offset: 0x130

Reset value: 0x00E0 0000

Reset by power-on reset only.

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	LPWRRSTF	Res.	WWDGRSTF	Res.	IWDGRSTF	Res.	SFTRSTF	PORRSTF	PINRSTF	BORRSTF	Res.	Res.	Res.	OBLRSTF	RMVF
	r		r		r		r	r	r	r				r	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **LPWRRSTF**: reset due to illegal Stop or Standby flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when the CPU goes erroneously in Stop or Standby mode,
0: No illegal reset occurred (default after power-on reset)
1: Illegal Stop or Standby reset occurred

Bit 29 Reserved, must be kept at reset value.

Bit 28 **WWDGRSTF**: window watchdog reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when a window watchdog reset occurs.
0: No window watchdog reset occurred from WWDG (default after power-on reset)
1: Window watchdog reset occurred from WWDG

Bit 27 Reserved, must be kept at reset value.

Bit 26 **IWDGRSTF**: independent watchdog reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when an independent watchdog reset occurs.
0: No independent watchdog reset occurred (default after power-on reset)
1: Independent watchdog reset occurred

Bit 25 Reserved, must be kept at reset value.

Bit 24 **SFTRSTF**: system reset from CPU reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when the system reset is due to CPU.The CPU can generate a system reset by writing SYSRESETREQ bit of AIRCR register of the core M7.
0: No CPU software reset occurred (default after power-on reset)
1: A system reset has been generated by the CPU

Bit 23 **PORRSTF**: POR/PDR reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when a POR/PDR reset occurs.
0: No POR/PDR reset occurred
1: POR/PDR reset occurred (default after power-on reset)

Bit 22 **PINRSTF**: pin reset flag (NRST) (1)
Reset by software by writing the RMVF bit.
Set by hardware when a reset from pin occurs.
0: No reset from pin occurred
1: Reset from pin occurred (default after power-on reset)

Bit 21 **BORRSTF**: BOR reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when a BOR reset occurs (**pwr_bor_rst**).
0: No BOR reset occurred
1: BOR reset occurred (default after power-on reset)

Bits 20:18 Reserved, must be kept at reset value.

Bit 17 **OBLRSTF**: Option byte loading reset flag (1)
Reset by software by the RMVF bit.
Set by hardware when a reset from the option byte loading occurs.
0: No reset from option byte loading occurred
1: Reset from option byte loading occurred

Bit 16 **RMVF**: remove reset flags
Set by software to reset the value of the reset flags.
This bit is reset to 0 by hardware.
0: No effect (default after power-on reset)
1: Resets the value of the reset flags

Bits 15:0 Reserved, must be kept at reset value.

1. Refer to *Table 52: Reset source identification (RCC_RSR)* for details on flag behavior.

7.8.44 RCC AHB1 clock enable register (RCC_AHB1ENR)

Address offset: 0x138

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw			

Bit 31 **ADF1EN**: ADF clocks enable
Set and reset by software.
0: ADF clocks disabled (default after reset)
1: ADF clocks enabled

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 **OTGFSEN**: OTGFS peripheral clocks enable
Set and reset by software.
0: OTGFS peripheral clocks disabled (default after reset)
1: OTGFS peripheral clocks enabled

Bits 26:5 Reserved, must be kept at reset value.

Bit 4 **GPDMA1EN**: GPDMA1 clock enable
Set and reset by software.
0: GPDMA1 clock disabled (default after reset)
1: GPDMA1 clock enabled

Bit 3 **HSP1EN**: HSP clock enable
Set and reset by software.
0: HSP clock disabled (default after reset)
1: HSP clock and AHBSRAM3 clock enabled

Bits 2:0 Reserved, must be kept at reset value.

7.8.45 RCC AHB2 clock enable register (RCC_AHB2ENR)

Address offset: 0x13C

Reset value: 0xE000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw														

Bit 31 **AHBSRAM3EN**: AHBSRAM3 clock enable
Set and reset by software.
0: AHBSRAM3 clock disabled (if HSP1EN = 0)
1: AHBSRAM3 clock enabled (default after reset)

Bit 30 **AHBSRAM2EN**: AHBSRAM2 clock enable
Set and reset by software.
0: AHBSRAM2 clock disabled
1: AHBSRAM2 clock enabled (default after reset)

Bit 29 **AHBSRAM1EN**: AHBSRAM1 clock enable
Set and reset by software.
0: AHBSRAM1 clock disabled
1: AHBSRAM1 clock enabled (default after reset)

Bits 28:16 Reserved, must be kept at reset value.

Bit 15 **FMAC1EN**: FMAC1 clock enable
Set and reset by software.
0: FMAC1 clock disabled (default after reset)
1: FMAC1 clock enabled

Bit 14 **CORDICEN**: CORDIC clock enable
Set and reset by software.
0: CORDIC clock disabled (default after reset)
1: CORDIC clock enabled

Bits 13:0 Reserved, must be kept at reset value.

7.8.46 RCC AHB3 clock enable register (RCC_AHB3ENR)

Address offset: 0x158

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **DAC4EN**: DAC4 peripheral clock enable
Set and reset by software.
0: DAC4 peripheral clock disabled (default after reset)
1: DAC4 peripheral clock enabled

Bit 30 **DAC3EN**: DAC3 peripheral clock enable
Set and reset by software.
0: DAC3 peripheral clock disabled (default after reset)
1: DAC3 peripheral clock enabled

Bit 29 **DAC2EN**: DAC2 peripheral clock enable
Set and reset by software.
0: DAC2 peripheral clock disabled (default after reset)
1: DAC2 peripheral clock enabled

Bit 28 **DAC1EN**: DAC1 peripheral clock enable
Set and reset by software.
0: DAC1 peripheral clock disabled (default after reset)
1: DAC1 peripheral clock enabled

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **ADC34EN**: ADC34 peripheral clock enable
Set and reset by software.
0: ADC34 peripheral clock disabled (default after reset)
1: ADC34 peripheral clock enabled

Bit 24 **ADC12EN**: ADC12 peripheral clock enable
Set and reset by software.
0: ADC12 peripheral clock disabled (default after reset)
1: ADC12 peripheral clock enabled

Bits 23:2 Reserved, must be kept at reset value.

Bit 1 **HASHEN**: HASH peripheral clock enable
Set and reset by software.
0: HASH peripheral clock disabled (default after reset)
1: HASH peripheral clock enabled

Bit 0 **RNGEN**: RNG peripheral clocks enable
Set and reset by software.
0: RNG peripheral clocks disabled (default after reset)
1: RNG peripheral clocks enabled

7.8.47 RCC AHB4 clock enable register (RCC_AHB4ENR)

Address offset: 0x140

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **BKPRAMEN**: Backup RAM clock enable
Set and reset by software.
0: Backup RAM clock disabled (default after reset)
1: Backup RAM clock enabled

Bits 27:20 Reserved, must be kept at reset value.

Bit 19 **CRCEN**: CRC clock enable
Set and reset by software.
0: CRC clock disabled (default after reset)
1: CRC clock enabled

Bits 18:9 Reserved, must be kept at reset value.

Bit 8 **GPIOIEN**: GPIOI peripheral clock enable
Set and reset by software.
0: GPIOI peripheral clock disabled (default after reset)
1: GPIOI peripheral clock enabled

Bit 7 **GPIOHEN**: GPIOH peripheral clock enable
Set and reset by software.
0: GPIOH peripheral clock disabled (default after reset)
1: GPIOH peripheral clock enabled

Bit 6 **GPIOGEN**: GPIOG peripheral clock enable
Set and reset by software.
0: GPIOG peripheral clock disabled (default after reset)
1: GPIOG peripheral clock enabled

Bit 5 **GPIOFEN**: GPIOF peripheral clock enable
Set and reset by software.
0: GPIOF peripheral clock disabled (default after reset)
1: GPIOF peripheral clock enabled

Bit 4 **GPIOEEN**: GPIOE peripheral clock enable
Set and reset by software.
0: GPIOE peripheral clock disabled (default after reset)
1: GPIOE peripheral clock enabled

Bit 3 **GPIODEN**: GPIOD peripheral clock enable
Set and reset by software.
0: GPIOD peripheral clock disabled (default after reset)
1: GPIOD peripheral clock enabled

Bit 2 **GPIOCEN**: GPIOC peripheral clock enable
Set and reset by software.
0: GPIOC peripheral clock disabled (default after reset)
1: GPIOC peripheral clock enabled

Bit 1 **GPIOBEN**: GPIOB peripheral clock enable
Set and reset by software.
0: GPIOB peripheral clock disabled (default after reset)
1: GPIOB peripheral clock enabled

Bit 0 **GPIOAEN**: GPIOA peripheral clock enable
Set and reset by software.
0: GPIOA peripheral clock disabled (default after reset)
1: GPIOA peripheral clock enabled

7.8.48 RCC AHB5 clock enable register (RCC_AHB5ENR)

Address offset: 0x134

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw			rw	rw				rw

Bit 31 **NPUEN**: NPU clock enable
Set and reset by software.
0: NPU clock disabled (default after reset)
1: NPU clock enabled

Bits 30:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1EN**: SDMMC1 and DB_SDMMC1 peripheral clocks enable
Set and reset by software.
0: SDMMC1 and DB_SDMMC1 peripheral clocks disabled (default after reset)
1: SDMMC1 and DB_SDMMC1 peripheral clocks enabled

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **XSPI1EN**: XSPI1 peripheral clocks enable
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: XSPI1 peripheral clocks disabled (default after reset)
1: XSPI1 peripheral clocks enabled

Bit 4 **FMCEN**: FMC peripheral clocks enable
Set and reset by software.
The hardware prevents writing this bit if FMCCKP = 1.
0: FMC peripheral clocks disabled (default after reset)
1: FMC peripheral clocks enabled
The peripheral clocks of the FMC are the kernel clock selected by FMCSEL, and the **hclk5** bus interface clock.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **HPDMA1EN**: HPDMA1 peripheral clock enable
Set and reset by software.
0: HPDMA1 peripheral clock disabled (default after reset)
1: HPDMA1 peripheral clock enabled

7.8.49 RCC APB1 clock enable register 1 (RCC_APB1ENR1)

Address offset: 0x148

Reset value: 0x0000 0000

rw	rw	rw	rw	rs		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UART8EN**: UART8 peripheral clocks enable
Set and reset by software.
0: UART8 peripheral clocks disabled (default after reset)
1: UART8 peripheral clocks enabled

Bit 30 **UART7EN**: UART7 peripheral clocks enable
Set and reset by software.
0: UART7 peripheral clocks disabled (default after reset)
1: UART7 peripheral clocks enabled

Bits 29:25 Reserved, must be kept at reset value.

Bit 24 **I3C1EN**: I3C1 peripheral clocks enable
Set and reset by software.
0: I3C1 peripheral clocks disabled (default after reset)
1: I3C1 peripheral clocks enabled

Bit 23 **I2C3EN**: I2C3 peripheral clocks enable
Set and reset by software.
0: I2C3 peripheral clocks disabled (default after reset)
1: I2C3 peripheral clocks enabled

Bit 22 **I2C2EN**: I2C2 peripheral clocks enable
Set and reset by software.
0: I2C2 peripheral clocks disabled (default after reset)
1: I2C2 peripheral clocks enabled

Bit 21 **I2C1EN**: I2C1 peripheral clocks enable
Set and reset by software.
0: I2C1 peripheral clocks disabled (default after reset)
1: I2C1 peripheral clocks enabled

Bit 20 **UART5EN**: UART5 peripheral clocks enable
Set and reset by software.
0: UART5 peripheral clocks disabled (default after reset)
1: UART5 peripheral clocks enabled

Bit 19 **UART4EN**: UART4 peripheral clocks enable
Set and reset by software.
0: UART4 peripheral clocks disabled (default after reset)
1: UART4 peripheral clocks enabled
The peripheral clocks of the UART4 are the kernel clock selected by USART234578SEL and provided to UCLK input, and the **rcc_pclk1** bus interface clock.

Bit 18 **USART3EN**: USART3 peripheral clocks enable
Set and reset by software.
0: USART3 peripheral clocks disabled (default after reset)
1: USART3 peripheral clocks enabled
The peripheral clocks of the USART3 are the kernel clock selected by USART234578SEL and provided to UCLK input, and the **rcc_pclk1** bus interface clock.

Bit 17 **USART2EN**: USART2peripheral clocks enable
Set and reset by software.
0: USART2 peripheral clocks disabled (default after reset)
1: USART2 peripheral clocks enabled
The peripheral clocks of the USART2 are the kernel clock selected by USART234578SEL and provided to UCLK input, and the **rcc_pclk1** bus interface clock.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3EN**: SPI3 peripheral clocks enable
Set and reset by software.
0: SPI3 peripheral clocks disabled (default after reset)
1: SPI3 peripheral clocks enabled
The peripheral clocks of the SPI3 are the kernel clock selected by I2S123SRC and provided to **com_clk** input, and the **rcc_pclk1** bus interface clock.

Bit 14 **SPI2EN**: SPI2 peripheral clocks enable
Set and reset by software.
0: SPI2 peripheral clocks disabled (default after reset)
1: SPI2 peripheral clocks enabled
The peripheral clocks of the SPI2 are the kernel clock selected by I2S123SRC and provided to **com_clk** input, and the **rcc_pclk1** bus interface clock.

Bit 13 **TIM11EN**: TIM11 peripheral clock enable
Set and reset by software.
0: TIM11 peripheral clock disabled (default after reset)
1: TIM11 peripheral clock enabled

Bit 12 **TIM10EN**: TIM10 peripheral clock enable
Set and reset by software.
0: TIM10 peripheral clock disabled (default after reset)
1: TIM10 peripheral clock enabled

Bit 11 **WWDGEN**: WWDG clock enable
Set by software, and reset by hardware when a system reset occurs.
0: WWDG peripheral clock disable (default after reset)
1: WWDG peripheral clock enabled

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1EN**: LPTIM1 peripheral clocks enable
Set and reset by software.
0: LPTIM1 peripheral clocks disabled (default after reset)
1: LPTIM1 peripheral clocks enabled
The peripheral clocks of the LPTIM1 are the kernel clock selected by LPTIM1SEL and provided to **clk_lpt** input, and the **rcc_pclk1** bus interface clock.

Bit 8 **TIM14EN**: TIM14 peripheral clock enable
Set and reset by software.
0: TIM14 peripheral clock disabled (default after reset)
1: TIM14 peripheral clock enabled

Bit 7 **TIM13EN**: TIM13 peripheral clock enable
Set and reset by software.
0: TIM13 peripheral clock disabled (default after reset)
1: TIM13 peripheral clock enabled

Bit 6 **TIM12EN**: TIM12 peripheral clock enable
Set and reset by software.
0: TIM12 peripheral clock disabled (default after reset)
1: TIM12 peripheral clock enabled

Bit 5 **TIM7EN**: TIM7 peripheral clock enable
Set and reset by software.
0: TIM7 peripheral clock disabled (default after reset)
1: TIM7 peripheral clock enabled

Bit 4 **TIM6EN**: TIM6 peripheral clock enable
Set and reset by software.
0: TIM6 peripheral clock disabled (default after reset)
1: TIM6 peripheral clock enabled

Bit 3 **TIM5EN**: TIM5 peripheral clock enable
Set and reset by software.
0: TIM5 peripheral clock disabled (default after reset)
1: TIM5 peripheral clock enabled

Bit 2 **TIM4EN**: TIM4 peripheral clock enable
Set and reset by software.
0: TIM4 peripheral clock disable (default after reset)
1: TIM4 peripheral clock enabled

Bit 1 **TIM3EN**: TIM3 peripheral clock enable
Set and reset by software.
0: TIM3 peripheral clock disabled (default after reset)
1: TIM3 peripheral clock enabled

Bit 0 **TIM2EN**: TIM2 peripheral clock enable
Set and reset by software.
0: TIM2 peripheral clock disabled (default after reset)
1: TIM2 peripheral clock enabled

7.8.50 RCC APB1 clock enable register 2 (RCC_APB1ENR2)

Address offset: 0x14C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	UCPD1EN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	FDCANEN	Res.	Res.	Res.	Res.	Res.	Res.	CRSEN	Res.
							rw							rw	

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **UCPD1EN**: UCPD peripheral clock enable
Set and reset by software.
0: UCPD peripheral clock disabled (default after reset)
1: UCPD peripheral clock enabled

Bits 26:9 Reserved, must be kept at reset value.

Bit 8 **FDCANEN**: FDCAN peripheral clock enable
Set and reset by software.
0: FDCAN peripheral clock disabled (default after reset)
1: FDCAN peripheral clock enabled

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CRSEN**: Clock recovery system peripheral clock enable
Set and reset by software.
0: CRS peripheral clock disabled (default after reset)
1: CRS peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

7.8.51 RCC APB2 clock enable register (RCC_APB2ENR)

Address offset: 0x150

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	HRTIM 2EN	Res.	Res.	Res.	HRTIM 1EN	Res.	Res.	Res.	SPI5E N	TIM9E N	TIM17E N	TIM16E N	TIM15E N

		rw	rw					rw	rw	rw	rw		rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **HRTIM2EN**: HRTIM2 peripheral clock enable
Set and reset by software.
0: HRTIM2 peripheral clock disabled (default after reset)
1: HRTIM2 peripheral clock enabled

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **HRTIM1EN**: HRTIM1 peripheral clock enable
Set and reset by software.
0: HRTIM1 peripheral clock disabled (default after reset)
1: HRTIM1 peripheral clock enabled

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **SPI5EN**: SPI5 peripheral clocks enable
Set and reset by software.
0: SPI5 peripheral clocks disabled (default after reset)
1: SPI5 peripheral clocks enabled:
The peripheral clocks of the SPI5 are the kernel clock selected by SPI45SEL, and the **pclk2** bus interface clock.

Bit 19 **TIM9EN**: TIM9 peripheral clock enable
Set and reset by software.
0: TIM9 peripheral clock disabled (default after reset)
1: TIM9 peripheral clock enabled

Bit 18 **TIM17EN**: TIM17 peripheral clock enable
Set and reset by software.
0: TIM17 peripheral clock disabled (default after reset)
1: TIM17 peripheral clock enabled

Bit 17 **TIM16EN**: TIM16 peripheral clock enable
Set and reset by software.
0: TIM16 peripheral clock disabled (default after reset)
1: TIM16 peripheral clock enabled

Bit 16 **TIM15EN**: TIM15 peripheral clock enable
Set and reset by software.
0: TIM15 peripheral clock disabled (default after reset)
1: TIM15 peripheral clock enabled

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4EN**: SPI4 Peripheral Clocks Enable

Set and reset by software.

0: SPI4 peripheral clocks disabled (default after reset)

1: SPI4 peripheral clocks enabled:

The peripheral clocks of the SPI4 are: the kernel clock selected by SPI45SEL, and the **pclk2** bus interface clock.

Bit 12 **SPI1EN**: SPI2S1 Peripheral Clocks Enable

Set and reset by software.

0: SPI2S1 peripheral clocks disabled (default after reset)

1: SPI2S1 peripheral clocks enabled:

The peripheral clocks of the SPI2S1 are: the kernel clock selected by SPI1SEL, and the **pclk2** bus interface clock.

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **USART10EN**: USART10 peripheral clocks enable

Set and reset by software.

0: USART10 peripheral clocks disabled (default after reset)

1: USART10 peripheral clocks enabled:

The peripheral clocks of the USART10 are the kernel clock selected by USART16910SEL, and the **pclk2** bus interface clock.

Bit 6 **USART9EN**: USART9 peripheral clocks enable

Set and reset by software.

0: USART9 peripheral clocks disabled (default after reset)

1: USART9 peripheral clocks enabled:

The peripheral clocks of the USART9 are the kernel clock selected by USART16910SEL, and the **pclk2** bus interface clock.

Bit 5 **USART6EN**: USART6 peripheral clocks enable

Set and reset by software.

0: USART6 peripheral clocks disabled (default after reset)

1: USART6 peripheral clocks enabled:

The peripheral clocks of the USART6 are the kernel clock selected by USART16910SEL, and the **pclk2** bus interface clock.

Bit 4 **USART1EN**: USART1 peripheral clocks enable

Set and reset by software.

0: USART1 peripheral clocks disabled (default after reset)

1: USART1 peripheral clocks enabled:

The peripheral clocks of the USART1 are the kernel clock selected by USART16910SEL, and the **pclk2** bus interface clock.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TIM20EN**: TIM20 peripheral clock enable
Set and reset by software.
0: TIM20 peripheral clock disabled (default after reset)
1: TIM20 peripheral clock enabled

Bit 1 **TIM8EN**: TIM8 peripheral clock enable
Set and reset by software.
0: TIM8 peripheral clock disabled (default after reset)
1: TIM8 peripheral clock enabled

Bit 0 **TIM1EN**: TIM1 peripheral clock enable
Set and reset by software.
0: TIM1 peripheral clock disabled (default after reset)
1: TIM1 peripheral clock enabled

7.8.52 RCC APB4 clock enable register (RCC_APB4ENR)

Address offset: 0x154

Reset value: 0x0001 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw			rw	rw	rw	rw				rw		rw		rw	

Bit 31 **COMP78EN**: COMP78 peripheral clock enable
Set and reset by software.
0: COMP78 peripheral clock disabled (default after reset)
1: COMP78 peripheral clock enabled

Bit 30 **COMP56EN**: COMP56 peripheral clock enable
Set and reset by software.
0: COMP56 peripheral clock disabled (default after reset)
1: COMP56 peripheral clock enabled

Bit 29 **COMP34EN**: COMP34 peripheral clock enable
Set and reset by software.
0: COMP34 peripheral clock disabled (default after reset)
1: COMP34 peripheral clock enabled

Bit 28 **COMP12EN**: COMP12 peripheral clock enable
Set and reset by software.
0: COMP12 peripheral clock disabled (default after reset)
1: COMP12 peripheral clock enabled

Bit 27 Reserved, must be kept at reset value.

Bit 26 **DTSEN**: Temperature Sensor peripheral clock enable
Set and reset by software.
0: DTS peripheral clock disabled (default after reset)
1: DTS peripheral clock enabled

Bits 25:17 Reserved, must be kept at reset value.

Bit 16 **RTCAPBEN**: RTC APB clock enable
Set and reset by software.
0: The register clock interface of the RTC (APB) is disabled
1: The register clock interface of the RTC (APB) is enabled (default after reset)

Bit 15 **VREFEN**: VREF peripheral clock enable
Set and reset by software.
0: VREF peripheral clock disabled (default after reset)
1: VREF peripheral clock enabled

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5EN**: LPTIM5 peripheral clocks enable
Set and reset by software.
0: LPTIM5 peripheral clocks disabled (default after reset)
1: LPTIM5 peripheral clocks enabled
The LPTIM5 kernel clock can be selected by LPTIM45SEL.

Bit 11 **LPTIM4EN**: LPTIM4 peripheral clocks enable
Set and reset by software.
0: LPTIM4 peripheral clocks disabled (default after reset)
1: LPTIM4 peripheral clocks enabled
The LPTIM4 kernel clock can be selected by LPTIM45SEL.

Bit 10 **LPTIM3EN**: LPTIM3 peripheral clocks enable
Set and reset by software.
0: LPTIM3 peripheral clocks disabled (default after reset)
1: LPTIM3 peripheral clocks enabled
The LPTIM3 kernel clock can be selected by LPTIM23SEL.

Bit 9 **LPTIM2EN**: LPTIM2 peripheral clocks enable
Set and reset by software.
0: LPTIM2 peripheral clocks disabled (default after reset)
1: LPTIM2 peripheral clocks enabled
The LPTIM2 kernel clock can be selected by LPTIM23SEL.

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **SPI6EN**: SPI/I2S6 peripheral clocks enable
Set and reset by software.
0: SPI/I2S6 peripheral clocks disabled (default after reset)
1: SPI/I2S6 peripheral clocks enabled
The peripheral clocks of the SPI/I2S6 are the kernel clock selected by SPI6SEL and provided to **com_clk** input, and the **pclk4** bus interface clock.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1EN**: LPUART1 peripheral clocks enable
Set and reset by software.
0: LPUART1 peripheral clocks disabled (default after reset)
1: LPUART1 peripheral clocks enabled
The peripheral clocks of the LPUART1 are the kernel clock selected by LPUART1SEL and provided to UCLK input, and the **pclk4** bus interface clock.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SBSEN**: SBS peripheral clock enable
Set and reset by software.
0: SBS peripheral clock disabled (default after reset)
1: SBS peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

7.8.53 RCC AHB5 low-power clock enable register (RCC_AHB5LPENR)

Address offset: 0x15C

Reset value: 0xF800 0135

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw			rw	rw		rw		rw

Bit 31 **NPULPEN**:
NPU low-power peripheral clock enable
Set and reset by software.
0: NPU peripheral clock disabled in low-power mode
1: NPU peripheral clock enabled in low-power mode (default after reset)

Bit 30 **ITCMLPEN**: ITCM low-power peripheral clock enable
Set and reset by software.
0: ITCM interface peripheral clock disabled in low-power mode
1: ITCM interface peripheral clock enabled in low-power mode (default after reset)

Bit 29 **DTCM2LPEN**: DTCM2 low-power peripheral clock enable
Set and reset by software.
0: DTCM2 interface peripheral clock disabled in low-power mode
1: DTCM2 interface peripheral clock enabled in low-power mode (default after reset)

Bit 28 **DTCM1LPEN**: DTCM1 low-power peripheral clock enable
Set and reset by software.
0: DTCM1 interface peripheral clock disabled in low-power mode
1: DTCM1 interface peripheral clock enabled in low-power mode (default after reset)

Bit 27 **AXISRAMLPEN**:
AXISRAM[4:1] low-power peripheral clock enable
Set and reset by software.
0: AXISRAM[4:1] interface peripheral clock disabled in low-power mode
1: AXISRAM[4:1] interface peripheral clock enabled in low-power mode (default after reset)

Bits 26:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1LPEN**: SDMMC1 and SDMMC1 delay low-power peripheral clock enable
Set and reset by software.
0: SDMMC1 and SDMMC1 delay peripheral clock disabled in low-power mode
1: SDMMC1 and SDMMC1 delay peripheral clock enabled in low-power mode (default after reset)

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **XSPI1LPEN**: XSPI1 and MCE1 low-power peripheral clock enable
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: XSPI1 and MCE1 peripheral clock disabled in low-power mode
1: XSPI1 and MCE1 peripheral clock enabled in low-power mode (default after reset)

Bit 4 **FMCLPEN**: FMC and MCE3 peripheral clocks enable in low-power mode
Set and reset by software.
The hardware prevents writing this bit if FMCCKP = 1.
0: FMC and MCE3 peripheral clocks disabled in low-power mode
1: FMC and MCE3 peripheral clocks enabled in low-power mode (default after reset):
The peripheral clocks of the FMC are the kernel clock selected by FMCSEL, and the **hclk5** bus interface clock.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FLASHLPEN**: FLASH low-power peripheral clock enable
Set and reset by software.
0: FLASH peripheral clock disabled in low-power mode
1: FLASH peripheral clock enabled in low-power mode (default after reset)

Bit 1 Reserved, must be kept at reset value.

Bit 0 **HPDMA1LPEN**: HPDMA1 low-power peripheral clock enable
Set and reset by software.
0: HPDMA1 peripheral clock disabled in low-power mode
1: HPDMA1 peripheral clock enabled in low-power mode (default after reset)

7.8.54 RCC AHB1 low-power clock enable register (RCC_AHB1LPENR)

Address offset: 0x160

Reset value: 0x8800 0018

Bit 31 **ADF1LPEN**: ADF clock enable in low-power mode
Set and reset by software.
0: ADF peripheral clock disabled in low-power mode
1: ADF peripheral clock enabled in low-power mode (default after reset)

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 **OTGFSLPEN**: OTGFS clock enable in low-power mode
Set and reset by software.
0: OTGFS peripheral clock disabled in low-power mode
1: OTGFS peripheral clock enabled in low-power mode (default after reset)

Bits 26:5 Reserved, must be kept at reset value.

Bit 4 **GPDMA1LPEN**: GPDMA1 clock enable in low-power mode
Set and reset by software.
0: GPDMA1 clock disabled in low-power mode
1: GPDMA1 clock enabled in low-power mode (default after reset)

Bit 3 **HSP1LPEN**: HSP clock enable in low-power mode
Set and reset by software.
0: HSP clock disabled in low-power mode
1: HSP clock and AHBSRAM3 enabled in low-power mode (default after reset)

Bits 2:0 Reserved, must be kept at reset value.

7.8.55 RCC AHB2 low-power clock enable register (RCC_AHB2LPENR)

Address offset: 0x164

Reset value: 0xE000 C000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **AHBSRAM3LPEN**: AHBSRAM3 clock enable in low-power mode
Set and reset by software.
0: AHBSRAM3 clock disabled in low-power mode (if HSP1LPEN = 0)
1: AHBSRAM3 clock enabled in low-power mode (default after reset)

Bit 30 **AHBSRAM2LPEN**: AHBSRAM2 clock enable in low-power mode
Set and reset by software.
0: AHBSRAM2 clock disabled in low-power mode
1: AHBSRAM2 clock enabled in low-power mode (default after reset)

Bit 29 **AHBSRAM1LPEN**: AHBSRAM1 clock enable in low-power mode
Set and reset by software.
0: AHBSRAM1 clock disabled in low-power mode
1: AHBSRAM1 clock enabled in low-power mode (default after reset)

Bits 28:16 Reserved, must be kept at reset value.

Bit 15 **FMAC1LPEN**: FMAC1 clock enable in low-power mode
Set and reset by software.
0: FMAC1 clock disabled in low-power mode
1: FMAC1 clock enabled in low-power mode (default after reset)

Bit 14 **CORDICLPEN**: CORDIC clock enable in low-power mode
Set and reset by software.
0: CORDIC clock disabled in low-power mode
1: CORDIC clock enabled in low-power mode (default after reset)

Bits 13:0 Reserved, must be kept at reset value.

7.8.56 RCC AHB3 low-power clock enable register (RCC_AHB3LPENR)

Address offset: 0x16C

Reset value: 0xF300 0003

Bit 31 **DAC4LPEN**: DAC4 peripheral clock enable in low-power mode
Set and reset by software.
0: DAC4 peripheral clock disabled in low-power mode
1: DAC4 peripheral clock enabled in low-power mode (default after reset)

Bit 30 **DAC3LPEN**: DAC3 peripheral clock enable in low-power mode
Set and reset by software.
0: DAC3 peripheral clock disabled in low-power mode
1: DAC3 peripheral clock enabled in low-power mode (default after reset)

Bit 29 **DAC2LPEN**: DAC2 peripheral clock enable in low-power mode
Set and reset by software.
0: DAC2 peripheral clock disabled in low-power mode
1: DAC2 peripheral clock enabled in low-power mode (default after reset)

Bit 28 **DAC1LPEN**: DAC1 peripheral clock enable in low-power mode
Set and reset by software.
0: DAC1 peripheral clock disabled in low-power mode
1: DAC1 peripheral clock enabled in low-power mode (default after reset)

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **ADC34LPEN**: ADC34 peripheral clock enable in low-power mode
Set and reset by software.
0: ADC34 peripheral clock disabled in low-power mode
1: ADC34 peripheral clock enabled in low-power mode (default after reset)

Bit 24 **ADC12LPEN**: ADC12 peripheral clock enable in low-power mode
Set and reset by software.
0: ADC12 peripheral clock disabled in low-power mode
1: ADC12 peripheral clock enabled in low-power mode (default after reset)

Bits 23:2 Reserved, must be kept at reset value.

Bit 1 **HASHLPEN**: HASH peripheral clock enable in low-power mode
Set and reset by software.
0: HASH peripheral clock disabled in low-power mode
1: HASH peripheral clock enabled in low-power mode (default after reset)

Bit 0 **RNGLPEN**: RNG peripheral clock enable in low-power mode
Set and reset by software.
0: RNG peripheral clocks disabled in low-power mode
1: RNG peripheral clock enabled in low-power mode (default after reset)

7.8.57 RCC AHB4 low-power clock enable register (RCC_AHB4LPENR)

Address offset: 0x168

Reset value: 0x1008 01FF

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **BKPRAMLPEN**: Backup RAM clock enable in low-power mode
Set and reset by software.
0: Backup RAM clock disabled in low-power mode
1: Backup RAM clock enabled in low-power mode (default after reset)

Bits 27:20 Reserved, must be kept at reset value.

Bit 19 **CRCLPEN**: CRC clock enable in low-power mode
Set and reset by software.
0: CRC clock disabled in low-power mode
1: CRC clock enabled in low-power mode (default after reset)

Bits 18:9 Reserved, must be kept at reset value.

Bit 8 **GPIOILPEN**: GPIOI peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOI peripheral clock disabled in low-power mode
1: GPIOI peripheral clock enabled in low-power mode (default after reset)

Bit 7 **GPIOHLPEN**: GPIOH peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOH peripheral clock disabled in low-power mode
1: GPIOH peripheral clock enabled in low-power mode (default after reset)

Bit 6 **GPIOGLPEN**: GPIOG peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOG peripheral clock disabled in low-power mode
1: GPIOG peripheral clock enabled in low-power mode (default after reset)

Bit 5 **GPIOFLPEN**: GPIOF peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOF peripheral clock disabled in low-power mode
1: GPIOF peripheral clock enabled in low-power mode (default after reset)

Bit 4 **GPIOELPEN**: GPIOE peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOE peripheral clock disabled in low-power mode
1: GPIOE peripheral clock enabled in low-power mode (default after reset)

Bit 3 **GPIODLPEN**: GPIOD peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOD peripheral clock disabled in low-power mode
1: GPIOD peripheral clock enabled in low-power mode (default after reset)

Bit 2 **GPIOCLPEN**: GPIOC peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOC peripheral clock disabled in low-power mode
1: GPIOC peripheral clock enabled in low-power mode (default after reset)

Bit 1 **GPIOBLPEN**: GPIOB peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOB peripheral clock disabled in low-power mode
1: GPIOB peripheral clock enabled in low-power mode (default after reset)

Bit 0 **GPIOALPEN**: GPIOA peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOA peripheral clock disabled in low-power mode
1: GPIOA peripheral clock enabled in low-power mode (default after reset)

7.8.58 RCC APB1 low-power clock enable register 1 (RCC_APB1LPENR1)

Address offset: 0x170

Reset value: 0xC1FE FBFF

Bit 31 **UART8LPEN**: UART8 peripheral clocks enable in low-power mode
Set and reset by software.
0: UART8 peripheral clocks disabled in low-power mode
1: UART8 peripheral clocks enabled in low-power mode (default after reset)

Bit 30 **UART7LPEN**: UART7 peripheral clocks enable in low-power mode
Set and reset by software.
0: UART7 peripheral clocks disabled in low-power mode
1: UART7 peripheral clocks enabled in low-power mode (default after reset)

Bits 29:25 Reserved, must be kept at reset value.

Bit 24 **I3C1LPEN**: I3C1 peripheral clocks enable in low-power mode
Set and reset by software.
0: I3C1 peripheral clocks disabled in low-power mode
1: I3C1peripheral clocks enabled in low-power mode (default after reset)

Bit 23 **I2C3LPEN**: I2C3 peripheral clocks enable in low-power mode
Set and reset by software.
0: I2C3 peripheral clocks disabled in low-power mode
1: I2C3 peripheral clocks enabled in low-power mode (default after reset)

Bit 22 **I2C2LPEN**: I2C2 peripheral clocks enable in low-power mode
Set and reset by software.
0: I2C2 peripheral clocks disabled in low-power mode
1: I2C2 peripheral clocks enabled in low-power mode (default after reset)

Bit 21 **I2C1LPEN**: I2C1 peripheral clocks enable in low-power mode
Set and reset by software.
0: I2C1 peripheral clocks disabled in low-power mode
1: I2C1 peripheral clocks enabled in low-power mode (default after reset)

Bit 20 **UART5LPEN**: UART5 peripheral clocks enable in low-power mode
Set and reset by software.
0: UART5 peripheral clocks disabled in low-power mode
1: UART5 peripheral clocks enabled in low-power mode (default after reset)

Bit 19 **UART4LPEN**: UART4 peripheral clocks enable in low-power mode
Set and reset by software.
0: UART4 peripheral clocks disabled in low-power mode
1: UART4 peripheral clocks enabled in low-power mode (default after reset)

Bit 18 **USART3LPEN**: USART3 peripheral clocks enable in low-power mode
Set and reset by software.
0: USART3 peripheral clocks disabled in low-power mode
1: USART3 peripheral clocks enabled in low-power mode (default after reset):

Bit 17 **USART2LPEN**: USART2 peripheral clocks enable in low-power mode
Set and reset by software.
0: USART2 peripheral clocks disabled in low-power mode
1: USART2 peripheral clocks enabled in low-power mode (default after reset).

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3LPEN**: SPI3 peripheral clocks enable in low-power mode
Set and reset by software.
0: SPI3 peripheral clocks disabled in low-power mode
1: SPI3 peripheral clocks enabled in low-power mode (default after reset).

Bit 14 **SPI2LPEN**: SPI2 peripheral clocks enable in low-power mode
Set and reset by software.
0: SPI2 peripheral clocks disabled in low-power mode
1: SPI2 peripheral clocks enabled in low-power mode (default after reset).

Bit 13 **TIM11LPEN**: TIM11 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM11 peripheral clock disabled in low-power mode
1: TIM11 peripheral clock enabled in low-power mode (default after reset)

Bit 12 **TIM10LPEN**: TIM10 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM10 peripheral clock disabled in low-power mode
1: TIM10 peripheral clock enabled in low-power mode (default after reset)

Bit 11 **WWDGLPEN**: WWDG clock enable in low-power mode
Set and reset by software.
0: WWDG clock disable in low-power mode
1: WWDG clock enabled in low-power mode (default after reset)

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1LPEN**: LPTIM1 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPTIM1 peripheral clocks disabled in low-power mode
1: LPTIM1 peripheral clocks enabled in low-power mode (default after reset).

Bit 8 **TIM14LPEN**: TIM14 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM14 peripheral clock disabled in low-power mode
1: TIM14 peripheral clock enabled in low-power mode (default after reset)

Bit 7 **TIM13LPEN**: TIM13 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM13 peripheral clock disabled in low-power mode
1: TIM13 peripheral clock enabled in low-power mode (default after reset)

Bit 6 **TIM12LPEN**: TIM12 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM12 peripheral clock disabled in low-power mode
1: TIM12 peripheral clock enabled in low-power mode (default after reset)

Bit 5 **TIM7LPEN**: TIM7 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM7 peripheral clock disabled in low-power mode
1: TIM7 peripheral clock enabled in low-power mode (default after reset)

Bit 4 **TIM6LPEN**: TIM6 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM6 peripheral clock disabled in low-power mode
1: TIM6 peripheral clock enabled in low-power mode (default after reset)

Bit 3 **TIM5LPEN**: TIM5 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM5 peripheral clock disabled in low-power mode
1: TIM5 peripheral clock enabled in low-power mode (default after reset)

Bit 2 **TIM4LPEN**: TIM4 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM4 peripheral clock disabled in low-power mode
1: TIM4 peripheral clock enabled in low-power mode (default after reset)

Bit 1 **TIM3LPEN**: TIM3 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM3 peripheral clock disabled in low-power mode
1: TIM3 peripheral clock enabled in low-power mode (default after reset)

Bit 0 **TIM2LPEN**: TIM2 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM2 peripheral clock disabled in low-power mode
1: TIM2 peripheral clock enabled in low-power mode (default after reset)

7.8.59 RCC APB1 low-power clock enable register 2 (RCC_APB1LPENR2)

Address offset: 0x174

Reset value: 0x0800 0102

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw							rw	

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **UCPD1LPEN**: UCPD peripheral clock enable in low-power mode
Set and reset by software.
0: UCPD peripheral clock disabled in low-power mode
1: UCPD peripheral clock enabled in low-power mode (default after reset)

Bits 26:9 Reserved, must be kept at reset value.

Bit 8 **FDCANLPEN**: FDCAN peripheral clock enable in low-power mode
Set and reset by software.
0: FDCAN peripheral clock disabled in low-power mode
1: FDCAN peripheral clock enabled in low-power mode (default after reset)

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CRSLPEN**: Clock recovery system peripheral clock enable in low-power mode
Set and reset by software.
0: CRS peripheral clock disabled in low-power mode
1: CRS peripheral clock enabled in low-power mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

7.8.60 RCC APB2 low-power clock enable register (RCC_APB2LPENR)

Address offset: 0x178

Reset value: 0x111F 30F7

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw					rw	rw	rw	rw		rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **HRTIM2LPEN**: HRTIM2 peripheral clock enable in low-power mode
Set and reset by software.
0: HRTIM2 peripheral clock disabled in low-power mode
1: HRTIM2 peripheral clock enabled in low-power mode (default after reset)

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **HRTIM1LPEN**: HRTIM1 peripheral clock enable in low-power mode
Set and reset by software.
0: HRTIM1 peripheral clock disabled in low-power mode
1: HRTIM1 peripheral clock enabled in low-power mode (default after reset)

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **SPI5LPEN**: SPI5 peripheral clocks enable in low-power mode
Set and reset by software.
0: SPI5 peripheral clocks disabled in low-power mode
1: SPI5 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the SPI5 are the kernel clock selected by SPI45SEL and provided to **com_clk** input, and the **pclk2** bus interface clock.

Bit 19 **TIM9LPEN**: TIM9 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM9 peripheral clock disabled in low-power mode
1: TIM9 peripheral clock enabled in low-power mode (default after reset)

Bit 18 **TIM17LPEN**: TIM17 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM17 peripheral clock disabled in low-power mode
1: TIM17 peripheral clock enabled in low-power mode (default after reset)

Bit 17 **TIM16LPEN**: TIM16 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM16 peripheral clock disabled in low-power mode
1: TIM16 peripheral clock enabled in low-power mode (default after reset)

Bit 16 **TIM15LPEN**: TIM15 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM15 peripheral clock disabled in low-power mode
1: TIM15 peripheral clock enabled in low-power mode (default after reset)

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4LPEN**: SPI4 peripheral clock enable in low-power mode
Set and reset by software.
0: SPI4 peripheral clocks disabled in low-power mode
1: SPI4 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the SPI4 are: the kernel clock selected by SPI45SEL and provided to **com_clk** input, and the **pclk2** bus interface clock.

Bit 12 **SPI1LPEN**: SPI2S1 peripheral clock enable in low-power mode
Set and reset by software.
0: SPI2S1 peripheral clocks disabled in low-power mode
1: SPI2S1 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the SPI2S1 are: the kernel clock selected by I2S1SEL and provided to **spi_ker_ck** input, and the **pclk2** bus interface clock.

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **USART10LPEN**: USART10 peripheral clock enable in low-power mode
Set and reset by software.
0: USART10 peripheral clocks disabled in low-power mode
1: USART10 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the USART0 are the kernel clock selected by USART16910SEL and provided to UCLK inputs, and the **pclk2** bus interface clock.

Bit 6 **USART9LPEN**: USART9 peripheral clock enable in low-power mode
Set and reset by software.
0: USART9 peripheral clocks disabled in low-power mode
1: USART9 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the USART9 are the kernel clock selected by USART16910SEL and provided to UCLK inputs, and the **pclk2** bus interface clock.

Bit 5 **USART6LPEN**: USART6 peripheral clock enable in low-power mode
Set and reset by software.
0: USART6 peripheral clocks disabled in low-power mode
1: USART6 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the USART6 are the kernel clock selected by USART16910SEL and provided to UCLK inputs, and the **pclk2** bus interface clock.

Bit 4 **USART1LPEN**: USART1 peripheral clock enable in low-power mode
Set and reset by software.
0: USART1 peripheral clocks disabled in low-power mode
1: USART1 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the USART1 are the kernel clock selected by USART16910SEL and provided to UCLK inputs, and the **pclk2** bus interface clock.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TIM20LPEN**: TIM20 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM20 peripheral clock disabled in low-power mode
1: TIM20 peripheral clock enabled in low-power mode (default after reset)

Bit 1 **TIM8LPEN**: TIM8 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM8 peripheral clock disabled in low-power mode
1: TIM8 peripheral clock enabled in low-power mode (default after reset)

Bit 0 **TIM1LPEN**: TIM1 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM1 peripheral clock disabled in low-power mode
1: TIM1 peripheral clock enabled in low-power mode (default after reset)

7.8.61 RCC APB4 low-power clock enable register (RCC_APB4LPENR)

Address offset: 0x17C

Reset value: 0xF401 9E2A

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **COMP78LPEN**: temperature sensor peripheral clock enable in low-power mode
Set and reset by software.
0: COMP78 peripheral clock disabled in low-power mode
1: COMP78 peripheral clock enabled in low-power mode (default after reset)

Bit 30 **COMP56LPEN**: temperature sensor peripheral clock enable in low-power mode
Set and reset by software.
0: COMP56 peripheral clock disabled in low-power mode
1: COMP56 peripheral clock enabled in low-power mode (default after reset)

Bit 29 **COMP34LPEN**: temperature sensor peripheral clock enable in low-power mode
Set and reset by software.
0: COMP34 peripheral clock disabled in low-power mode
1: COMP34 peripheral clock enabled in low-power mode (default after reset)

Bit 28 **COMP12LPEN**: temperature sensor peripheral clock enable in low-power mode
Set and reset by software.
0: COMP12 peripheral clock disabled in low-power mode
1: COMP12 peripheral clock enabled in low-power mode (default after reset)

Bit 27 Reserved, must be kept at reset value.

Bit 26 **DTSLPEN**: temperature sensor peripheral clock enable in low-power mode
Set and reset by software.
0: DTS peripheral clock disabled in low-power mode
1: DTS peripheral clock enabled in low-power mode (default after reset)

Bits 25:17 Reserved, must be kept at reset value.

Bit 16 **RTCAPBLPEN**: RTC APB clock enable in low-power mode
Set and reset by software.
0: The register clock interface of the RTC (APB) is disabled in low-power mode
1: The register clock interface of the RTC (APB) is enabled in low-power mode (default after reset)

Bit 15 **VREFLPEN**: VREF peripheral clock enable in low-power mode
Set and reset by software.
0: VREF peripheral clock disabled in low-power mode
1: VREF peripheral clock enabled in low-power mode (default after reset)

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5LPEN**: LPTIM5 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPTIM5 peripheral clocks disabled in low-power mode
1: LPTIM5 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the LPTIM5 are the kernel clock selected by LPTIM45SEL and provided to **clk_lpt** input, and the **pclk4** bus interface clock.

Bit 11 **LPTIM4LPEN**: LPTIM4 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPTIM4 peripheral clocks disabled in low-power mode
1: LPTIM4 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the LPTIM4 are the kernel clock selected by LPTIM45SEL and provided to **clk_lpt** input, and the **pclk4** bus interface clock.

Bit 10 **LPTIM3LPEN**: LPTIM3 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPTIM3 peripheral clocks disabled in low-power mode
1: LPTIM3 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the LPTIM3 are the kernel clock selected by LPTIM23SEL and provided to **clk_lpt** input, and the **pclk4** bus interface clock.

Bit 9 **LPTIM2LPEN**: LPTIM2 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPTIM2 peripheral clocks disabled in low-power mode
1: LPTIM2 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the LPTIM2 are the kernel clock selected by LPTIM23SEL and provided to **clk_lpt** input, and the **pclk4** bus interface clock.

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **SPI6LPEN**: SPI/I2S6 peripheral clocks enable in low-power mode
Set and reset by software.
0: SPI/I2S6 peripheral clocks disabled in low-power mode
1: SPI/I2S6 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the SPI/I2S6 are the kernel clock selected by SPI6SEL and provided to **com_ck** input, and the **rcc_pclk4** bus interface clock.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1LPEN**: LPUART1 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPUART1 peripheral clocks disabled in low-power mode
1: LPUART1 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the LPUART1 are the kernel clock selected by LPUART1SEL and provided to UCLK input, and the **rcc_pclk4** bus interface clock.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SBSLPEN**: SBS peripheral clock enable in low-power mode
Set and reset by software.
0: SBS peripheral clock disabled in low-power mode
1: SBS peripheral clock enabled in low-power mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

7.9 RCC register map

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

8 Clock recovery system (CRS)

8.1 CRS introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means to evaluate the oscillator output frequency, based on comparison with a selectable synchronization signal. The CRS can perform automatic trimming adjustments based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In this case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from alternative synchronization or generated by the user software.

8.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity (see *Section 8.4.2: CRS internal signals*)
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster startup convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

8.3 CRS implementation

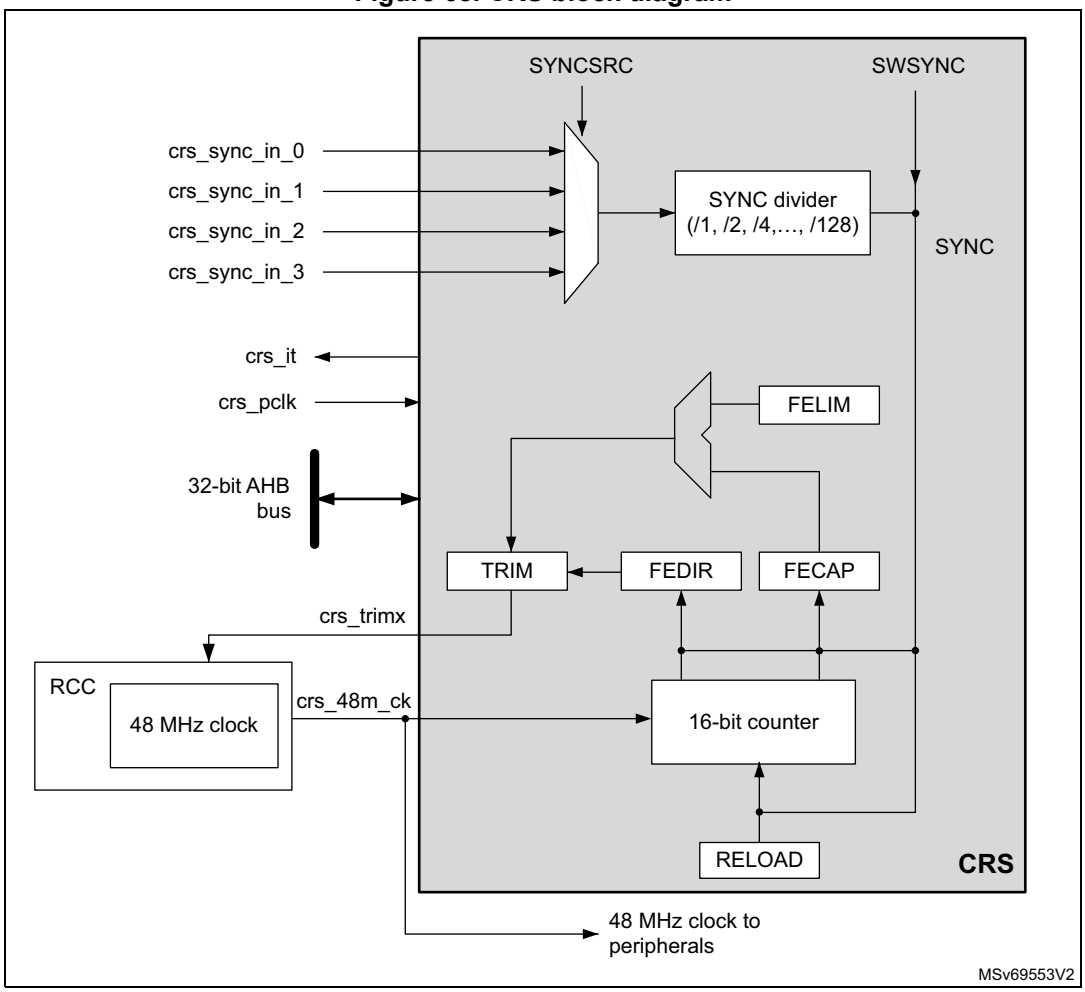

Table 68. CRS features

Feature	CRS
TRIM width	6 bits

8.4 CRS functional description

Figure 68. CRS block diagram

8.4.2 CRS internal signals

Below the list of CRS internal signals.

Table 69. CRS internal input/output signals

Internal signal name	Signal type	Description
crs_it	Digital output	CRS interrupt
crs_pclk	Digital input	AHB bus clock
crs_48m_ck	Digital input	HSI48 48 MHz clock
crs_trim[0:5]	Digital output	HSI48 oscillator smooth trimming value

Table 69. CRS internal input/output signals (continued)

Internal signal name	Signal type	Description
crs_sync_in_0	Digital input	SYNC signal source
crs_sync_in_1		
crs_sync_in_2		
crs_sync_in_3		

Table 70. CRS interconnection

Internal signal name	Source
crs_sync_in_0	CRS_SYNC pin selected as SYNC signal source
crs_sync_in_1	LSE selected as SYNC signal source
crs_sync_in_2	OTG FS SOF selected as SYNC signal source (default)
crs_sync_in_3	Reserved

8.4.3 Synchronization input

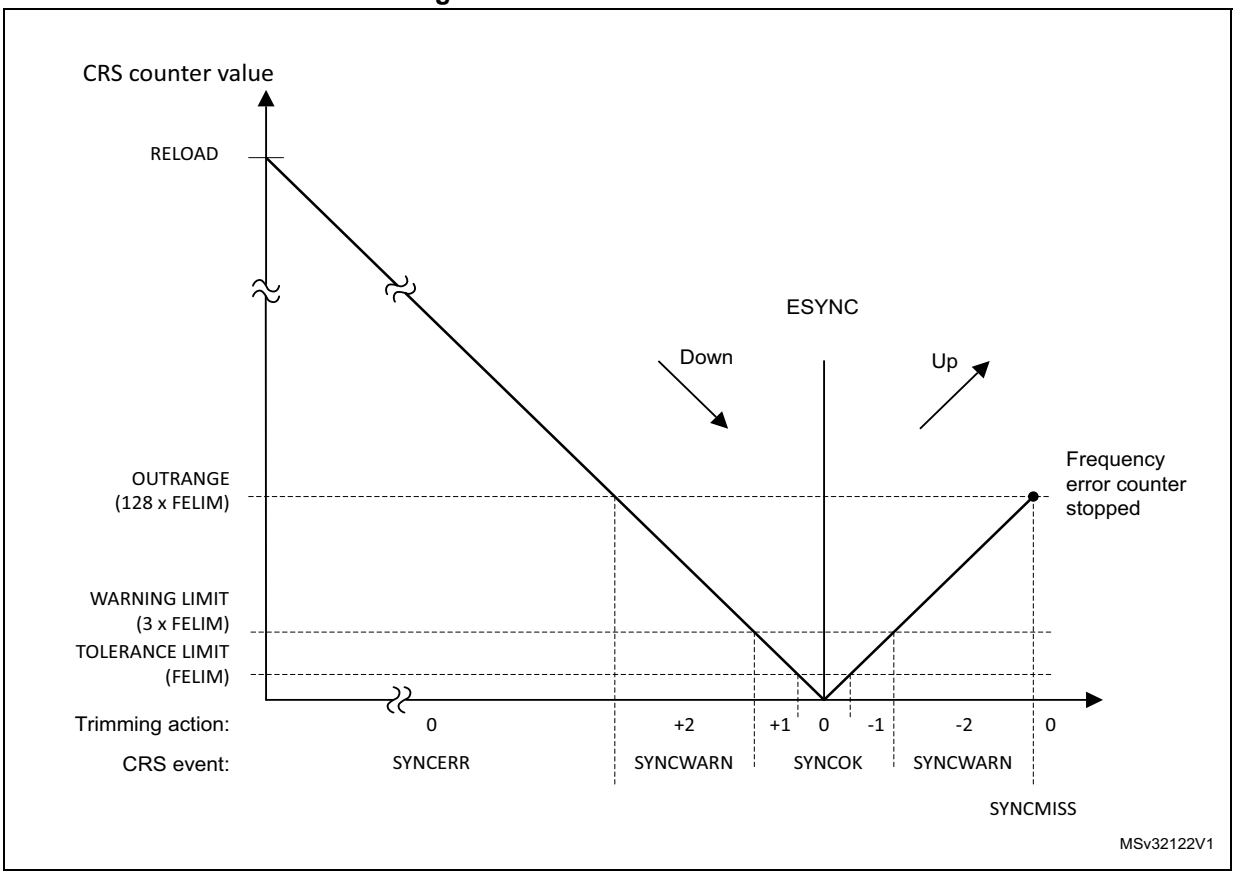
The CRS synchronization source (crs_sync_in_x) can be selected through SYNCSRC[1:0] bitfield of CRS_CFGR register (refer to *Section 8.4.2: CRS internal signals* for the possible sources). For a better robustness of the crs_sync_in_x input, a simple digital filter (2 out of 3 majority votes, sampled by the 48 MHz clock) is implemented to filter out glitches. In addition, the source signal has a configurable polarity (selected through SYNCPOL bit of CRS_CFGR). The signal can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to CRS_CFGR register.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

For more information on the CRS synchronization source configuration, refer to *CRS configuration register (CRS_CFGR)*.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.



8.4.4 Frequency error measurement

The frequency error counter is a 16-bit down/up counter, reloaded with the RELOAD value on each SYNC event. It starts counting down until it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit, where it eventually stops (if no SYNC event is received), and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the down-counting phase (before reaching the zero value), it means that the actual

frequency is lower than the target (the TRIM value must be incremented). When it is detected during the up-counting phase, it means that the actual frequency is higher (the TRIM value must be decremented).

Figure 69. CRS counter behavior

8.4.5 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 × FELIM value
- OUTRANGE (error limit), defined as 128 × FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming, which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated

  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, the frequency is out of the trimming range. This can also happen when the SYNC input is not clean, or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is close to its limits and the automatic trimming can force it to overflow or underflow, the TRIM value is set to the limit, and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

8.4.6 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. This value is decreased by 1, to reach the expected synchronization on the zero value. The formula is the following:

$$RELOAD = (f_{TARGET} / f_{SYNC}) - 1$$

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of oscillator clock ticks. The following formula can be used:

$$FELIM = (f_{TARGET} / f_{SYNC}) * STEP[\%] / 100\% / 2$$

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to $(f_{TARGET} / f_{SYNC}) = 48000$, and to a typical trimming step size of 0.14%.

Note: The trimming step size depends upon the product, check the datasheet for accurate setting.

Caution: There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields, this can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

8.5 CRS in low-power modes

Table 71. Effect of low-power modes on CRS

Mode	Description
Sleep	No effect. CRS interrupts cause the device to exit the Sleep mode.
Stop	CRS registers are frozen. The CRS stops operating until the Stop mode is exited and the HSI48 oscillator is restarted.
Standby	The peripheral is powered down and must be reinitialized after exiting Standby mode.
Shutdown	The peripheral is powered down and must be reinitialized after exiting Shutdown mode.

8.6 CRS interrupts

Table 72. Interrupt control bits

Interrupt event	Event flag	Enable control bit	Clear flag bit
Expected synchronization	ESYNCF	ESYNCIE	ESYNCC
Synchronization OK	SYNCOKF	SYNCOKIE	SYNCOKC
Synchronization warning	SYNCWARNF	SYNCWARNIE	SYNCWARNC
Synchronization or trimming error (TRIMOVF, SYNCMISS, SYNCERR)	ERRF	ERRIE	ERRC

8.7 CRS registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed only by words (32-bit).

8.7.1 CRS control register (CRS_CR)

Address offset: 0x00

Reset value: 0x0000 2000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	TRIM[5:0]						SW SYNC	AUTO TRIMEN	CEN	Res.	ESYNC IE	ERR IE	SYNC WARNIE	SYNC OKIE
		rw	rw	rw	rw	rw	rw	rt_w1	rw	rw		rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **TRIM[5:0]**: HSI48 oscillator smooth trimming

These bits provide a user-programmable trimming value to the HSI48 oscillator. They can be programmed to adjust to variations in voltage and temperature that influence the oscillator frequency.

The default value of the HSI48 oscillator smooth trimming is 32, for a complete TRIM range of 64 steps.

The trimming step is specified in the product datasheet. A higher TRIM value corresponds to a higher output frequency.

When the AUTOTRIMEN bit is set, this field is controlled by hardware and is read-only.

Bit 7 **SWSYNC**: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action

1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to *Section 8.4.5* for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.

1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled

1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **ESYNCIE**: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled

1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable

0: Synchronization or trimming error (ERRF) interrupt disabled

1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable

0: SYNC warning (SYNCWARNF) interrupt disabled

1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable

0: SYNC event OK (SYNCOKF) interrupt disabled

1: SYNC event OK (SYNCOKF) interrupt enabled

8.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (the CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SYNCPOL	Res.	SYNCSRC[1:0]		Res.	SYNCDIV[2:0]			FELIM[7:0]							
rw		rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SYNCPOL**: SYNC polarity selection

This bit is set and cleared by software to select the input polarity for the SYNC signal source.

0: SYNC active on rising edge (default)

1: SYNC active on falling edge

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection

These bits are set and cleared by software to select the SYNC signal source (see *Section 8.4.2: CRS internal signals*).

00: crs_sync_in_0 selected as SYNC signal source

01: crs_sync_in_1 selected as SYNC signal source

10: crs_sync_in_2 selected as SYNC signal source

11: crs_sync_in_3 selected as SYNC signal source

Note: When using USB LPM (link power management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the 48 MHz clock on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE clock or the SYNC pin must be used as SYNC signal.

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SYNCDIV[2:0]**: SYNC divider

These bits are set and cleared by software to control the division factor of the SYNC signal.

000: SYNC not divided (default)

001: SYNC divided by 2

010: SYNC divided by 4

011: SYNC divided by 8

100: SYNC divided by 16

101: SYNC divided by 32

110: SYNC divided by 64

111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit

FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to *Section 8.4.5* for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value

RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to *Section 8.4.4* for more details about counter behavior.

8.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FECAP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEDIR	Res.	Res.	Res.	Res.	TRIM OVF	SYNC MISS	SYNC ERR	Res.	Res.	Res.	Res.	ESYNCF	ERRF	SYNC WARNF	SYNC OKF
r					r	r	r					r	r	r	r

Bits 31:16 **FECAP[15:0]**: Frequency error capture

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to *Section 8.4.5* for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.

0: Up-counting direction, the actual frequency is above the target

1: Down-counting direction, the actual frequency is below the target

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No trimming error signaled

1: Trimming error signaled

Bit 9 **SYNCMISS**: SYNC missed

This flag is set by hardware when the frequency error counter reaches value FELIM * 128 and no SYNC is detected, meaning either that a SYNC pulse was missed, or the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, hence some other action must be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC), and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signaled

1: SYNC missed error signaled

Bit 8 **SYNCERR**: SYNC error

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signaled

1: SYNC error signaled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCF**: Expected SYNC flag

This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signaled

1: Expected SYNC signaled

Bit 2 **ERRF**: Error flag

This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.

0: No synchronization or trimming error signaled

1: Synchronization or trimming error signaled

Bit 1 **SYNCWARNF**: SYNC warning flag

This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signaled

1: SYNC warning signaled

Bit 0 **SYNCOKF**: SYNC event OK flag

This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCOKC bit in the CRS_ICR register.

0: No SYNC event OK signaled

1: SYNC event OK signaled

8.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ESYNCC	ERRC	SYNC WARNC	SYNC OKC
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCC**: Expected SYNC clear flag
Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

Bit 2 **ERRC**: Error clear flag
Writing 1 to this bit clears TRIMOVF, SYNCMISS, and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Bit 1 **SYNCWARNC**: SYNC warning clear flag
Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

Bit 0 **SYNCOKC**: SYNC event OK clear flag
Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.

8.7.5 CRS register map

Table 73. CRS register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

9 General-purpose I/Os (GPIO)

9.1 Introduction

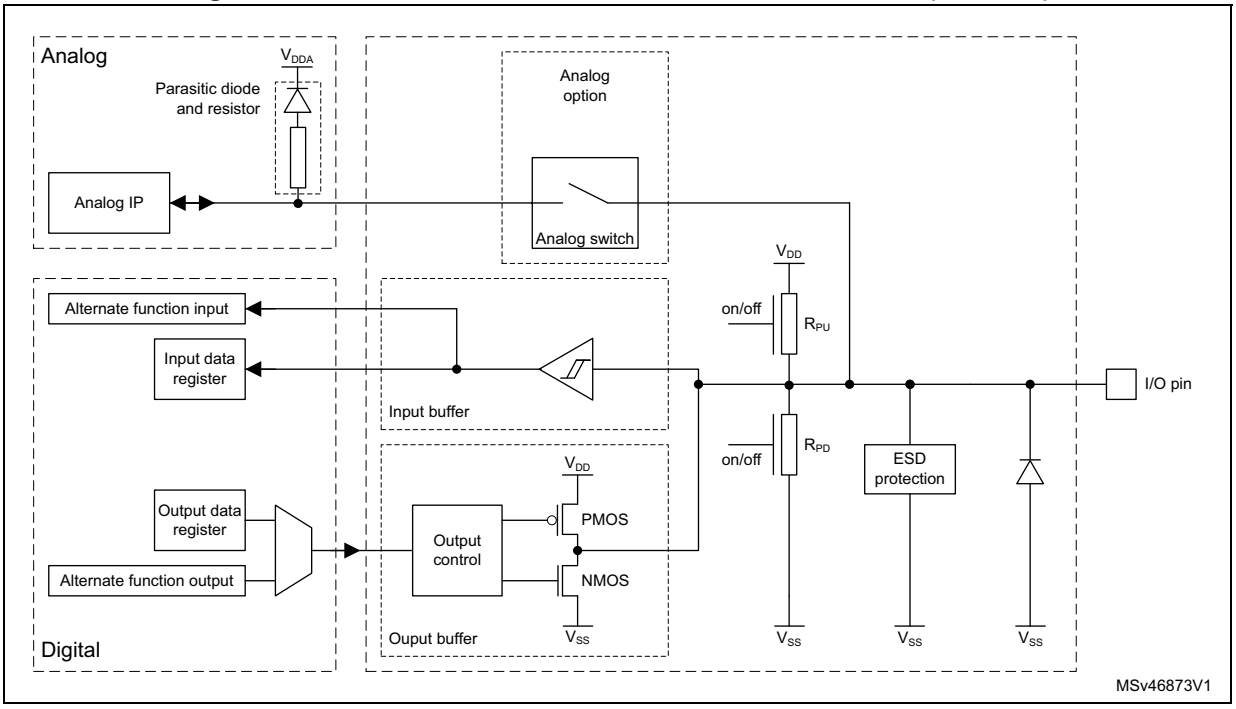
Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16-bit reset register (GPIOx_BRR) and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR), two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

9.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_ BSRR) for bitwise write access to GPIOx_ODR
- Lock mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

9.3 GPIO functional description



Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words, or bytes. The GPIOx_BSRR and GPIOx_BRR registers allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

The following figure shows the basic structure of a three-volt or five-volt tolerant GPIO (TT or FT). The *Table 74* gives the possible port bit configurations.

Figure 70. Structure of three-volt or five-volt tolerant GPIO (TT or FT)

Note: On a TT GPIO, the analog switch is not present and replaced by a direct connection. The analog bloc parasitic circuitry does not allow five-volt tolerance.

Table 74. Port bit configuration(1)

MODE(i) [1:0]	OTYPE(i)	OSPEED(i) [1:0]	PUPD(i) [1:0]		I/O configuration	
01	0	SPEED [1:0]	0	0	GP output	PP

	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0	Input/output	Analog, PD
	x	x	x	1	1	Reserved	

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

9.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO/TRACESWO in floating state no pull-up/pull-down

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, the high level is high-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors that can be activated or not depending on the value in the GPIOx_PUPDR register.

9.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset, the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages. The I/O pins on port P and port O do not have alternate functions as these are dedicated for the XSPI interface.

To use an I/O in a given configuration, the user must proceed as follows:

- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host.
- **GPIO**: configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function**:
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down, and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDR registers respectively.
  - Configure the desired I/O as an alternate function in the GPIOx_MODER register.
- **Additional functions:**
  - For all ADCs, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC registers.
  - For the additional functions like RTC, WKUPx, and oscillators, configure the required function in the related RTC, PWR, and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

9.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

9.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (*GPIO port input data register (GPIOx_IDR) (x = A to I)* and *GPIO port output data register (GPIOx_ODR) (x = A to I)*).

GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O is stored into the input data register (GPIOx_IDR), a read-only register.

9.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register that allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, BS(i) sets the corresponding ODR(i) bit. When written to 1, BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

9.3.6 GPIO locking mechanism

The GPIO control registers can be frozen by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write/read sequence must be applied. When the right LOCK sequence is applied to the bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence is applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence can only be performed using a word (32-bit long) access to the GPIOx_LCKR register because GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

9.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

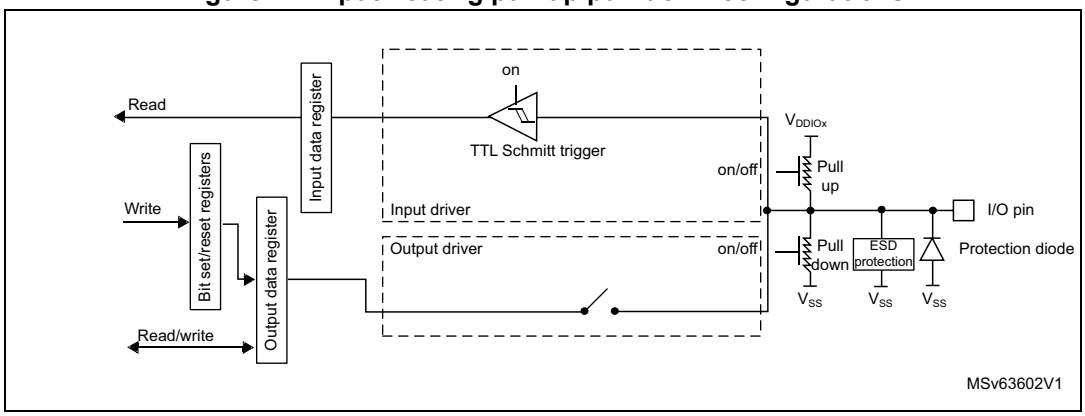
This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can

thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

9.3.8 External interrupt/wake-up lines

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output, or alternate function mode (the port must not be configured in analog mode). Refer to *Section 16: Extended interrupt and event controller (EXTI)*.



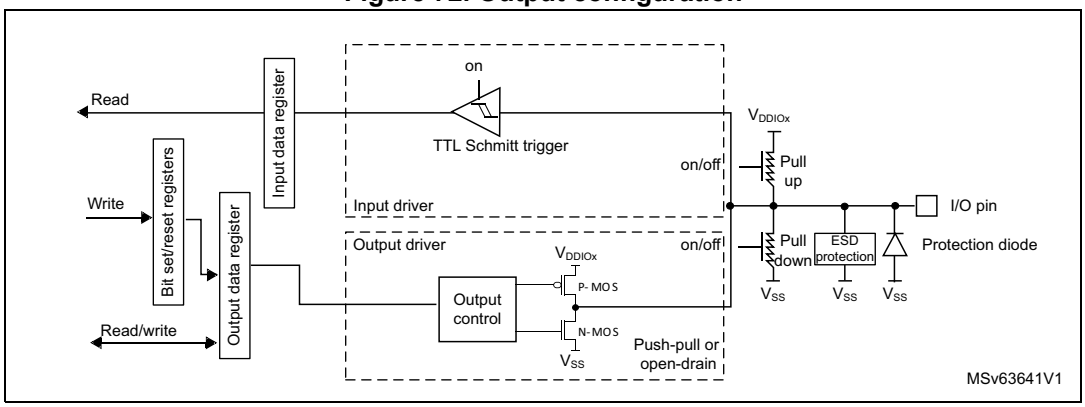
9.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register provides the I/O state.

The figure below shows the input configuration of the I/O port bit.

Figure 71. Input floating/pull-up/pull-down configurations



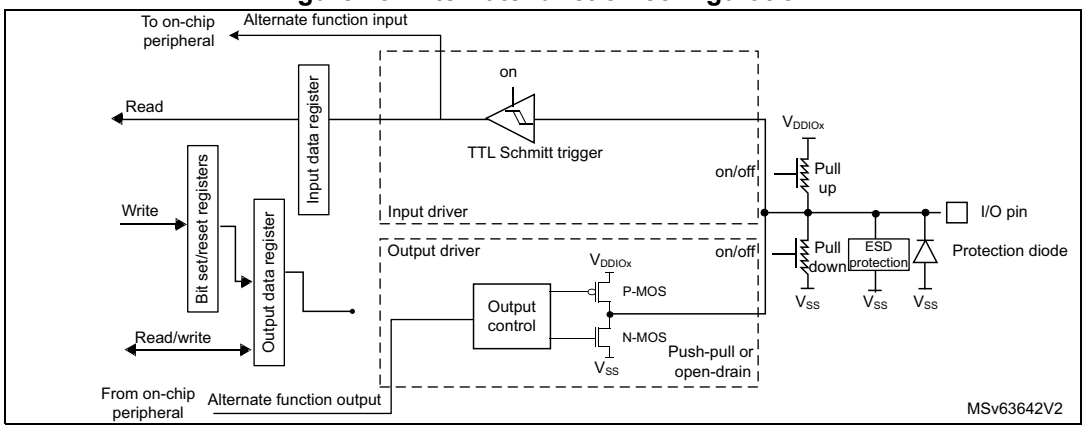
9.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open-drain mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register leaves the port in high-Z (the P-MOS is never activated).
  - Push-pull mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register activates the P-MOS.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.

The figure below shows the output configuration of the I/O port bit.

Figure 72. Output configuration



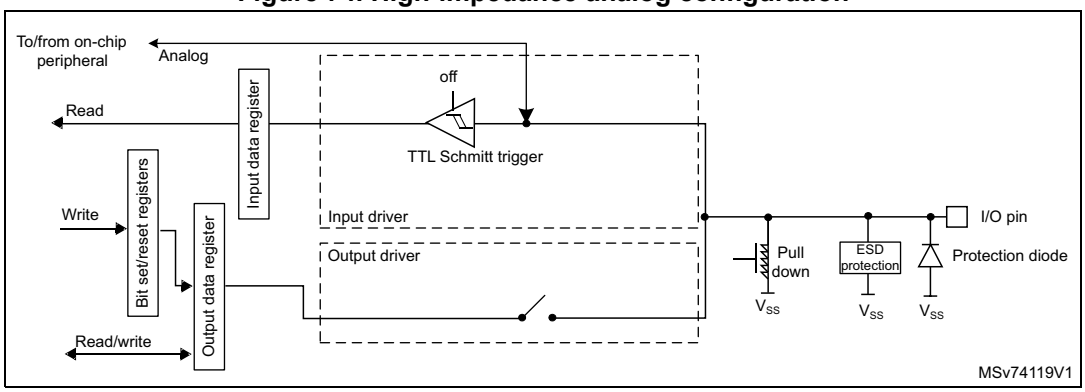
9.3.11 Alternate function configuration

When the I/O port is programmed as an alternate function:

- The output buffer can be configured in open-drain or push-pull mode.
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data).
- The Schmitt trigger input is activated.
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.

The figure below shows the alternate function configuration of the I/O port bit.

Figure 73. Alternate function configuration



9.3.12 Analog configuration

When the I/O port is programmed as an analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up is disabled by hardware. The weak pull-down is configurable.
- Read access to the input data register gets the value 0.

The figure below shows the high-Z, analog-input configuration of the I/O port bits.

Figure 74. High-impedance analog configuration

9.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched on (by setting the HSEON or LSEON bit in the RCC_CSR register), the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input, and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

9.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to *Section 42.3: RTC functional description*

9.3.15 Privileged and unprivileged modes

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or nonsecure).

9.3.16 High-speed low-voltage mode (HSLV)

The I/Os can increase their maximum speed at low voltage by configuring them in HSLV mode. The I/O HSLV bit controls whether the I/O output speed is optimized to operate at 3.3 V (default setting) or at 1.8 V (HSLV = 1). The CSI must be enabled to configure the I/Os in HSLV mode.

Procedure to set the HSLV mode:

1. Set the user option byte for the GPIO (VDDIO_HSLV) in the *FLASH option byte word 1 status register (FLASH_OBW1SR)*
2. Activate the HSLV (IOHSLV) in the *SBS I/O compensation cell control and status register (SBS_CCCSR)*.

Caution: The I/O HSLV configuration bit must not be set if the I/O supply (V_{DD}) is above 2.7 V. Setting it while the voltage is higher than 2.7 V can damage the device.

There is no hardware protection associated with this feature so it is recommended to use it only as a static configuration for fixed I/O supply.

Caution: The GPIOs are all programed with the same HSLV setting.

GPIOs that are shared with the USB are limited in terms of frequency, to hundreds of kHz for UCPD-based GPIOs, and up to 1 MHz for USBFS-based GPIOs. Refer to the datasheet for the exact values. In order to be used, the I/O supply must be above 2.7 V for the USBFS.

9.3.17 I/O compensation cell

The I/O commutation slew rate (t_{fall} / t_{rise}) can be adapted by software depending on process, voltage, and temperature conditions, to reduce the I/O noise on the power supply. The I/O compensation can be enabled and applied in the *SBS I/O compensation cell control and status register (SBS_CCCSR)*.

9.4 GPIO registers

This section gives a detailed description of the GPIO registers.

The peripheral registers can be written in word, half-word or byte mode.

9.4.1 GPIO port mode register (GPIOx_MODER) (x = A to I)

Address offset: 0x00

Reset value: 0xABFF FFFF (port A)

Reset value: 0xFFFF FEBF (port B)

Reset value: 0xFFFF FFFF (ports C...H)

Reset value: 0x0003 03FF (port I)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODE15[1:0]		MODE14[1:0]		MODE13[1:0]		MODE12[1:0]		MODE11[1:0]		MODE10[1:0]		MODE9[1:0]		MODE8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODE7[1:0]		MODE6[1:0]		MODE5[1:0]		MODE4[1:0]		MODE3[1:0]		MODE2[1:0]		MODE1[1:0]		MODE0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MODEy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O mode.

00: Input mode

01: General purpose output mode

10: Alternate function mode

11: Analog mode (reset state)

Note: The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to I)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTy:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output type.

0: Output push-pull (reset state)

1: Output open-drain

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to I)

Address offset: 0x08

Reset value: 0x0C00 0000 (for port A)

Reset value: 0x0000 00C0 (for port B)

Reset value: 0x0000 0000 (for the other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OSPEED15[1:0]		OSPEED14[1:0]		OSPEED13[1:0]		OSPEED12[1:0]		OSPEED11[1:0]		OSPEED10[1:0]		OSPEED9[1:0]		OSPEED8[1:0]

OSPEED7[1:0]		OSPEED6[1:0]		OSPEED5[1:0]		OSPEED4[1:0]		OSPEED3[1:0]		OSPEED2[1:0]		OSPEED1[1:0]		OSPEED0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OSPEEDy[1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output speed.

00: Low speed

01: Medium speed

10: High speed

11: Very-high speed

Note: Refer to the device datasheet for the frequency specifications and the power supply and load conditions for each speed.

The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to I)

Address offset: 0x0C

Reset value: 0x6400 0000 (for port A)

Reset value: 0x0000 0100 (for port B)

Reset value: 0x0000 0000 (for the other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PUPD15[1:0]		PUPD14[1:0]		PUPD13[1:0]		PUPD12[1:0]		PUPD11[1:0]		PUPD10[1:0]		PUPD9[1:0]		PUPD8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PUPDy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

Note: The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.4.5 GPIO port input data register (GPIOx_IDR) (x = A to I)

Address offset: 0x10

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDy:** Port x input data I/O pin y (y = 15 to 0)

These bits are read-only. They contain the input value of the corresponding I/O port.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.4.6 GPIO port output data register (GPIOx_ODR) (x = A to I)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OD15	OD14	OD13	OD12	OD11	OD10	OD9	OD8	OD7	OD6	OD5	OD4	OD3	OD2	OD1	OD0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODy:** Port output data I/O pin y (y = 15 to 0)

These bits can be read and written by software.

Note: For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the GPIOx_BSRR or GPIOx_BRR registers (x = A to I).

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to I)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BS15	BS14	BS13	BS12	BS11	BS10	BS9	BS8	BS7	BS6	BS5	BS4	BS3	BS2	BS1	BS0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy:** Port x reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bits 15:0 **BSy:** Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Sets the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to I)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK:** Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

- LOCK key write sequence:
  WR LCKR[16] = 1 + LCKR[15:0]
  WR LCKR[16] = 0 + LCKR[15:0]
  WR LCKR[16] = 1 + LCKR[15:0]
- LOCK key read:
  RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.
Any error in the lock sequence aborts the LOCK.
After the first LOCK sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 **LCKy:** Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is 0

0: Port configuration not locked

1: Port configuration locked

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to I)

Address offset: 0x20

Reset value: 0x0000 0000

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BRy:** Port x reset IO pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Reset the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

9.4.12 GPIO register map

Table 75. GPIO register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

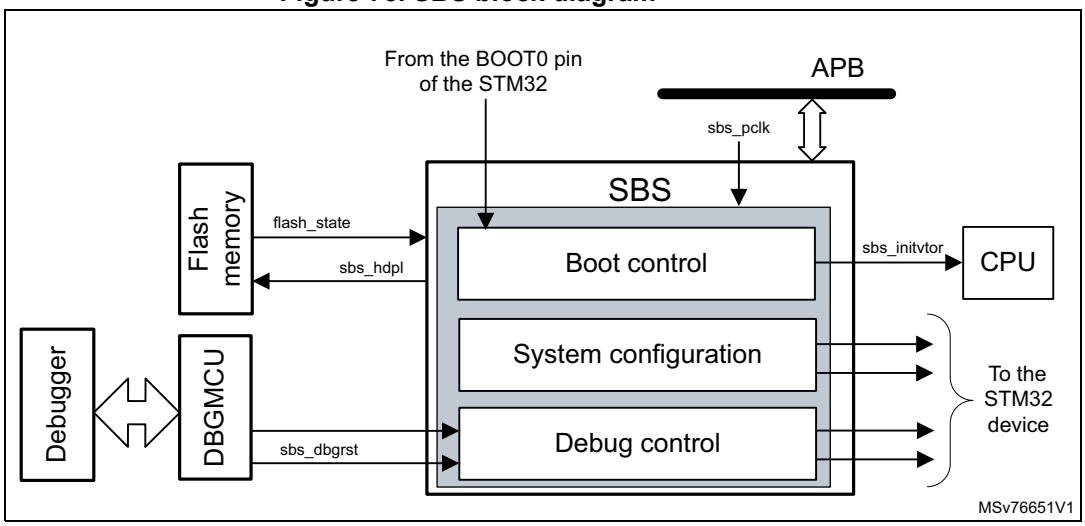
Refer to *Section 2.3: Memory organization* for the register boundary addresses.

10 System configuration, boot and security (SBS)

10.1 SBS introduction

The STM32H7Pxxx devices feature a set of configuration registers located in the SBS. On top of various device configurations, this SBS peripheral controls key boot and security features, including debug.



10.2 SBS main features

- Boot control
  - Upon system reset, configure the Cortex-M7 boot address and the hide protection level (HDPL) depending on the device life cycle (open or close).
- Debug control
  - Control the opening of the device debug interface, ensuring the sequencing of events that guarantee the device security
- System configuration
  - Analog switch configuration management
  - I/O compensation cell management
  - Selection of source input to the EXTI inputs used for external interrupt/event detection
  - Configuration for Cortex-M7 FPU interrupts
- Security status
  - BKPRAM and AXISRAM1 erase
- Register for applications to pass on a command to the RSS (root secure services), executed at the next reset

10.3 SBS functional description

10.3.1 SBS block diagram

Figure 75. SBS block diagram

10.3.2 SBS internal signals

The tables below detail the SBS pins and internal signals.

Table 76. SBS input/output pins

Pin name	Type	Description
BOOT0	Input	Boot from flash memory or bootloader.

Table 77. SBS internal input/output signals

Signal name	Type	Description
sbs_pclk	Input	APB bus clock
sbs_dbgrst		Debug configuration reset from DBGMCU
flash_state		Nonvolatile security status input from flash memory
sbs_hdpl	Output	Hide protection level information
sbs_initvtor		Vector address for Cortex-M7. See *Section 10.3.5* for more details.

10.3.3 SBS reset and clocks

The SBS configuration port is clocked by the APB bus clock. There is a general reset and a debug configuration reset controlled in DBGMCU.

10.3.4 SBS hide protection management

The HDPL is a monotonic counter incremented during the boot stages. It is reset to its default value only following a power-on reset or a system reset. This default value (0 or 1) depends on the device lifecycle, as defined in *Table 78: SBS boot control*.

The device uses HDPL information to automatically isolate code and its associated secrets (like keys) during the boot process. Incrementing HDPL ensures that private code and data for one boot stage cannot be directly accessible from later boot stages.

Note: The use of HDPL in the embedded flash memory is detailed in Section 5: Embedded flash memory (FLASH).

The HDPL value can be set between 0 and 3. When reaching the value 3, the HDPL keeps this value until reset. The current HDPL value is readable in the HDPL bitfield of SBS_HDPLSR register.

Incrementing HDPL

The application must write 0x6A to the INCR_HDPL bitfield in the SBS_HDPLCR register to increment the HDPL by one.

After such increment, and before doing any subsequent action, the application must check if the HDPL has effectively been incremented, by reading SBS_HDPLSR.

10.3.5 SBS boot control

Figure 76 and *Table 78* show how the SBS uses multiple information to define the Cortex-M7 boot address (INITVTOR) and the HDPL before the CPU reset is released.

Figure 76. SBS boot control

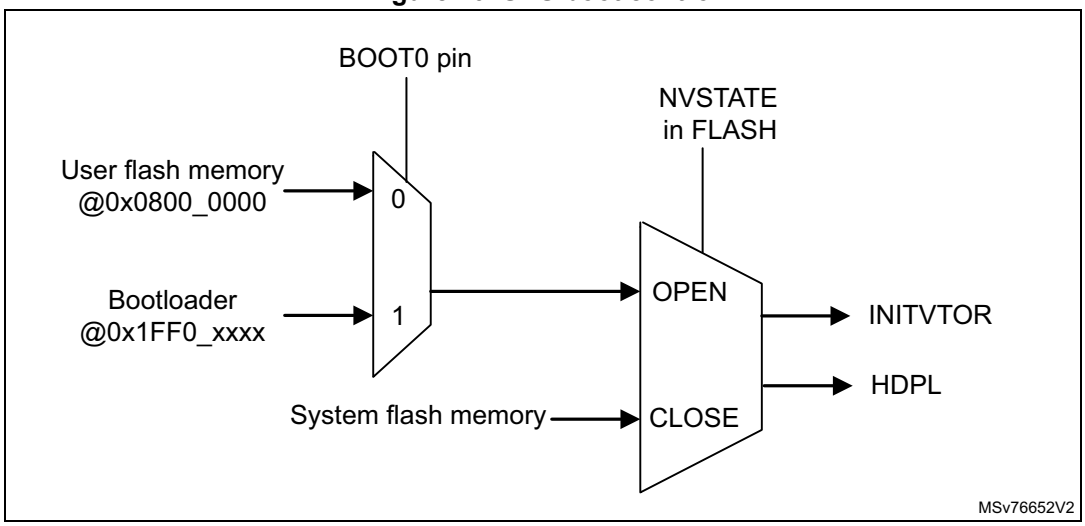


Table 78. SBS boot control

SBS input		SBS output		
NVSTATE (from FLASH)	**BOOT0 pin**	**Boot address**	**INITVTOR(1) (to Cortex-M7)**	**HDPL value in SBS_HDPLSR**
NVOPEN	0	User flash memory	0x0800 0000	1
	1	Bootloader(2)	Defined by ST	1
NVCLOSE	x	System flash memory (ST RSS)		0

1. Readable in SBS_BOOTSR register.
2. Located in the system memory. It is used to reprogram the flash memory by using USART, I2C/I3C, SPI, FDCAN, or USB_OTG in device mode through the DFU (device firmware upgrade).

The BOOT0 value from the external pin is latched when the power-on reset is released or when the device exits standby mode. This pin is in input mode during the complete reset phase, and then switches automatically in analog mode after reset is released.

The NVSTATE value comes from the flash memory interface, following an automatic option-byte load sequence (see *Section 5: Embedded flash memory (FLASH)* for details).

10.3.6 SBS debug management

Device debugging may or may not be allowed, depending on the device life cycle:

- For open devices (NVSTATE = NVOPEN), the debug is always allowed.
- For close devices (NVSTATE = NVCLOSE), the debug is disabled at boot with a policy defined by the option byte DBG_AUTH[7:0] in the FLASH_ROTSR. Possible options are:
  - 0xB4: locked device (no debug, no regression)
  - 0x8A: closed device (no debug).
  - 0x6F: closed device (no debug out of reset), with a possibility for user code executing in HDPL1 to open the debug. This user code can deactivate this debug opening feature by writing DBGCFG_LOCK[7:0] to 0xC3.

For both closed device options a regression option to NVOPEN state is possible using the 128-bit regression password provisioned during the manufacturing phase of the final product. Refer to **Life cycle management** in *Section 5: Embedded flash memory (FLASH)* for details on this opening sequence.

When NVSTATE = 0x51 in FLASH_NVSR the mailbox access port, CM7 access port, and CPU debug interface are locked. In this situation, the debugger cannot access the CPU and no effective debug can be done. Refer to *Section 52: Debug infrastructure* for more details.

Debug opening by OEM immutable RoT code

When DBG_AUTH[7:0] = 0x6F in FLASH_ROTSR and DBGCFG_LOCK[7:0] = 0xB4 in SBS_DBGLOCKR the OEM code executing in HDPL1 can program the opening of the Cortex-M7 access port by writing to the AP_UNLOCK[7:0] bitfield in the SBS_DBGCR register. In the same register it can also program the opening of the CPU debug interface by writing to the DBG_UNLOCK[7:0] bitfield.

Debug re-openings are effective only when the HDPL in the SBS_HDPLSR register has a value equal or superior to the value programmed in DBG_AUTH_HDPL of SBS_DBGCR register. If DBG_AUTH_HDPL bitfield is kept at 0x0, the debug never opens (forbidden value).

At any time, the application via DBGMCU can reset the debug configuration in the SBS_DBGCR register (see *Section 10.5.4: SBS debug control register (SBS_DBGCR)* for details).

10.3.7 SBS voltage booster for I/O analog switches

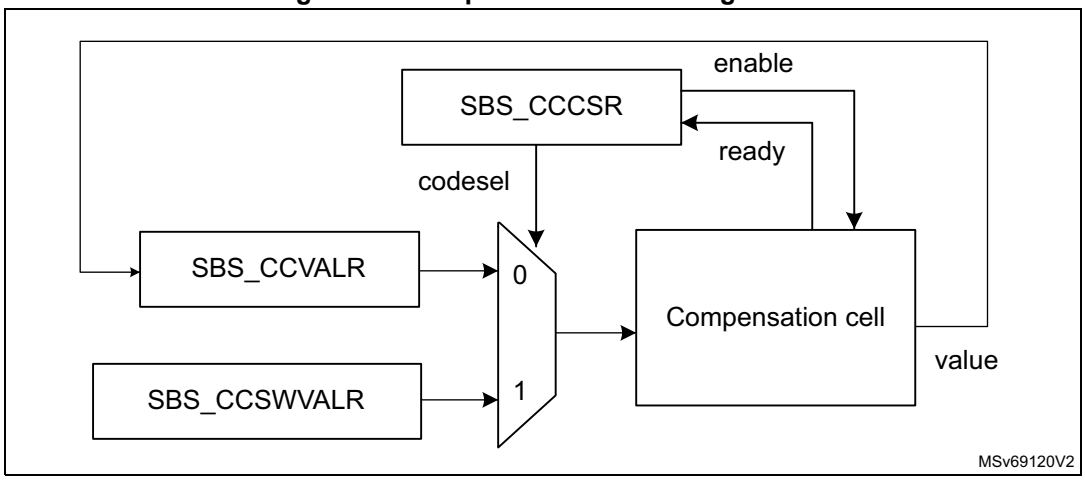
By setting BOOSTEN in the SBS_PMCR register, the application reduces the total harmonic distortion (THD) of the I/O analog switches when the supply voltage is below 2.7 V, to guarantee the same performance as with the full voltage range.

To avoid current consumption due to the booster activation when V_{DDA} < 2.7 V and V_{DD} > 2.7 V, V_{DD} can be selected as supply voltage for the analog switches, by setting BOOSTVDDSEL in the SBS_PMCR register.

In this case, BOOSTEN must be cleared to avoid unexpected power consumption.

Table 79. Analog switches recommended configuration

V_{DDA}	V_{DD}	BOOSTEN	BOOSTVDDSEL	Analog switch supply voltage
≤ 2.7 V	≤ 2.7 V	1	0	Booster
	> 2.7 V	0	1	V_{DD}
> 2.7V		0	0	V_{DDA}



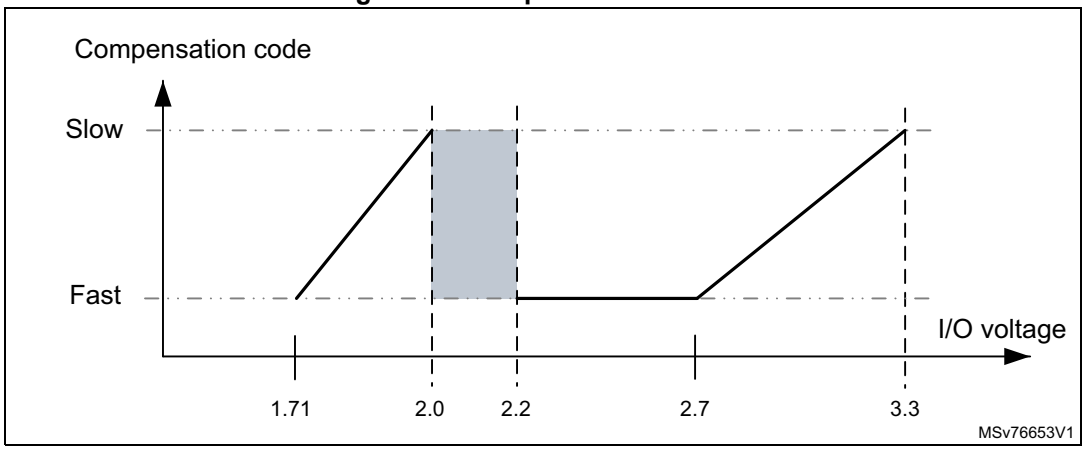
10.3.8 SBS I/O compensation cell management

The I/O compensation cell generates an 8-bit value for the I/O buffer (4 bits for N-MOS and 4 bits for P-MOS), that depends on PVT operating conditions (process, voltage, temperature). These bits are used to control the output impedance in the I/O buffer, and the slew rate of the I/O commutation (the t_{fall} and t_{rise} time), in order to reduce the I/O noise on the power supply.

The CSI is used by the compensation cells and must be enabled before enabling the compensation cells

As shown in *Figure 77*, the compensation cell is split into two blocks: one block to provide an optimal code for the current PVT, and one block to drive the block controlled by the software.

Figure 77. Compensation cell management



The compensation cell value can be read when the READY flag is set in the SBS_CCCSR register. With CODESEL in SBS_CCCSR register, the application can select the value to apply between the two options: the code from the cell or the code from SBS_CCSWVALR.

One compensation cell is embedded in STM32H7Pxxx devices, for the I/O supplied by V_{DD} or V_{DDA} (see *Section 10.3.7*). It is disabled by default, with a fixed code applied to all the I/Os.

Note: The compensation cell can be used only when 2.7 V ≤ V_{DD}/V_{DDA} ≤ 3.6 V or 1.71 V ≤ V_{DD}/V_{DDA} ≤ 2 V (see following figure).

Figure 78. Compensation cell use

10.3.9 SBS registers access control

Some SBS registers can be accessed only if HDPL = 0 in the SBS_HDPLSR register(hence only accessible by the ST RSS code).

Some bitfields in SBS are security critical, reset in non-secure state (coded as 0xB4) or in secure state (any other values). For bitfields reset in non-secure state, when the secure state is selected writing any value but 0xB4, the bitfield is no more writable until a reset occurs.

As a general rule, it is recommended to write 0xC3 to select a secure state and read back 0x6A to acknowledge the write is effective. The following bitfields implement these protections:

- INCR_HDPL
- DBGCFG_LOCK

10.3.10 SBS error management

The SBS does not manage errors.

10.4 SBS interrupts

The SBS does not support interrupts.

10.5 SBS registers

10.5.1 SBS boot status register (SBS_BOOTSR)

Address offset: 0x000

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INITVTOR[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INITVTOR[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **INITVTOR[31:0]**: Initial vector for Cortex-M7
This is the physical boot address used by the Cortex-M7 out of reset

10.5.2 SBS hide protection control register (SBS_HDPLCR)

Address offset: 0x010

Reset value: 0x0000 00B4

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	INCR_HDPL[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **INCR_HDPL[7:0]**: Increment HDPL
Write 0x6A to increment device HDPL by one.
After a write, the register value reverts to its default value (0xB4).

10.5.3 SBS hide protection status register (SBS_HDPLSR)

Address offset: 0x014

Reset value: 0x0000 00XX (see *Section 10.3.5*)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDPL[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **HDPL[7:0]**: Hide protection level
This bitfield returns the current HDPL of the device.
0xB4: HDPL0, corresponding to ST-RSS (default when device is CLOSE)
0x51: HDPL1
0x8A: HDPL2
Others: HDPL3, corresponding to non-boot application

Note: The device nonvolatile state is defined in FLASH_NVSR register of the embedded flash memory.

10.5.4 SBS debug control register (SBS_DBGCR)

Address offset: 0x020

Reset value: 0x0000 0000

Read as zero and write is ignored if HDPL is different from 0 or 1 in SBS_HDPLSR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBG_AUTH_HDPL[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBG_UNLOCK[7:0]								AP_UNLOCK[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **DBG_AUTH_HDPL[7:0]**: Authenticated debug hide protection level
Writing to this bitfield defines at which HDPL the debug opens.
0x51: HDPL1
0x8A: HDPL2
0x6F: HDPL3
Note: Writing any other values is ignored. Reading any other value means the debug opening always fails.

Bits 15:8 **DBG_UNLOCK[7:0]**: Debug unlock
Write 0xB4 to this bitfield to open the debug when HDPL in SBS_HDPLSR equals to DBG_AUTH_HDPL in this register.

Bits 7:0 **AP_UNLOCK[7:0]**: Access port unlock
Write 0xB4 to this bitfield to open the device access port.

10.5.5 SBS debug lock register (SBS_DBGLOCKR)

Address offset: 0x024

Reset value: 0x0000 00B4

This register is reset when sbs_dbgrst is asserted.

Read as zero and write is ignored if HDPL is different from 0 or 1 in SBS_HDPLSR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBGCFG_LOCK[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **DBGCFG_LOCK[7:0]**: Debug configuration lock
Reading this bitfield returns 0x6A if the bitfield value is different from 0xB4.
0xB4: Writes to SBS_DBGCR allowed (default)
Others: Writes to SBS_DBGCR ignored
Note: 0xC3 is the recommended value to lock the debug configuration using this bitfield.

10.5.6 SBS RSS command register (SBS_RSSCMDR)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSSCMD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RSSCMD[15:0]**: RSS command

The application can use this bitfield to pass on a command to the RSS, executed at the next reset.

10.5.7 SBS product mode and configuration register (SBS_PMCR)

Address offset: 0x100

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	BOOSTVDDSEL	BOOSTEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **BOOSTVDDSEL**: Booster V_{DD} selection

This bit selects the analog switch supply voltage, between V_{DD}, V_{DDA} and booster.
To avoid current consumption due to booster activation when V_{DDA} < 2.7 V and V_{DD} > 2.7 V, V_{DD} can be selected as supply voltage for analog switches. In this case, the BOOSTEN bit must be cleared to avoid unwanted power consumption.
When both $V_{DD\ and}$ V_{DDA} are below 2.7 V, the booster is still needed to obtain full AC performances from the I/O analog switches.
0: V_{DDA} selected as analog switch booster voltage supply (when BOOSTEN bit is cleared)
1: V_{DD} selected as analog switch booster voltage supply

Bit 8 **BOOSTEN**: Booster enable

Set this bit to reduce the THD of the analog switches when the supply voltage is below 2.7 V. guaranteeing the same performance as with the full voltage range. To avoid current consumption due to booster activation when V_{DDA} < 2.7 V and V_{DD} > 2.7 V, V_{DD} can be selected as supply voltage for analog switches by setting BOOSTVDDSEL bit in SBS_PMCR. In this case, the BOOSTEN bit must be cleared to avoid unwanted power consumption.
0: Booster disabled
1: Booster enabled

Bits 7:0 Reserved, must be kept at reset value.

10.5.8 SBS FPU interrupt mask register (SBS_FPUIMR)

Address offset: 0x104

Reset value: 0x0000 001F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPU_IE[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **FPU_IE[5:0]**: FPU interrupt enable

Set and cleared by software to enable the Cortex-M7 FPU interrupts
xxxxx1: Invalid operation interrupt enabled (xxxxx0 to disable)
xxxx1x: Divide-by-zero interrupt enabled (xxxx0x to disable)
xxx1xx: Underflow interrupt enabled (xxx0xx to disable)
xx1xxx: Overflow interrupt enabled (xx0xxx to disable)
x1xxxx: Input denormal interrupt enabled (x0xxxx to disable)
1xxxxx: Inexact interrupt enabled (0xxxxx to disable), disabled by default

10.5.9 SBS memory erase status register (SBS_MESR)

Address offset: 0x108

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AXIRMEF	BKPMEF
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **AXIRMEF**: AXISRAM1 memory erase flag

This bit is set by hardware when AXISRAM1 erase is ongoing after a power-on reset or a tamper event (see *Section 43: Tamper and backup registers (TAMP)* for details). This bit is set when the erase is done.
0: Automatic erase of AXISRAM1 memory ongoing
1: Automatic erase of AXISRAM1 memory done

Bit 0 **BKPMEF**: Backup SRAM memory erase flag

This bit is set by hardware when BKPRAM erase is ongoing after a power-on reset or a tamper event (see *Section 43: Tamper and backup registers (TAMP)* for details). This bit is set when the erase is done.
0: Automatic erase of BKPRAM memory ongoing
1: Automatic erase of BKPRAM memory done

10.5.10 SBS I/O compensation cell control and status register (SBS_CCCSR)

Address offset: 0x110

Reset value: 0x0000 0000

For more details on this register, refer to *Section 10.3.7* and *Section 10.3.8*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IOHSLV
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	COMP_RDY	Res.	Res.	Res.	Res.	Res.	Res.	COMP_CODESEL	COMP_EN
							r							rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **IOHSLV**: I/O high speed at low voltage

When this bit is set, the speed of the I/Os is optimized when the device voltage is low.
This bit is active only if VDDIO_HSLV user option bit is set in FLASH. It must be used only if the device supply voltage is below 2.7 V. Setting this bit when V_{DD} is higher than 2.7 V may be destructive.
0: No I/O speed optimization when device voltage is low
1: I/O speed optimized when device voltage is low, if VDDIO_HSLV user option is set (no effect otherwise)

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **COMP_RDY**: Compensation cell ready

This bit provides the status of the compensation cell.
0: I/O compensation cell not ready
1: I/O compensation cell ready. The code value provided by the cell can be used.

Note: The CSI clock is required for the compensation cell to work properly. The compensation cell ready bit (COMP_RDY) is not set if the CSI clock is not enabled.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **COMP_CODESEL**: Compensation cell code selection

This bit selects the code to be applied for the I/O compensation cell.
0: Code from the cell (available in the SBS_CCVALR)
1: Code from the SBS software value register (SBS_CCSWVALR)

Bit 0 **COMP_EN**: Compensation cell enable

Set this bit to enable the compensation cell.
0: Compensation cell disabled
1: Compensation cell enabled

10.5.11 SBS compensation cell for I/Os value register (SBS_CCVALR)

Address offset: 0x114

Reset value: 0x0000 0088

Reset: system reset

For more details on this register, refer to *Section 10.3.8*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PSRC[3:0]				NSRC[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **PSRC[3:0]**: PMOS transistors slew-rate compensation

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the PMOS transistors slew rate in the functional range if COMP_CODESEL = 0 in SBS_CCCSR register.

Bits 3:0 **NSRC[3:0]**: NMOS transistors slew-rate compensation

This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the NMOS transistors slew rate in the functional range if COMP_CODESEL = 0 in SBS_CCCSR register.

10.5.12 SBS compensation cell for I/Os software value register (SBS_CCSWVALR)

Address offset: 0x118

Reset value: 0x0000 0088

For more details on this register, refer to *Section 10.3.8*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SW_PSRC[3:0]				SW_NSRC[3:0]			
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **SW_PSRC[3:0]**: Software PMOS transistors slew-rate compensation

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the PMOS transistors slew rate in the functional range if COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 3:0 **SW_NSRC[3:0]**: Software NMOS transistors slew-rate compensation

This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the NMOS transistors slew rate in the functional range if COMP_CODESEL = 1 in SBS_CCCSR register.

10.5.13 SBS break lock register (SBS_BKLOCKR)

Address offset: 0x120

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARAM1ECC_BL	ARAM2ECC_BL	ARAM3ECC_BL	ARAM4ECC_BL	Res.	Res.	Res.	Res.
								rs	rs	rs	rs				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ITCMECC_BL	DTCMECC_BL	Res.	Res.	Res.	Res.	DCACHEECC_BL	BKRAMECC_BL	CM7LCKUP_BL	Res.	Res.	FLASHECC_BL	PVD_BL	Res.	Res.
	rs	rs					rs	rs	rs			rs	rs		

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **ARAM1ECC_BL**: AXISRAM1 ECC error break lock

Set this bit to enable and lock the connection between AXISRAM1 ECC double error detection flag and break inputs of TIM1/8/15/16/17/20 and HRTIMER1/2 peripherals.
Once set, this bit is cleared only by a system reset.
0: AXISRAM1 ECC double error detection flag disconnected from TIM1/8/5/16/17/20 and HRTIMER1/2 break inputs
1: AXISRAM1 ECC double error detection flag connected to TIM1/8/15/16/17/20 and HRTIMER1/2break inputs

Bit 22 **ARAM2ECC_BL**: AXISRAM2 ECC error break lock

Set this bit to enable and lock the connection between AXISRAM2 ECC double error detection flag and break inputs of TIM1/8/15/16/17/20 and HRTIMER1/2 peripherals.
Once set, this bit is cleared only by a system reset.
0: AXISRAM2 ECC double error detection flag disconnected from TIM1/8/5/16/17/20 and HRTIMER1/2 break inputs
1: AXISRAM2 ECC double error detection flag connected to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

Bit 21 **ARAM3ECC_BL**: AXISRAM3 ECC error break lock

Set this bit to enable and lock the connection between AXISRAM3 ECC double error detection flag and break inputs of TIM1/8/15/16/17/20 and HRTIMER1/2 peripherals.
Once set this bit is cleared only by a system reset.
0: AXISRAM3 ECC double error detection flag disconnected from TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs
1: AXISRAM3 ECC double error detection flag connected to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

Bit 20 **ARAM4ECC_BL**: AXISRAM4 ECC error break lock

Set this bit to enable and lock the connection between AXISRAM4 ECC double error detection flag and break inputs of TIM1/8/15/16/17/20 and HRTIMER1/2 peripherals.
Once set this bit is cleared only by a system reset.
0: AXISRAM4 ECC double error detection flag disconnected from TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs
1: AXISRAM4 ECC double error detection flag connected to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

Bits 19:15 Reserved, must be kept at reset value.

Bit 14 **ITCMECC_BL**: ITCM ECC error break lock

Set this bit to enable and lock the connection between ITCM ECC double error detection flag and break inputs of TIM1/8/15/16/17/20 and HRTIMER1/2 peripherals.

Once set, this bit is cleared only by a system reset.

0: ITCM ECC double error detection flag disconnected from TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

1: ITCM ECC double error detection flag connected to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

Bit 13 **DTCMECC_BL**: DTCM ECC error break lock

Set this bit to enable and lock the connection between DTCM ECC double error detection flag and break inputs of TIM1/8/15/16/17/20 and HRTIMER1/2 peripherals.

Once set, this bit is cleared only by a system reset.

0: DTCM ECC double error detection flag disconnected from TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

1: DTCM ECC double error detection flag connected to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

Note: The DTCM0 and DTCM1 are Or'ed to give DTCMECC

Bits 12:9 Reserved, must be kept at reset value.

Bit 8 **DCACHEECC_BL**: D-Cache ECC error break lock

Set this bit to enable and lock the connection between D-Cache ECC double error detection flag and break inputs of TIM1/8/15/16/17/20 and HRTIMER1/2 peripherals.

Once set, this bit is cleared only by a system reset.

0: D-Cache ECC double error detection flag disconnected from TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

1: Cache ECC double error detection flag connected to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

Bit 7 **BKRAMECC_BL**: Backup RAM ECC error break lock

Set this bit to enable and lock the connection between backup RAM ECC double error detection flag and break inputs of TIM1/8/15/16/17/20 and HRTIMER1/2 peripherals.

Once set, this bit is cleared only by a system reset.

0: Backup RAM ECC double error detection flag disconnected from TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs.

1: Backup RAM ECC double error detection flag connected to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs.

Bit 6 **CM7LCKUP_BL**: Cortex-M7 lockup break lock

Set this bit to enable and lock the connection between the Cortex-M7 lockup (HardFault) output and break inputs of TIM1/8/15/16/17/20 and HRTIMER1/2 peripherals.

Once set, this bit is cleared only by a system reset.

0: Cortex-M7 lockup output disconnected from TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

1: Cortex-M7 lockup output connected to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **FLASHECC_BL**: Flash ECC error break lock

Set this bit to enable and lock the connection between embedded flash memory ECC double error detection flag and break inputs of TIM1/8/15/16/17/20 and HRTIMER1/2 peripherals.

Once set, this bit is cleared only by a system reset.

0: FLASH ECC double error detection flag disconnected from TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

1: FLASH ECC double error detection flag connected to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs

Bit 2 **PVD_BL**: PVD break lock

This bit is set by software and cleared only by a system reset. it can be used to enable and lock the connection to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs as well as the PVDE and PLS[2:0] bitfields in the PWR_CR1 register.

Once set, this bit is cleared only by a system reset.

0: PVD interrupt disconnected from TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs. PVDE and PLS[2:0] bitfields can be programmed by the application.

1: PVD output connected to TIM1/8/15/16/17/20 and HRTIMER1/2 break inputs. PVDE and PLS[2:0] bits are read only.

Bits 1:0 Reserved, must be kept at reset value.

10.5.14 SBS external interrupt configuration register x (SBS_EXTICRx)

Address offset: 0x130 + 0x4 * (x-1), (x = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PC_EXTI{(x-1) * 4 + 3}				PC_EXTI{(x-1) * 4 + 2}				PC_EXTI{(x-1) * 4 + 1}				PC_EXTI{(x-1) * 4}			
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **PC_EXTI{(x-1) * 4 + 3}**: Port configuration for EXTI{(x-1) * 4 + 3}

This bitfield selects the source input to the EXTI input {(x-1) * 4 + 3} used for external interrupt/event detection.

0x0: PA{(x-1)*4+3} pin
0x1: PB{(x-1)*4+3} pin
0x2: PC{(x-1)*4+3} pin
0x3: PD{(x-1)*4+3} pin
0x4: PE{(x-1)*4+3} pin
0x5: PF{(x-1)*4+3} pin
0x6: PG{(x-1)*4+3} pin
0x7: PH{(x-1)*4+3} pin
0x8: PI{(x-1)*4+3} pin
Others: reserved

Bits 11:8 **PC_EXTI{(x-1) * 4 + 2}**: Port configuration for EXTI{(x-1) * 4 + 2}

This bitfield selects the source input to the EXTI input {(x-1) * 4 + 2} used for external interrupt/event detection.

0x0: PA{(x-1)*4+2} pin
0x1: PB{(x-1)*4+2} pin
0x2: PC{(x-1)*4+2} pin
0x3: PD{(x-1)*4+2} pin
0x4: PE{(x-1)*4+2} pin
0x5: PF{(x-1)*4+2} pin

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

11 Peripheral interconnect

11.1 Introduction

Several peripherals have direct connections between them. This allows autonomous communication and/or synchronization between peripherals, saving CPU resources, thus power supply consumption.

In addition, these hardware connections remove software latency and allow the design of a predictable system.

Depending on peripherals, these interconnections can operate in various power modes: Run, Sleep, or Stop modes.

11.2 Connection summary

Table 81. Peripheral interconnect matrix (1)

Source	Destination

11.3 Interconnection details

11.3.1 Master to slave interconnection for timers

From timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM9/TIM12/TIM15/TIM16/TIM17/TIM20/HRTIM1/HRTIM2) to timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM9/TIM12/TIM15/TIM16/TIM17/TIM20/HRTIM1/HRTIM2)

Purpose

The timers are linked together internally for timer synchronization or chaining.

When one timer is configured in master mode, it can reset, start, stop, or clock the counter of another timer configured in slave mode.

Timer synchronization

The synchronization modes are detailed in:

- *Section 34.3.35: Timer synchronization* for advanced-control timers TIM1/TIM8/TIM20
- *Section 35.4.27: Timer synchronization* for general-purpose timers TIM2/TIM3/TIM4/TIM5
- *Section 37.4.21: Timer synchronization (TIM9/TIM12 only)* for the general-purpose timers TIM9/TIM12
- *Section 38.4.33: Timer synchronization (TIM15 only)* for the general-purpose timer TIM15

Triggering signals

The output (from master) is on signal tim*x*_trgo for TIM1-9/12/15/20 as well as tim*x*_trgo2 for TIM1/8/20. In the case of TIM10/11/13/14/16/17, the output is on signal tim*x*_oc1. On HRTIM1/2, the output is hrtim*x*_out_sync2

The input (to slave) is on signals tim*x*_itr0-22 of TIM1-9/12/15/20, and hrtim*x*_eev1-16 of HRTIM1/2.

The possible master/slave connections are given in:

- *Table 373: Internal trigger connection* for advanced-control timers TIM1/TIM8/TIM20
- *Table 399: TIMx internal trigger connection* for the general-purpose timers TIM2/TIM3/TIM4/TIM5
- *Table 423: TIMx internal trigger connection* for general-purpose timers TIM9/TIM12
- *Table 435: TIMx internal trigger connection* for general-purpose timer TIM15
- Section 3.3.2: HRTIM pins and internal signals

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 388: Effect of low-power modes on TIM1/TIM8/TIM20*
- *Table 416: Effect of low-power modes on TIM6/TIM7*
- *Table 409: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 425: Effect of low-power modes on TIM9/TIM10/TIM11/TIM12/TIM13/TIM14*
- *Table 446: Effect of low-power modes on TIM15/TIM16/TIM17*

11.3.2 Triggers to ADCs

From EXTI, timers TIM1/TIM2/TIM3/TIM4/TIM6/TIM9/TIM12/TIM15/TIM20, low-power timer LPTIM1, and HR timers HRTIM1/HRTIM2, to ADC1/2 and ADC3/4

Purpose

An analog to digital conversion, or sequence of conversions, can be triggered by a timer output capture or trigger, or an external event via an EXTI pin. For more details, see *Section 25.4.21: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)*.

Triggering signals

Triggers are on ADC inputs adc_ext0-31_trg for regular channels, and adc_jext0-31_trg for injected channels.

The trigger sources are:

- tim*x*_oc1-4 for TIM1-4/8/16/17/20
- tim*x*_trgo/trgo2 for TIM1-4/6-9/12/15/20
- hrtim*x*_adc_trg1-6 for HRTIM1/2
- lptim1_ch1/2 for LPTIM1
- EXTI11/EXTI2/EXTI15/EXTI3

See *Table 241: ADC1/2/3/4 interconnection* for details.

Active power mode

This interconnection is active in Run and Sleep modes for all ADCs. The timers are active in Run and Sleep mode only. The effects of low-power modes are given in:

- *Table 388: Effect of low-power modes on TIM1/TIM8/TIM20*
- *Table 409: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 425: Effect of low-power modes on TIM9/TIM10/TIM11/TIM12/TIM13/TIM14*

11.3.3 ADC analog watchdogs as triggers to timers

From ADC1/ADC2/ADC3/ADC4 to TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM20 and HRTIM1/HRTIM2

Purpose

The internal analog watchdog output signals coming from ADC1-4, are connected to on-chip timers. ADC1-4 can provide trigger event through analog watchdog signals to advanced-control timers TIM1-5/TIM8/TIM20 and to high-resolution timers HRTIM1/2 in order to reset, start, stop, or clock the counter.

For details on how to configure the external triggers on the timers, refer to:

- *Section 34.3.6: External trigger input* (TIM1/8/20)
- *Section 35.4.5: External trigger input* (TIM2/3/4/5)
- *Section 33.3.8: External events global conditioning* (HRTIM1/2)

For details of the analog watchdog configuration in the A-to-D converters, see:

- *Section 25.4.31: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)*

Triggering signals

The output from the ADC is on signals adc*x*_awd1-3. The input to timer TIM*x* is on signals tim*x*_etr17-22 (external trigger). The input to high-resolution timer HRTIM*x* is on signals hrtim*x*_eev1-16.

See *Table 374: Interconnect to the tim_etr input multiplexer* for the ADC analog watchdog connections to TIM1/8/20.

See *Table 400: Interconnect to the tim_etr input multiplexer* for the ADC analog watchdog connections to TIM2/3/4/5.

See *Table 326: HRTIM1/HRTIM2 external events mapping and associated features* for the ADC analog watchdog connections to HRTIM1/2.

Active power mode

ADC1-4 and timers are active in Run and Sleep modes.

11.3.4 Comparator outputs to timers

From COMP1-8 to TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM9/TIM10/TIM11/TIM12/TIM13/TIM14/TIM15/TIM16/TIM17/TIM20 and HRTIM1/HRTIM2

Purpose

The comparator output signals coming from COMP1-8 are connected to:

- Input capture inputs on the timers. This allows the timer counter value to be captured at the moment the comparator output transitions.
- Timer triggers. This allows the timer counter to be started or stopped on the comparator transitions.
- PWM timer TIM1/TIM8/TIM15/TIM16/TIM17/TIM20 break inputs and HRTIM1/HRTIM2 fault inputs, to halt their respective PWM outputs in a safe state in case a fault condition is detected by the comparators (for example, voltage/current out of range).

The comparator outputs programming is described in:

- *Section 29.4: COMP functional description*

The timer input capture programming is described in:

- *Section 34.3.9: Input capture mode* (TIM1/8/20)
- *Section 35.4.8: Input capture mode* (TIM2/3/4/5)
- *Section 37.4.7: Input capture mode* (TIM9-14)
- *Section 38.4.8: Input capture mode* (TIM15-17)
- *Section 33.3.4: Timer A..F timing units* (HRTIM1/2)

The timer external trigger configuration is described in:

- *Section 34.3.6: External trigger input* (TIM1/8/20)
- *Section 35.4.5: External trigger input* (TIM2/3/4/5)
- *Section 33.3.8: External events global conditioning* (HRTIM1/2)

The timer break/fault input configuration is described in:

- *Section 34.3.19: Using the break function* (TIM1/8/20)
- *Section 38.4.17: Using the break function* (TIM15-17)

Triggering signals

The comparator outputs are comp*x*_out.

The timer inputs are:

- tim*x*_ti1/2 for input capture
- tim*x*_etr for trigger
- tim*x*_break/break2 for PWM “break”

The high-resolution timer inputs are:

- hrtim*x*_eev1-16 for trigger
- hrtim*x*_in_flt1-8 for PWM “break”

See *Table 369: Interconnect to the tim_ti1 input multiplexer* for the comparator connections to TIM1/8/20 input capture.

See *Table 395: Interconnect to the tim_ti1 input multiplexer* and *Table 396: Interconnect to the tim_ti2 input multiplexer* for the comparator connections to TIM2/3/4/5 input capture.

See *Table 421: Interconnect to the tim_ti1 input multiplexer* and *Table 422: Interconnect to the tim_ti2 input multiplexer* for the comparator connections to TIM9-14 input capture.

See *Table 433: Interconnect to the tim_ti1 input multiplexer* and *Table 434: Interconnect to the tim_ti2 input multiplexer* for the comparator connections to TIM15-17 input capture.

See *Table 374: Interconnect to the tim_etr input multiplexer* for the comparator connections to TIM1/8/20 triggers.

See *Table 400: Interconnect to the tim_etr input multiplexer* for the comparator connections to TIM2/3/4/5 triggers.

See *Table 326: HRTIM1/HRTIM2 external events mapping and associated features* for the comparator connections to HRTIM1/2 input capture and triggers.

See *Table 375: Interconnect to the tim_brk_cmp multiplexer* and *Table 376: Timer break2 interconnect* for the comparator connections to TIM1/8/20 break inputs.

See *Table 436: Timer break interconnect* for the comparator connections to TIM15-17 break inputs.

Active power mode

COMP1-8 are active in Run, Sleep, and Stop (SVOS high) modes. Timers are active in Run and sleep modes.

11.3.5 HSP break to PWM timers

Break signals from HSP to PWM timers TIM1/TIM8/TIM15/TIM16/TIM17/TIM20 and HRTIM1/HRTIM2

Purpose

When the HSP stalls due to an error or in debug mode, the PWM timers can optionally be halted in safe state to avoid damage to the driver MOSFETs.

See *Section 34.3.19: Using the break function* for details of the break function in the PWM timers (TIM1/TIM8/TIM20).

See *Section 33.3.17: Fault protection* for details of the break function on the high-resolution timers (HRTIM1/HRTIM2). Note that the HSP break input is combined with the system fault input, and enabled via a programmable bit in the HRTIM option register.

See *Section 20.4.19: Break interface (BKITF)* for details of the HSP break feature.

Triggering signals

The HSP outputs are hsp_brk_out0/1/2/3. See *Table 139: HSP break connections on STM32H7Power* for the connections to the timers.

The PWM timer inputs are tim*x*_break/break2.

The high-resolution timer input is hrtim_sys_flt.

11.3.6 Triggers on ADF1

From EXTI to ADF1

Purpose

EXTI (EXTI15) can be used to generate a triggering event on ADF1 module and start an A-to-D conversion.

A description is given in:

- *Section 25.4.2: ADC pins and internal signals*
- *Section 30.4.9: Start-up sequence examples*

Triggering signals

The adf_trgi trigger input is the triggering input signal. The ADF trigger inputs connections are detailed in:

- *Table 294: ADF trigger connections*

Active power mode

This interconnection remains active down to Stop (SVOS high) for ADF1, assuming the trigger source remains active.

11.3.7 Internal input and clock sources to timers

From HSE, LSE, HSI, LSI, CSI, and MCO to TIM (TIM9/TIM12/TIM15/TIM16/TIM17) and LP timers (LPTIM1/LPTIM2/LPTIM3/LPTIM4/LPTIM5)

Purpose

A number of clock sources are connected to timer inputs to allow calibration of low accuracy sources against high accuracy clocks, and monitoring of external clock sources.

- HSI/1024 (HSI clock frequency divided by 1024) is connected to general-purpose timers TIM12 and TIM15 inputs, for calibrating the HSI oscillator frequency.
- HSE is connected to general-purpose timer TIM17 input, for monitoring the external crystal oscillator.
- LSE is connected to general-purpose timers TIM15 and TIM16 inputs, and as an external trigger on TIM2. This allows the external LSE crystal oscillator to be monitored, and also used to trigger a timer at the LSE frequency.
- LSI is connected to general-purpose timer TIM16 input, for calibrating the LSI oscillator frequency.
- The microcontroller output clock (MCO1/2) is connected as external input to general-purpose timers TIM9, TIM12, TIM15, and TIM17.
- LSI and LSE are connected to LPTIM1 inputs.
- HSI/1024 and CSI/128 are connected to LPTIM2 inputs.

Triggering signals

The TIM12/TIM15 inputs connected to the HSI/1024 are tim*x*_ti1_in4.

The HSE clock is connected to tim17_ti1_in2.

The LSE is connected to tim15_ti1_in10 and tim16_ti1_in3.

The LSI is connected to tim16_ti1_in2.

HSI/1024 is also connected to lptim2_ic2_mux1.

CSI/1024 is connected to lptim2_ic2_mux2.

LSE is connected to lptim1_ic2_mux2.

LSI is connected to lptim1_ic2_mux1.

See *Table 421: Interconnect to the tim_ti1 input multiplexer* for the TIM9/12 input connections.

See *Table 433: Interconnect to the tim_ti1 input multiplexer* for the TIM15/16/17 input connections.

See *Table 461: LPTIM1 input capture 2 connections* and *Table 462: LPTIM2 input capture 2 connections* for the LPTIM1/2 input connections.

Active power mode

This feature is available under Run and Sleep modes.

11.3.8 Triggers to low-power timers

From TAMP and RTC alarm to LP timers (LPTIM1/LPTIM2)

Purpose

LPTIM1/LPTIM2 counters may be started either by an active edge on one of the eight trigger inputs. This trigger feature is described in *Section 39.4.7: Trigger multiplexer* and the following sections.

Triggering signals

The input selection is described in *Table 457: LPTIM1/2/3/4/5 external trigger connections*.

Active power mode

This interconnection remains active down to Stop mode.

11.3.9 RTC wake-up as inputs to timers

From RTC to timers (TIM16)

Purpose

RTC wake-up interrupt can be used as input to general-purpose timer TIM16.

Triggering signals

RTC wake-up signal is connected to TIM16 tim_ti1_in4 signal as described in *Table 369: Interconnect to the tim_ti1 input multiplexer*.

Active power mode

This interconnection is active down to Stop. Timers are not active but the count is performed at wake-up.

11.3.10 OTG_FS SOF as trigger to timers

From OTG_HS to TIM2/TIM3/TIM4/TIM5/TIM9/TIM12

Purpose

OTG_HS SOF (start-of-frame) can generate triggers to the general-purpose timers TIM2/TIM3/TIM4/TIM5.

It can also generate triggers to the input capture inputs of TIM9/12.

This can be used, for example, to monitor and track audio packets received over the USB link.

Triggering signals

The otg_fs_sof is connected to tim_itr19 input of TIM2/TIM5, as well as tim_etr20 input of TIM2/TIM3/TIM4/TIM5, and the tim_ti1 inputs of TIM9/TIM12.

The connections to TIM2-5 are described in *Table 399: TIMx internal trigger connection* and *Table 400: Interconnect to the tim_etr input multiplexer*.

The connections to TIM9 and TIM12 are described in *Table 421: Interconnect to the tim_ti1 input multiplexer*.

Active power mode

This interconnection is active in Run and Sleep modes.

11.3.11 System errors as break signals to timers

The following system-level errors can trigger a break event in TIM1/TIM8/TIM15/TIM16/TIM17/TIM20 and HRTIM1/HRTIM2:

- Cortex-M7 lockup
- PVD low threshold
- CSS
- Double ECC errors in AXISRAM1-4, ITCM, DTCM, data cache, backup RAM, and flash memory.

Purpose

The purpose of the break event is to disable the timer outputs to protect the power transistors they control.

Triggering signals

The system level errors are connected to the tim_sys_brk0-5 inputs on TIM1/8/15-17/20. On HRTIM1/2, they are combined and connected to hrtim_sys_flt.

Active power mode

Timers are optionally active in Run and Sleep modes. System errors apply in RUN and Sleep modes.

11.3.12 Triggers to GPDMA/HPDMA

From EXTI, RTC, timers (TIM1/TIM2/TIM3/TIM4/TIM5/TIM6/TIM7/TIM9/TIM12/TIM15), LP timers (LPTIM1/LPTIM2/LPTIM3/LPTIM4/LPTIM5), HSP, HPDMA1/GPDMA1, SPI6, LPUART to HPDMA1/GPDMA1

Purpose

A HP/GPDMA trigger can be assigned to a HP/GPDMA channel x. A programmed HP/GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event. The trigger mode can also be programmed to condition the LLI link transfer. More details are given in the sections below:

- *Section 13.3.6: GPDMA triggers* and *Section 12.3.6: HPDMA triggers*
- *Section 13.4.13: GPDMA triggered transfer* and *Section 12.4.13: HPDMA triggered transfer*

Triggering signals

The input triggers to the HPDMA and GPDMA are connected to the following signals:

- tim_trgo/trgo2 of TIM1/8/20
- tim_trgo of TIM2-7/9/12/15
- hsp1_trgo0-3 of HSP
- lptim_ch1/2 of LPTIM1-3
- lptim_out of LPTIM4/5
- exti0_wkup
- rtc_wkup
- lpuart_it
- spi6_it
- gpdma/hpdma_ch0-15_tc

GPDMA trigger mapping is specified in *Table 99: Programmed GPDMA1 trigger*, according to GPDMA_CxTR2.TRIGSEL[5:0].

HPDMA trigger mapping is specified in *Table 87: Programmed HPDMA1 trigger*, according to HPDMA_CxTR2.TRIGSEL[5:0].

Active power mode

Assuming sources are active in Stop modes, this interconnection remains functional in Stop.

Refer to:

- *Section 13.6: GPDMA in low-power modes*
- *Section 12.6: HPDMA in low-power modes*

11.3.13 Internal analog signals to analog peripherals

From internal analog source to ADC (ADC1/ADC2/ADC3/ADC4)

Purpose

The internal reference voltage (V_{REFINT}) is connected to ADC1/ADC2/ADC3/ADC4, mainly for safety reasons, to check if the ADC is still working. The internal temperature sensor (V_{SENSE}) monitoring channel is connected to ADC1. The internal digital core voltage (V_{CORE}) is connected to ADC3 for monitoring the core power supply. V_{BAT} is divided by four and connected to ADC1 for monitoring the back-up battery voltage. For more information refer to:

- *Section 25.4.35: Temperature sensor*
- *Section 25.4.36: VBAT supply monitoring*
- *Section 25.4.37: Monitoring the internal voltage reference*
- *Section 25.4.39: Monitoring the supply voltage*

Active power mode

These interconnections remain in Stop modes if the selected peripheral is kept active. Refer to *Section 25.5: ADC interrupts*.

11.3.14 ADC data filtering by the ADF1

From ADC1/ADC2 to ADF1

Purpose

ADC samples can be directly passed to the ADF for filtering, without the need for GP/HPDMA or software intervention.

See *Section 25.4.29: Managing conversions using the ADF*.

Triggering signals

See *Table 241: ADC1/2/3/4 interconnection*.

Active power mode

This feature is available in Run and Sleep mode.

11.3.15 Internal tamper sources

From internal peripherals, clocks or monitoring to tamper.

Purpose

Critical parameters, such as oscillator frequencies, power supply voltages, or on-chip temperature can be monitored and generate tamper events if out-of-specification values are detected. Tamper events can also be generated on system fault (for example, memory error) or unexpected debug activation.

A list of internal tamper sources can be found in *Table 134. TAMP interconnection*.

Active power mode

This interconnection is active in all power modes if the tamper source is activated.

11.3.16 Output from tamper to RTC

From TAMP to RTC

Purpose

The RTC can timestamp a tamper event in order to retrieve history in time of such detection. The RTC can also control GPIOs and set a signal based on tamp or alarm status outside the MCU.

Refer to *Section 43.3.3: GPIOs controlled by the RTC and TAMP* for more details.

Active power mode

This interconnection remains active in all power modes.

11.3.17 I3C in-band interrupt acknowledge to timers

From I3C to TIM10/TIM13

Purpose

When the I3C generates an in-band interrupt acknowledge, the timer counter value is captured in order to obtain a timestamp for I3C IBI sampled data.

Refer to *Section 45.9.14: I3C IBI transfer, as controller/target*.

Active power mode

This interconnection is active in Run and Sleep modes.

11.3.18 NPU input triggers

From TIM, HSP and HPDMA/GPDMA to NPU

Purpose

The NPU processing can be triggered by:

- TIM6 basic timer output trigger.
- HSP as part of a handshake with the NPU interrupt 3 output (npu_rdy).
- HPDMA or GPDMA channel 15 transfer complete trigger.

Triggering signals

TIM6 output trigger: tim6_trgo

HSP output triggers: hsp1_trgi5 - see *Table 138: HSP trigger output connections for STM32H7Power*.

HP/GPDMA transfer complete trigger: hp/gpdma1_ch15_tc

Active power mode

This interconnection is active in Run and Sleep modes.

11.3.19 HSP input triggers

Trigger signals from: Timers; NPU; ADF sound activity detector (SAD); GPDMA/HPDMA transfer complete (TC); EXTI0.

Purpose

The HSP processing can be triggered by the following events, in addition to software:

- Timer output triggers from TIM1/TIM2/TIM3/TIM6/TIM7/TIM8/TIM15
- NPU ready status on the npu_rdy signal (host interrupt #3). This signals to the HSP that the NPU is busy, or ready to read a batch of data from the HSP memory (SRAM3). The HSP acknowledges the latter by raising an hsp1_gpo output, upon which the NPU starts the transfer.
- ADF sound activity detection (SAD) signal, which goes active to prepare the HSP to receive and process audio samples. Refer to section *Section 30.4.4: ADC slave interface (ADCITF)*.
- HPDMA/GPDMA transfer complete events. These indicate that a transfer has completed on the associated DMA channel. If the DMA channel is used to transfer data to or from the HSP, the transfer complete event can trigger processing of the transferred data, or some other activity in the HSP.
- External event/interrupt. EXTI0 can be used to trigger HSP activity on an asynchronous external event.

The HSP input trigger behavior is described in *Section 20.4.9: Trigger input interface (TRGITF)*.

Triggering signals

See *Table 137: HSP trigger input connections for STM32H7Power* for the list of signals connected to HSP input triggers.

Active power mode

The HSP can be active in Run and Sleep modes.

12 High-performance direct memory access controller (HPDMA)

12.1 HPDMA introduction

The high-performance direct memory access (HPDMA) controller is a bus master and system peripheral.

The HPDMA is used to perform programmable data transfers between memory-mapped peripherals, and/or memories via linked-lists, upon the control of an off-loaded CPU.

12.2 HPDMA main features

- Single bidirectional 64-bit AXI master and single bidirectional 32-bit AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half-transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent HPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 12.3.1*)
  - Intra-channel HPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level and byte-based padding
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at block level, between successive burst transfers
  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block,

combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 12.3.1*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Selection of programmable HPDMA request and trigger
  - Generation of programmable HPDMA half-transfer and transfer-complete event
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the HPDMA linked-list control registers
  - Channel abort and restart
  - Channel terminate with FIFO draining
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- Privileged/unprivileged support:
  - Support for privileged and unprivileged HPDMA transfers, independently at channel level
  - Privileged-aware AHB slave port

12.3 HPDMA implementation

12.3.1 HPDMA channels

A given HPDMA channel x is implemented with the following features and intended use.

To make the best use of the HPDMA performance, the following table lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested HPDMA transfer.

Table 82. Implementation of HPDMA1 channels

Channel x	Hardware parameters		Features
	dma_fifo_size[x]	dma_addressing[x]	
x = 0 to 11	3	0	Channel x (x = 0 to 11) is implemented with: – a FIFO of 16 bytes, 4 words, 2 double-words – fixed/contiguously incremented addressing These channels can be used for HPDMA transfers between an APB or AHB peripheral, an AHB/AXI SRAM, or CPU TCM.
x = 12 to 15	5	1	Channel x (x = 12 to 15) is implemented with: – a FIFO of 64 bytes, 8 double-words – 2D addressing These channels can be also used for HPDMA transfers, including AXI external memories.

12.3.2 HPDMA in low-power modes

The HPDMA wake-up feature is implemented in the device low-power modes as per the table below.

Table 83. HPDMA1 in low-power modes

Feature	Low-power modes
Wake-up	HPDMA1 in Sleep mode

12.3.3 HPDMA requests

An HPDMA request from a peripheral can be assigned to a HPDMA channel x, via REQSEL[7:0] in HPDMA_CxTR2, provided that SWREQ = 0.

The HPDMA requests mapping is specified in the table below.

Table 84. Programmed HPDMA1 request

12.3.4 HPDMA block requests

Some HPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in HPDMA_CxTR2 must be set for a correct HPDMA execution of the requested peripheral transfer at the hardware level.

Table 85. Programmed HPDMA1 request as a block request

HPDMA block requests
lptim1_ue_dma
lptim2_ue_dma
lptim3_ue_dma

12.3.5 HPDMA channels with peripheral early termination

An HPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 86. HPDMA1 channel with peripheral early termination

HPDMA channel x with peripheral early termination
x = 0, x = 1, and x = 15

This HPDMA support is activated when the channel x is programmed with HPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before the HPDMA has transferred the whole block (see *Section 12.4.15* for more details).

12.3.6 HPDMA triggers

An HPDMA trigger can be assigned to an HPDMA channel x, via TRIGSEL[**5**:0] in HPDMA_CXTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

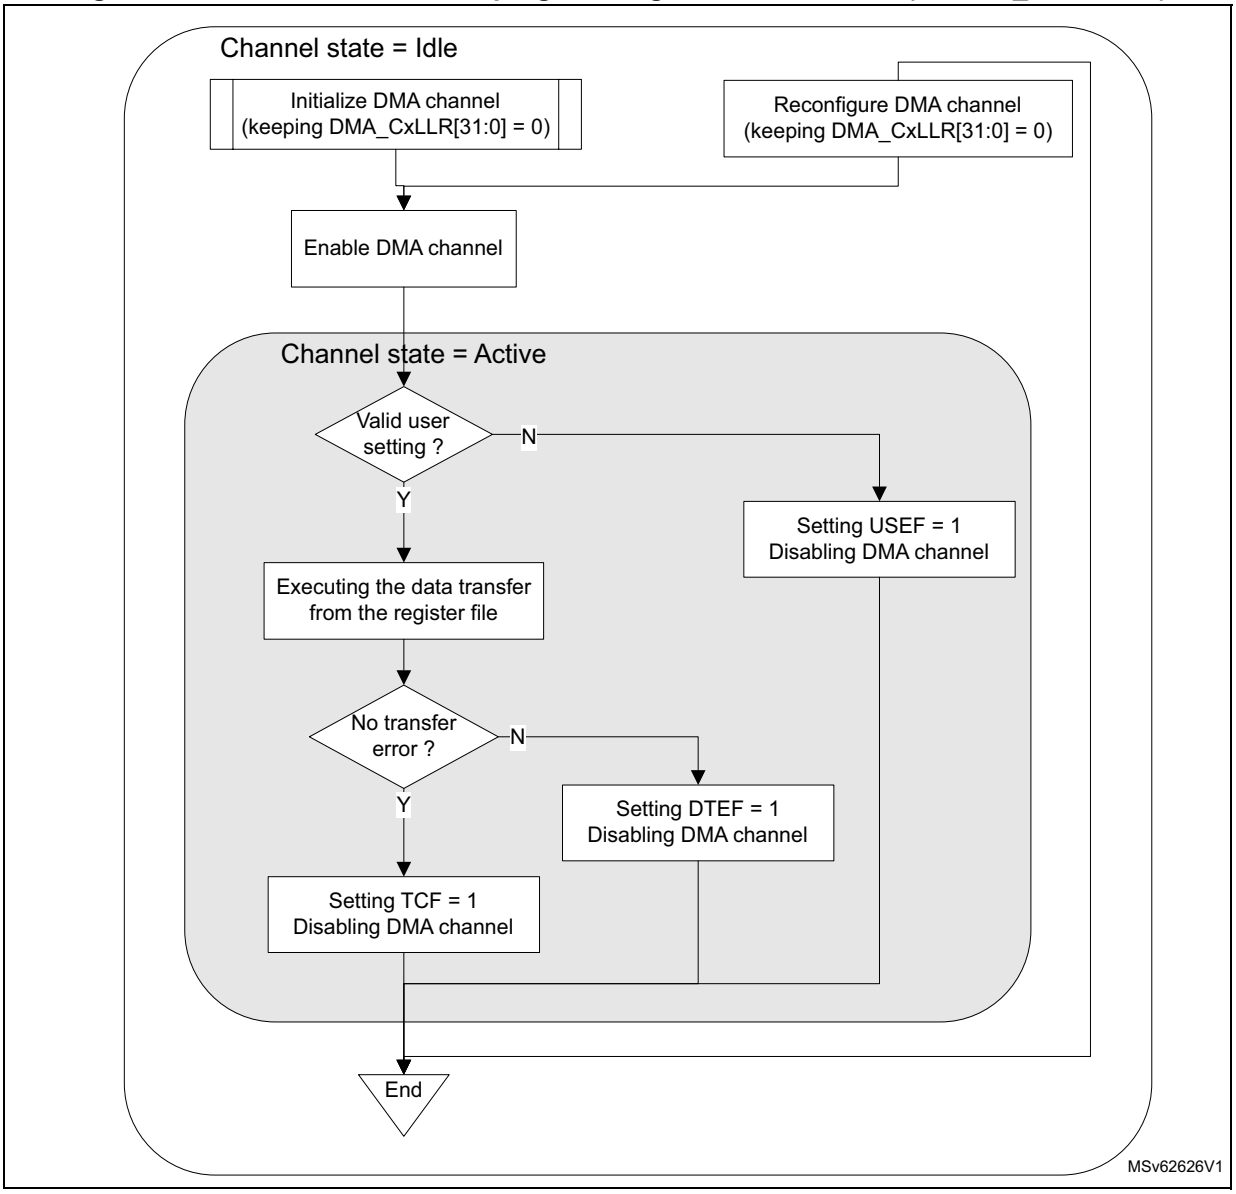
12.4 HPDMA functional description

12.4.1 HPDMA block diagram

Figure 79. HPDMA block diagram



12.4.2 HPDMA channel state and direct programming without any linked-list

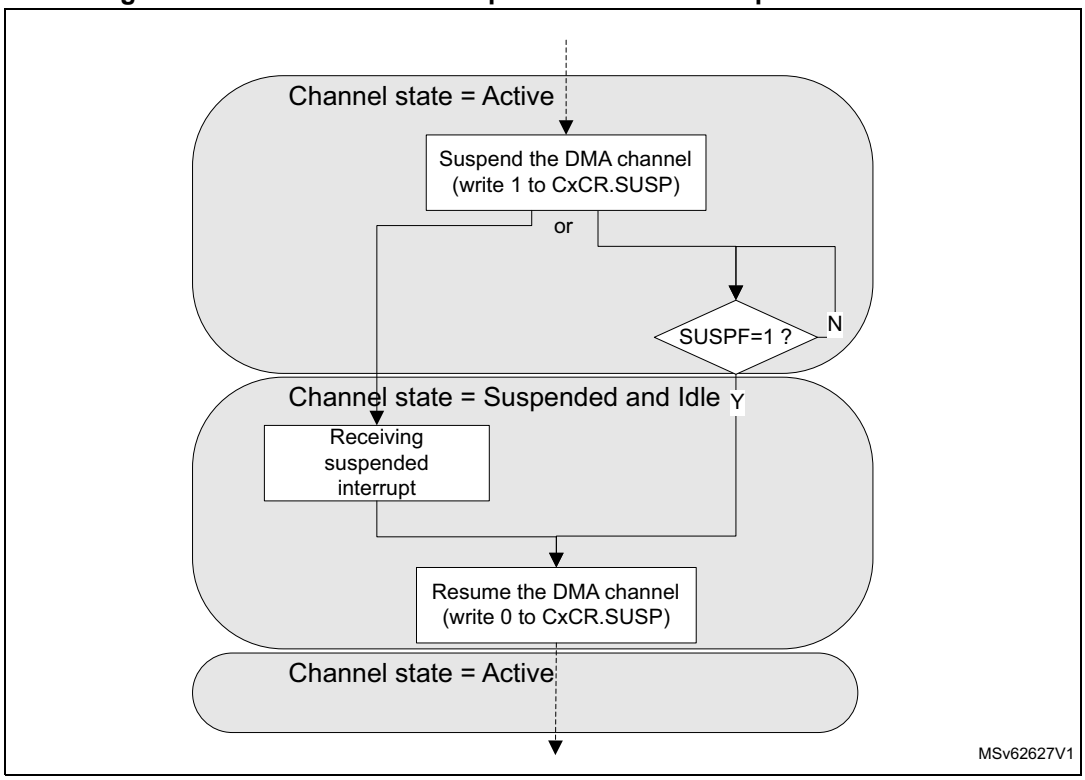
After an HPDMA reset, an HPDMA channel x is in idle state. When the software writes 1 into the HPDMA_CxCR.EN enable control bit, the channel takes into account the value of the different channel configuration registers (HPDMA_CxXXX), switches to the active/non-idle state, and starts to execute the corresponding requested data transfers.

After enabling/starting an HPDMA channel transfer by writing 1 into HPDMA_CxCR.EN, an HPDMA channel interrupt on a complete transfer notifies the software that the HPDMA channel is back in idle state (EN is then deasserted by hardware), and that the channel is ready to be reconfigured then enabled again.

The figure below illustrates this HPDMA direct programming without any linked-list (HPDMA_CxLLR = 0).

Figure 80. HPDMA channel direct programming without linked-list (HPDMA_CxLLR = 0)

12.4.3 HPDMA channel suspend and resume



The software can suspend on its own a channel still active, with the following sequence:

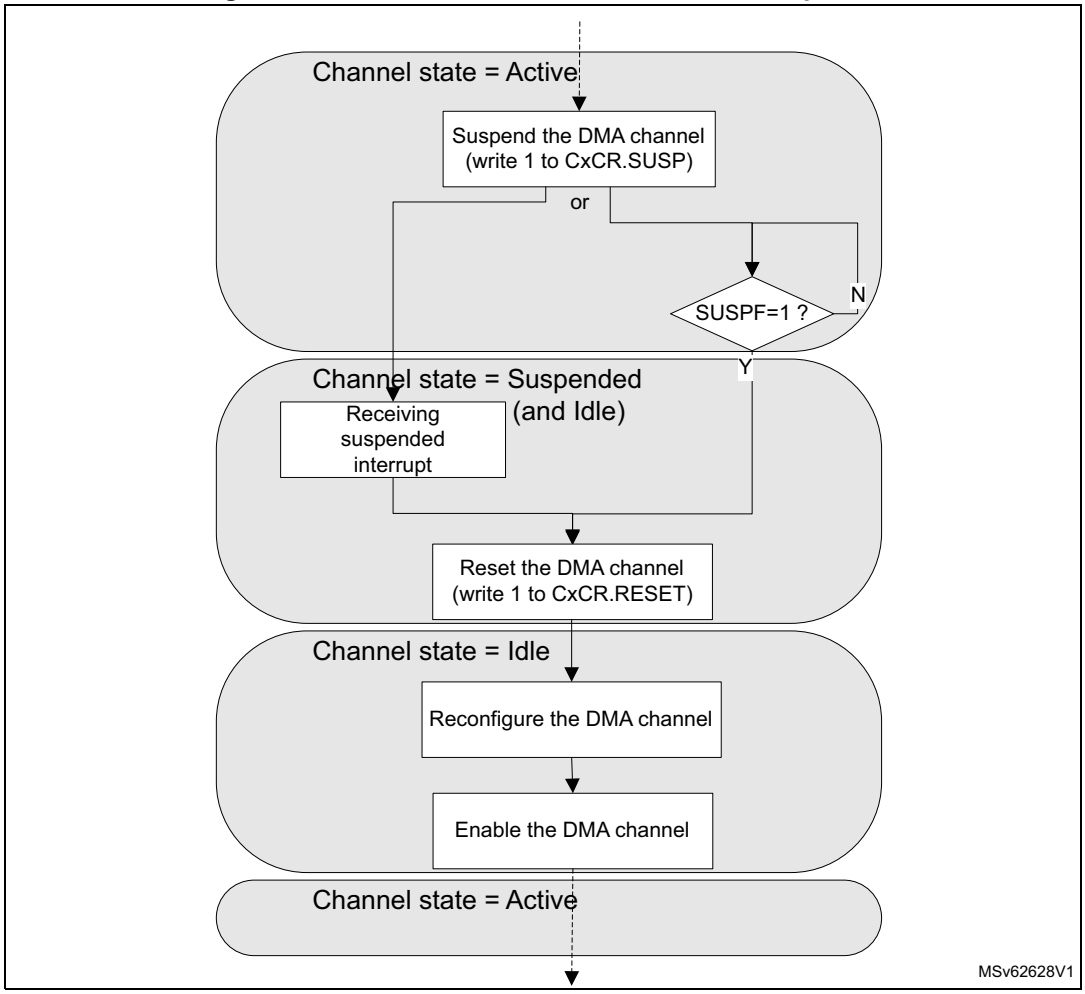
1. The software writes 1 into the HPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag HPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to HPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing HPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or bitfield that is hardware modifiable.

Note: An ongoing HPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to HPDMACxCR.SUSP.

Figure 81. HPDMA channel suspend and resume sequence

Note: A suspend and resume sequence does not impact the HPDMA_*CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.*



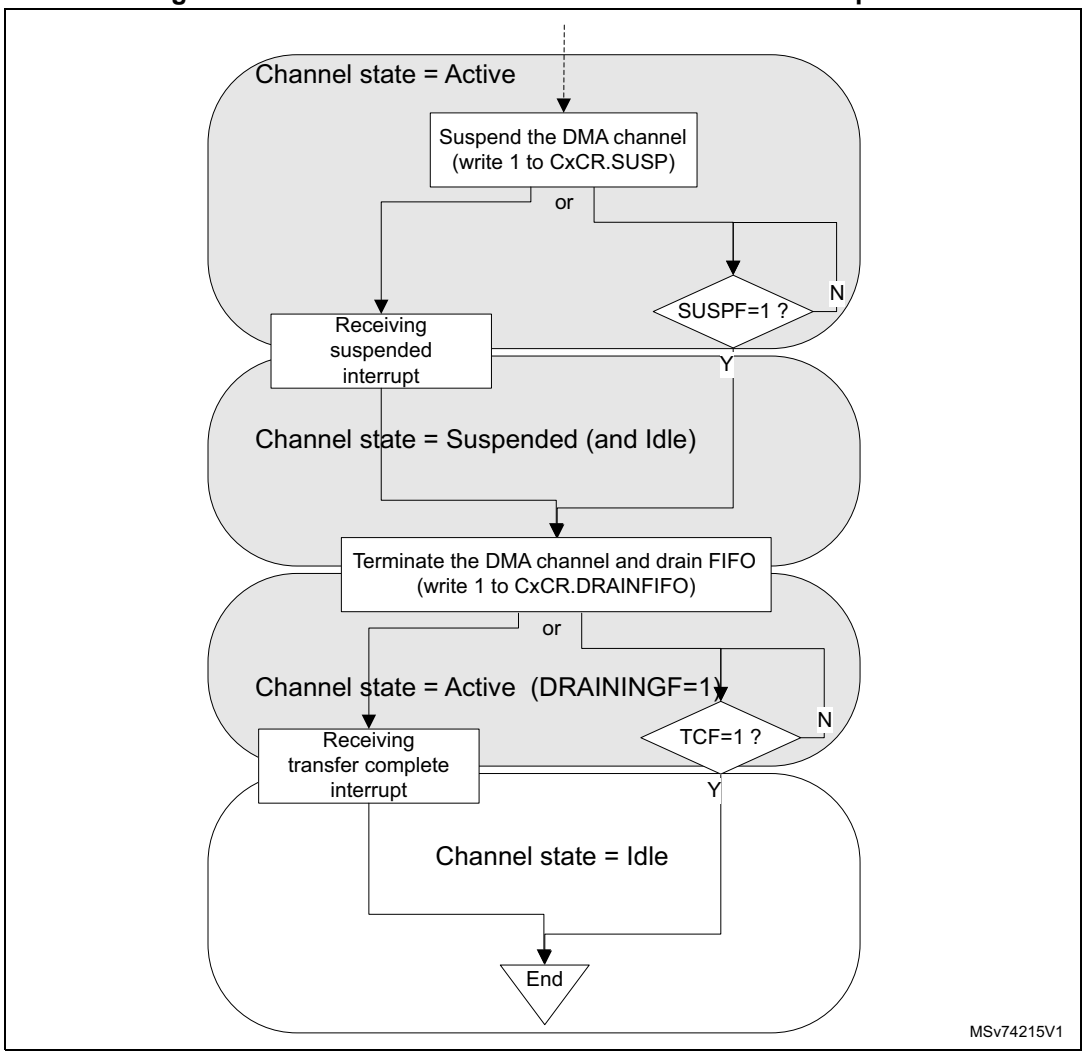
12.4.4 HPDMA channel abort and restart

Alternatively, like for aborting a continuous HPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the HPDMA_CxCR.SUSP bit.
2. The software polls suspended flag HPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to HPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing HPDMA transfer over its master port.
3. The software resets the channel by writing 1 to HPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the HPDMA_CxCR.EN bit, and the reset of the HPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram hardware-modified HPDMA_CxBR1, HPDMA_CxSAR, and HPDMA_CxDAR.

5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the HPDMA_CxCR.EN bit.

Figure 82. HPDMA channel abort and restart sequence



12.4.5 HPDMA channel terminate and drain FIFO

Alternatively, for terminating a continuous HPDMA transfer with a circular buffering or a double buffering, and having popped out any residual byte(s) in the channel FIFO and writing them to the destination, the software can terminate an active channel and drain the channel FIFO with the following sequence:

1. The software writes 1 into the HPDMA_CxCR.SUSP bit.
2. The software polls suspended flag HPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to HPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing HPDMA transfer over its master port.
3. The software orders to drain the channel FIFO by writing 1 to HPDMA_CxCR.DRAINFIFO.
4. The software polls transfer complete flag HPDMA_CxSR.TCF until TCF = 1, or waits for an interrupt previously enabled by writing 1 to HPDMA_CxCR.TCIE. Wait for the

channel to be effectively with a drained FIFO means wait for completion of any residual write burst from the FIFO to the destination. Then the channel is disabled by hardware and in IDLE state.

Figure 83. HPDMA channel terminate and drain FIFO sequence

Note: If the softwares writes the HPDMA_CxCR register in a single shot with concurrently SUSP = 1, DRAINFIFO = 1, and RESET = 0, then the sequence for terminating and draining the FIFO also occurs.

HPDMA_CxTR2.DREQ = 1 and HPDMA_CxCR.DRAINFIFO = 1 is not supported, only peripheral-to-memory and memory-to-memory transfers are supported to be terminated with drained FIFO.

12.4.6 HPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

For a channel x, the base address in memory of the data structure of a next LLI_{n+1} is the sum of the following:

- The link base address of the channel x (in HPDMA_CxLBAR)
- The link address offset LA[15:2] bitfield in HPDMA_CxLLR, that is the updated result from the data structure of the previous LLIn of the channel x

The data structure for each LLI can be specific.

A linked-list data structure is addressed following the value of UT1, UT2, UB1, USA, UDA, and ULL bits, plus UB2 and UT3 when present, in HPDMA_CxLLR.

In linked-list mode, each HPDMA linked-list register (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR or HPDMA_CxLLR, plus HPDMA_CxTR3 or HPDMA_CxBR2 when present) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of HPDMA_CxLLR that was conditionally updated from the linked-list data structure of the previous LLI.

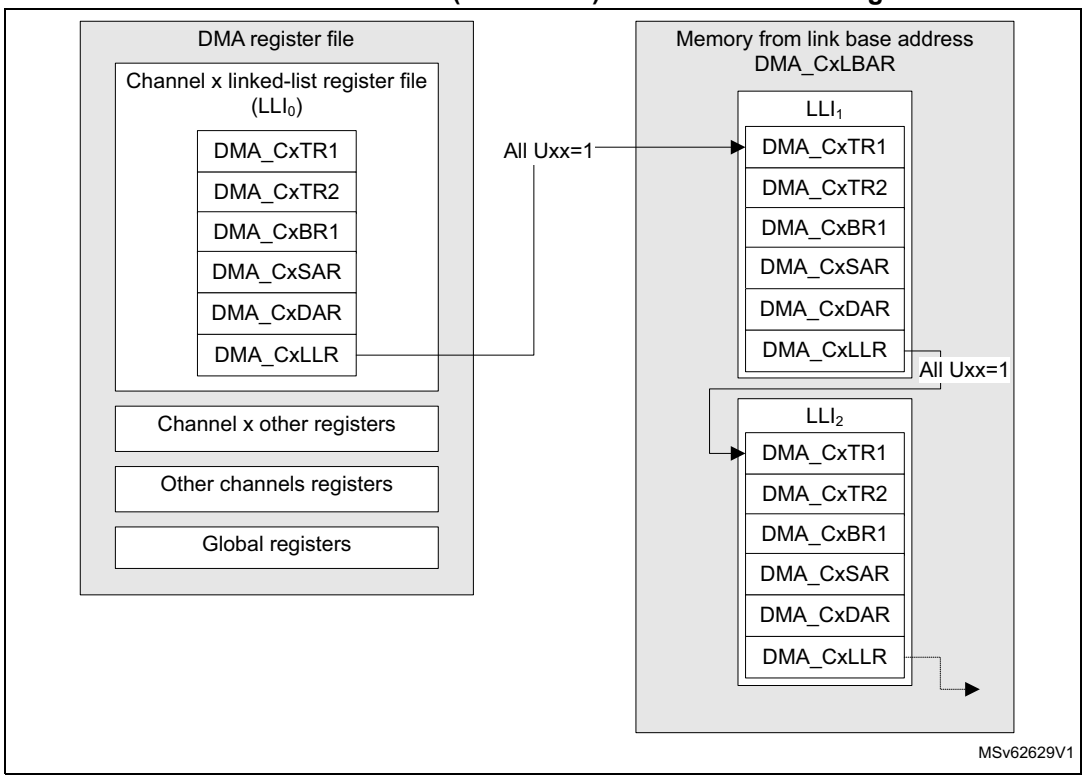
Caution: The user must program the pointer to the next linked-list data structure (HPDMA_CxLLR[15:0]) not to exceed the 64-Kbyte addressable space defined by the link base address register (HPDMA_CxLBAR). The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA, and ULL, plus UB2 and UT3 when present) in HPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- For channels without 2D addressing capability: Six contiguous 32-bit locations, including HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR (see *Figure 84*) and including the first linked-list register file (LLI_0), and the next LLIs (LLI_1, LLI_2,...) in the memory
- For channels with 2D addressing capability: eight contiguous 32-bit locations, including HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 (see *Figure 85*), including the first linked-list register file (LLI_0), and the next LLIs (LLI_1, LLI_2,...) in the memory

Figure 84. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x



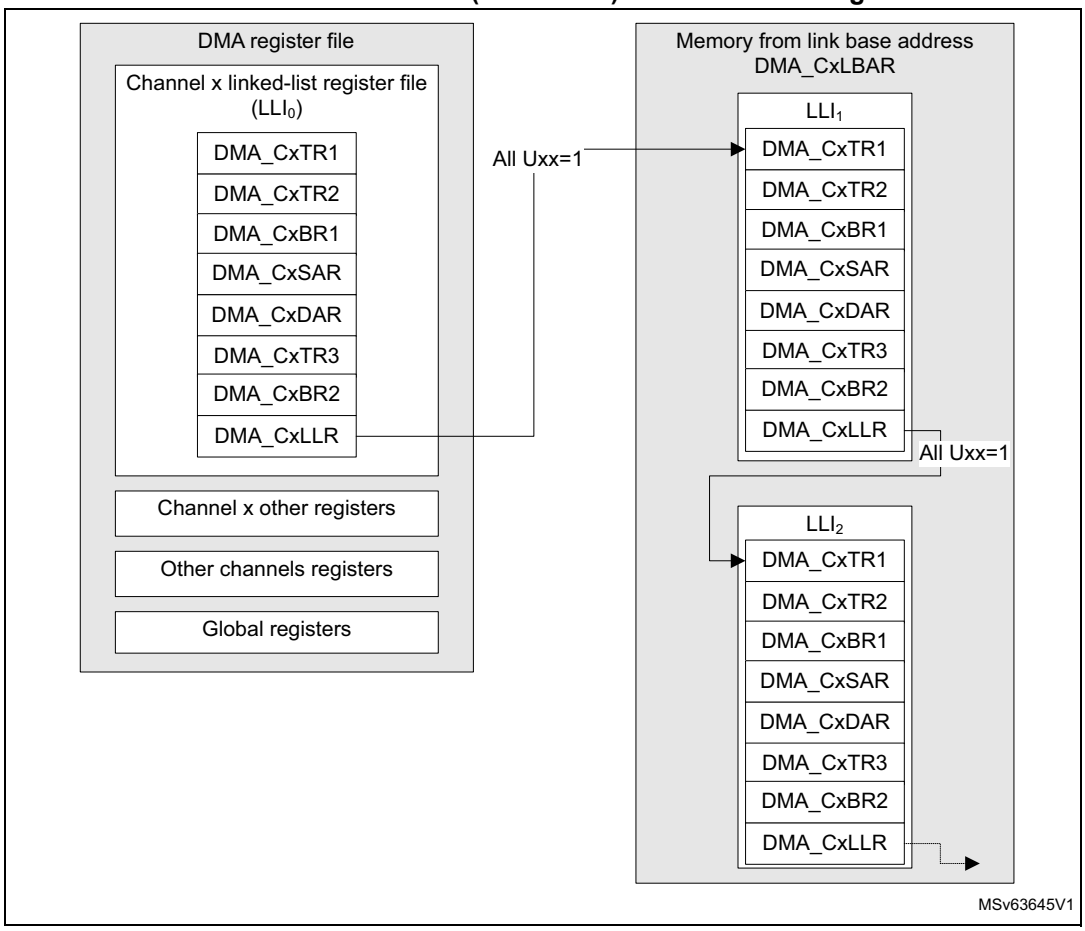


Figure 85. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

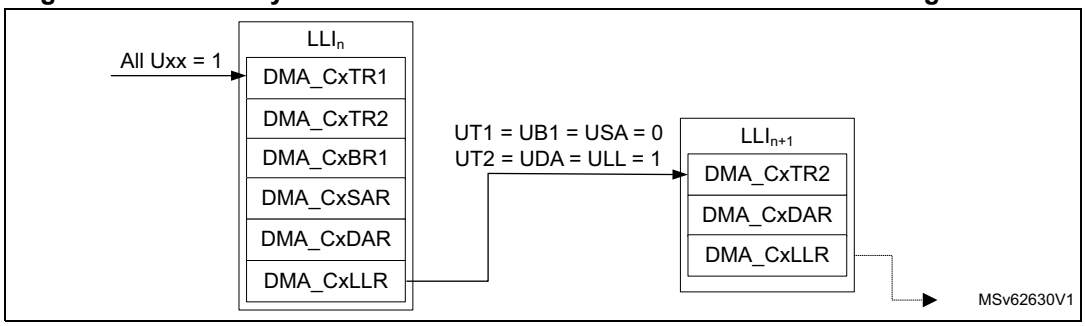
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of HPDMA_CxLLR points to the updated value of HPDMA_CxTR2, instead of HPDMA_CxTR1 which is not to be modified (see *Figure 86*).

Example: if UT1 = UB1 = USA = 0, and if UT3 = UB2 = 0 when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for HPDMA_CxTR1, nor HPDMA_CxBR1, nor HPDMA_CxSAR, nor HPDMA_CxTR3, nor HPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for HPDMA_CxTR2, HPDMA_CxDAR, and HPDMA_CxLLR, as shown in *Figure 87*.

Figure 86. HPDMA dynamic linked-list data structure of linear addressing channel x



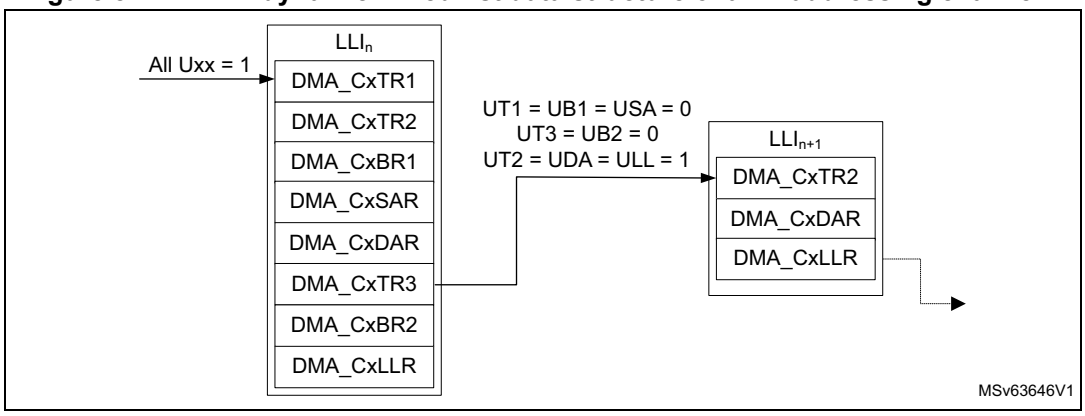


Figure 87. HPDMA dynamic linked-list data structure of a 2D addressing channel x

12.4.7 Linked-list item transfer execution

An LLI_n transfer is the sequence of:

1. A data transfer: the HPDMA executes the data transfer as described by the HPDMA internal register file (this data transfer can be void/null for LLI_0).
2. A conditional link transfer: the HPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the HPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer, as defined by the internal register file (LLI_0), can be null (HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxTR2.PFREQ = 0), provided that UB1 is set in HPDMA_CxLLR (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended HPDMA use, an HPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, HPDMA_CxCR.LSM = 0), or can be programmed for a single execution of a LLI (link step mode, HPDMA_CxCR.LSM = 1), as described in the next sections.

12.4.8 HPDMA channel state and linked-list programming in run-to-completion mode

When HPDMA_CxCR.LSM = 0 (in full-list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), an HPDMA channel x is initially programmed, started

by writing 1 to HPDMA_CxCR.EN, and after completed at channel level.
The channel transfer is:

- Configured with at least the following:
  - The first LLI_0, internal linked-list register file: HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 when present
  - The last LLI_N described by the linked-list data structure in memory, as defined by HPDMA_CxLLR reflecting the before last LLI_{N-1}
- Completed when HPDMA_CxLLR[31:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0, if BRC[10:0] is present and HPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

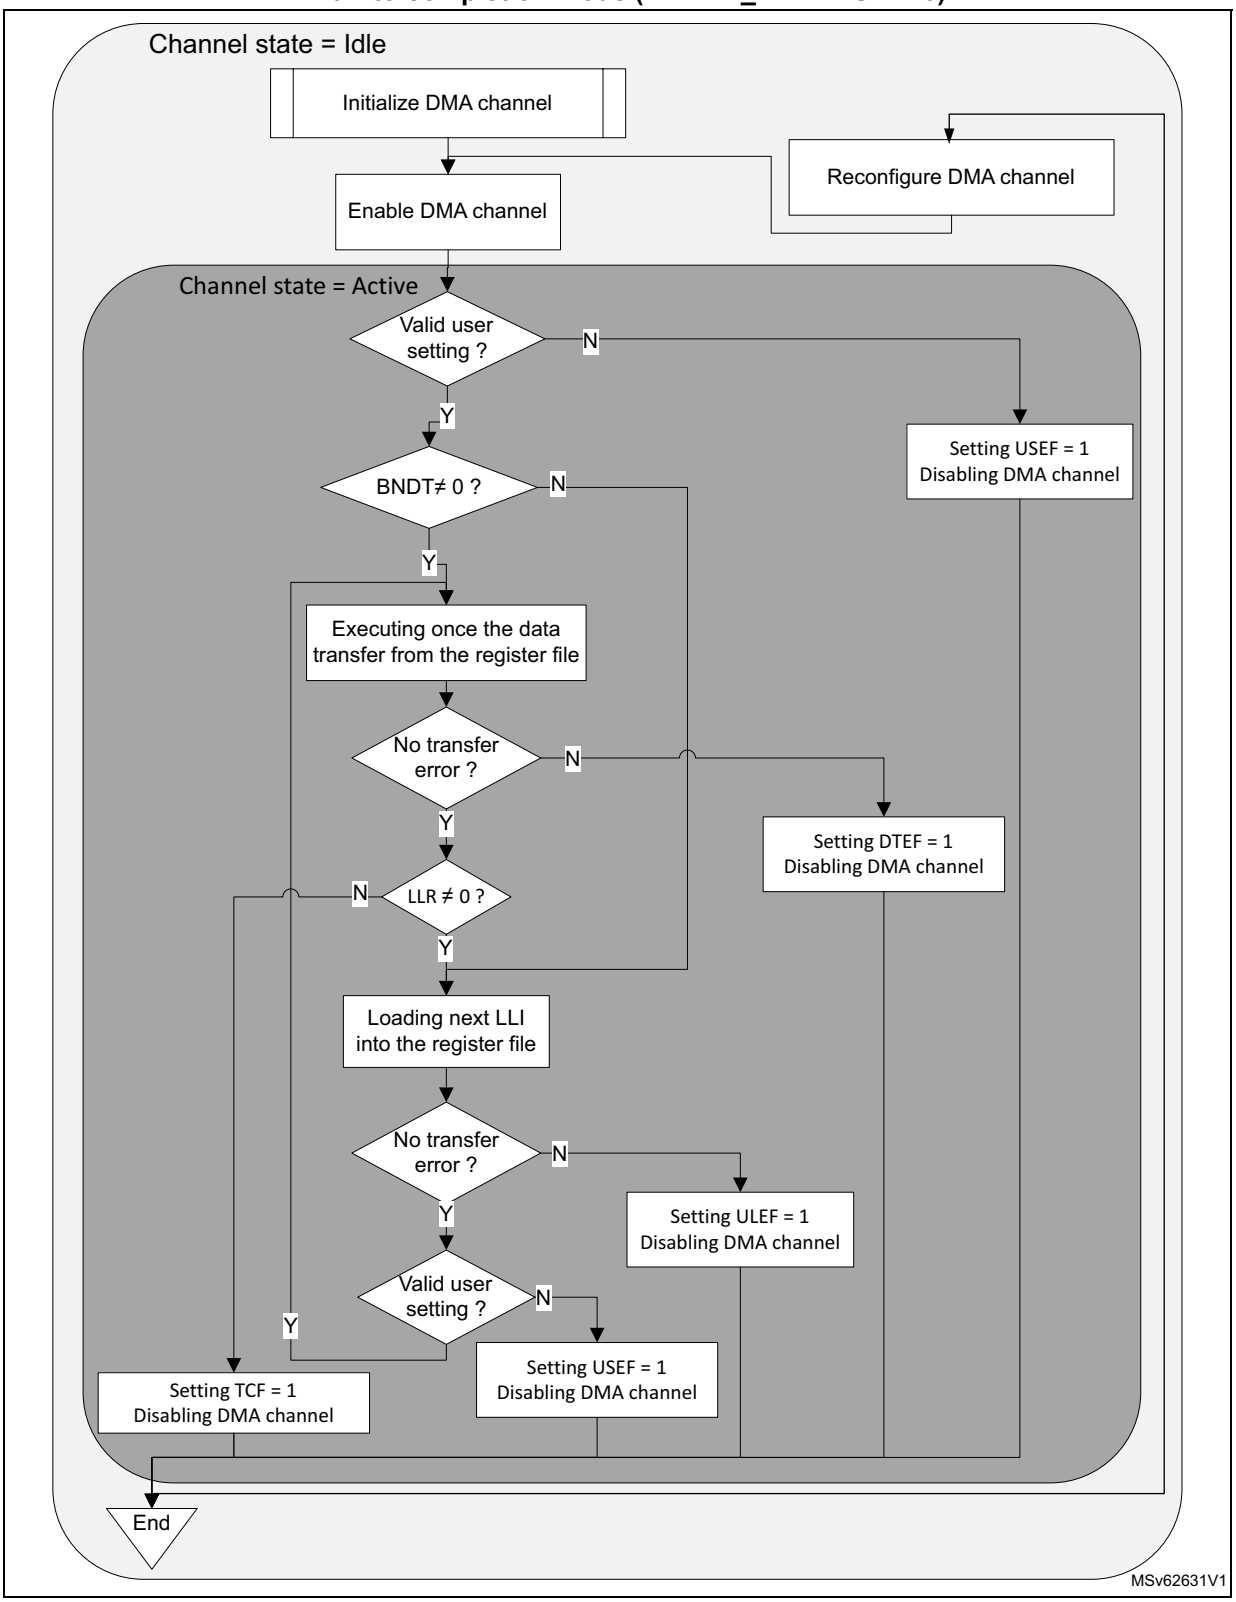
HPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion, and means the following:

- The 16 low significant bits HPDMA_CxLLR.LA[15:0] of the next link address are null.
- All bits HPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA, and ULL, plus UB2 and UT3 when present).

The channel may never be completed when HPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI, in one of the following:
  - HPDMA_CxLLR.ULL = 1 and HPDMA_CxLLR.LA[15:2] is updated with the same value.
  - HPDMA_CxLLR.ULL = 0
- If LLI_N points to a previous LLI

At the regular data transfer completion at a block level, HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 12.4.15* for more details).



In typical run-to-completion mode, allocation of an HPDMA channel, including detailed programming, occurs once during HPDMA initialization. This process reserves a data communication link and HPDMA service during run-time for repeated transfers, such as transfers from a peripheral to memory, from memory to a peripheral, or memory-to-memory transfers. The reserved data communication link may consist of a dedicated channel, or the channel may be shared. A repeated transfer consists of a sequence of linked list items (LLIs).

Figure 88 depicts the HPDMA channel execution and its registers programming in run-to-completion mode.

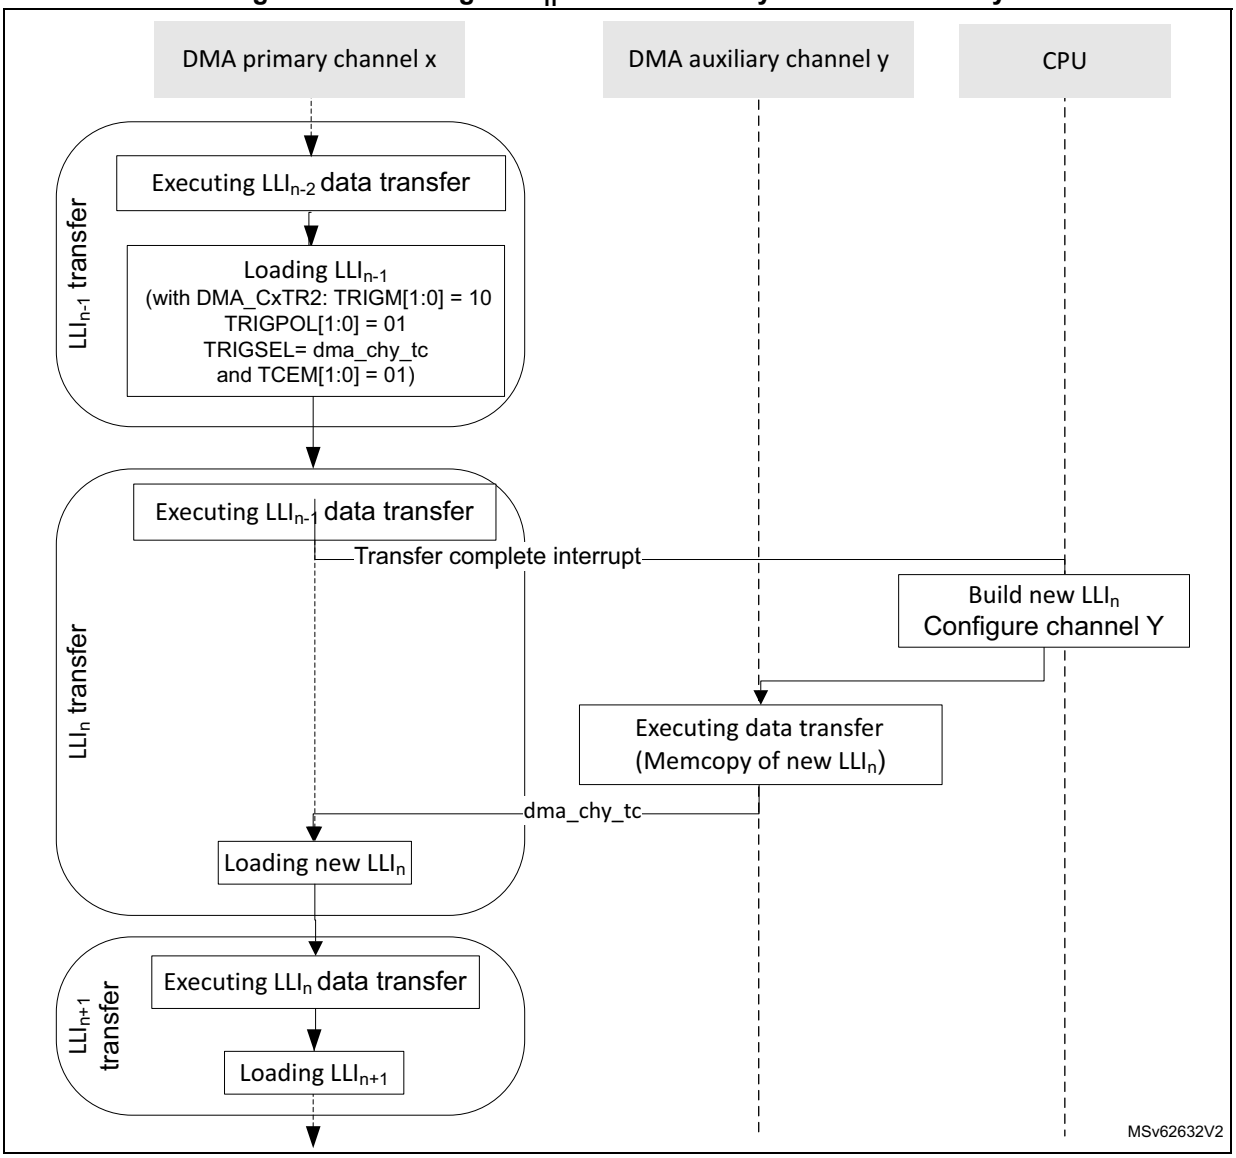
Note: Figure 88 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 88, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 12.3.5).

Figure 88. HPDMA channel execution and linked-list programming in run-to-completion mode (HPDMA_CxCR.LSM = 0)

Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following bitfields of HPDMA_CxTR2 in the data structure of the LLI_{n-1}:



- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see *Section 12.3.6* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory, and to generate a transfer complete event hpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 89 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with an LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 89. Inserting a LLI_n with an auxiliary HPDMA channel y

12.4.9 HPDMA channel state and linked-list programming in link step mode

When HPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

An HPDMA channel transfer can be programmed at an LLI level, started by writing 1 into HPDMA_CxCR.EN, and after completed at LLI level:

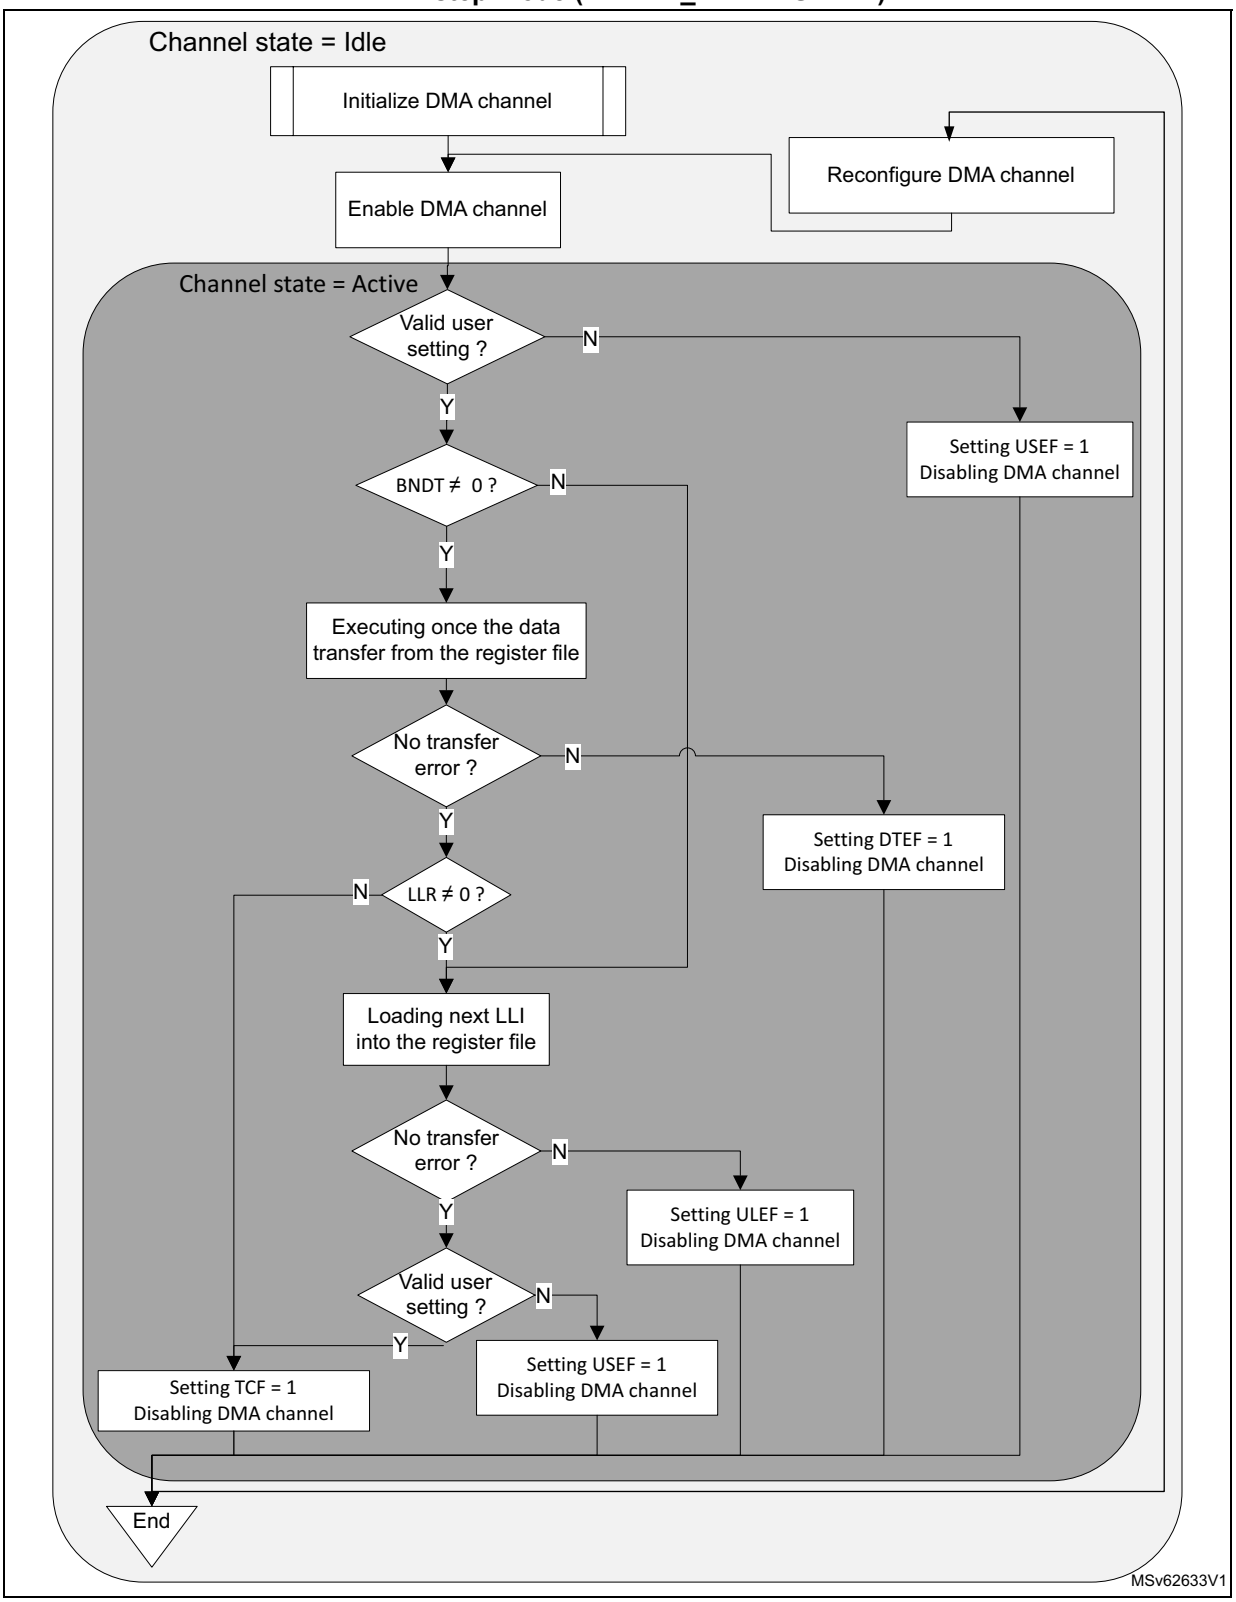
- The current LLI_n transfer is described with the following:
  - HPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - HPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]), and for channels with 2D addressing it defines also the number of blocks at a

2D/repeated block level (BRC[10:0]+1), and the incrementing/decrementing mode for address offsets.

  - HPDMA_CxTR2 defines the input control (request, trigger), and the output control (transfer-complete event) of the transfer.
  - HPDMA_CxSAR and HPDMA_CxDAR define the source/destination transfer start address.
  - HPDMA_CxTR3 for channels with 2D addressing defines the source/destination additional address offset between burst transfers.
  - HPDMA_CxBR2 for channels with 2D addressing defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - HPDMA_CxLLR defines the data structure, and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - After the (conditional) data transfer completion (when HPDMA_CxBR1.BRC[10:0] = 0 if BRC[10:0] is present, and HPDMA_CxBR1.BNDT[15:0] = 0)
  - After the (conditional) update of the HPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If an LLI is recursive (pointing to itself as a next LLI, either HPDMA_CxLLR.ULL = 1 and HPDMA_CxLLR.LA[15:2] is updated with the same value, or HPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

At the regular data transfer completion at a block level, HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer can be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 12.4.15* for more details).



The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of HPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 90 depicts the HPDMA channel execution mode, and its programming in link step mode.

Note: Figure 90 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 90, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes BNDT ≠ 0 and PFREQ = 1 if the peripheral requests a data transfer with early termination (see Section 12.3.5).

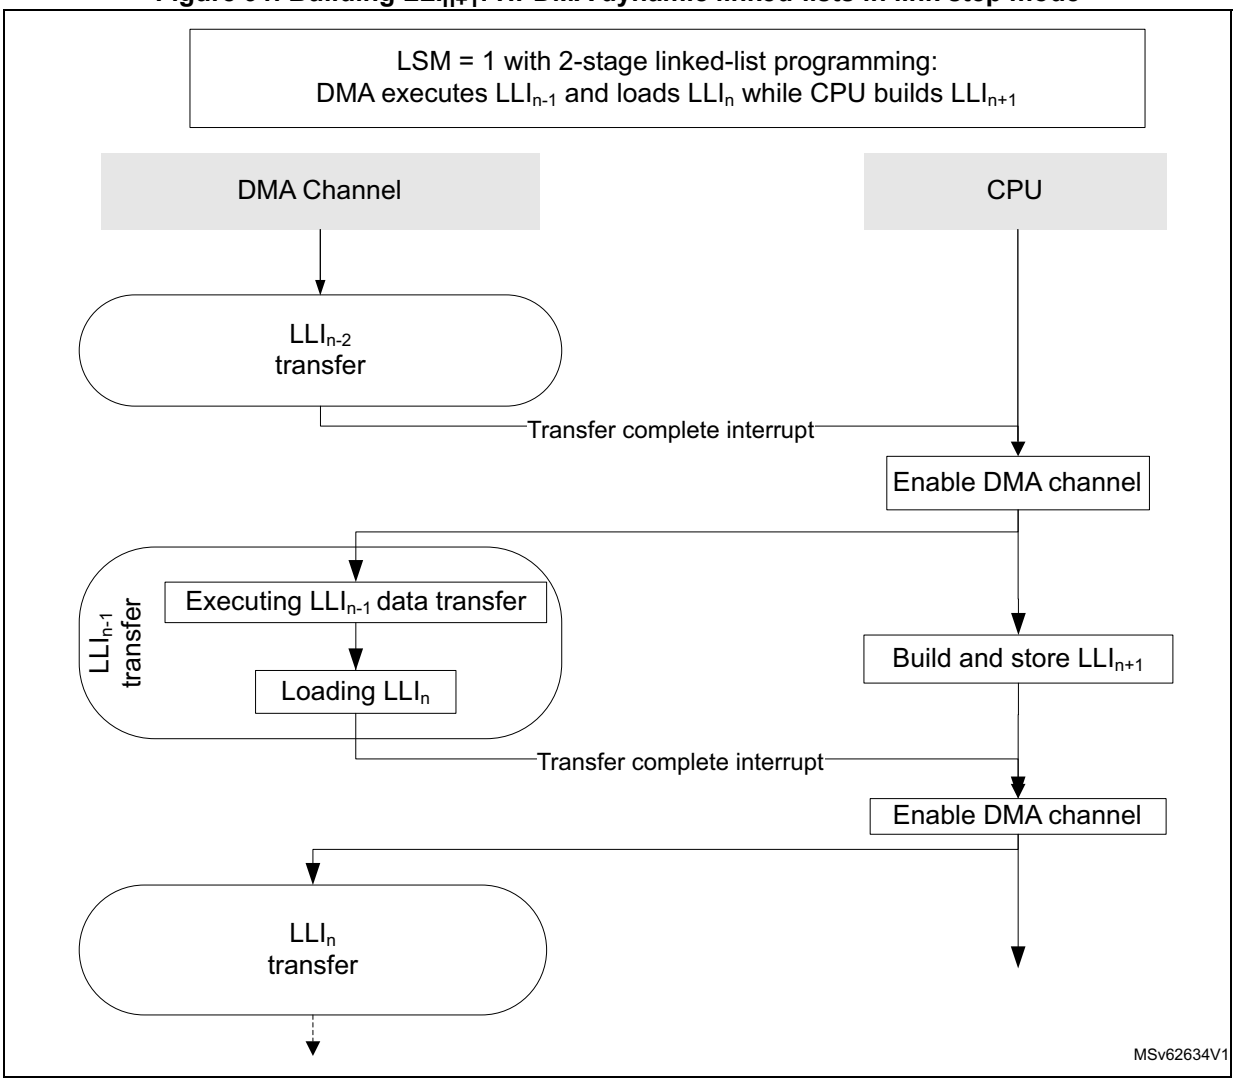


Figure 90. HPDMA channel execution and linked-list programming in link step mode (HPDMA_CxCR.LSM = 1)

Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after the HPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in the figure below.

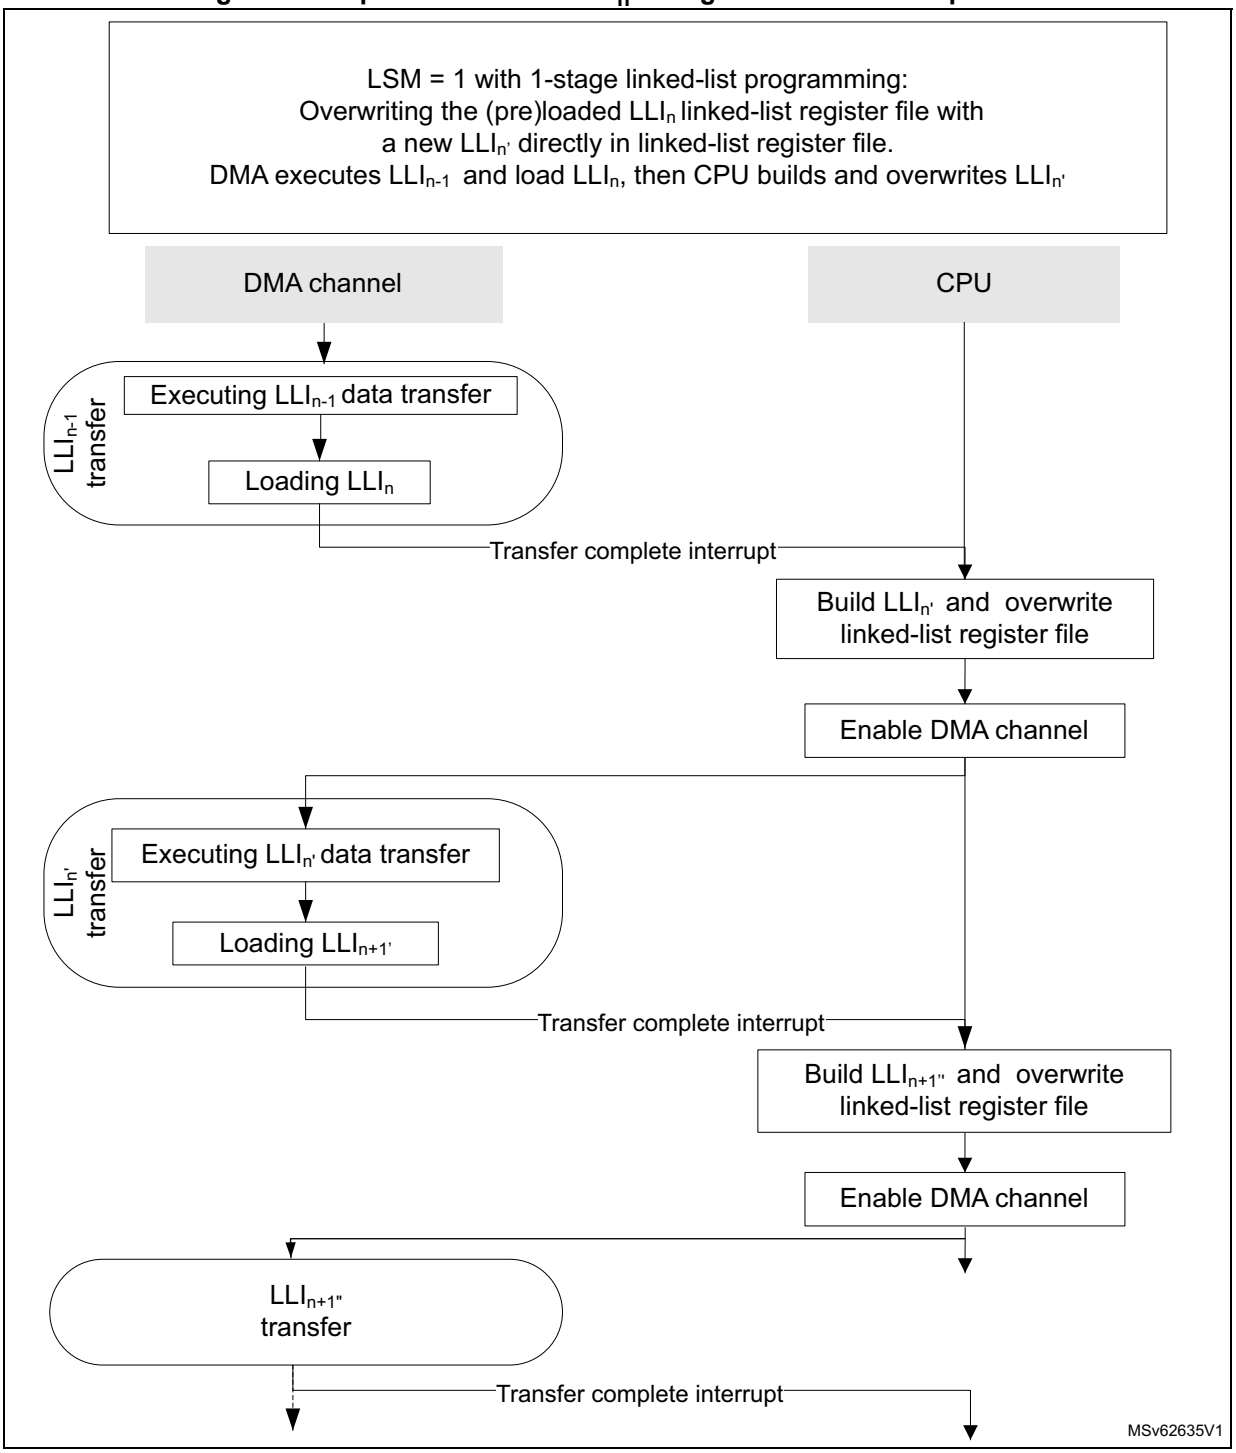

Figure 91. Building LLI_{n+1}: HPDMA dynamic linked-lists in link step mode

Run-time replacing an LLI_n with a new LLI_n', in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after the HPDMA executed the transfer from the LLI_{n-1}, and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in *Figure 92*.

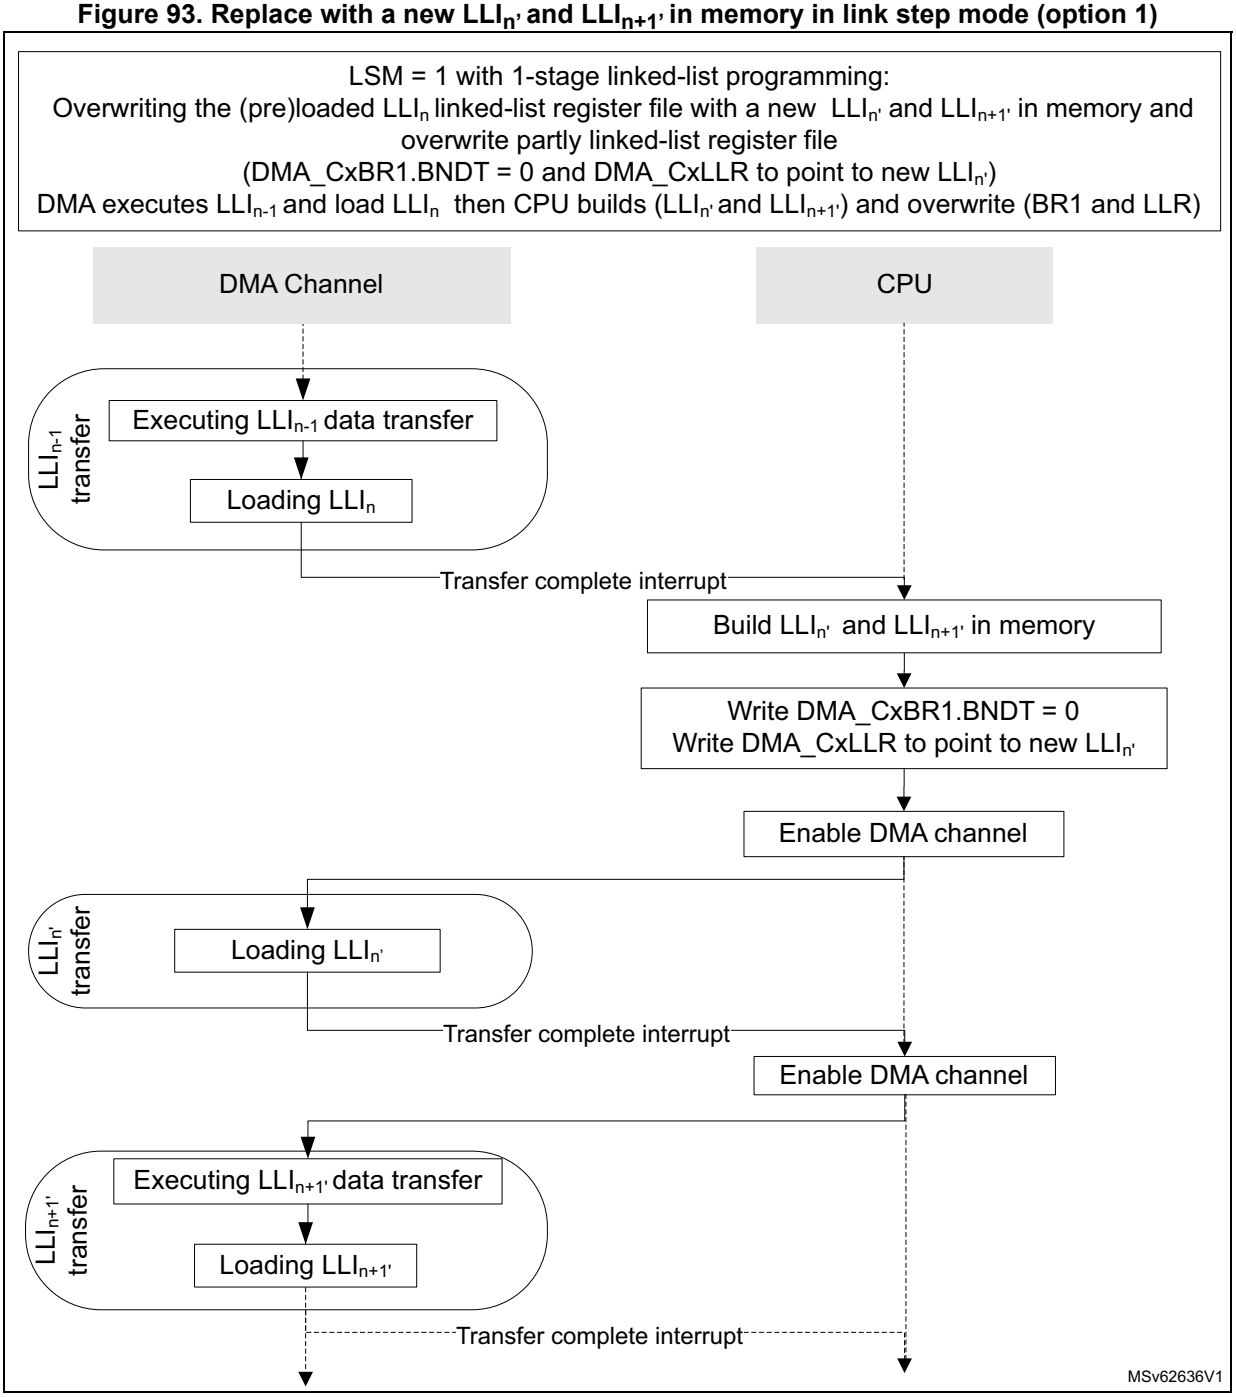

Figure 92. Replace with a new $LLI_{n'}$ in register file in link step mode

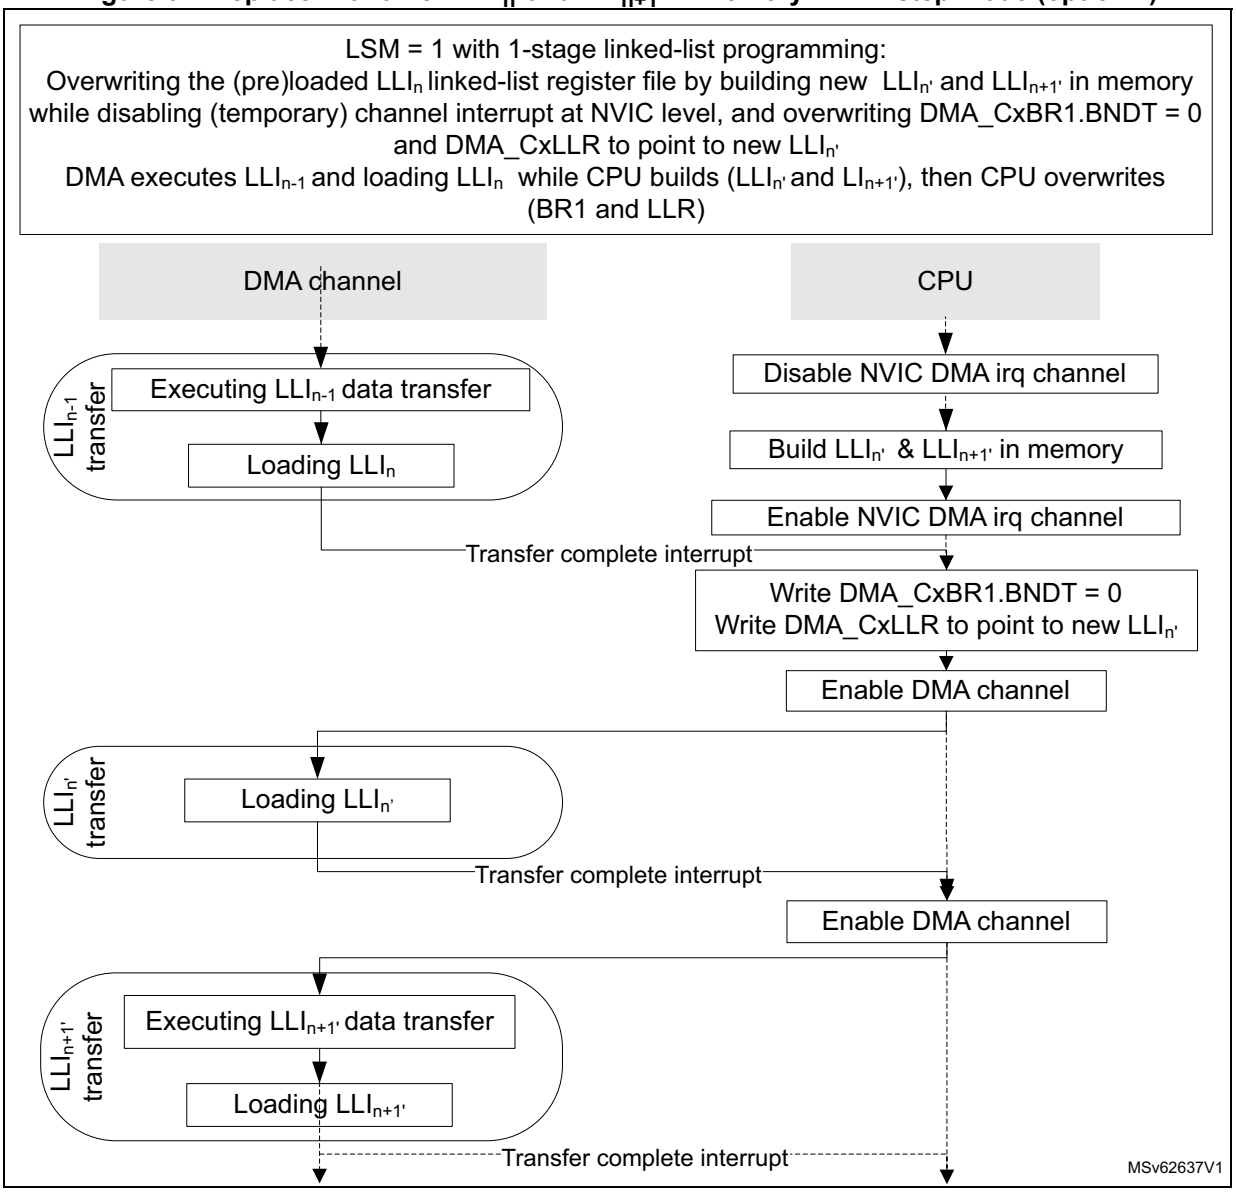
Run-time replacing an LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after HPDMA executed the transfer from the LLI_{n-1}, and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (HPDMA_CxBR1.BNDT[15:0] to be null, and HPDMA_CxLLR to point to new LLI_n) as shown in *Figure 93*.

Figure 93. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile the HPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite HPDMA_CxBR1.BNDT[15:0] to be null and HPDMA_CxLLR to point to new $LLI_{n'}$, as shown in the figure below.

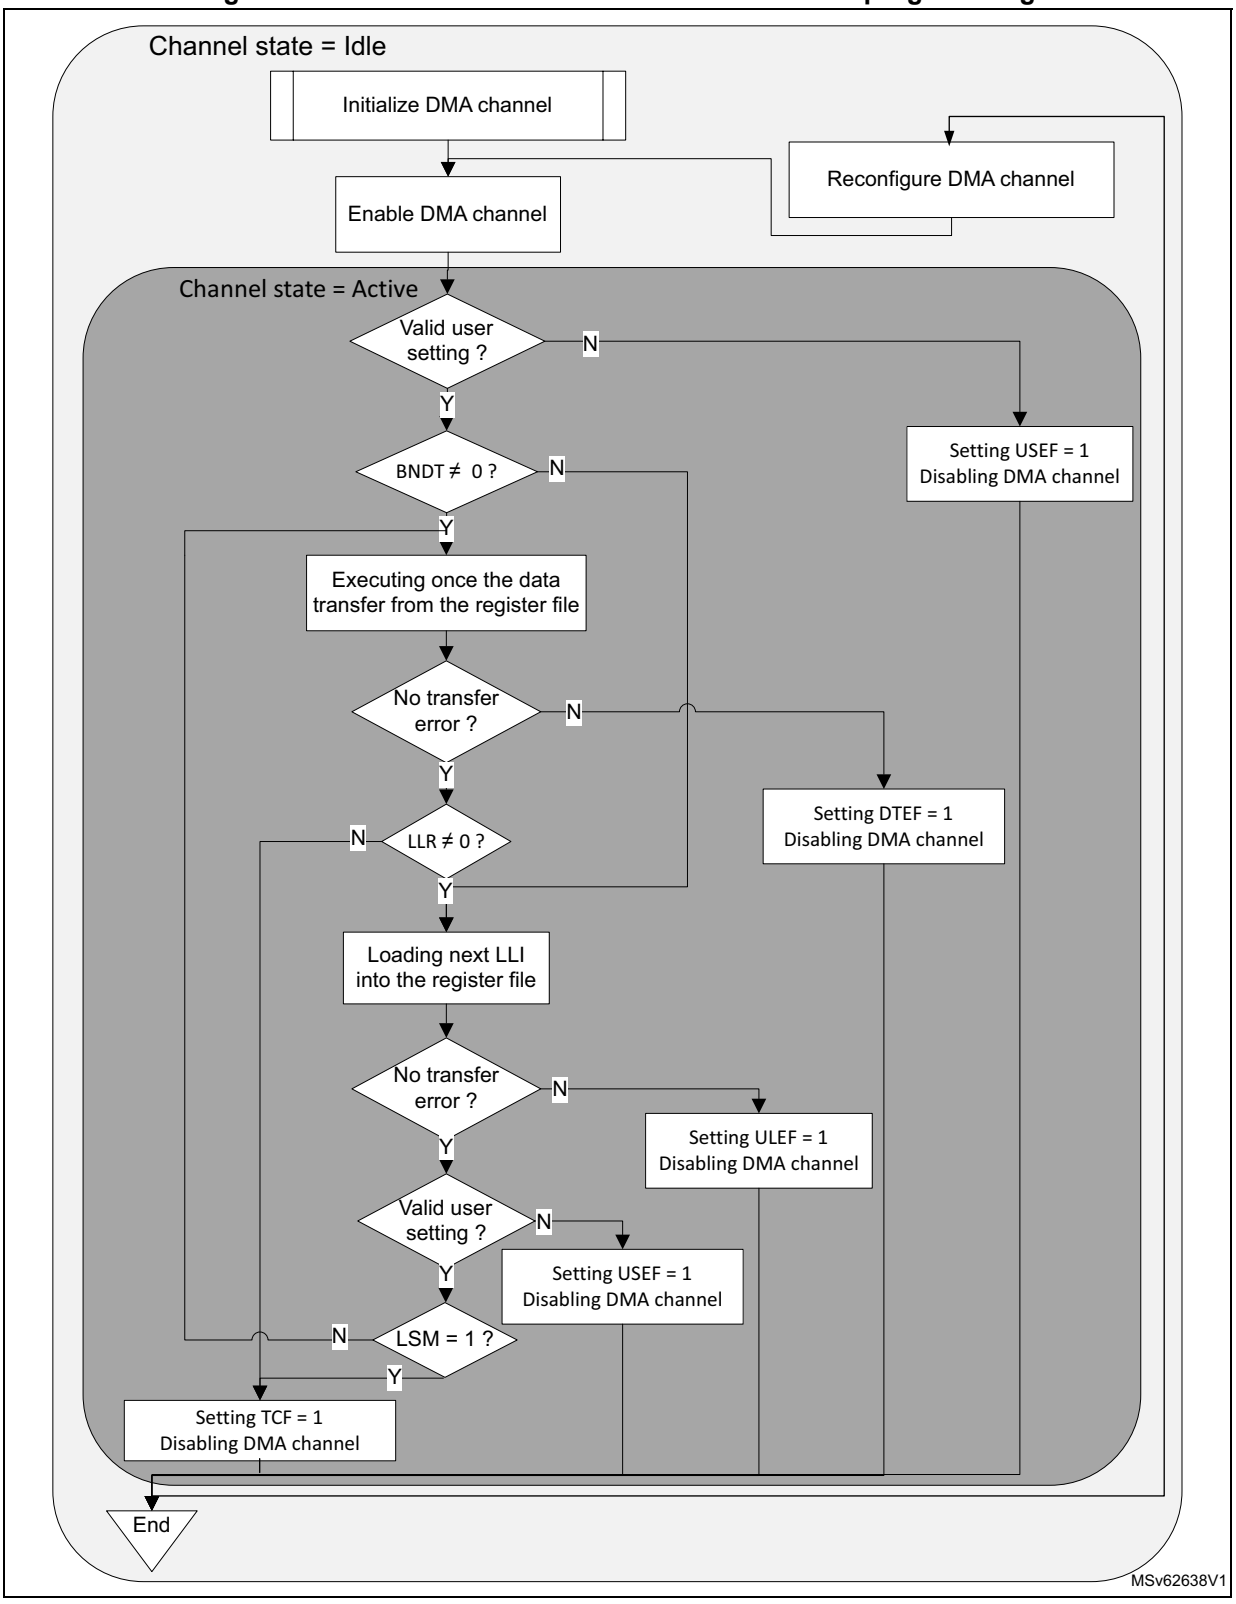
Figure 94. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)

12.4.10 HPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (HPDMA_CxCR.EN = 0), and update the execution mode (HPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- Reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the HPDMA_CxLLR of this LLI_{n+1}), before this LLI_{n+1} is loaded/used by the HPDMA channel
- Abort and reconfigure the channel with an LSM update (see *Section 12.4.4*.)



In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 95 shows the overall and unified HPDMA linked-list programming, whatever is the execution mode.

Note: Figure 95 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 95, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes BNDT ≠ 0 and PFREQ = 1 if the peripheral requests a data transfer with early termination (see Section 12.3.5).

Figure 95. HPDMA channel execution and linked-list programming

12.4.11 HPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 12.3.1* for more details).

HPDMA burst

A programmed transfer at the lowest level is an HPDMA burst.

An HPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in HPDMA_CxTR1.

The addressing mode after each data (named beat) of an HPDMA burst is defined by SINC and DINC in HPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of an HPDMA source/destination burst (defined by HPDMA_CxSAR and HPDMA_CxDAR) must be aligned with the respective data width.

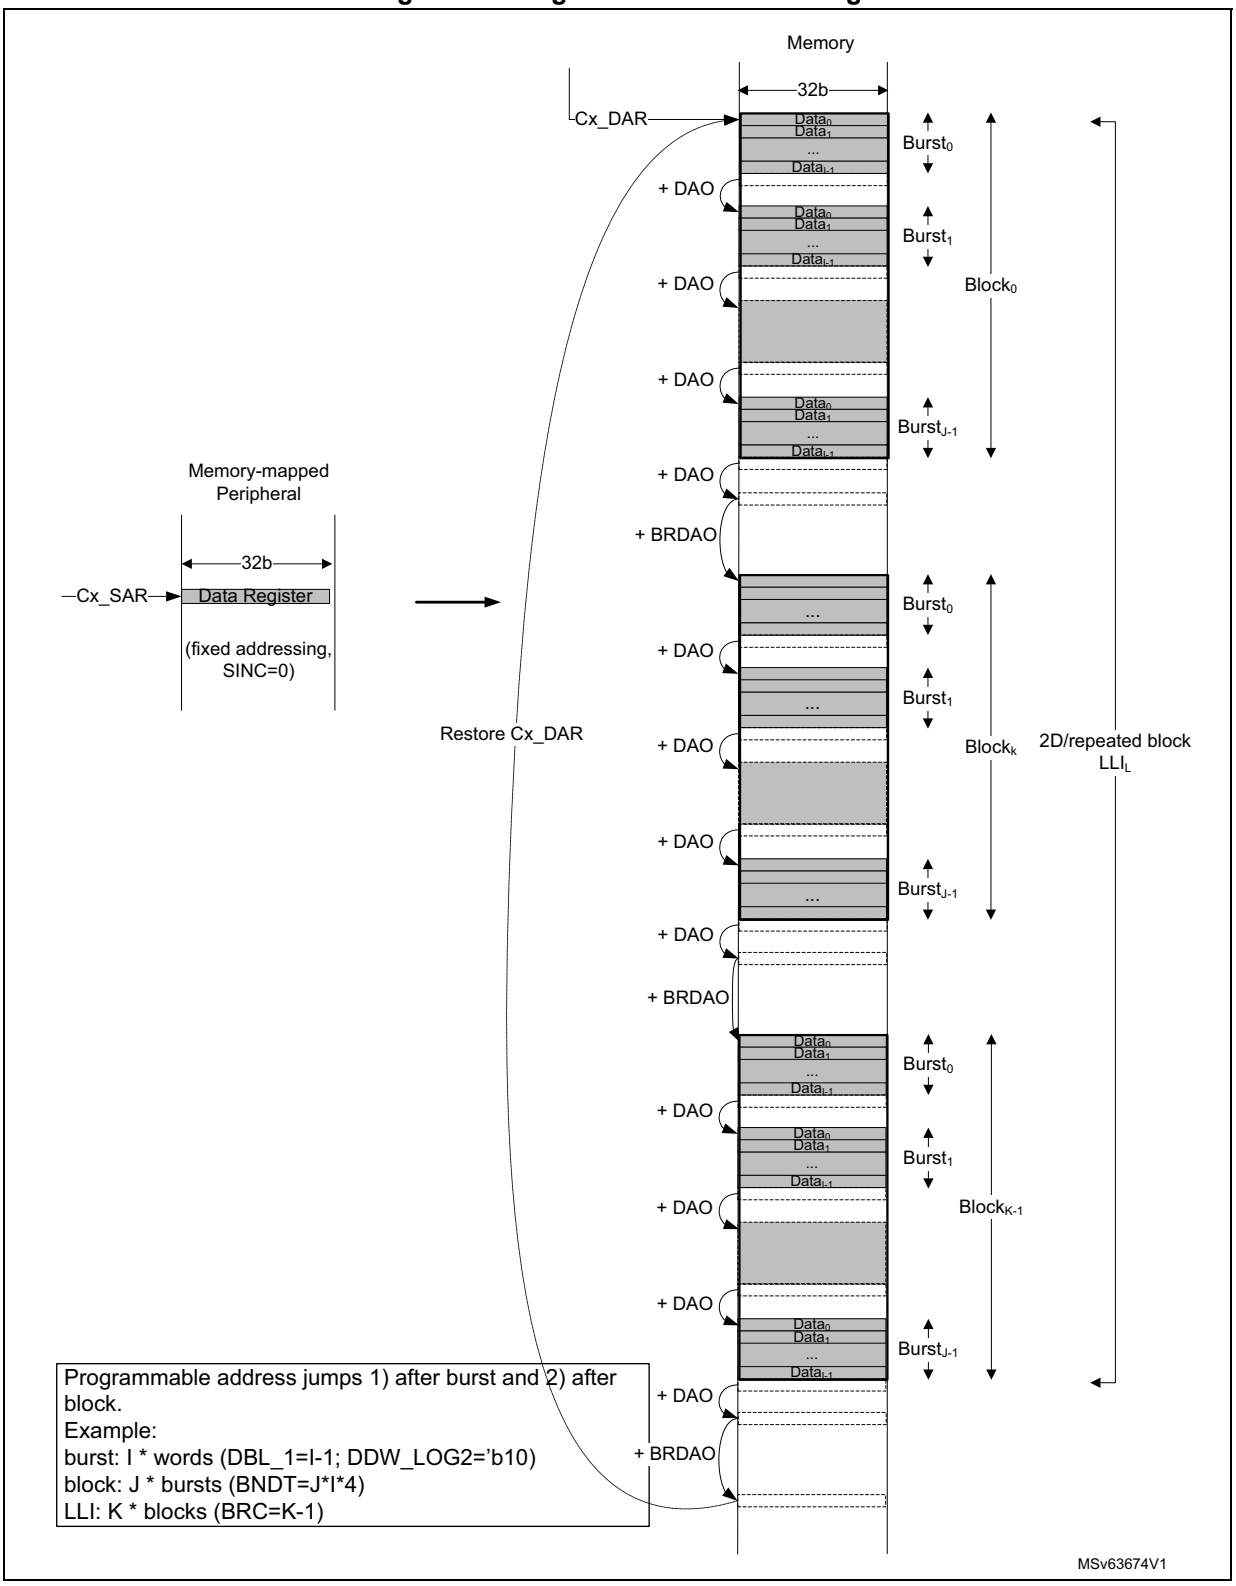
The table below lists the main characteristics of an HPDMA burst.

Table 88. Programmed HPDMA source/destination burst

<table>
<tr><th>SAP/DAP (allocated port)</th><th>SDW_LOG2[1:0] DDW_LOG2[1:0]</th><th>Data width (bytes)</th><th>SINC/DINC</th><th>SBL_1[5:0] DBL_1[5:0]</th><th>Burst length (data/ beats)</th><th>Next data/ beat address</th><th>Next burst address</th><th>Burst address alignment</th></tr>
<tr><td rowspan="8">0: AXI
1: AHB</td><td>00</td><td>1</td><td rowspan="4">0 (fixed)</td><td rowspan="8">n = 0 to 63(1)</td><td rowspan="8">n+1</td><td rowspan="4">+ 0</td><td rowspan="4">+ 0</td><td>1</td></tr>
<tr><td>01</td><td>2</td><td>2</td></tr>
<tr><td>10</td><td>4</td><td>4</td></tr>
<tr><td>11(2)</td><td>8(2)</td><td>8(2)</td></tr>
<tr><td>00</td><td>1</td><td rowspan="4">1 (contiguously incremented)</td><td>+ 1</td><td>+ (n + 1)</td><td>1</td></tr>
<tr><td>01</td><td>2</td><td>+ 2</td><td>+ 2 * (n + 1)</td><td>2</td></tr>
<tr><td>10</td><td>4</td><td>+ 4</td><td>+ 4 * (n + 1)</td><td>4</td></tr>
<tr><td>11(2)</td><td>8(2)</td><td>+ 8(2)</td><td>+ 8 * (n + 1)(2)</td><td>8(2)</td></tr>
</table>

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.
2. Programming a source/destination data width of 8 bytes is allowed only if the allocated port (by SAP/DAP) is 64 bits. Otherwise, a user setting error is reported and no transfer is issued.

The next burst address in the above table is the next source/destination default address pointed by HPDMA_CxSAR or HPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.



HPDMA burst with 2D addressing

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- After each completed source/destination burst, as defined respectively by HPDMA_CxTR2.SAO[12:0]/DAO[12:0] and HPDMA_CxBR1.SDEC/DDEC
- After each completed block, as defined respectively by HPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and HPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by *Figure 96* with a 2D destination buffer.

Figure 96. Programmed 2D addressing

HPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- One burst from the source to the FIFO over the allocated source master port, as defined by HPDMA_CxTR1.SAP
- One burst from the FIFO to the destination over the allocated destination master port, as defined by HPDMA_CxTR1.DAP

HPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma_fifo_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma_fifo_size[x]}$ is half the FIFO size of channel x, in bytes (see *Section 12.3.1* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (HPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

HPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

HPDMA burst versus source block size, 1- or 4-Kbyte address boundary and FIFO size

The programmed source/destination HPDMA burst is implemented with an AHB/AXI burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination HPDMA burst is implemented with a series of singles or bursts of a lower size. Each transfer is of a size that is lower than or equal than half of the FIFO size, without any user constraint.
- If the source block size (HPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (HPDMA_CxTR1.SDW_LOG2[1:0]), the HPDMA modifies and shortens bursts into

singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- If the source/destination burst transfer have crossed the 1- or 4-Kbyte address boundary on, respectively, an AHB or AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, or if the source/destination burst on an AXI transfer is both with fixed addressing and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol, without any user constraint.

In any case, the HPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in HPDMA_CxSR) is compared to and updated with the effective transfer size, and the HPDMA re-arbitrates between each AHB/AXI single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the HPDMA read transfers related to the update of the linked-list parameters from the memory to the internal HPDMA registers, are scheduled over the link allocated port, as programmed by HPDMA_CxCR.LAP.

HPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension, and left/right alignment

The data handling is controlled by HPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word, word, or double-word, as per SDW_LOG2[1:0] and DDW_LOG2[1:0] (see *Table 89*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if the source data width is a word or a double-word (for AXI source bus, SAP = 0), the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data-width conversion by packing, unpacking, padding, or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.

3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.
   - If DWX = 1 and if the destination data width is a double-word and if the selected destination port (via DAP) is 64-bit capable, the two aligned words are exchanged within aligned (post PAM[1:0]) double-words).

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding, and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 89. Programmed data handling

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.
3. RA= right aligned. LA = left aligned. RT = right truncated. LT = left truncated.
4. 0P= zero-bit padding up to the destination data width. SE = sign bit extended up to the destination data width.
5. if DDW_LOG2[1:0] = 11 and if the selected destination port (via DAP) is 64-bit capable. If DDW_LOG2[1:0] = 11 and the selected destination port is not 64-bit capable, a user setting error (USEF) is reported.
6. if SDW_LOG2[1:0] = 11 and if the selected source port (via SAP) is 64-bit capable. If SDW_LOG2[1:0] = 11 and the selected source port is not 64-bit capable, a user setting error (USEF) is reported.

12.4.12 HPDMA transfer request and arbitration

HPDMA transfer request

As defined by HPDMA_CxTR2, a programmed HPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the HPDMA hardware peripheral request is driven by REQSEL[7:0] (see *Section 12.3.4*). The selected hardware request can be one of the following:
  - An hardware request from a peripheral configured in HPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - An hardware request from a peripheral for its control register update from the memory
  - An hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign the same input hardware peripheral HPDMA request via HPDMA_CxTR.REQSEL[7:0] to two different channels, if at a given time this request is asserted by the peripheral, and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

HPDMA transfer request for arbitration

A ready FIFO-based HPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (HPDMA_CxTR1.SAP) is arbitrated based on the channel priority (HPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested HPDMA transfers to the same master port.

A ready FIFO-based HPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (HPDMA_CxTR1.DAP) is arbitrated based on the channel priority (HPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested HPDMA transfers to the same master port.

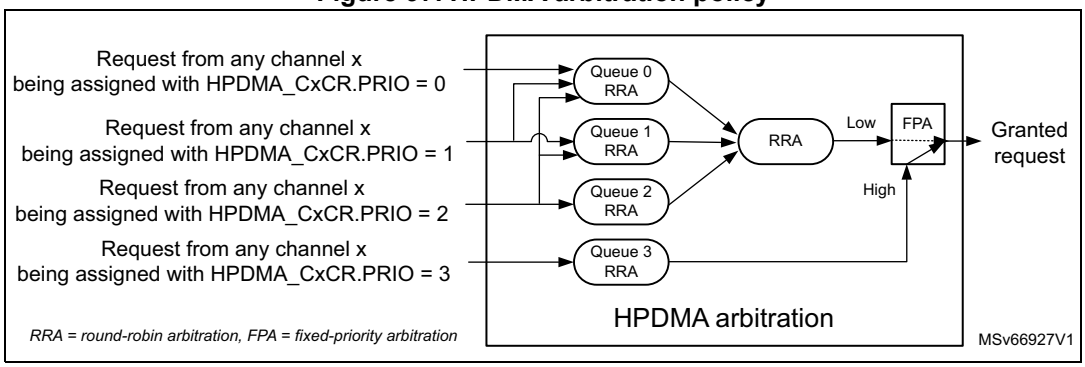
An arbitrated HPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in the memory to one of the linked-list registers (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, HPDMA_CxTR3, HPDMA_CxBR2 or HPDMA_CxLLR). Each 32-bit read from the memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (HPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (HPDMA_CxTR2.SWREQ = 1), or with a hardware request (HPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (HPDMA_CxTR2.SWREQ = 0 and HPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request

to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

HPDMA arbitration



The HPDMA arbitration is directed from the 4-grade assigned channel priority (HPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 97*, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
  - Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
  - Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
  - Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

Figure 97. HPDMA arbitration policy

HPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive HPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).

    $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).

    $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$

    $B_{req1} = B_{P1} = (1/2 + 1) * 1/2 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).

    $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$

    $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$

  The above computed bandwidth calculation is based on a theoretical input request, always active for any HPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one HPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.
- **Example 2**: application where the user distributes a same non-null N number of HPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is

    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1 (B_{P1}) is

    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2 (B_{P2}) is

    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority i ($B_{n, Pi}$) is

    $B_{n, P0} = 1/N * 1/9 * (1 - B_{Q3})$

    $B_{n, P1} = 1/N * 5/18 * (1 - B_{Q3})$

    $B_{n, P2} = 1/N * 11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for J > 0 (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ (K>0 in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 (K > 0)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 (K = 0)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the HPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

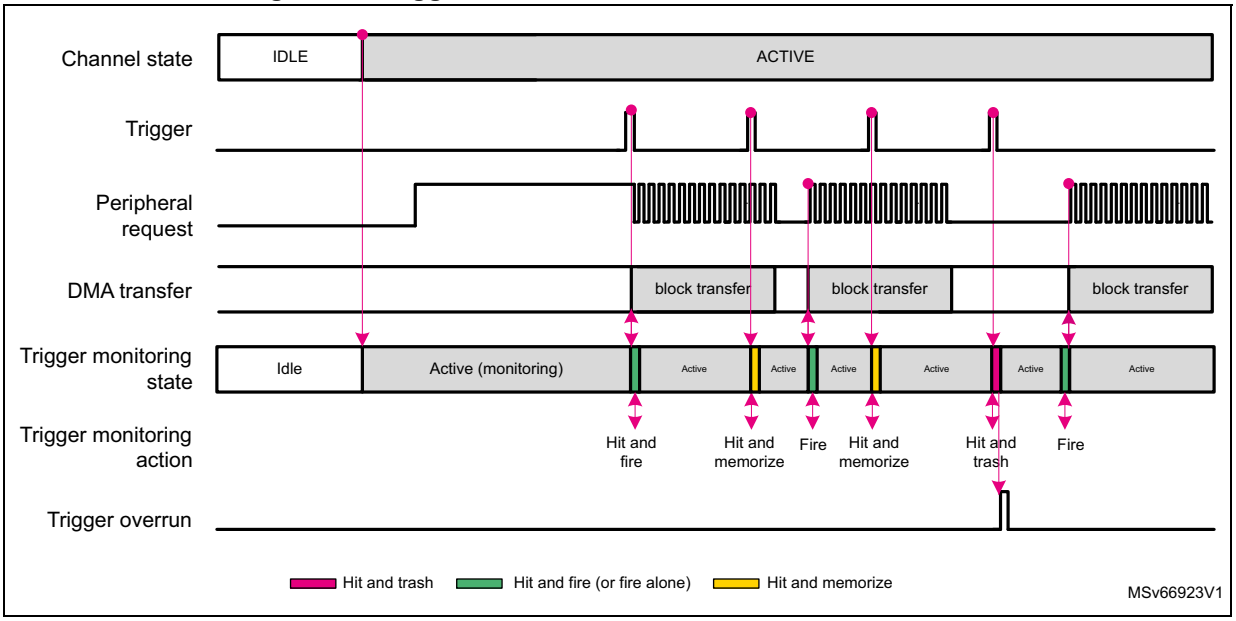
12.4.13 HPDMA triggered transfer

A programmed HPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by HPDMA_CxTR2.TRIGPOL[1:0] and HPDMA_CxTR2.TRIGSEL[5:0] (see *Section 12.3.6* for the trigger selection).

The triggered transfer, as defined by the trigger mode in HPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block (for channel x = 12 to 15), or each programmed burst read/write. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in *HPDMA channel x transfer register 2 (HPDMA_CxTR2)* for more details).

Trigger hit memorization and trigger overrun flag generation

The HPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).



The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates HPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

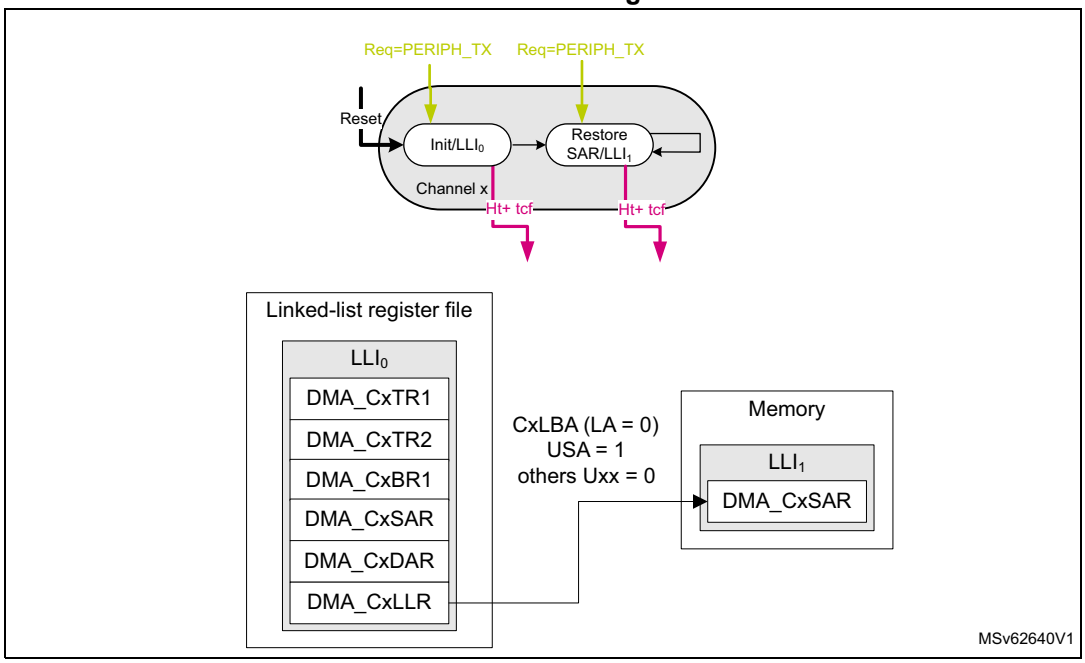
Caution: After a first new trigger, hit_{n+1} is memorized. If another trigger hit_{n+2} is detected, and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (HPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if HPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

The figure below illustrates the trigger hit, memorization, and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 98. Trigger hit, memorization and overrun waveform

Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

12.4.14 HPDMA circular buffering with linked-list programming



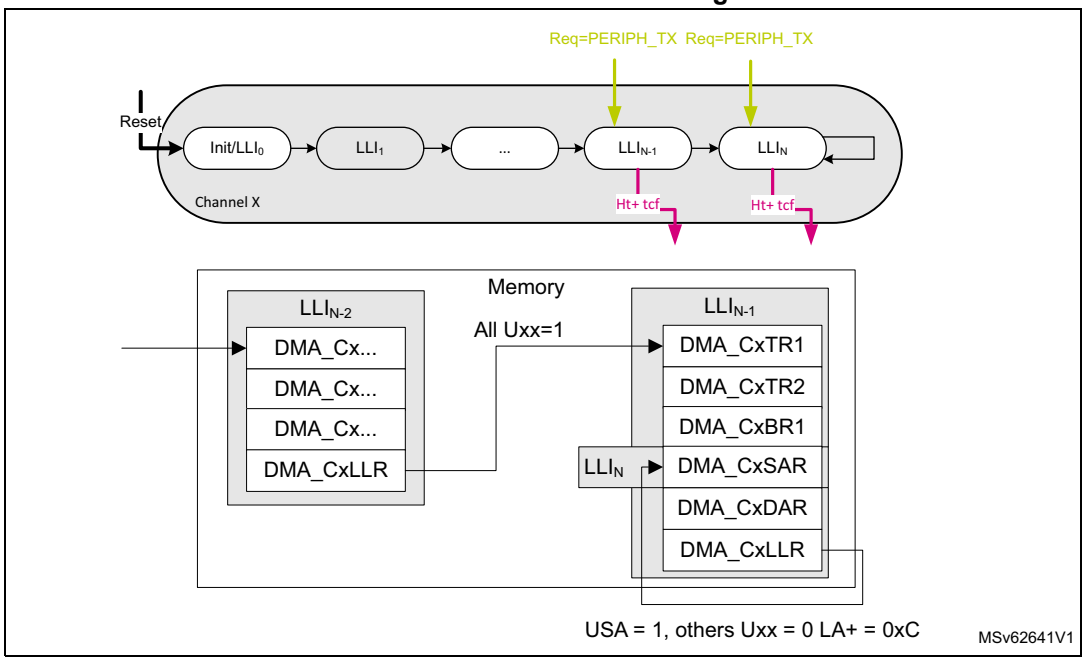
HPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel

For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half-transfer and complete-transfer event/interrupt generation (HPDMA_CxCR.HTIE = 1 and HPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel.
A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address for the memory-to-peripheral transfer (respectively the peripheral-to-memory).
The HPDMA automatically reloads the initially programmed HPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore HPDMA_CxBR1.

The figure below illustrates this programming with a linear addressing HPDMA channel and a source circular buffer.

Figure 99. HPDMA circular buffer programming: update of the memory start address with a linear addressing channel



Note: With a 2D addressing channel, a single LLI can be used with HPDMA_CxBR1.BRC[10:0] = 1. The user can program a negative memory block address offset with HDMA_CxBR2 and HDMA_CxBR1, in order to jump back to the memory source or destination start address.

If the circular buffering must be executed after some other transfers over the shared HPDMA channel x, the before-last LLI_{N-1} in the memory is needed to configure the first block transfer. The last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory).

The figure below illustrates this programming with a linear addressing shared HPDMA channel, and a source circular buffer.

Figure 100. Shared HPDMA channel with circular buffering: update of the memory start address with a linear addressing channel

12.4.15 HPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate an HPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 12.3.5*).

If the related HPDMA channel x is also programmed in peripheral flow-control mode (HPDMA_CxTR2.PFREQ = 1):

- The HPDMA block transfer starts as follows:
  - If HPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the HPDMA hardware.
  - If HPDMA_CxBR1.BNDT[15:0] = 0, the HPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The HPDMA block transfer is completed as soon as the first occurrence of any of the following condition occurs:
  - When HPDMA_CxBR1.BNDT[15:0] = 0
  - When the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on HPDMA_CxTR2. Then the software can read the current number of transferred bytes from the source (HPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (HPDMA_CxSAR[31:0] or HPDMA_CxDAR[31:0]).

In peripheral flow-control mode:

- A destination peripheral with an hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- HPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

12.4.16 HPDMA byte-based padding at the block level

For a given channel x, a LLI_n data transfer consists of a block transfer and is defined by the source block size HPDMA_CxBR1.BNDT[15:0], the size of the block of data to be transfered from the source, in bytes.

During a peripheral-to-memory transfer, a peripheral may be streaming and receiving a given number of bytes (for example, via an I2C, UART/USART/LPUART, ADC, DAC) or half-words, and this block size may not be a multiple of a word or a double-word. It is important to allow the user to program any number of bytes for the HPDMA source block size independently from the source data width and the destination data width, in order to use efficiently the bandwidth via the data width of the AHB system bus and/or the AXI system bus when accessing and writing into memory (embedded SRAM, NVM or external memory). This enables to decrease the bus bandwidth for the memory transfers by a ratio of up to 4 in 32-bit AHB and up to 8 in 64-bit AXI system. More generally, having the source block size independent from the source data width and the destination data width can be useful also with memory-to-peripheral transfers, and with memory-to-memory transfers (AHB from/to AXI).

A FIFO-based channel is able to perform byte-based padding on the last write(s) up to the fully transferred source block size. Then channel FIFO is empty. Data handling is performed on zero bytes in the same way as on regular data bytes from the source, as explained in *HPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension, and left/right alignment*.

There is byte-based padding at the block level:

1. If source data width is less than the destination data width, and if FIFO queuing and data packing is configured (PAM[1:0] = 1x):

- Padding with zero bytes. For example, if BNDT= 5, 8-bit reads, 32-bit writes:
  - If DBX = 0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> 000B_4, $B_3B_2B_1B_0$
  - If DBX = 0, DHX = 1: B_4,B_3,B_2,B_1,B_0 -> 0$B_4$00, $B_1B_0B_3B_2$
  - If DBX = 1, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> 00$B_4$0, $B_2B_3B_0B_1$
  - If DBX = 1, DHX = 1: B_4,B_3,B_2,B_1,B_0 -> $B_4$000, $B_0B_1B_2B_3$

2. If source data width > destination data width, and if FIFO queuing and data unpacking is configured (PAM[1:0] = 1x):

- Padding with zero bytes.
- On the last read, only the number of LSB(s) up to the block size are written to the FIFO. The last written data to the destination is padded with zero bytes up to the destination data width. For example, if BNDT= 5, 32-bit reads, 16-bit writes:
  - If DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 0B_4, B_3B_2, B_1B_0
  - If DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$, -> $B_4$0, B_2B_3, B_0B_1

3. If source data width = destination data width (and BNDT[15:0] is not a multiple of that value):

- Padding with zero bytes. For example, if BNDT= 6, 32-bit reads, 32-bit writes are configured
  - If SBX = 0, DBX = 0, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_5B_4$, $B_3B_2B_1B_0$
  - If SBX = 0, DBX = 0, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_5B_400, $B_1B_0B_3B_2$
  - If SBX = 0, DBX = 1, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_4B_5$, $B_2B_3B_0B_1$
  - If SBX = 0, DBX = 1, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_4B_500, $B_0B_1B_2B_3$
  - If SBX = 1, DBX = 0, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $000B_4$, $B_3B_1B_2B_0$
  - If SBX = 1, DBX = 0, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_400$, $B_2B_0B_3B_1$
  - If SBX = 1, DBX = 1, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_40$, $B_1B_3B_0B_2$
  - If SBX = 1, DBX = 1, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_4000, $B_0B_2B_1B_3$

4. If source data width < destination data width, and if destination data is configured as right-aligned and, either configured with zero padding bytes (PAM[1:0] = 00), or configured with sign extension (PAM[1:0] = 01):

- Padding with zero bytes if PAM[1:0] = 00. For example, BNDT = 5, 8-bit reads, 32-bit writes, PAM[1:0] = 00:
  - If DBX =0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> $000B_4$, $000B_3$, $000B_2$, $000B_1$, $000B_0$
- Padding with sign extension if PAM[1:0] = 01. For example, BNDT = 5, 8-bit reads, 32-bit writes, PAM[1:0] = 01:
  - If DBX = 0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> $SSSB_4$, $SSSB_3$, $SSSB_2$, $SSSB_1$, $SSSB_0$

5. If source data width > destination data width, and if destination data is configured as right-aligned (PAM[1:0] = 00), or left-aligned (PAM[1:0] = 01):

- Padding with zero bytes. For example, BNDT = 5, 32-bit reads, 16-bit writes:
  - If SBX = 0, PAM[1:0] = 00, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_4$, B_1B_0
  - If SBX = 0, PAM[1:0] = 00, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_40, B_0B_1
  - If SBX = 0, PAM[1:0] = 01, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_3B_2
  - If SBX = 0, PAM[1:0] = 01, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_2B_3
  - If SBX = 1, PAM[1:0] = 00, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_4$, B_2B_0
  - If SBX = 1, PAM[1:0] = 00, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_40, B_0B_2
  - If SBX = 1, PAM[1:0] = 01, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_3B_1
  - If SBX = 0, PAM[1:0] = 01, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_1B_3

12.4.17 HPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via HPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a bitfield of this channel is forced to return 0, except for HPDMA_PRIVCFGR that is readable by an unprivileged agent.
- An unprivileged write access to a bitfield of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB/AXI master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the HPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the HPDMA_CxCR.LAP allocated master port.

The HPDMA generates a privileged bus that reflects HPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each HPDMA channel x.

12.4.18 HPDMA error management

The HPDMA can manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as an AHB/AXI single or a burst) to the source or the destination

- The source or destination target reports an AHB/AXI error.
- The programmed channel transfer is stopped (HPDMA_CxCR.EN cleared by the HPDMA hardware). The channel status register reports an idle state (HPDMA_CxSR.IDLEF = 1) and the data error (HPDMA_CxSR.DTEF = 1).
- After an HPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After an HPDMA data transfer error, the user must issue a channel reset (set HPDMA_CxCR.RESET) to reset the hardware HPDMA channel data path and the FIFO content, before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a HPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB/AXI error.
- The programmed channel transfer is stopped (HPDMA_CxCR.EN cleared by the HPDMA hardware), the channel status register reports an idle state HPDMA_CxSR.IDLEF = 1), and the link error (HPDMA_CxSR.ULEF = 1).
- After an HPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (HPDMA_CxLBAR and HPDMA_CxLLR), including the protection attributes.
- After an HPDMA link error, the user must explicitly write the linked-list register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 when present), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of an HPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (HPDMA_CxCR.EN forced and cleared by the HPDMA hardware), preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (HPDMA_CxSR.IDLEF = 1), and a user setting error (HPDMA_CxSR.USEF = 1).

- After an HPDMA user setting error, the user must perform a debug session, taking care of the HPDMA channel programming. A user setting error can be caused by one of the following:
  - A programmed null source block size without a programmed update of this value from the next LLI_1 (HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxLLR.UB1 = 0)
  - A programmed unaligned source start address being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxSAR versus HPDMA_CxTR1.SDW_LOG2)
  - For a channel with 2D addressing, a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxTR3.SAO versus HPDMA_CxTR1.SDW_LOG2)
  - For a channel with 2D addressing, a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxBR2.BRSAO versus HPDMA_CxTR1.SDW_LOG2)
  - A programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxDAR versus HPDMA_CxTR1.DDW_LOG2)
  - For a channel with 2D addressing, a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxTR3.DAO versus HPDMA_CxTR1.DDW_LOG2)
  - For a channel with 2D addressing, a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxBR2.BRDAO versus HPDMA_CxTR1.DDW_LOG2)
  - A programmed source burst data width being superior than the data width of the allocated AXI/AHB source port (HPDMA_CxTR1.SDW_LOG2 and HPDMA_CxTR1.SAP vs the implemented AXI/AHB port data width).
  - A programmed destination burst data width being superior than the data width of the allocated AXI/AHB destination port (HPDMA_CxTR1.DDW_LOG2 and HPDMA_CxTR1.DAP vs the implemented AXI/AHB port data width).
  - A programmed linked-list item LLI_{n+1} with a null data transfer (HPDMA_CxLLR.UB1 = 1 and HPDMA_CxBR1. BNDT[15:0] = 0)

12.5 HPDMA in debug mode

When the device enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, HPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, HPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

12.6 HPDMA in low-power modes

Table 90. Effect of low-power modes on HPDMA

Mode	Description
Sleep	No effect. HPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of HPDMA registers is kept when entering Stop mode.
Standby	The HPDMA is powered down, and must be reinitialized after exiting Standby mode.

1. Refer to *Section 12.3.2* to know if Stop mode is supported or not.

12.7 HPDMA interrupts

There is one HPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 91. HPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
HPDMA_CHx	Transfer complete	HPDMA_CxCR.TCIE	HPDMA_CxSR.TCF	Writes 1 to HPDMA_CxFCR.TCF
	Half transfer	HPDMA_CxCR.HTIE	HPDMA_CxSR.HTF	Writes 1 to HPDMA_CxFCR.HTF
	Data transfer error	HPDMA_CxCR.DTEIE	HPDMA_CxSR.DTEF	Writes 1 to HPDMA_CxFCR.DTEF
	Update link error	HPDMA_CxCR.ULEIE	HPDMA_CxSR.ULEF	Writes 1 to HPDMA_CxFCR.ULEF
	User setting error	HPDMA_CxCR.USEIE	HPDMA_CxSR.USEF	Writes 1 to HPDMA_CxFCR.USEF
	Suspended	HPDMA_CxCR.SUSPIE	HPDMA_CxSR.SUSPF	Writes 1 to HPDMA_CxFCR.SUSPF
	Trigger overrun	HPDMA_CxCR.TOFIE	HPDMA_CxSR.TOF	Writes 1 to HPDMA_CxFCR.TOF

An HPDMA channel x event can be:

- A transfer complete
- A half-transfer complete
- A transfer error, due to either:
  - A data transfer error
  - An update link error
  - A user setting error completed suspension
- A trigger overrun

Note: When a channel x transfer complete event occurs, the output signal hpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- The corresponding interrupt event xx is enabled (HPDMA_CxCR.xxIE = 1)
- The corresponding event flag is cleared (HPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into HPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by HPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer-complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode HPDMA_CxTR2.TCEM[1:0].
- A half-transfer event is a half-block transfer, or a half 2D/repeated block transfer, depending on the transfer complete event mode HPDMA_CxTR2.TCEM[1:0].

  A half-block transfer occurs when half of the source block size bytes (rounded-up integer of HPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

  A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (HPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *HPDMA channel x transfer register 2 (HPDMA_CxTR2)* for more details.

Note: The interrupt mode must be used (not the polling mode) to be notified on a half transfer when the write data transaction has been completed over the AXI destination allocated port (written at the destination memory-mapped address), and not just before when has been issued, at HPDMA level, this AXI burst transaction.

A transfer error rises in one of the following situations:

- During a single/burst data transfer from the source or to the destination (DTEF)
- During an update of an HPDMA channel register from the programmed LLI in memory (ULEF)
- During a tentative execution of an HPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the HPDMA channel programming versus the USEF root causes list (see *Section 12.4.18*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

12.8 HPDMA registers

The HPDMA registers must be accessed with an aligned 32-bit word data access.

12.8.1 HPDMA privileged configuration register (HPDMA_PRIVCFGR)

Address offset: 0x004

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a HPDMA channel (HPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PRIVx**: Privileged state of channel x (x = 15 to 0)
0: Unprivileged
1: Privileged

12.8.2 HPDMA configuration lock register (HPDMA_RCFGLOCKR)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be written by a software agent with privileged attributes in order to individually lock, for example at boot time, the privileged attributes of any HPDMA channel/resource (to lock the setting of HPDMA_PRIVCFGR for any channel x at, for example at boot time).

A read access may be privileged or unprivileged.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LOCKx**: Lock of the configuration of HPDMA_PRIVCFGR.PRIVx until a global HPDMA reset (x = 15 to 0)
This bit is cleared after reset and, once set, it cannot be reset until a global HPDMA reset.
0: privilege configuration of the channel x is writable.
1: privilege configuration of the channel x is not writable.

12.8.3 HPDMA masked interrupt status register (HPDMA_MISR)

Address offset: 0x0C

Reset value: 0x0000 0000

This is a read register.

This register contains the masked interrupt status bit MISx for each channel x. It is a logical OR of all the HPDMA_CxSR flags, each source flag being enabled by the corresponding HPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when writing 1 to the corresponding HPDMA_CxFCR flag clear bit.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel HPDMA_PRIVCFGR.PRIVx. A privileged software can read the full interrupt status. An unprivileged software is restricted to read the status of unprivileged channels, other privileged bitfields returning zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISx**: Masked interrupt status of channel x (x = 15 to 0)
0: No interrupt occurred on channel x.
1: An interrupt occurred on channel x.

12.8.4 HPDMA channel x linked-list base address register (HPDMA_CxLBAR)

Address offset: 0x050 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x HPDMA_PRIVCFGR.PRIVx.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the HPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit HPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 **LBA[31:16]**: Linked-list base address of HPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

12.8.5 HPDMA channel x flag clear register (HPDMA_CxFCR)

Address offset: 0x05C+ 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This is a write register privileged or unprivileged, depending on the privileged state of the channel x (HPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: Trigger overrun flag clear
0: No effect
1: Corresponding TOF flag cleared

Bit 13 **SUSPF**: Completed suspension flag clear
0: No effect
1: Corresponding SUSPF flag cleared

Bit 12 **USEF**: User setting error flag clear
0: No effect
1: Corresponding USEF flag cleared

Bit 11 **ULEF**: Update link transfer error flag clear
0: No effect
1: Corresponding ULEF flag cleared

Bit 10 **DTEF**: Data transfer error flag clear
0: No effect
1: Corresponding DTEF flag cleared

Bit 9 **HTF**: Half-transfer flag clear
0: No effect
1: Corresponding HTF flag cleared

Bit 8 **TCF**: Transfer complete flag clear
0: No effect
1: Corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

12.8.6 HPDMA channel x status register (HPDMA_CxSR)

Address offset: 0x060 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is privileged or unprivileged, depending on the privileged state of the channel (HPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[8:0]								
							r	r	r	r	r	r	r	r	r

	r	r	r	r	r	r	r							r	r

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **FIFOL[8:0]**: Monitored FIFO level (in bytes)
Number of available bytes in the FIFO.

Note: After having suspended an active transfer, the user may need to read FIFOL[8:0], additionally to HPDMA_CxBR1.BDNT[15:0] and HPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (HPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: Trigger overrun flag
0: No trigger overrun event
1: A trigger overrun event occurred.

Bit 13 **SUSPF**: Completed suspension flag
0: No completed suspension event
1: A completed suspension event occurred.

Bit 12 **USEF**: User setting error flag
0: No user setting error event
1: A user setting error event occurred.

Bit 11 **ULEF**: Update link transfer error flag
0: No update link transfer error event
1: A master bus error event occurred while updating a linked-list register from memory.

Bit 10 **DTEF**: Data transfer error flag
0: No data transfer error event
1: A master bus error event occurred on a data transfer.

Bit 9 **HTF**: Half-transfer flag
0: No half-transfer event
1: A half-transfer event occurred.
A half-transfer event is either a half-block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (HPDMA_CxTR2.TCEM[1:0]).
A half-block transfer occurs when half of the bytes of the source block size (rounded up integer of HPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.
A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (HPDMA_CxBR1.BRC[10:0]+1)/2)) has been transferred to the destination.

Bit 8 **TCF**: Transfer complete flag
0: No transfer complete event
1: A transfer complete event occurred.
A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (HPDMA_CxTR2.TCEM[1:0]).

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **DRAININGF**: FIFO draining flag
0: No received order to drain the FIFO or channel FIFO draining completed
1: Ongoing channel FIFO draining and channel termination
This flag is asserted after that the order to drain the FIFO is received, and meanwhile that the channel is enabled and draining the FIFO and before the channel is terminated with a drained FIFO.
This flag is deasserted by hardware when the enabled channel has been ordered to be terminated with FIFO draining, and the hardware effectively terminates.

Bit 0 **IDLEF**: Idle flag
0: Channel not in idle state
1: Channel in idle state
This idle flag is deasserted by hardware when the channel is enabled (HPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

12.8.7 HPDMA channel x control register (HPDMA_CxCR)

Address offset: 0x064 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x (HPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	LAP	LSM

Res.	TOIE	SUSPIE	USEIE	ULEIE	DTEIE	HTIE	TCIE	Res.	Res.	Res.	Res.	DRAIN FIFO	SUSP	RESET	EN
	rw	rw	rw	rw	rw	rw	rw					w	rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** Priority level of the channel x HPDMA transfer versus others
00: Low priority, low weight
01: Low priority, mid weight
10: Low priority, high weight
11: High priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: Linked-list allocated port
This bit is used to allocate the master port for the update of the HPDMA linked-list registers from the memory.
0: Port 0 (AXI) allocated
1: Port 1 (AHB) allocated
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 **LSM**: Link step mode
0: Channel executed for the full linked-list and completed at the end of the last LLI (HPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0 if present). Then HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 if present.
1: Channel executed once for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0, if present. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by HPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: Trigger overrun interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 13 **SUSPIE**: Completed suspension interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 12 **USEIE**: User setting error interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 11 **ULEIE**: Update link transfer error interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 10 **DTEIE**: Data transfer error interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 9 **HTIE**: Half-transfer complete interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 8 **TCIE**: Transfer complete interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DRAINFIFO:** Empty FIFO
This bit is write only. Writing 0 has no impact.
Writing 1 to RESET in this register causes the hardware to deassert this DRAINFIFO bit, whatever is written into this DRAINFIFO. Else:
Software must write 1 in order to drain the channel FIFO on a suspended channel.
If the software concurrently writes 1 to DRAINFIFO and 1 to SUSP and 0 to reset, the hardware suspends the channel and drains the FIFO by popping out the residual FIFO bytes to the destination (see the programming sequence in *Figure 83*).
0: Write: no action
1: Write: drain FIFO after having suspended the channel

Bit 2 **SUSP:** Suspend
Writing 1 to RESET in this register causes the hardware to deassert this SUSP bit, whatever is written into this SUSP. Else:
Software must write 1 in order to suspend an active channel (a channel with an ongoing HPDMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 81*.
0: Write: resume channel, read: channel not suspended
1: Write: suspend channel, read: channel suspended

Bit 1 **RESET:** Reset

This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP, DRAINFIFO and EN bits (whatever is written receptively in bit 3 and bit 2 and bit 0).

The reset is effective when the channel is in steady state, meaning one of the following:

- active channel in suspended state (HPDMA_CxSR.SUSPF = 1 and HPDMA_CxSR.IDLEF = HPDMA_CxCR.EN = 1 and HPDMA_CxSR.DRAININGF = 0)
- channel in disabled state (HPDMA_CxSR.IDLEF = 1 and HPDMA_CxCR.EN = 0).

After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (HPDMA_CxBR1, HPDMA_CxSAR and HPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 82*).

0: No channel reset

1: Channel reset

Bit 0 **EN:** Enable

Writing 1 to RESET in this register causes the hardware to deassert this EN bit, whatever is written into this bit 0. Else:

This bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: Write: ignored, read: channel disabled

1: Write: enable channel, read: channel enabled

12.8.8 HPDMA channel x transfer register 1 (HPDMA_CxTR1)

Address offset: 0x090 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x in HPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory if HPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	DAP	Res.	DWX	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]

	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **DAP**: Destination allocated port

This bit is used to allocate the master port for the destination transfer

0: Port 0 (AXI) allocated

1: Port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DWX**: Destination word exchange

If the destination data size is not a double-word, this bit is ignored.

If the destination data size is a double-word and if destination bus is AXI (DAP = 0):

0: No word-based exchanged within double-word

1: The two consecutive (post PAM) words are exchanged in each destination double-word.

Bit 27 **DHX**: Destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word or double-word and if destination bus is AXI (DAP = 0):

0: No half-word-based exchanged within word

1: The two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: Destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0: No byte-based exchange within half-word

1: The two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: Destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Note: If a burst transfer crossed a 1- or 4-Kbyte address boundary on respectively an AHB or AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol.

If the burst length exceeds 16 on an AHB transfer, or if the burst on an AXI transfer is both with fixed addressing (DINC = 0) and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into bursts of lower length, to be compliant with the AHB or AXI protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with HPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: Destination incrementing burst

0: Fixed burst

1: Contiguously incremented burst

The destination address, pointed by HPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: Binary logarithm of the destination data width of a burst, in bytes
00: Byte
01: Half-word (2 bytes)
10: Word (4 bytes)
11: Double-word (8 bytes)

Note: A destination burst data width must be less or equal to the implemented data width of the allocated AXI/AHB destination port via the DAP bit (it is recommended to be equal for best performance). Otherwise a user setting error is reported and no transfer is issued.

A destination burst transfer must have an aligned destination i) address (HPDMA_CxDAR[2:0]), ii) address offset HPDMA_CxTR3.DAO[2:0] if present, with its destination data width (DDW_LOG2[2:0]). Otherwise a user setting error is reported and no transfer is issued.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **SAP**: Source allocated port
This bit is used to allocate the master port for the source transfer
0: Port 0 (AXI) allocated
1: Port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: Source byte exchange within the unaligned half-word of each source word
If the source data width is shorter than a word, this bit is ignored.
If the source data width is a word or a double-word, and if source bus is AXI (SAP = 0):
0: No byte-based exchange within the unaligned half-word of each source word
1: The two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: Padding/alignment mode
If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.
Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.
Condition: PAM_1
00: Source data is transferred as right aligned, padded with 0s up to the destination data width
01: Source data is transferred as right aligned, sign extended up to the destination data width
10-11: Successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer
Condition: PAM_2
00: Source data is transferred as right aligned, left-truncated down to the destination data width
01: Source data is transferred as left-aligned, right-truncated down to the destination data width
10-11: Source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Note: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: Source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Note: If a burst transfer crossed a 1- or 4-Kbyte address boundary on respectively an AHB or an AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If the burst length exceeds 16 on a AHB transfer, or if the burst on a AXI transfer is both with fixed addressing (SINC = 0) and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with HPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: Source incrementing burst

0: Fixed burst

1: Contiguously incremented burst

The source address, pointed by HPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: Binary logarithm of the source data width of a burst in bytes

00: Byte

01: Half-word (2 bytes)

10: Word (4 bytes)

11: Double-word (8 bytes)

Note: A source burst data width must be less or equal to the implemented data width of the allocated AXI/AHB source port via the SAP bit (it is recommended to be equal for best performance). Otherwise a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned source i) address (HPDMA_CxSAR[2:0]), ii) address offset HPDMA_CxTR3.SAO[2:0] if present, with its source data width (SDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

12.8.9 HPDMA channel x transfer register 2 (HPDMA_CxTR2)

Address offset: 0x094 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory, if HPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	Res.	TRIGSEL[5:0]					
rw	rw					rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	DREQ	SWREQ	Res.	REQSEL[7:0]							
rw	rw		rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: Transfer complete event mode

These bits define the transfer granularity for the transfer complete and half-transfer complete events generation.

00: At block level (when HPDMA_CxBR1.BNDT[15:0] = 0): The complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half-transfer event is generated.

01: if the channel is not 2D addressing capable: same as 00; if the channel is 2D addressing capable: at 2D/repeated block level, meaning when HPDMA_CxBR1.BRC[10:0] = 0 and HPDMA_CxBR1.BNDT[15:0] = 0), the complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half-transfer event is generated.

10: At LLI level: The complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half-transfer event is generated at the half of the LLI data transfer (the LLI data transfer being a block transfer or a 2D/repeated block transfer for a 2D addressing capable channel), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then the half-transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: At channel level: The complete transfer event is generated at the end of the last LLI transfer. The half-transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address HPDMA_CxLLR.LA[15:2] to zero and clears all the HPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2 if present). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: Trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: No trigger (masked trigger event)

01: Trigger on the rising edge

10: Trigger on the falling edge

11: Same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]**: Trigger event input selection

These bits select the trigger event input of the HPDMA transfer (as per *Section 12.3.6*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: Trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (HPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, an HPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger. This is also valid for a 2D addressing capable channel: for each block even if a 2D/repeated block is configured with HPDMA_CxBR1.BRC[10:0] ≠ 0.

01: if the channel is not 2D addressing capable: same as 00; if the channel is 2D addressing capable: at 2D/repeated block level, meaning the first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The HPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the HPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (HPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (HPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1/4-Kbyte boundary address crossing maximum burst length versus AHB/AXI protocol): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 12.3.5 for the list of the implemented channels with this feature.

If the channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in HPDMA control mode. The HPDMA is programmed with HPDMA_CxCBR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The HPDMA block transfer can be early completed by the peripheral itself (see *Section 12.3.5* for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (HPDMA_CxBR1.BRC[10:0] must be set to 0 if present)

- the peripheral must be set as the source of the transfer (DREQ = 0).

- data packing to a wider destination width is not supported (if destination width > source data width, HPDMA_CxTR1.PAM[1] must be set to 0).

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 12.3.4*).

Bit 10 **DREQ**: Destination hardware request

This bit is ignored if channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: Selected hardware request driven by a source peripheral (request signal taken into account by the HPDMA transfer scheduler over the source/read port)

1: Selected hardware request driven by a destination peripheral (request signal taken into account by the HPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (HPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: Software request

This bit is internally taken into account when HPDMA_CxCR.EN is asserted.

0: No software request. The selected hardware request REQSEL[7:0] is taken into account.

1: Software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[7:0] is ignored.

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **REQSEL[7:0]**: Hardware request selection

These bits are ignored if channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 12.3.3*.

Caution: The user must not assign a same input hardware request (same REQSEL[7:0] value) to different active HPDMA channels (HPDMA_CxCR.EN = 1 and HPDMA_CxTR2.SWREQ = 0 for these channels). The HPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

12.8.10 HPDMA channel x block register 1 (HPDMA_CxBR1)

Address offset: 0x098 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer:

- If HPDMA_CxLLR.UB1 = 1, this register is automatically updated by the HPDMA from the next LLI in memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the bitfield BNDT[15:0].
- If all the update bits HPDMA_CxLLR.Uxx are null and if HPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If HPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: Block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this bitfield becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if HPDMA_CxLLR.UB1 = 1, this bitfield is updated with the LLI in the memory.
- if HPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this bitfield is internally restored to the programmed value.
- if all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] = 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).
  - if HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI data transfer.

12.8.11 HPDMA channel x alternate block register 1 (HPDMA_CxBR1)

Address offset: 0x098 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer:

- if HPDMA_CxLLR.UB1 = 1, this register is automatically updated by the HPDMA from the next LLI in memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the bitfields BNDT[15:0] and BRC[10:0].
- If all the update bits HPDMA_CxLLR.Uxx are null and if HPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for the bitfields BNDT[15:0] and BRC[10:0] after each execution of this final LLI
- If HPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: At the end of a block transfer, the HPDMA_CxDAR register is updated by adding the programmed offset HPDMA_CxBR2.BRDAO to the current HPDMA_CxDAR value (current destination address)

1: At the end of a block transfer, the HPDMA_CxDAR register is updated by subtracting the programmed offset HPDMA_CxBR2.BRDAO from the current HPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), HPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the HPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: At the end of a block transfer, the HPDMA_CxSAR register is updated by adding the programmed offset HPDMA_CxBR2.BRSAO to the current HPDMA_CxSAR value (current source address)

1: At the end of a block transfer, the HPDMA_CxSAR register is updated by subtracting the programmed offset HPDMA_CxBR2.BRSAO from the current HPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), HPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the HPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the HPDMA_CxDAR register is updated by adding the programmed offset HPDMA_CxTR3.DAO to the current HPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the HPDMA_CxDAR register is updated by subtracting the programmed offset HPDMA_CxTR3.DAO to the current HPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the HPDMA_CxSAR register is updated by adding the programmed offset HPDMA_CxTR3.SAO to the current HPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the HPDMA_CxSAR register is updated by subtracting the programmed offset HPDMA_CxTR3.SAO to the current HPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This bitfield contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this bitfield becomes read-only. After decrements, this bitfield indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

- If HPDMA_CxLLR.UB1 = 1, all HPDMA_CxBR1 bitfields are updated by the next LLI in the memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this bitfield is internally restored to the programmed value.
- If all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] ≠ 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).
- If HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: Block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this bitfield becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred.

BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- If HPDMA_CxLLR.UB1 = 1, this bitfield is updated with the LLI in the memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this bitfield is internally restored to the programmed value.
- If all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] ≠ 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).

If HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI data transfer.

12.8.12 HPDMA channel x source address register (HPDMA_CxSAR)

Address offset: 0x09C + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: Source address

This bitfield is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (HPDMA_CxTR1.SINC), this bitfield is kept fixed or incremented by the data width (HPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

- The programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (HPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by HPDMA_CxTR1.SBL_1[5:0] and HPDMA_CxTR1.SDW_LOG2[1:0]
- The additional source incremented/decremented offset value as programmed by HPDMA_CxBR1.SDEC and HPDMA_CxTR3.SAO[12:0]
- Once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15). additional block repeat source incremented/decremented offset value as programmed by HPDMA_CxBR1.BRSDEC and HPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by HPDMA from the memory, provided the LLI is set with HPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA versus HPDMA_CxTR1.SDW_LOG2). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional HPDMA_CxTR3.SAO[12:0] is not applied.

12.8.13 HPDMA channel x destination address register (HPDMA_CxDAR)

Address offset: 0x0A0 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory if HPDMA_CxLLR.UDA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This bitfield is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (HPDMA_CxTR1.DINC), this bitfield is kept fixed or incremented by the data width (HPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (HPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by HPDMA_CxTR1.DBL_1[5:0] and HPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by HPDMA_CxBR1.DDEC and HPDMA_CxTR3.DAO[12:0]

– once/if completed destination block transfer, for a channel x with 2D addressing capability , the additional block repeat destination incremented/decremented offset value as programmed by HPDMA_CxBR1.BRDDEC and HPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the HPDMA from the memory, provided the LLI is set with HPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA versus HPDMA_CxTR1.DDW_LOG2). Else, a user setting error is reported and no transfer is issued.

12.8.14 HPDMA channel x transfer register 3 (HPDMA_CxTR3)

Address offset: 0x0A4 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.UT3 = 1.

Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: Destination address offset increment

The destination address, pointed by HPDMA_CxDAR, is incremented or decremented (depending on HPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (HPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO versus HPDMA_CxTR1.DDW_LOG2). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: Source address offset increment

The source address, pointed by HPDMA_CxSAR, is incremented or decremented (depending on HPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (HPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO versus HPDMA_CxTR1.SDW_LOG2). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional HPDMA_CxTR3.SAO[12:0] is not applied.

12.8.15 HPDMA channel x block register 2 (HPDMA_CxBR2)

Address offset: 0x0A8 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this bitfield is used to update (by addition or subtraction depending on HPDMA_CxBR1.BRDDEC) the current destination address (HPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO versus HPDMA_CxTR1.DDW_LOG2). Else a user setting error is reported and no transfer is issued.
BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if HPDMA_CxTR2.PFREQ = 1).

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this bitfield is used to update (by addition or subtraction depending on HPDMA_CxBR1.BRSDEC) the current source address (HPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO versus HPDMA_CxTR1.SDW_LOG2). Else a user setting error is reported and no transfer is issued.
BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if HPDMA_CxTR2.PFREQ = 1).

12.8.16 HPDMA channel x linked-list address register (HPDMA_CxLLR)

Address offset: 0x0CC + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.ULL = 1.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update HPDMA_CxTR1 from memory

This bit controls the update of HPDMA_CxTR1 from the memory during the link transfer.
0: No HPDMA_CxTR1 update
1: HPDMA_CxTR1 update

Bit 30 **UT2**: Update HPDMA_CxTR2 from memory

This bit controls the update of HPDMA_CxTR2 from the memory during the link transfer.
0: No HPDMA_CxTR2 update
1: HPDMA_CxTR2 update

Bit 29 **UB1**: Update HPDMA_CxBR1 from memory

This bit controls the update of HPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if HPDMA_CxLLR ≠ 0, the linked-list is not completed.
HPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: No HPDMA_CxBR1 update from memory (HPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: HPDMA_CxBR1 update

Bit 28 **USA**: Update HPDMA_CxSAR from memory

This bit controls the update of HPDMA_CxSAR from the memory during the link transfer.
0: No HPDMA_CxSAR update
1: HPDMA_CxSAR update

Bit 27 **UDA**: Update HPDMA_CxDAR register from memory
This bit is used to control the update of HPDMA_CxDAR from the memory during the link transfer.
0: No HPDMA_CxDAR update
1: HPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update HPDMA_CxLLR register from memory
This bit is used to control the update of HPDMA_CxLLR from the memory during the link transfer.
0: No HPDMA_CxLLR update
1: HPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: Pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list HPDMA register file.
Else, this bitfield is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list HPDMA internal register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR).

Caution: the user must program this pointer not to exceed the 64-Kbyte addressable space defined by the link base address register HPDMA_CxLBAR. The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

12.8.17 HPDMA channel x alternate linked-list address register (HPDMA_CxLLR)

Address offset: 0x0CC + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update HPDMA_CxTR1 from memory

This bit controls the update of HPDMA_CxTR1 from the memory during the link transfer.

0: No HPDMA_CxTR1 update

1: HPDMA_CxTR1 update

Bit 30 **UT2**: Update HPDMA_CxTR2 from memory

This bit controls the update of HPDMA_CxTR2 from the memory during the link transfer.

0: No HPDMA_CxTR2 update

1: HPDMA_CxTR2 update

Bit 29 **UB1**: Update HPDMA_CxBR1 from memory

This bit controls the update of HPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if HPDMA_CxLLR ≠ 0, the linked-list is not completed.
HPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.

0: No HPDMA_CxBR1 update from memory (HPDMA_CxBR1.BNDT[15:0] restored if any link transfer)

1: HPDMA_CxBR1 update

Bit 28 **USA**: Update HPDMA_CxSAR from memory

This bit controls the update of HPDMA_CxSAR from the memory during the link transfer.

0: No HPDMA_CxSAR update

1: HPDMA_CxSAR update

Bit 27 **UDA**: Update HPDMA_CxDAR register from memory
This bit is used to control the update of HPDMA_CxDAR from the memory during the link transfer.
0:No HPDMA_CxDAR update
1: HPDMA_CxDAR update

Bit 26 **UT3**: Update HPDMA_CxTR3 from memory
This bit controls the update of HPDMA_CxTR3 from the memory during the link transfer.
0: No HPDMA_CxTR3 update
1: HPDMA_CxTR3 update

Bit 25 **UB2**: Update HPDMA_CxBR2 from memory
This bit controls the update of HPDMA_CxBR2 from the memory during the link transfer.
0: No HPDMA_CxBR2 update
1: HPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update HPDMA_CxLLR register from memory
This bit is used to control the update of HPDMA_CxLLR from the memory during the link transfer.
0: No HPDMA_CxLLR update
1: HPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: Pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL= 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list HPDMA register file.
Else, this bitfield is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list HPDMA internal register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR and HPDMA_CxLLR).

Caution: the user must program this pointer not to exceed the 64-Kbyte addressable space defined by the link base address register HPDMA_CxLBAR. The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

12.8.18 HPDMA register map

Table 92. HPDMA register map and reset values

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

13 General purpose direct memory access controller (GPDMA)

13.1 GPDMA introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

13.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half-transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 13.3.1*)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level and byte-based padding
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers

  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 13.3.1*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Programmable GPDMA request and trigger selection
  - Programmable GPDMA half-transfer and transfer complete events generation
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers
  - Channel abort and restart
  - Channel terminate with FIFO draining
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- Privileged/unprivileged support:
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

13.3 GPDMA implementation

13.3.1 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.

Table 93. GPDMA1 channel implementation

Channel x	Hardware parameters		Features
	dma_fifo_size[x]	dma_addressing[x]	
x = 0 to 11	2	0	Channel x (x = 0 to 11) is implemented with: – a FIFO of 8 bytes, 2 words – fixed/contiguously incremented addressing These channels must be typically allocated for GPDMA transfers between an APB or AHB peripheral and AHB SRAM.
x = 12 to 15	4	1	Channel x (x = 12 to 15) is implemented with: – a FIFO of 32 bytes, 8 words – 2D addressing These channels may be also used for GPDMA transfers, between a demanding AHB peripheral and AHB SRAM, or for transfers from/to AXI SRAM or external AXI memories.

13.3.2 GPDMA in low-power modes

The GPDMA wake-up feature is implemented in the device low-power modes as per the table below.

Table 94. GPDMA1 wake-up in low-power modes

Feature	Low-power modes
Wake-up	GPDMA1 in Sleep mode

13.3.3 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via REQSEL[7:0] in GPDMA_CxTR2, provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

13.3.4 GPDMA block requests

Some GPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in GPDMA_CxTR2 must be set for a correct GPDMA execution of the requested peripheral transfer at the hardware level.

Table 96. Programmed GPDMA1 request as a block request

GPDMA block requests
lptim1_ue_dma
lptim2_ue_dma
lptim3_ue_dma

13.3.5 GPDMA channels with peripheral early termination

A GPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 97. GPDMA1 channel with peripheral early termination

GPDMA channel x with peripheral early termination
x = 0 and x = 15

This GPDMA support is activated when the channel x is programmed with GPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before the GPDMA has transferred the whole block (see *Section 13.4.15* for more details).

Table 98. Programmed GPDMA1 request with peripheral early termination

Programmed GPDMA channel x request with peripheral early termination
i3c1_rx_dma

13.3.6 GPDMA triggers

A GPDMA trigger can be assigned to a GPDMA channel x, via TRIGSEL[5:0] in GPDMA_CxTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

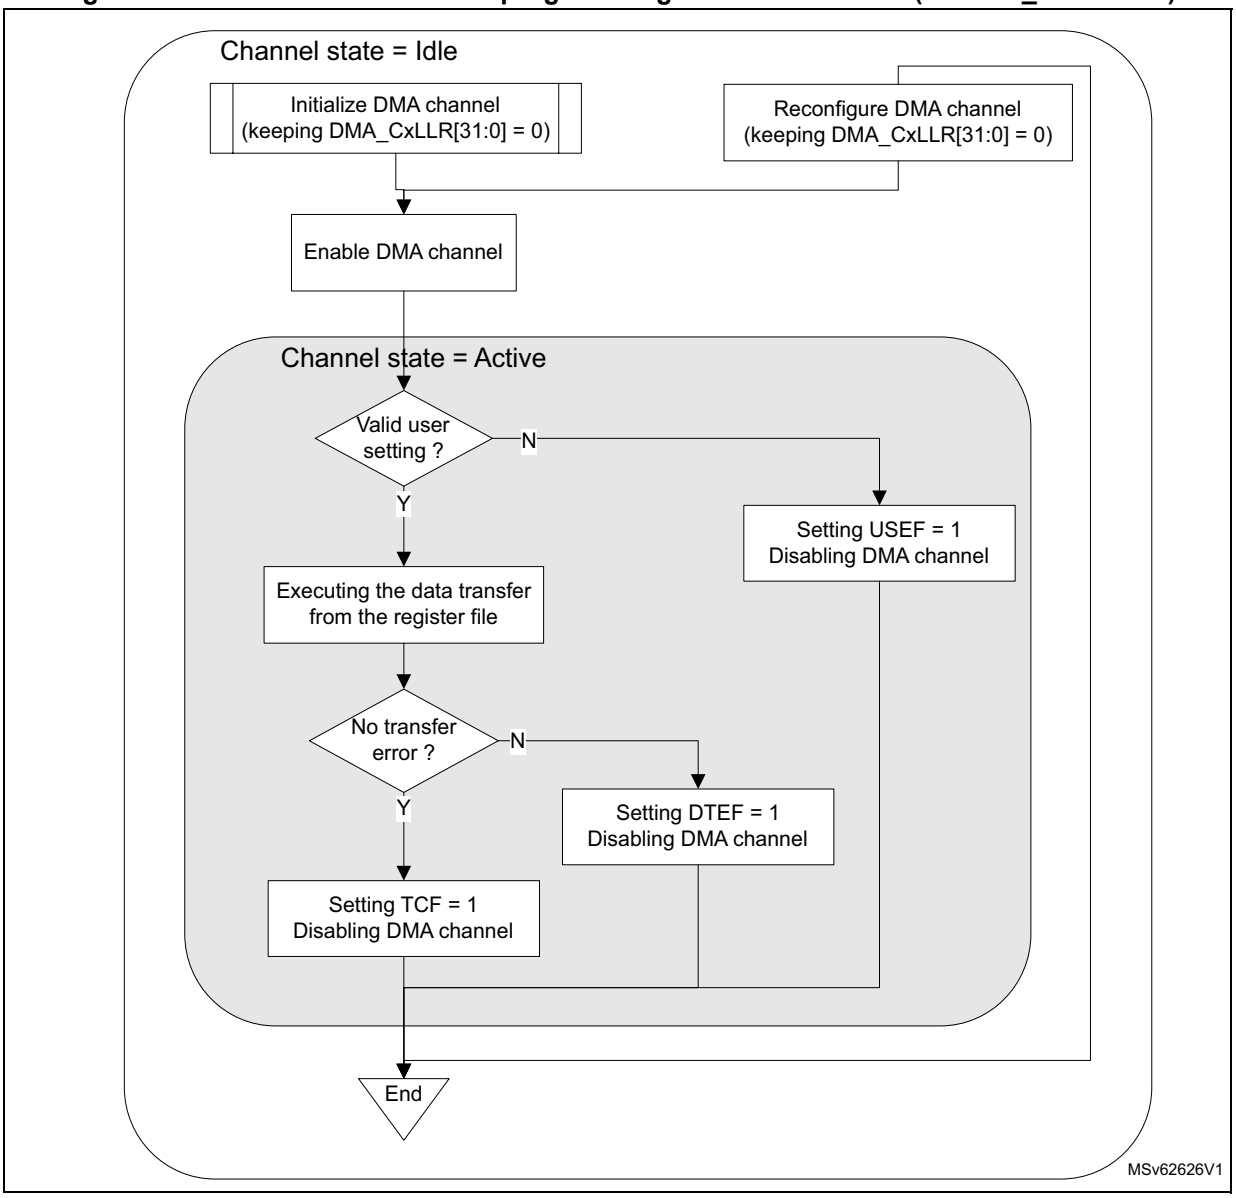
13.4 GPDMA functional description

13.4.1 GPDMA block diagram

Figure 101. GPDMA block diagram



13.4.2 GPDMA channel state and direct programming without any linked-list

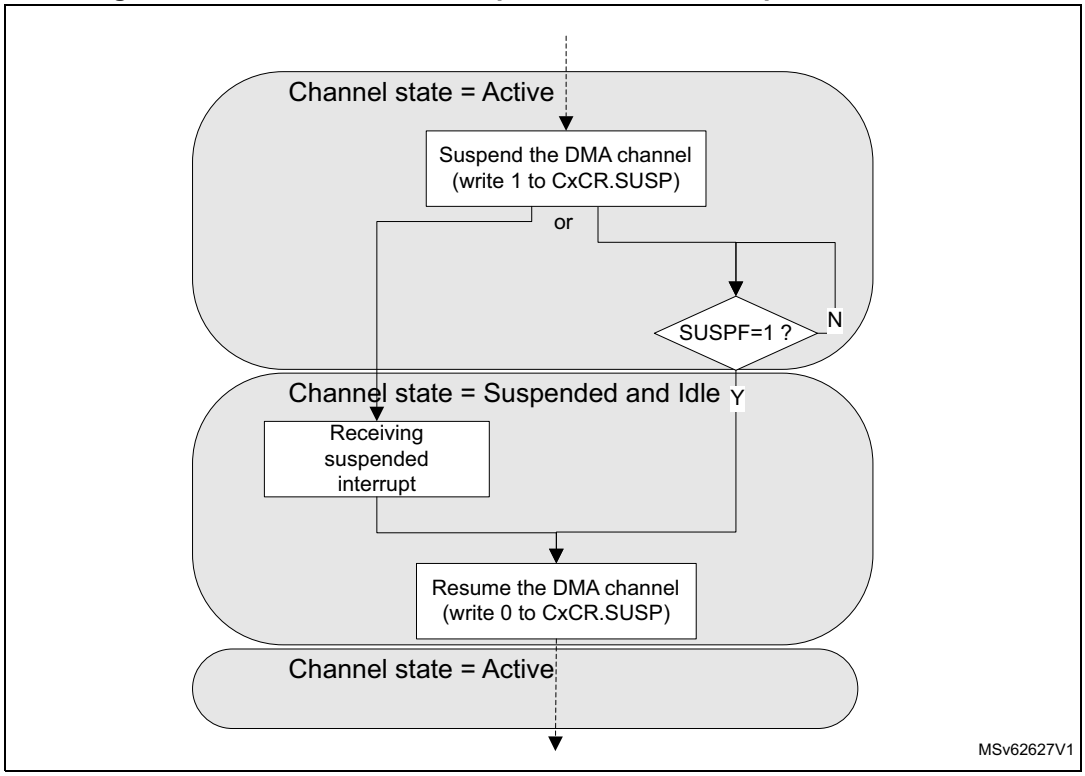
After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 in GPDMA_CxCR.EN, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 in GPDMA_CxCR.EN, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA channel is back in idle state (EN is then deasserted by hardware) and that the channel is ready to be reconfigured then enabled again.

Figure 102 illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

Figure 102. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)

13.4.3 GPDMA channel suspend and resume



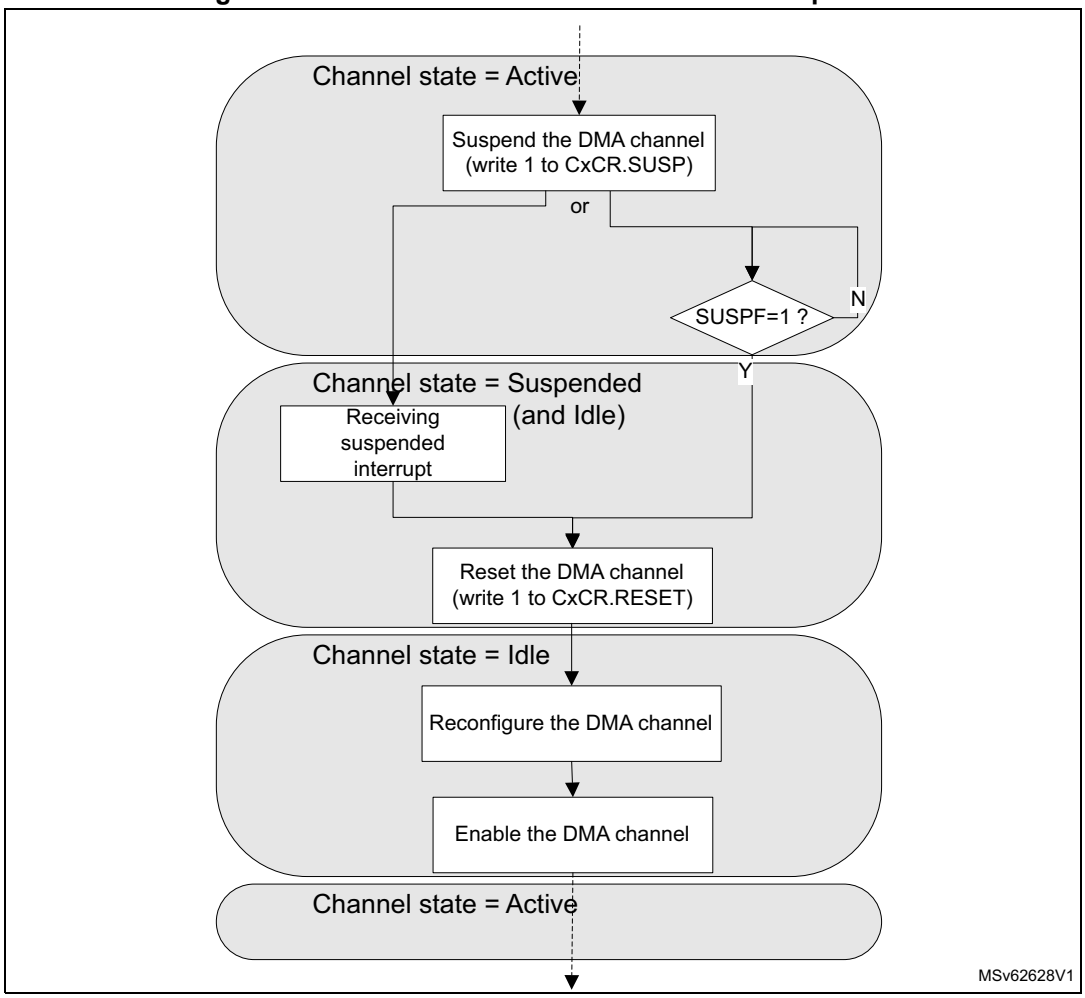
The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

Note: An ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

Figure 103. GPDMA channel suspend and resume sequence



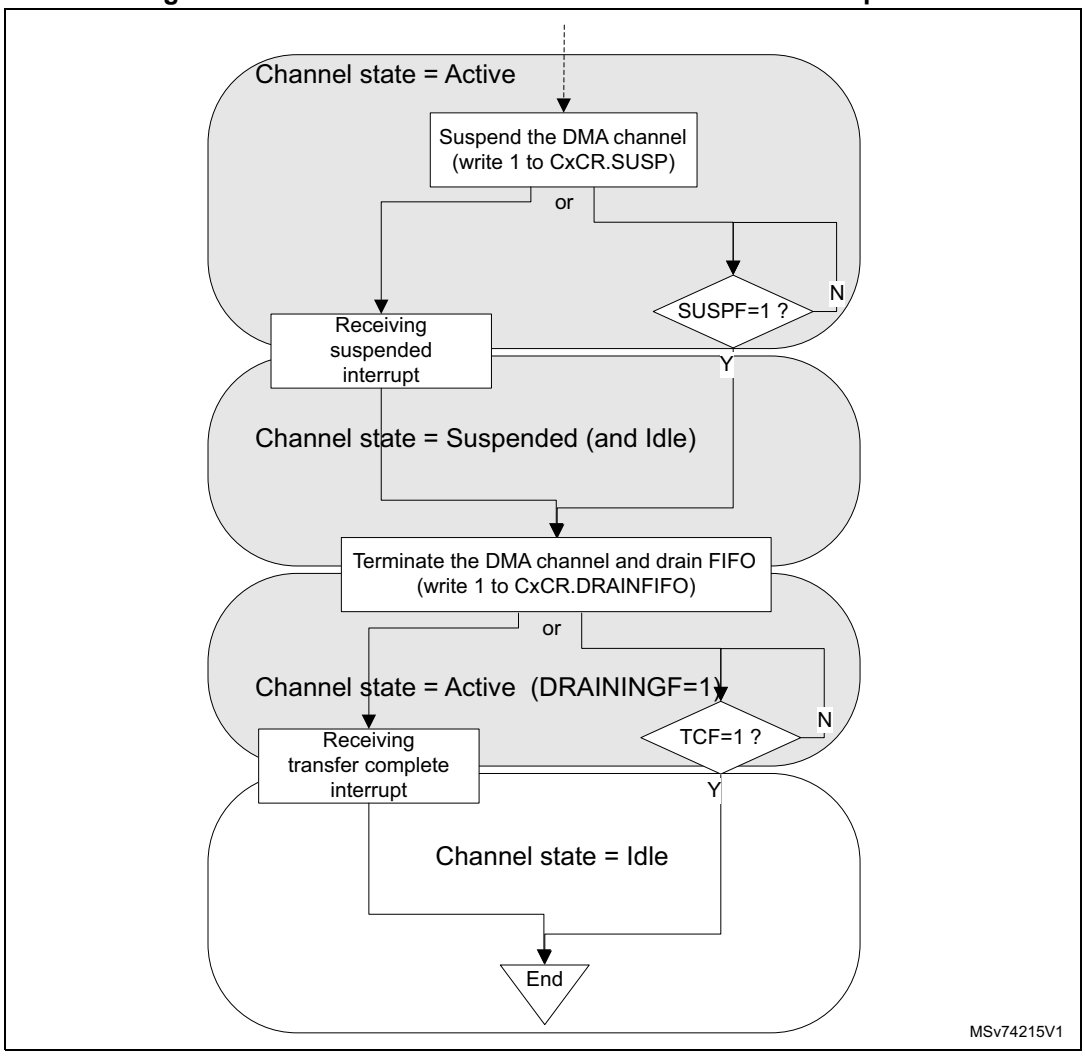
Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

13.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR.EN bit, and the reset of the GPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

Figure 104. GPDMA channel abort and restart sequence



13.4.5 GPDMA channel terminate and drain FIFO

Alternatively, for terminating a continuous GPDMA transfer with a circular buffering or a double buffering, and having popped out any residual byte(s) in the channel FIFO and writing them to the destination, the software can terminate an active channel and drain the channel FIFO with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software orders to drain the channel FIFO by writing 1 to GPDMA_CxCR.DRAINFIFO.
4. The software polls transfer complete flag GPDMA_CxSR.TCF until TCF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.TCIE. Wait for the channel to be effectively with a drained FIFO means wait for completion of any residual write burst from the FIFO to the destination. Then the channel is disabled by hardware and in IDLE state.

Figure 105. GPDMA channel terminate and drain FIFO sequence

Note: If the softwares writes the GPDMA_CxCR register in a single shot with concurrently SUSP = 1, DRAINFIFO = 1, and RESET = 0, then the sequence for terminating and draining the FIFO also occurs.

GPDMA_CxTR2.DREQ = 1 and GPDMA_CxCR.DRAINFIFO = 1 is not supported, only peripheral-to-memory and memory-to-memory transfers are supported to be terminated with drained FIFO.

13.4.6 GPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:

- the link base address of the channel x (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLIn of the channel x.

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the following UT1, UT2, UB1, USA, UDA, UT3 and UB2 if present, and ULL bits in GPDMA_CxLLR.

In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, GPDMA_CxTR3 and GPDMA_CxBR2 if present, and GPDMA_CxLLR) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

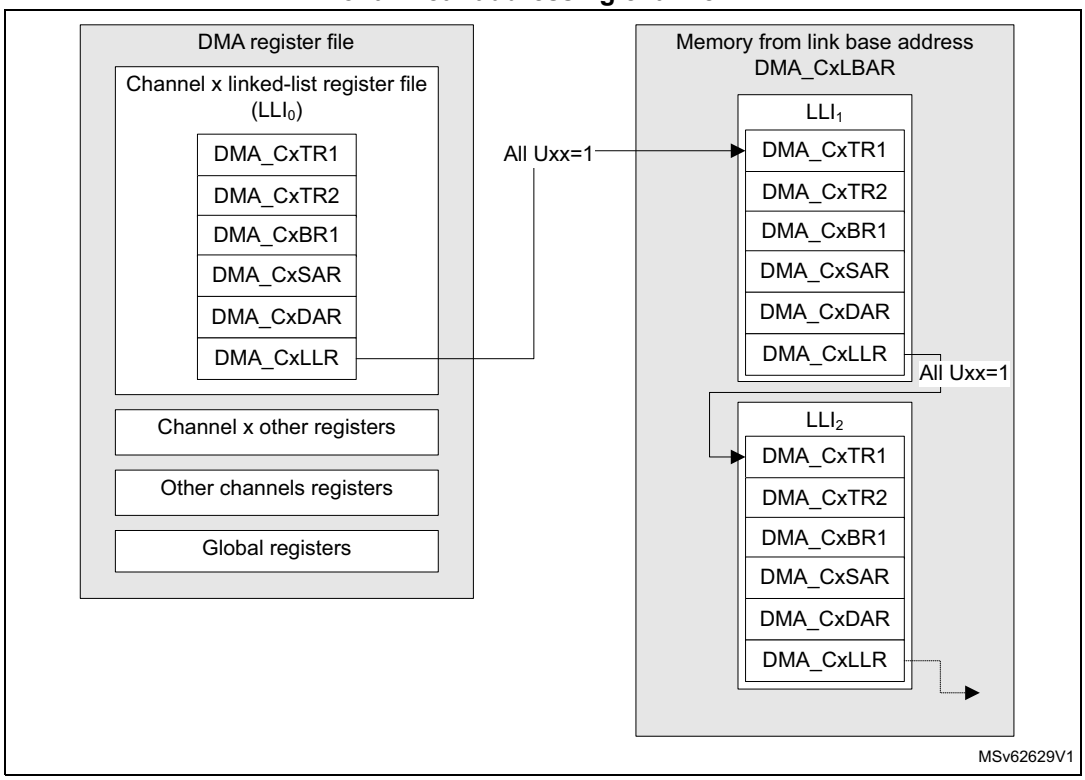
Caution: The user must program the pointer to the next linked-list data structure (GPDMA_CxLLR[15:0]) not to exceed the 64-Kbyte addressable space defined by the link base address register (GPDMA_CxLBAR). The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA, plus UB2 and UT3 if present, and ULL) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x (x = 0 to 11) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see *Figure 106*) and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory
- channel x (x = 12 to 15), contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, GPDMA_CxTR3, GPDMA_CxBR2 and GPDMA_CxLLR, (see *Figure 107*), and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory

Figure 106. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x



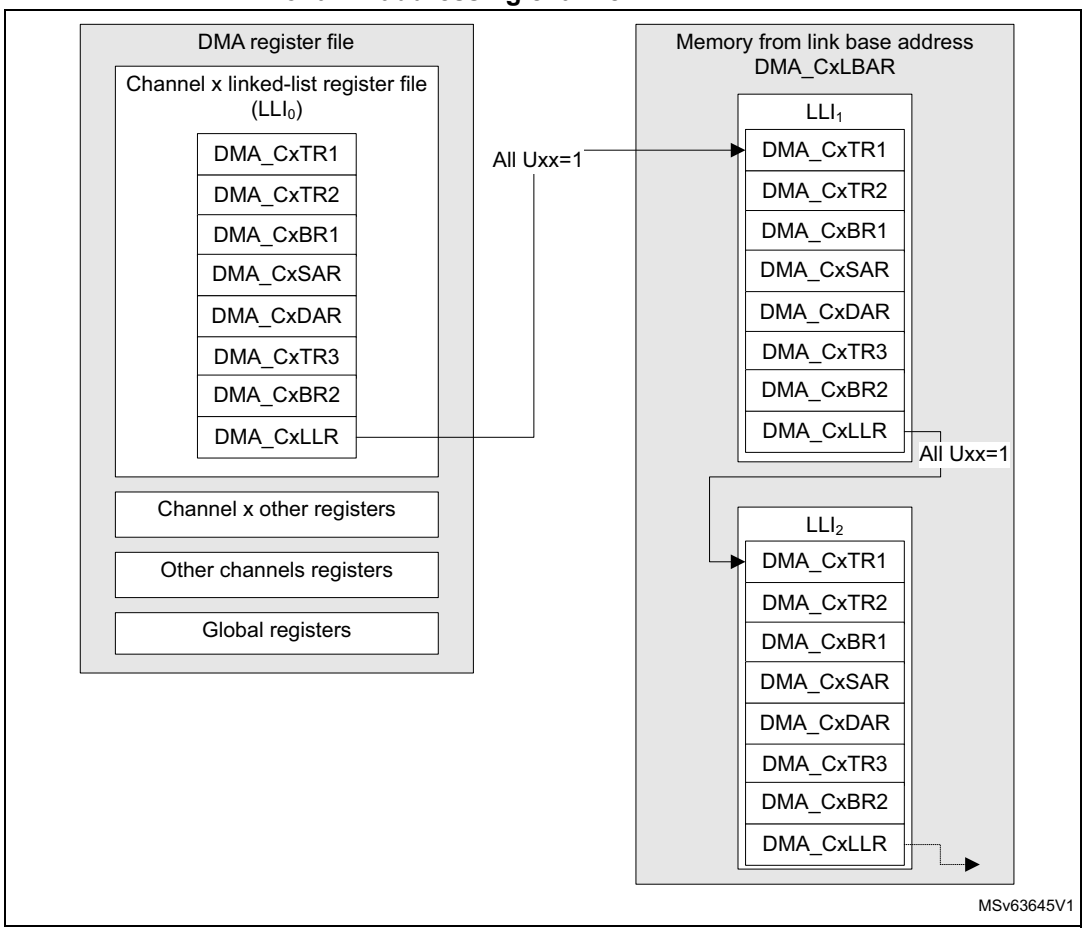


Figure 107. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

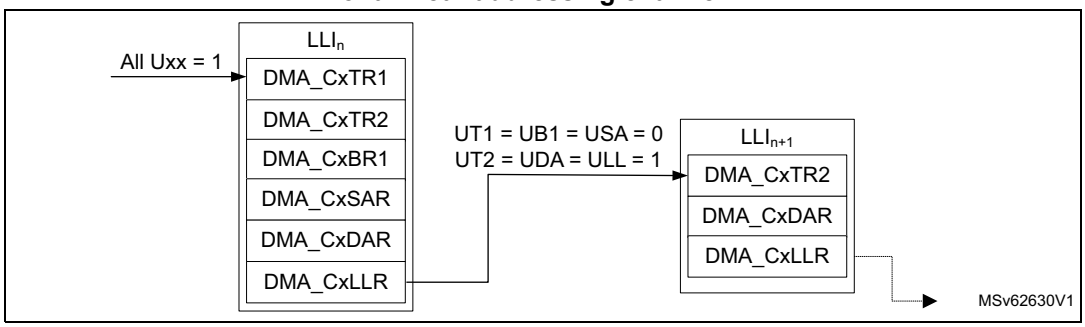
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see *Figure 108*).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UB2 = 0, when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in *Figure 109*.

Figure 108. GPDMA dynamic linked-list data structure of a linear addressing channel x



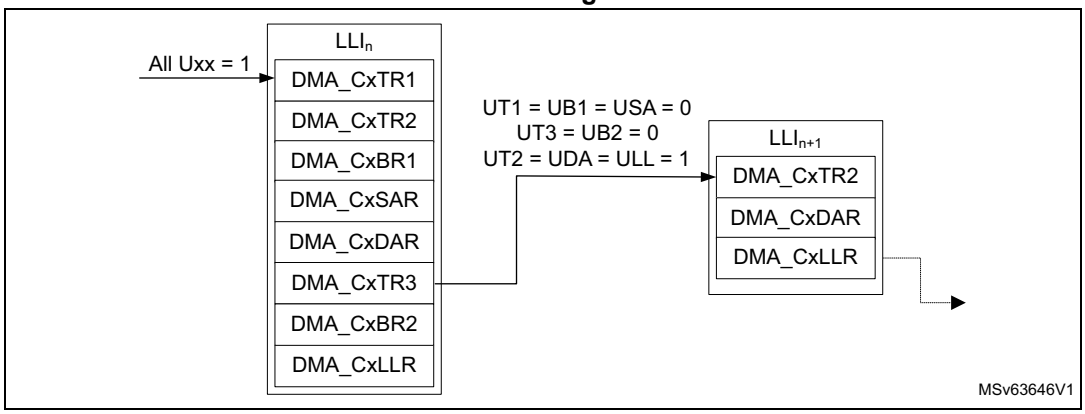


Figure 109. GPDMA dynamic linked-list data structure of a 2D addressing channel x

13.4.7 Linked-list item transfer execution

A LLI_n transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the GPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer as defined by the internal register file (LLI_0) can be null (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxTR2.PFREQ = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCR.LSM = 1), as described in the next sections.

13.4.8 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started

by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when GPDMA_CxLLR[31:0] = 0, GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

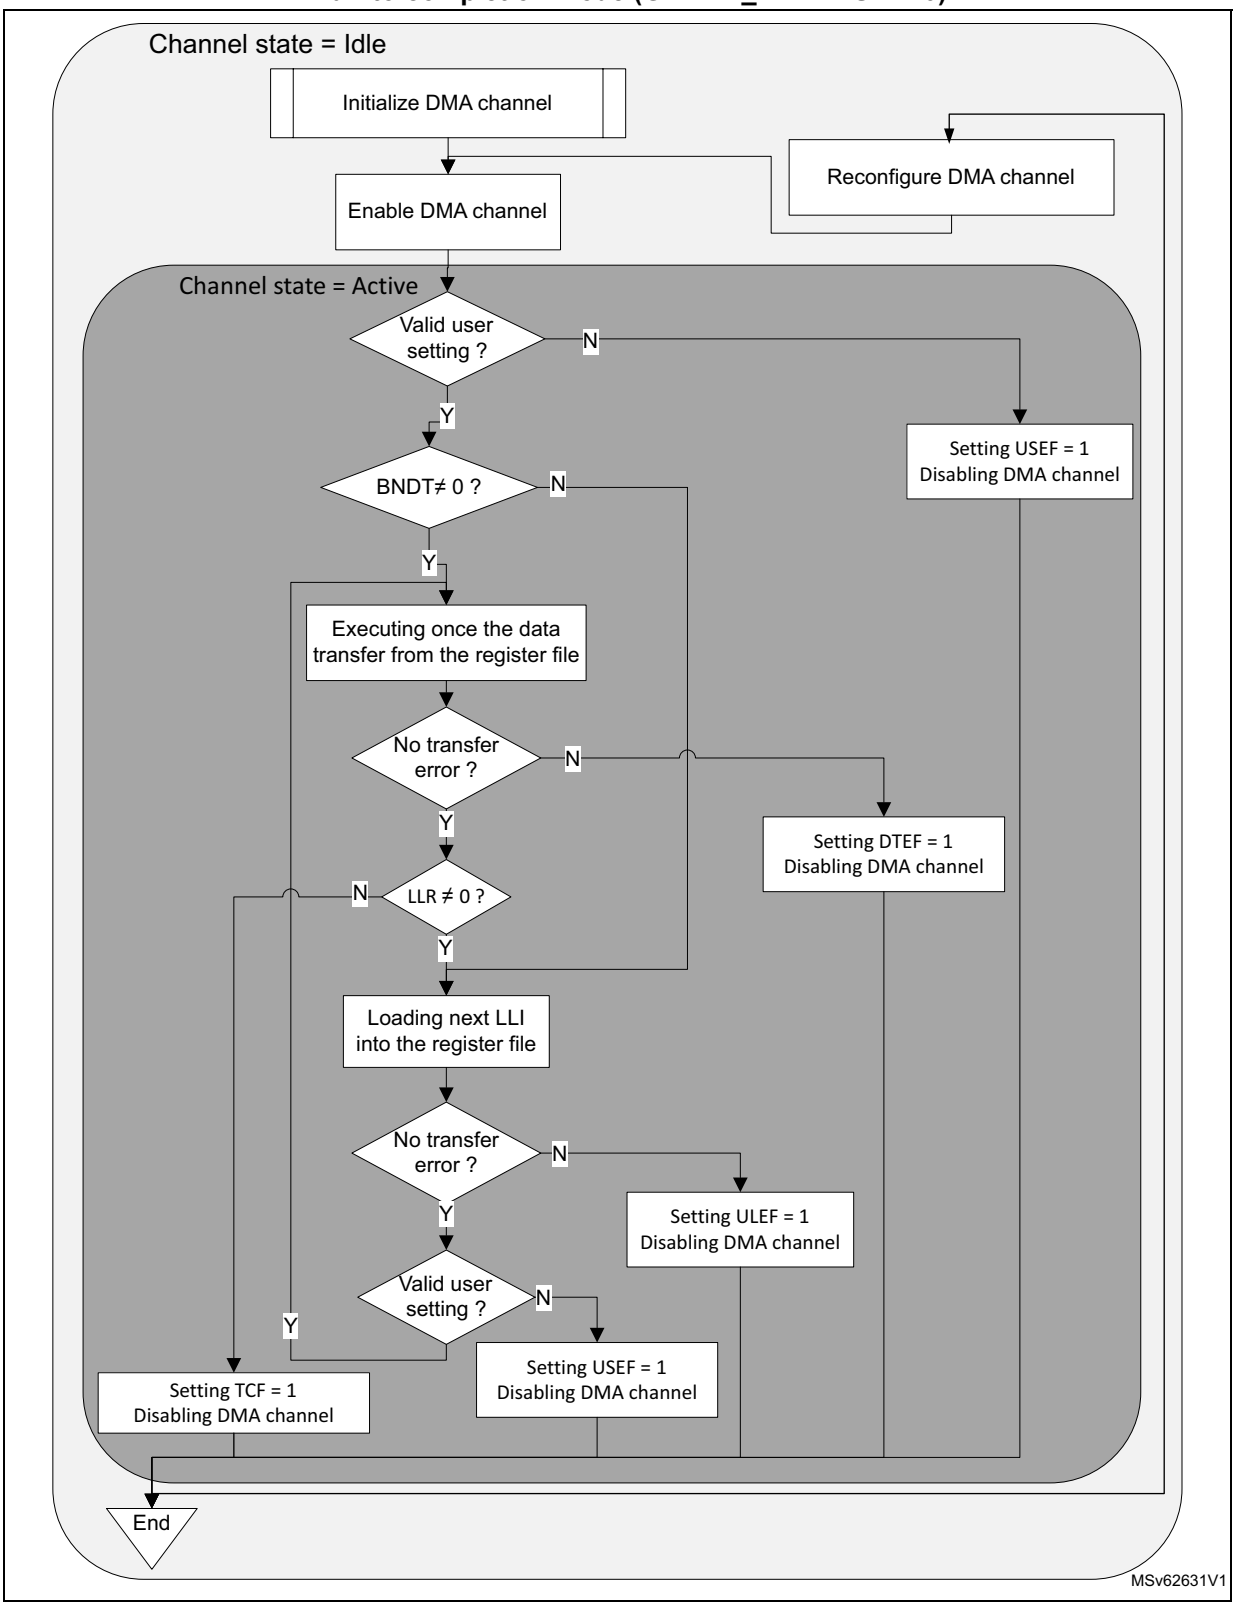
GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3).

The channel may never be completed when GPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated with the same value
  - or GPDMA_CxLLR.ULL = 0
- If LLI_N is pointing to a previous LLI

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 13.4.15* for more details).



In typical run-to-completion mode, allocation of an GPDMA channel, including detailed programming, occurs once during GPDMA initialization. This process reserves a data communication link and GPDMA service during run-time for repeated transfers, such as transfers from a peripheral to memory, from memory to a peripheral, or memory-to-memory transfers. The reserved data communication link may consist of a dedicated channel, or the channel may be shared. A repeated transfer consists of a sequence of linked list items (LLIs).

Figure 110 depicts the GPDMA channel execution and its registers programming in run-to-completion mode.

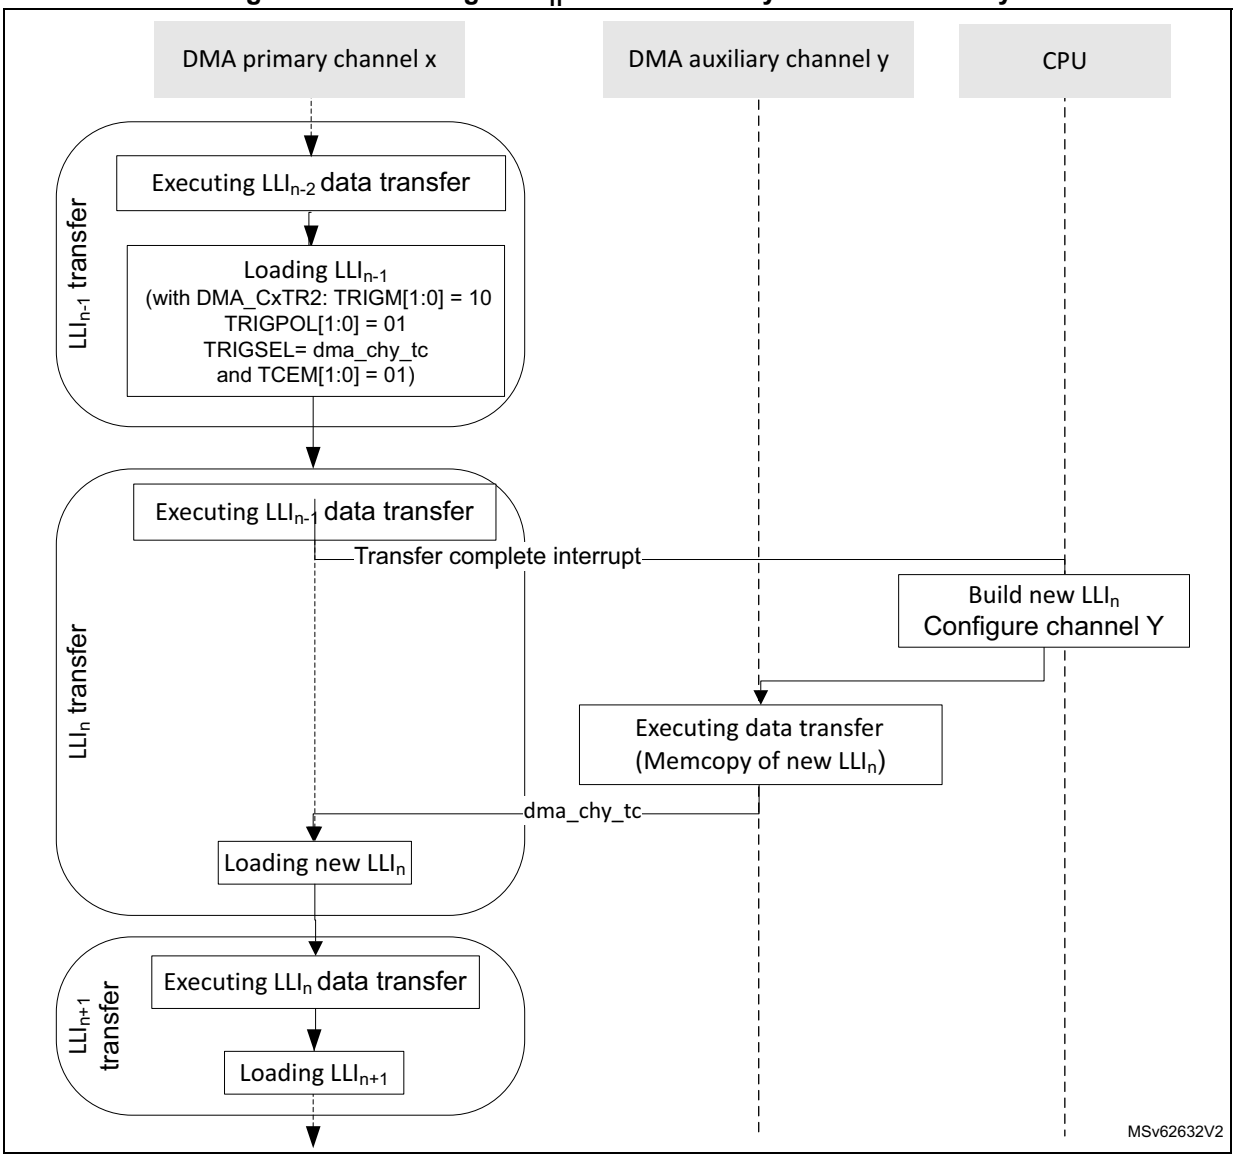
Note: Figure 110 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 110, BNDT ≠ 0 is the typical condition for starting the first data transfer in this figure. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 13.3.5).

Figure 110. GPDMA channel execution and linked-list programming in run-to-completion mode (GPDMA_CxCR.LSM = 0)

Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLI_{n-1}:



- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see *Section 13.3.6* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 111 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 111. Inserting a LLI_n with an auxiliary GPDMA channel y

13.4.9 GPDMA channel state and linked-list programming in link step mode

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

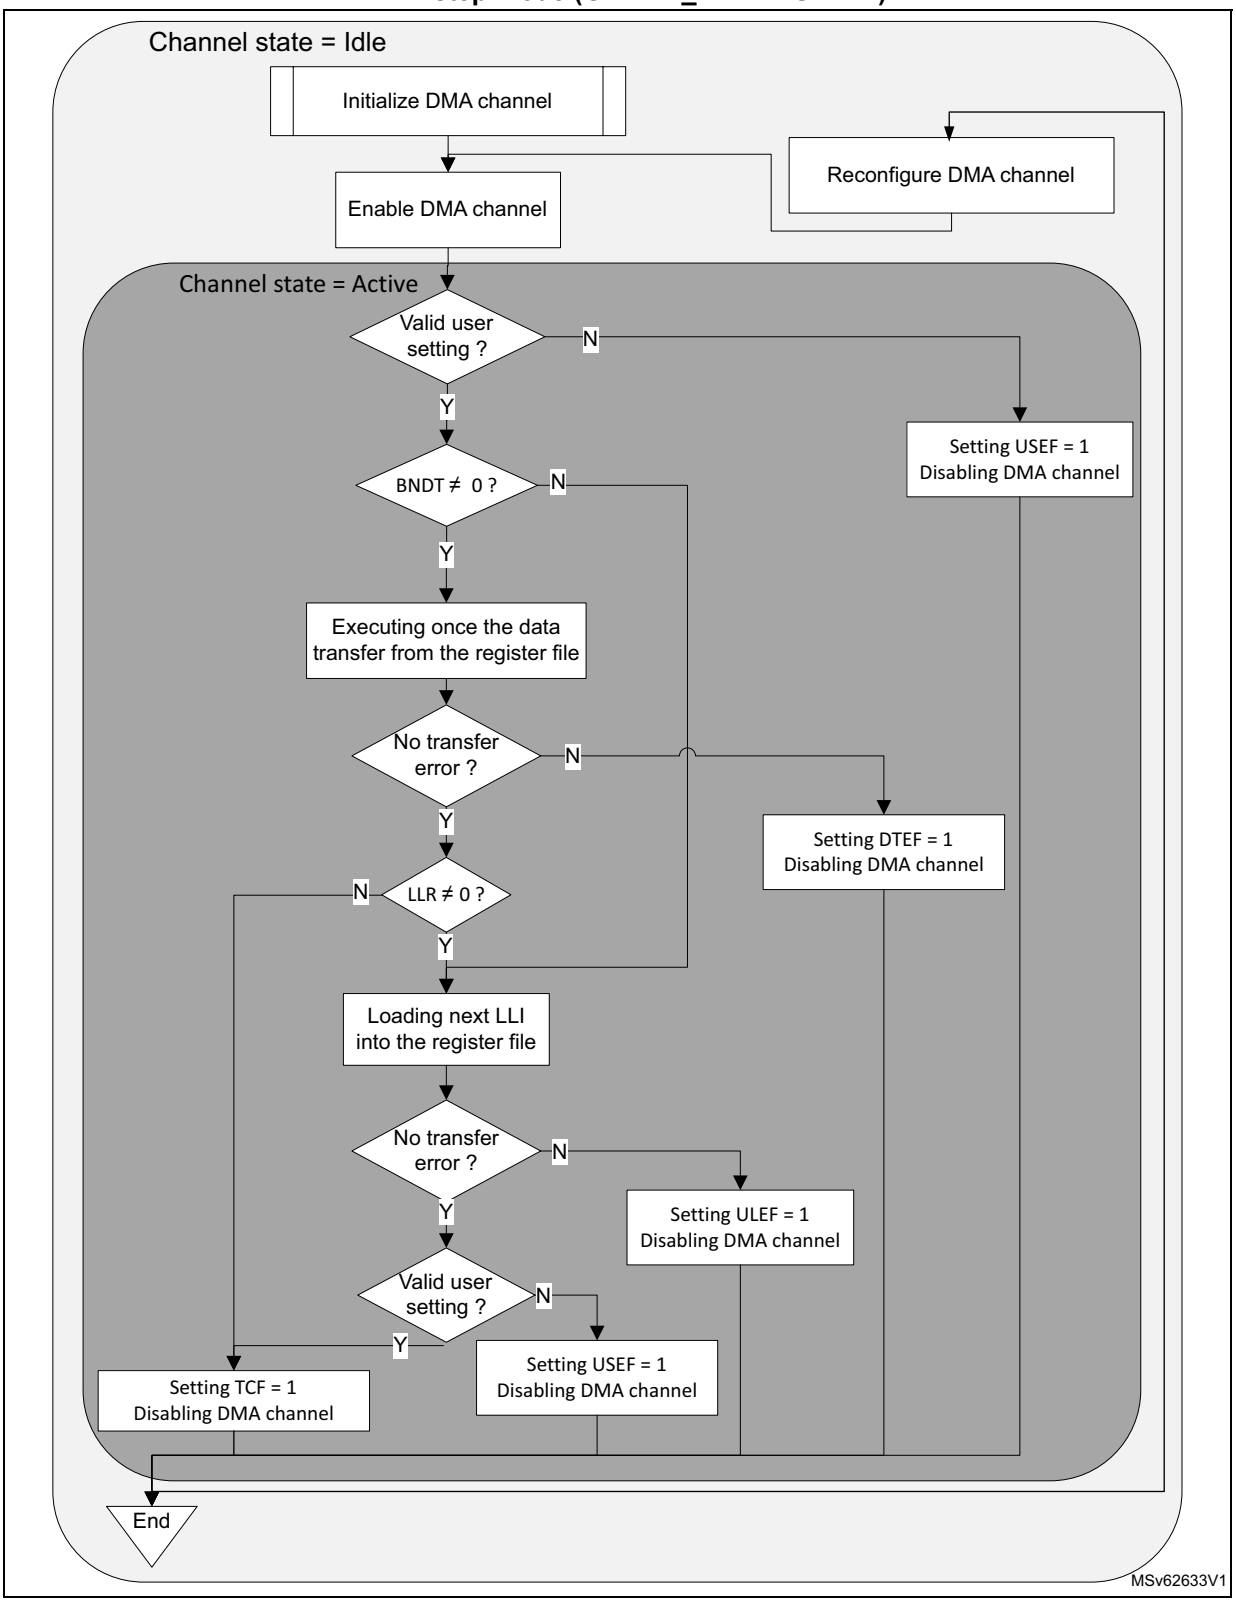
A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x (x = 12 to 15), the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.

  - GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
  - GPDMA_CxTR3 for channel x (x = 12 to 15) defines the source/destination additional address offset between burst transfers.
  - GPDMA_CxBR2 for channel x (x = 12 to 15) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated with the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 13.4.15* for more details).



The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of GPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 112 depicts the GPDMA channel execution mode, and its programming in link step mode.

Note: Figure 112 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 112, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 13.3.5).

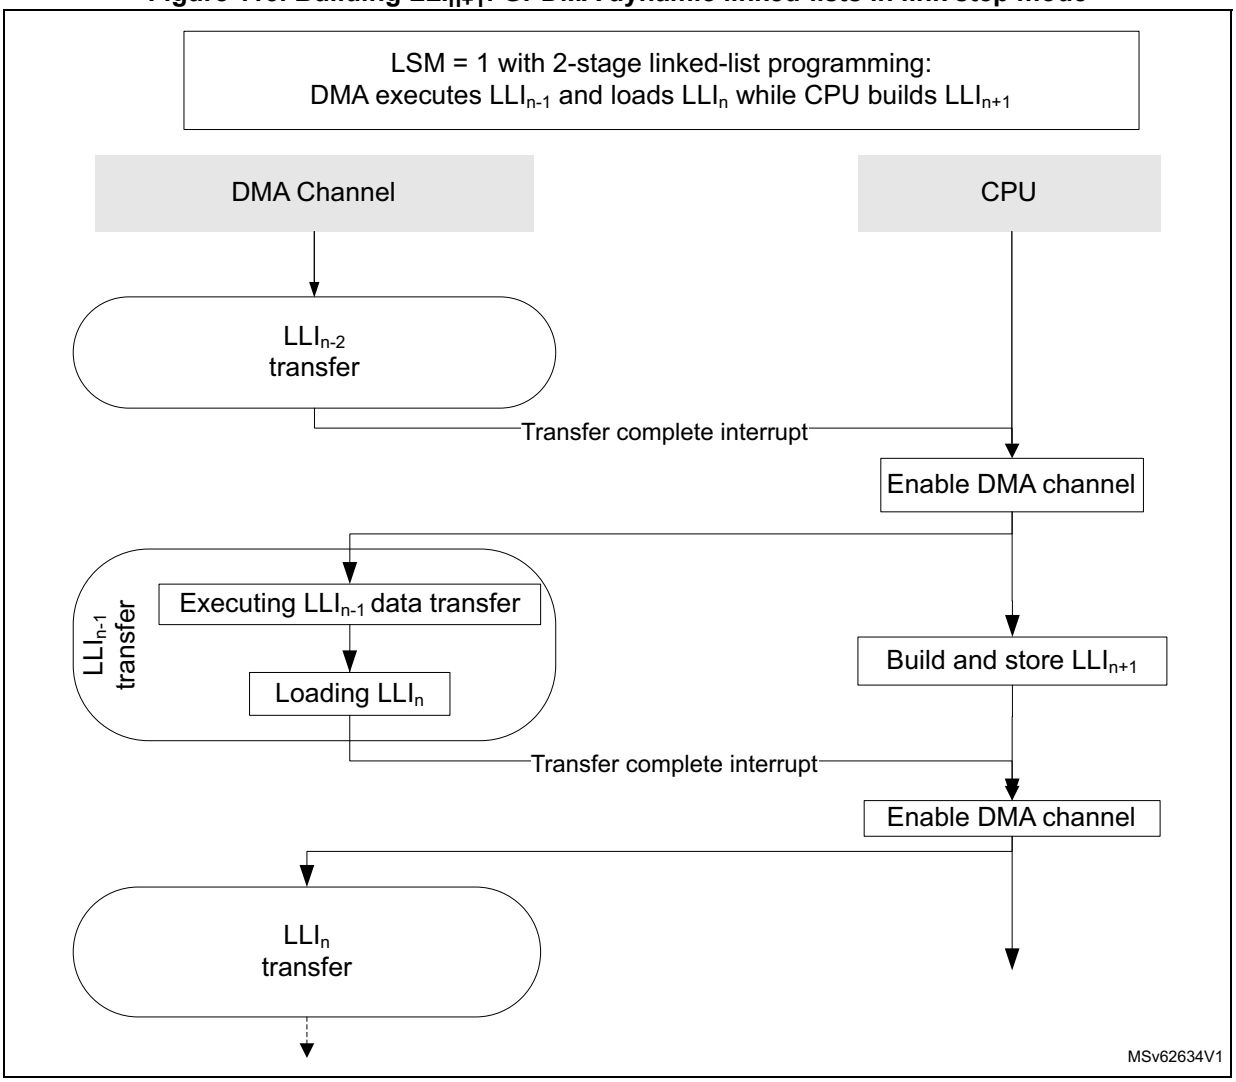


Figure 112. GPDMA channel execution and linked-list programming in link step mode (GPDMA_CxCR.LSM = 1)

Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in *Figure 113*.

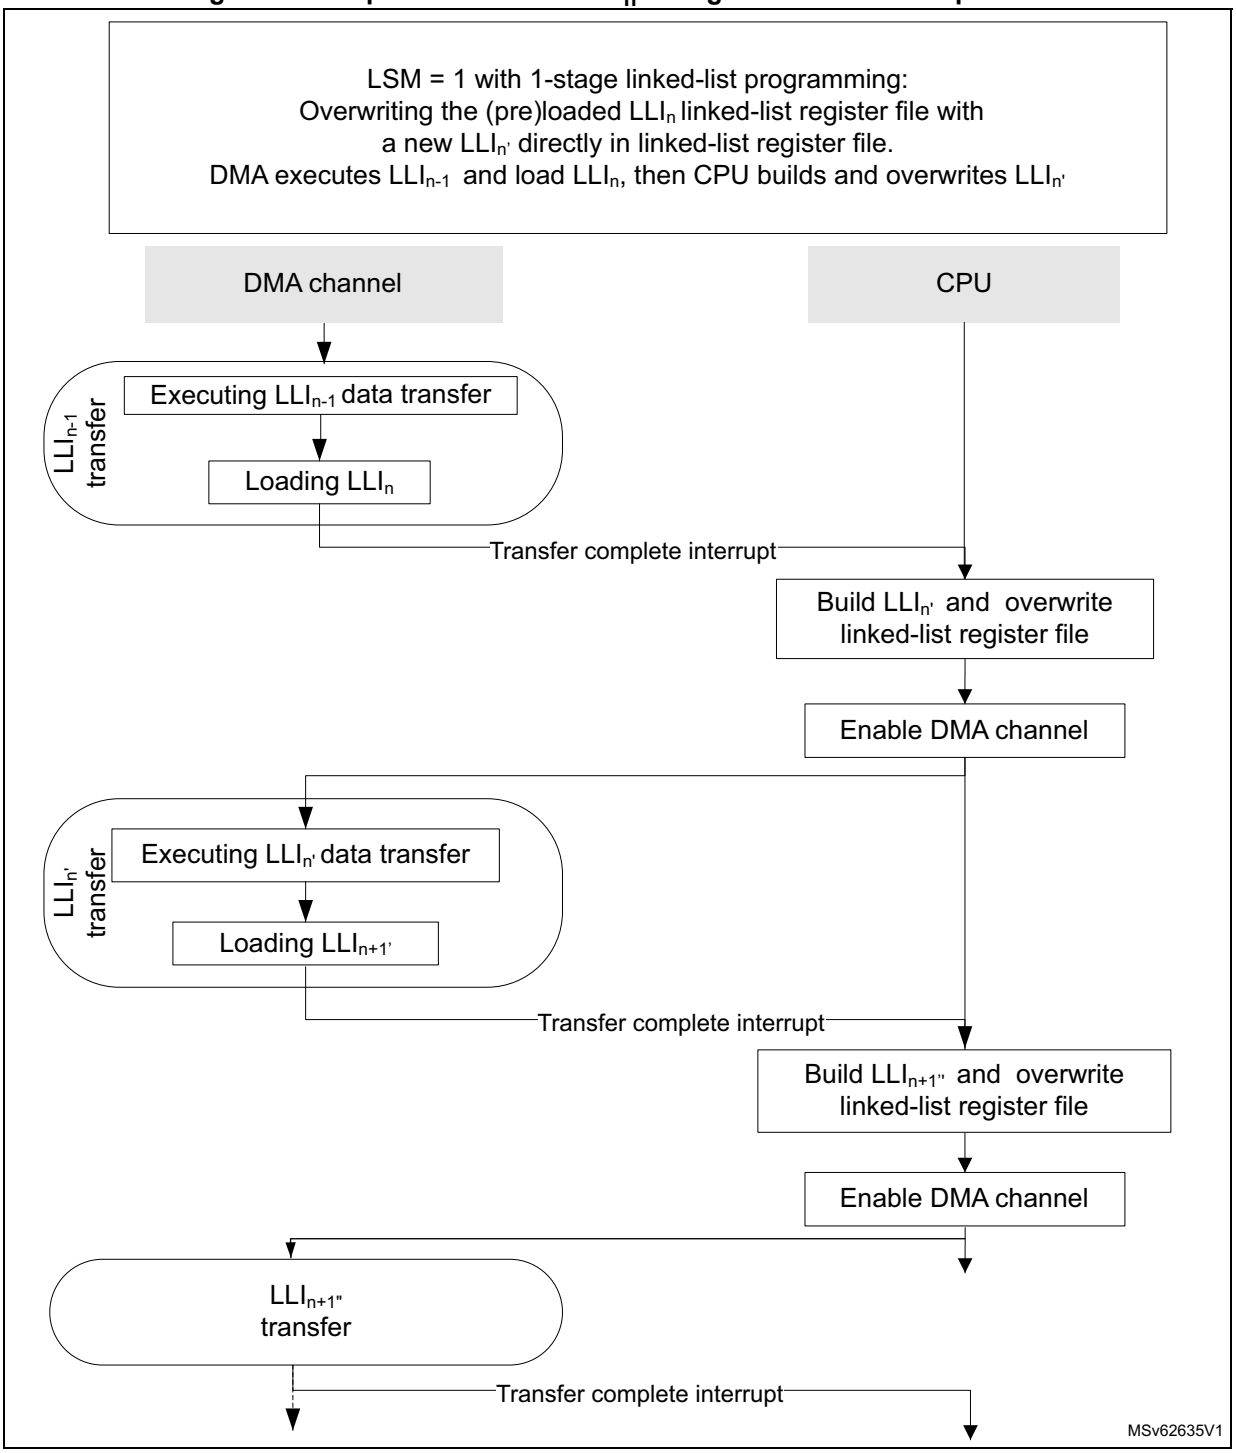

Figure 113. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode

Run-time replacing a LLI_n with a new LLI_n', in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in *Figure 114*.

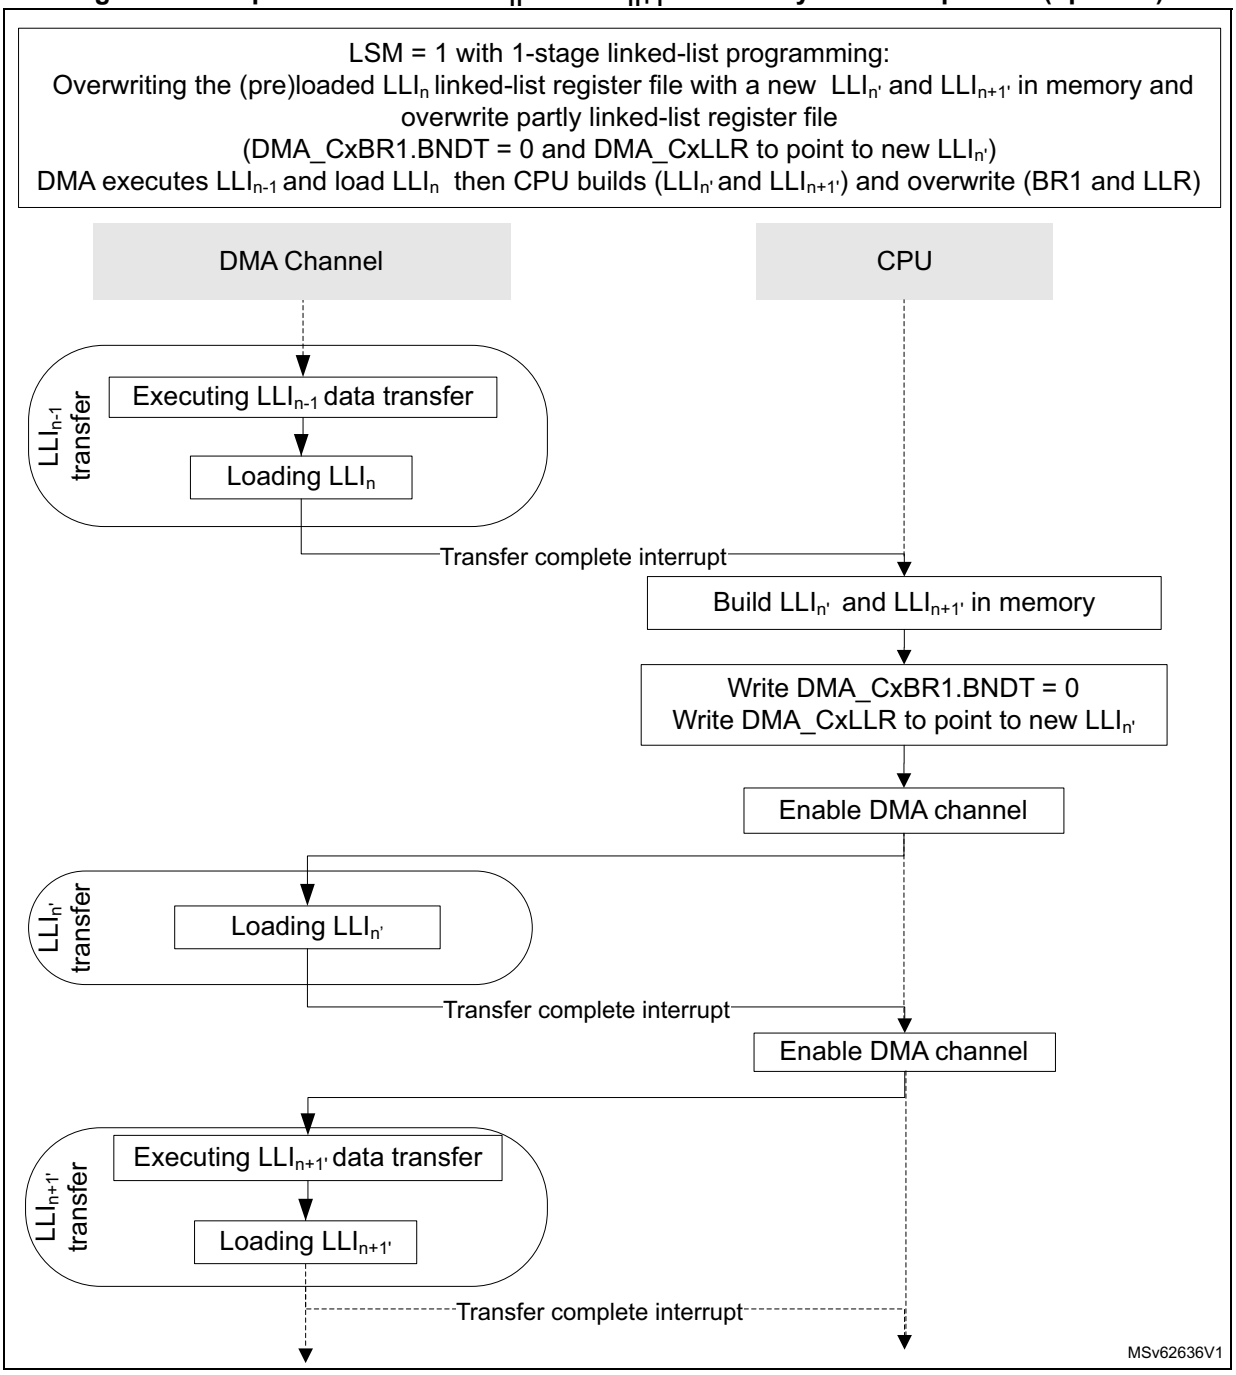

Figure 114. Replace with a new $LLI_{n'}$ in register file in link step mode

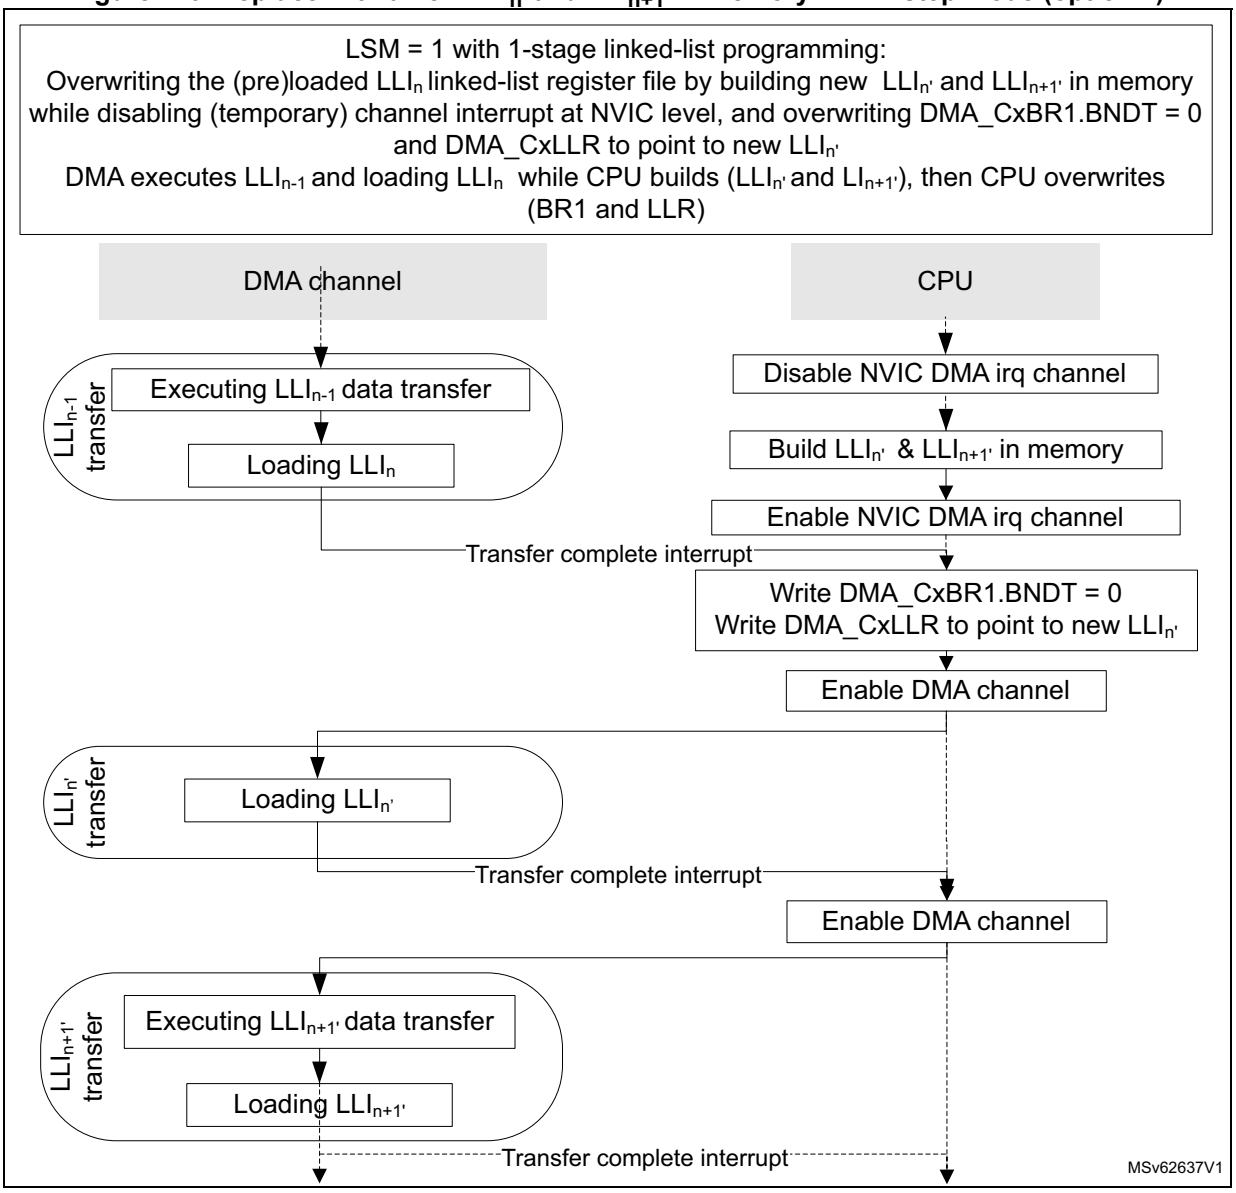
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n')}$ as shown in *Figure 115*.

Figure 115. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n'}$, as shown in *Figure 116*.

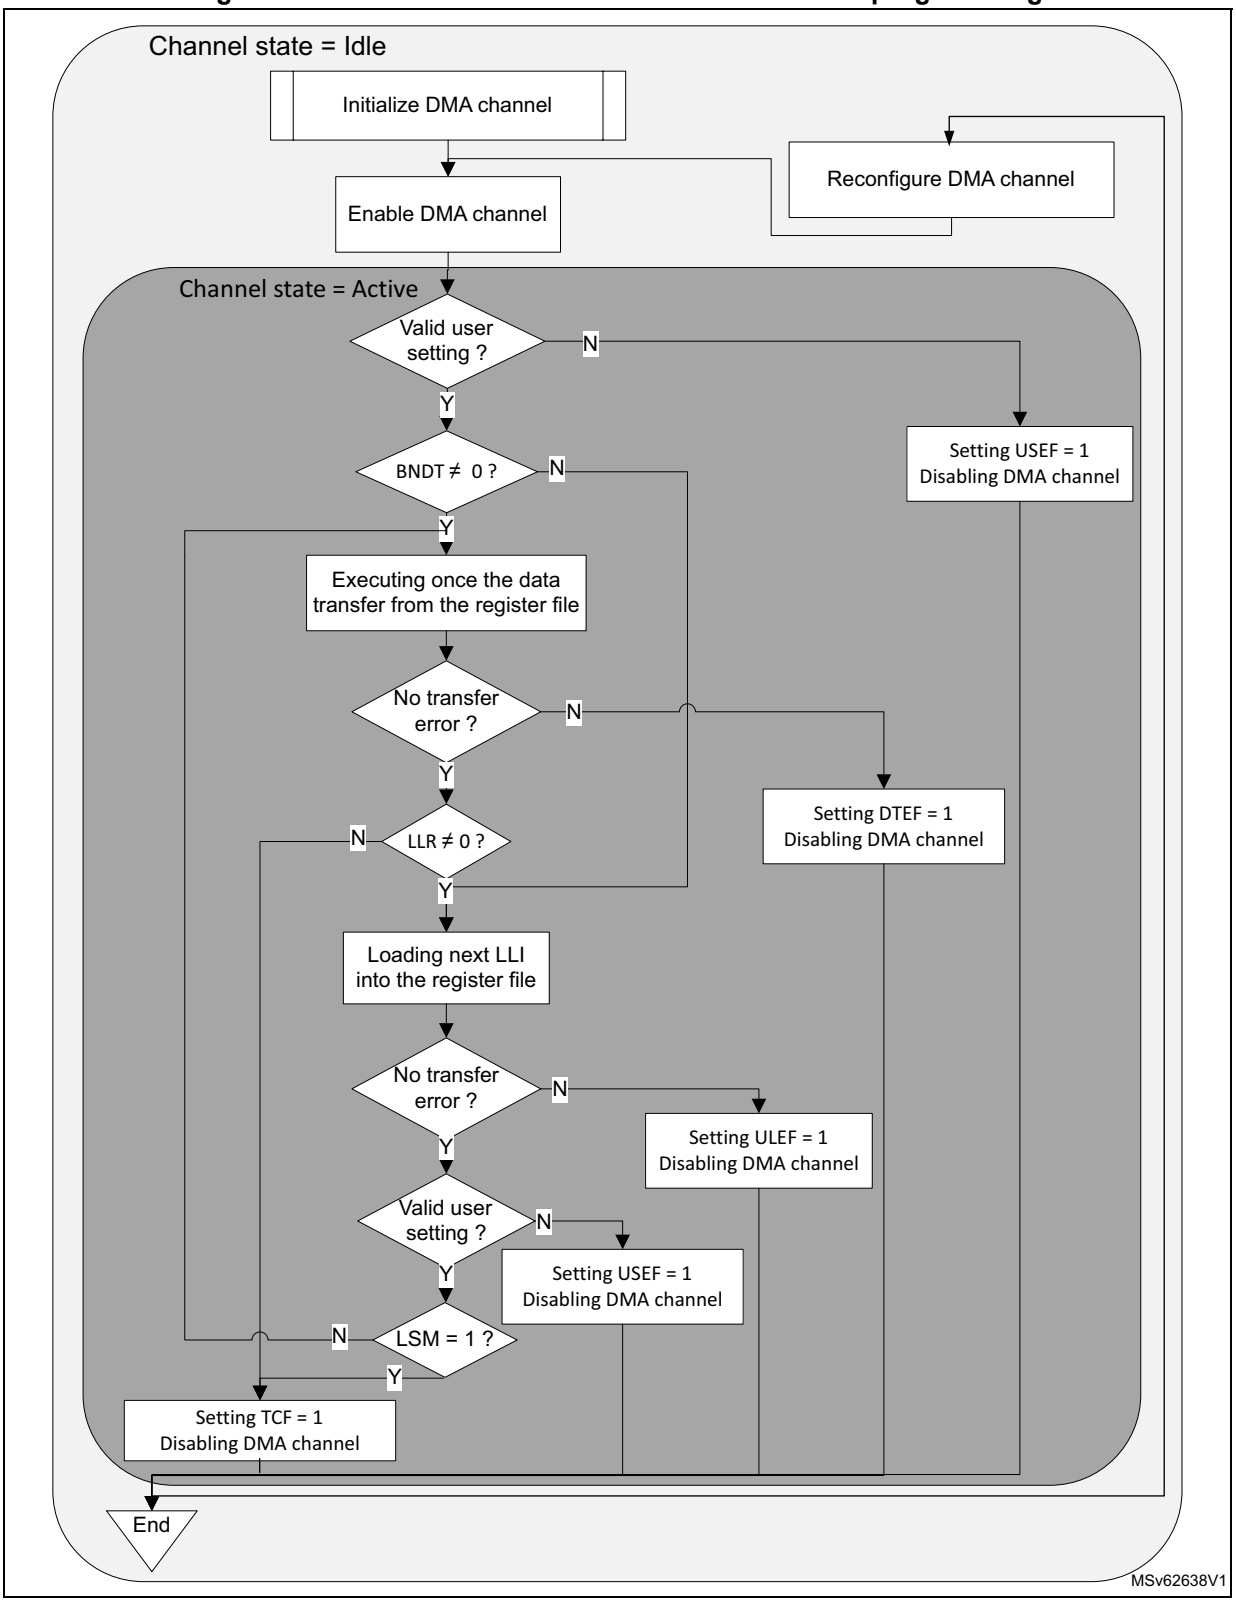
Figure 116. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)

13.4.10 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the GPDMA_CxLLR of this LLI_{n+1}), before this LLI_{n+1} is loaded/used by the GPDMA channel
- abort and reconfigure the channel with a LSM update (see *Section 13.4.4*.)



In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 117 shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.

Note: Figure 117 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 117, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 13.3.5).

Figure 117. GPDMA channel execution and linked-list programming

13.4.11 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 13.3.1* for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPDMA_CxDAR) must be aligned with the respective data width.

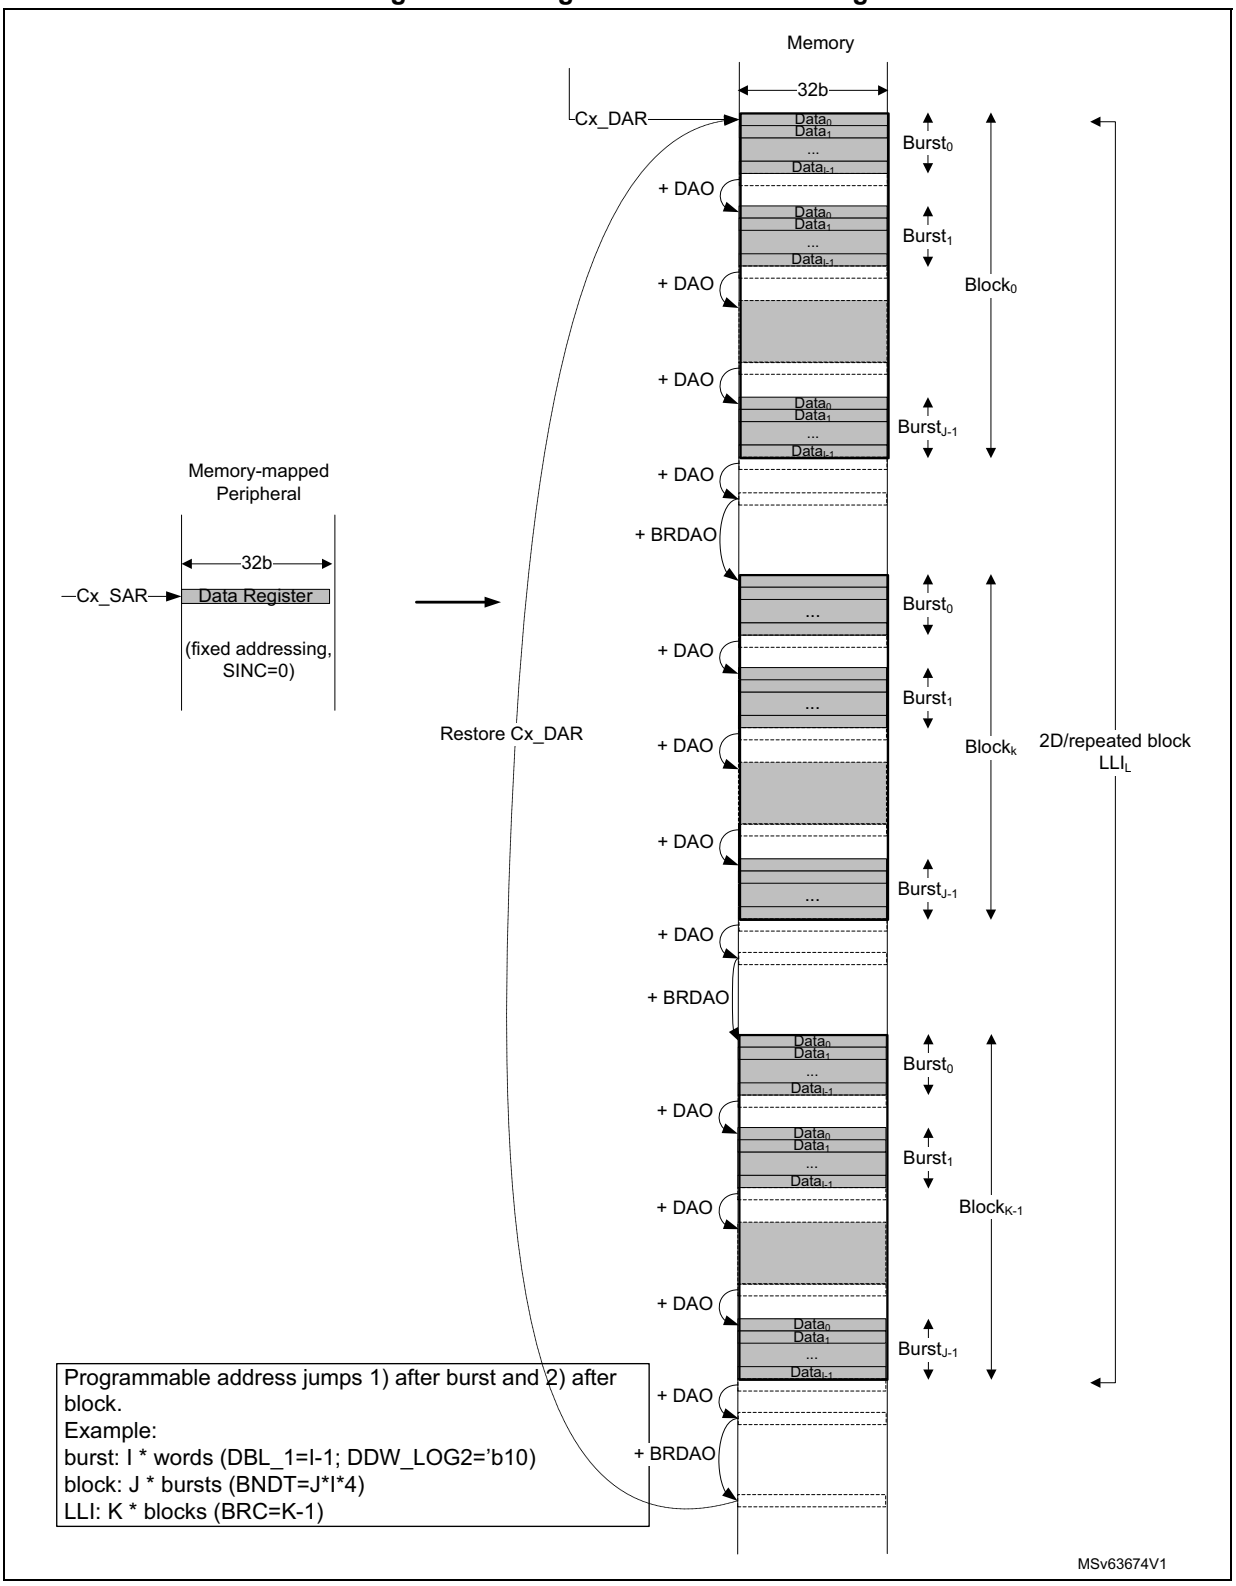
The table below lists the main characteristics of a GPDMA burst.

Table 100. Programmed GPDMA source/destination burst

SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/DINC	SBL_1[5:0] DBL_1[5:0]	Burst length (data/beats)	Next data/ beat address	Next burst address	Burst address alignment
00	1	0 (fixed)	n = 0 to 63(1)	n+1	+ 0	+ 0	1
01	2						2
10	4						4
00	1	1 (contiguously incremented)			+ 1	+ (n + 1)	1
01	2				+ 2	+ 2 * (n + 1)	2
10	4				+ 4	+ 4 * (n + 1)	4
11	forbidden user setting, causing USEF generation and none burst to be issued.						

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.



GPDMA burst with 2D addressing (channel x = 12 to 15)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by *Figure 118* with a 2D destination buffer.

Figure 118. Programmed 2D addressing

GPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

GPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma_fifo_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma_fifo_size[x]}$ is the half the FIFO size of channel x, in bytes (see *Section 13.3.1* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

GPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size. Each transfer is of a size that is lower than or equal to half of the FIFO size, without any user constraint.
- If the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SDW_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[1:0] and DDW_LOG2[1:0] fields (see *Table 101*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data width conversion by packing, unpacking, padding or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0 s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.
3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 101. Programmed data handling

SDW_LOG2 [1:0]	Source data	Source data stream(1)	SBX	DDW_LOG2 [1:0]	Destination data	PAM[1:0](2)	DBX	DHX	Destination data stream(1)
00	Byte	$B_7,B_6,B_5,B_4,B_3,B_2,B_1,B_0$	x	00	Byte	xx	x	x	$B_7,B_6,B_5,B_4,B_3,B_2,B_1,B_0$

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.

13.4.12 GPDMA transfer request and arbitration

GPDMA transfer request

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[7:0] field (see *Section 13.3.3*). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[7:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

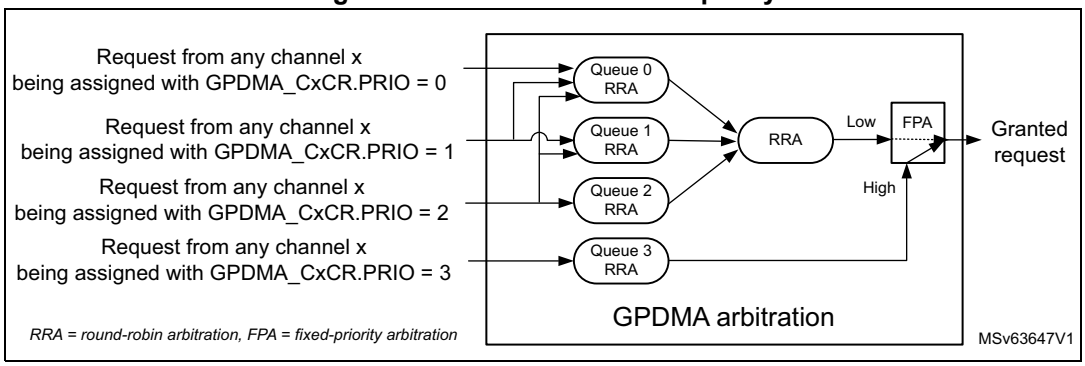
An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3, GPDMA_CxBR2). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 119*, is defined by:



- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1, or 2) for non time-sensitive channels with priority 0, 1, or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.

– Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
– Any queue 0, 1, or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
– Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1, and queue 2.

Figure 119. GPDMA arbitration policy

GPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  – If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).
  $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).
  $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$
  $B_{req1} = B_{P1} = (1/2 + 1) * 1/2 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).
  $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$
  $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$
  The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2**: application where the user distributes a same non-null N number of GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is
    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is
    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is
    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is
    $B_{n, P0} = 1/N *1/9 * (1 - B_{Q3})$
    $B_{n, P1} = 1/N *5/18 * (1 - B_{Q3})$
    $B_{n, P2} = 1/N *11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for $J > 0$ (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ ($K>0$ in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 ($K > 0$)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 ($K = 0$)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

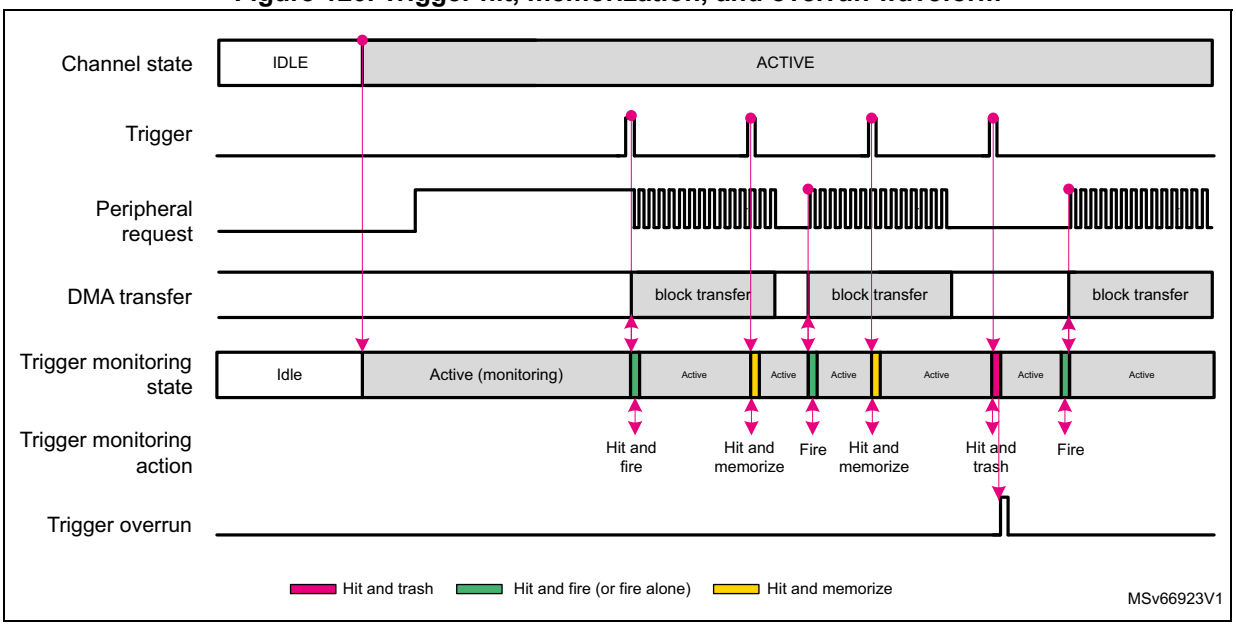
13.4.13 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[5:0] (see *Section 13.3.6* for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel x (x = 12 to 15), or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in GPDMA_CxTR2 for more details).

Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).



The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

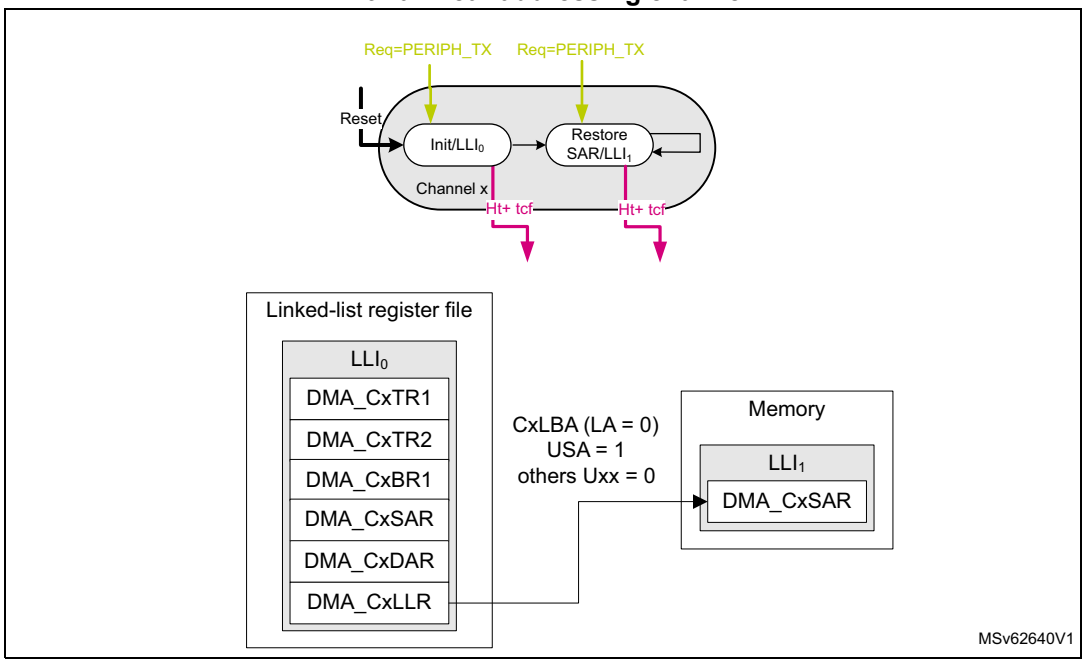
Figure 120 illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 120. Trigger hit, memorization, and overrun waveform

Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

13.4.14 GPDMA circular buffering with linked-list programming

GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel



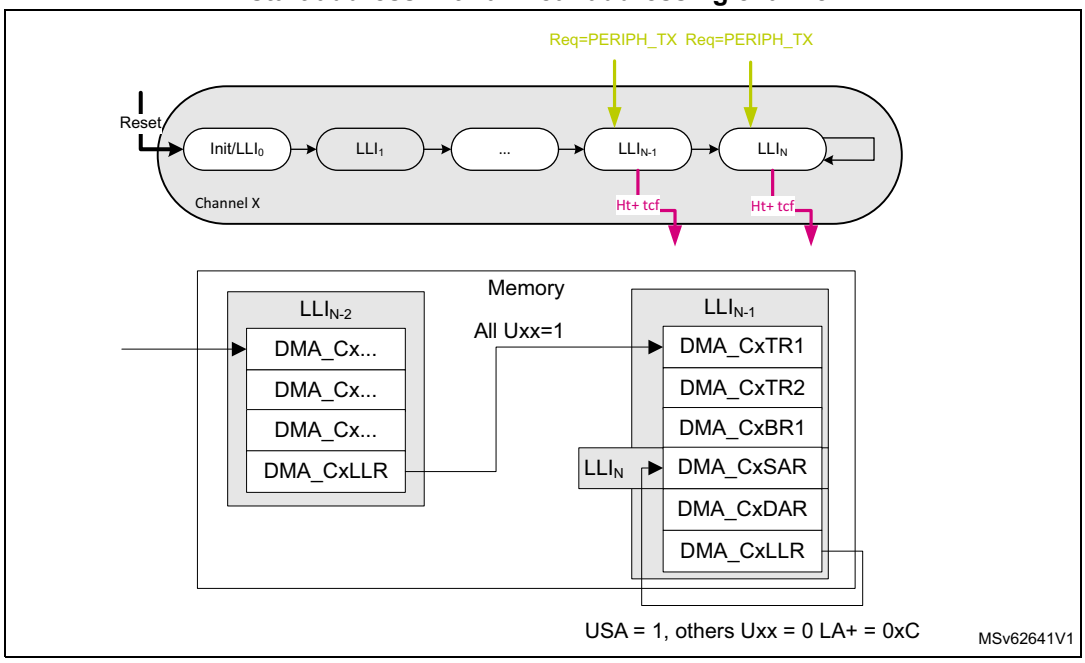
For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half-transfer and complete transfer

events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

Figure 121 illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

Figure 121. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel



Note: With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel x, the before-last LLI_{N-1} in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).

Figure 122 illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

Figure 122. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel

13.4.15 GPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate a GPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 13.3.5*).

If the related GPDMA channel x is also programmed in peripheral flow-control mode (GPDMA_CxTR2.PFREQ = 1):

- The GPDMA block transfer starts as follows:
  - If GPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the GPDMA hardware.
  - If GPDMA_CxBR1.BNDT[15:0] = 0, the GPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The GPDMA block transfer is completed as soon as the first occurrence of one of the following condition occurs:
  - when GPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on GPDMA_CxTR2 (see *GPDMA channel x transfer register 2 (GPDMA_CxTR2)*). Then the software can read the current number of transferred bytes from the source (GPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (GPDMA_CxSAR[31:0] or GPDMA_CxDAR[31:0]).

In peripheral flow-control mode:

- a destination peripheral with a hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

13.4.16 GPDMA byte-based padding at the block level

For a given channel x, a LLI_n data transfer consists of a block transfer and is defined by the source block size GPDMA_CxBR1.BNDT[15:0], the size of the block of data to be transfered from the source, in bytes.

During a peripheral-to-memory transfer, a peripheral may be streaming and receiving a given number of bytes (for example, via an I2C, UART/USART/LPUART, ADC, DAC) or half-words, and this block size may not be a multiple of a word or a double-word. It is important to allow the user to program any number of bytes for the GPDMA source block size independently from the source data width and the destination data width, in order to use efficiently the bandwidth of the 32-bit AHB system bus and/or the 64-bit AXI system bus when accessing and writing into memory (embedded SRAM, NVM or external memory). This enables to decrease the bus bandwidth for the memory transfers by a ratio of up to 4 in AHB and up to 8 in AXI. More generally, having the source block size independent from the source data width and the destination data width can be useful also with memory-to-peripheral transfers, and with memory-to-memory transfers (AHB from/to AXI).

A FIFO-based channel is able to perform byte-based padding on the last write(s) up to the fully transferred source block size. Then channel FIFO is empty. Data handling is performed on zero bytes in the same way as on regular data bytes from the source, as explained in *GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment*.

There is byte-based padding at the block level:

1. If source data width is less than the destination data width, and if FIFO queuing and data packing is configured (PAM[1:0] = 1x):

- Padding with zero bytes. For example, if BNDT= 5, 8-bit reads, 32-bit writes:
  - if DBX = 0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> 000B_4, $B_3B_2B_1B_0$
  - if DBX = 0, DHX = 1: B_4,B_3,B_2,B_1,B_0 -> 0$B_4$00, $B_1B_0B_3B_2$
  - if DBX = 1, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> 00$B_4$0, $B_2B_3B_0B_1$
  - if DBX = 1, DHX = 1: B_4,B_3,B_2,B_1,B_0 -> $B_4$000, $B_0B_1B_2B_3$

2. If source data width > destination data width, and if FIFO queuing and data unpacking is configured (PAM[1:0] = 1x):

- Padding with zero bytes.
- On the last read, only the number of LSB(s) up to the block size are written to the FIFO. The last written data to the destination is padded with zero bytes up to the destination data width. For example, if BNDT= 5, 32-bit reads, 16-bit writes:
  - if DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 0B_4, B_3B_2, B_1B_0
  - if DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$, -> $B_4$0, B_2B_3, B_0B_1

3. If source data width = destination data width (and BNDT[15:0] is not a multiple of that value):

- Padding with zero bytes. For example, if BNDT= 6, 32-bit reads, 32-bit writes are configured
  - if SBX = 0, DBX = 0, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_5B_4$, $B_3B_2B_1B_0$
  - if SBX = 0, DBX = 0, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_5B_400, $B_1B_0B_3B_2$
  - if SBX = 0, DBX = 1, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_4B_5$, $B_2B_3B_0B_1$
  - if SBX = 0, DBX = 1, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_4B_500, $B_0B_1B_2B_3$
  - if SBX = 1, DBX = 0, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $000B_4$, $B_3B_1B_2B_0$
  - if SBX = 1, DBX = 0, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_400$, $B_2B_0B_3B_1$
  - if SBX = 1, DBX = 1, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_40$, $B_1B_3B_0B_2$
  - if SBX = 1, DBX = 1, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_4000, $B_0B_2B_1B_3$

4. If source data width < destination data width, and if destination data is configured as right-aligned and, either configured with zero padding bytes (PAM[1:0] = 00), or configured with sign extension (PAM[1:0] = 01):

- Padding with zero bytes if PAM[1:0] = 00. For example, BNDT = 5, 8-bit reads, 32-bit writes, PAM[1:0] = 00:
  - if DBX =0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> $000B_4$, $000B_3$, $000B_2$, $000B_1$, $000B_0$
- Padding with sign extension if PAM[1:0] = 01. For example, BNDT = 5, 8-bit reads, 32-bit writes, PAM[1:0] = 01:
  - if DBX = 0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> $SSSB_4$, $SSSB_3$, $SSSB_2$, $SSSB_1$, $SSSB_0$

5. If source data width > destination data width, and if destination data is configured as right-aligned (PAM[1:0] = 00), or left-aligned (PAM[1:0] = 01):

- Padding with zero bytes. For example, BNDT = 5, 32-bit reads, 16-bit writes:
  - if SBX = 0, PAM[1:0] = 00, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_4$, B_1B_0
  - if SBX = 0, PAM[1:0] = 00, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_40, B_0B_1
  - if SBX = 0, PAM[1:0] = 01, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_3B_2
  - if SBX = 0, PAM[1:0] = 01, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_2B_3
  - if SBX = 1, PAM[1:0] = 00, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_4$, B_2B_0
  - If SBX = 1, PAM[1:0] = 00, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_40, B_0B_2
  - If SBX = 1, PAM[1:0] = 01, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_3B_1
  - If SBX = 0, PAM[1:0] = 01, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_1B_3

13.4.17 GPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via GPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for GPDMA_PRIVCFGR GPDMA_RCFGLOCKR that is readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

13.4.18 GPDMA error management

The GPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as a AHB single or a burst) to the source or the destination:

- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware). The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).
- After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a GPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).
- After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.
- After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR,

GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of a GPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).
- After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 12 to 15): a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 12 to 15): a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - for channel x (x = 12 to 15): a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - for channel x (x = 12 to 15): a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1. BNDT = 0)

13.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, GPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, GPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

13.6 GPDMA in low-power modes

Table 102. Effect of low-power modes on GPDMA

Mode	Description
Sleep	No effect. GPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the GPDMA registers is kept when entering Stop mode.
Standby	The GPDMA is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 13.3.2* to know if any Stop mode is supported.

13.7 GPDMA interrupts

There is one GPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 103. GPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
GPDMA_CHx	Transfer complete	GPDMA_CxCR.TCIE	GPDMA_CxSR.TCF	Write 1 to GPDMA_CxFCR.TCF
	Half transfer	GPDMA_CxCR.HTIE	GPDMA_CxSR.HTF	Write 1 to GPDMA_CxFCR.HTF
	Data transfer error	GPDMA_CxCR.DTEIE	GPDMA_CxSR.DTEF	Write 1 to GPDMA_CxFCR.DTEF
	Update link error	GPDMA_CxCR.ULEIE	GPDMA_CxSR.ULEF	Write 1 to GPDMA_CxFCR.ULEF
	User setting error	GPDMA_CxCR.USEIE	GPDMA_CxSR.USEF	Write 1 to GPDMA_CxFCR.USEF
	Suspended	GPDMA_CxCR.SUSPIE	GPDMA_CxSR.SUSPF	Write 1 to GPDMA_CxFCR.SUSPF
	Trigger overrun	GPDMA_CxCR.TOFIE	GPDMA_CxSR.TOF	Write 1 to GPDMA_CxFCR.TOF

A GPDMA channel x event may be:

- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].
- A half-transfer event is a half-block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

  A half-block transfer occurs when half of the source block size bytes (rounded-up integer of GPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

  A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see *Section 13.4.18*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

13.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

13.8.1 GPDMA privileged configuration register (GPDMA_PRIVCFGR)

Address offset: 0x04

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN =1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PRIVx**: privileged state of channel x (x = 15 to 0)
0: unprivileged
1: privileged

13.8.2 GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08

Reset value: 0x0000 0000

This register can be written by a software agent with privileged attributes in order to individually lock, for example at boot time, the privileged attributes of any GPDMA channel/resource (to lock the setting of GPDMA_CxPRIVCFGR for any channel x, for example at boot time).

A read access may be privileged or unprivileged.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LOCKx**: lock the configuration of GPDMA_PRIVCFGR.PRIVx until a global GPDMA reset (x = 15 to 0)
This bit is cleared after reset and, once set, it cannot be reset until a global GPDMA reset.
0: privilege configuration of the channel x is writable.
1: privilege configuration of the channel x is not writable.

13.8.3 GPDMA masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C

Reset value: 0x0000 0000

This is a read register.

This register contains the masked interrupt status bit MISx for each channel x. It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when writing 1 to the corresponding GPDMA_CxFCR flag clear bit.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full interrupt status. An unprivileged software is restricted to read the status of unprivileged channels, other privileged bit fields returning zero.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISx**: masked interrupt status of channel x (x = 15 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

13.8.4 GPDMA channel x linked-list base address register (GPDMA_CxLBAR)

Address offset: 0x50 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x GPDMA_PRIVCFGR.PRIVx.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 **LBA[31:16]**: linked-list base address of GPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

13.8.5 GPDMA channel x flag clear register (GPDMA_CxFCR)

Address offset: 0x5C+ 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This is a write register privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: corresponding TOF flag cleared

Bit 13 **SUSPF**: completed suspension flag clear
0: no effect
1: corresponding SUSPF flag cleared

Bit 12 **USEF**: user setting error flag clear
0: no effect
1: corresponding USEF flag cleared

Bit 11 **ULEF**: update link transfer error flag clear
0: no effect
1: corresponding ULEF flag cleared

Bit 10 **DTEF**: data transfer error flag clear
0: no effect
1: corresponding DTEF flag cleared

Bit 9 **HTF**: half-transfer flag clear
0: no effect
1: corresponding HTF flag cleared

Bit 8 **TCF**: transfer complete flag clear
0: no effect
1: corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

13.8.6 GPDMA channel x status register (GPDMA_CxSR)

Address offset: 0x60 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is privileged or unprivileged, depending on the privileged state of the channel (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[7:0]							
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	r	r	r	r	r	r	r							r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **FIFOL[7:0]**: monitored FIFO level (in bytes)
Number of available bytes in the FIFO.

Note: After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxBR1.BDNT[15:0] and GPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag
0: no trigger overrun event
1: a trigger overrun event occurred

Bit 13 **SUSPF**: completed suspension flag
0: no completed suspension event
1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag
0: no user setting error event
1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag
0: no update link transfer error event
1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag
0: no data transfer error event
1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half-transfer flag
0: no half-transfer event
1: a half-transfer event occurred
A half-transfer event is either a half-block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).
A half-block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.
A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2)) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag
0: no transfer complete event
1: a transfer complete event occurred
A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **DRAININGF**: FIFO draining flag
0: No received order to drain the FIFO or channel FIFO draining completed
1: Ongoing channel FIFO draining and channel termination
This flag is asserted after that the order to drain the FIFO is received, and meanwhile that the channel is enabled and draining the FIFO and before the channel is terminated with a drained FIFO.
This flag is deasserted by hardware when the enabled channel has been ordered to be terminated with FIFO draining, and the hardware effectively terminates.

Bit 0 **IDLEF**: idle flag
0: channel not in idle state
1: channel in idle state
This idle flag is deasserted by hardware when the channel is enabled (GPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

13.8.7 GPDMA channel x control register (GPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	LAP	LSM
								rw	rw					rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOIE	SUSPIE	USEIE	ULEIE	DTEIE	HTIE	TCIE	Res.	Res.	Res.	Res.	DRAIN FIFO	SUSP	RESET	EN
	rw	rw	rw	rw	rw	rw	rw					w	rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** priority level of the channel x GPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: linked-list allocated port
This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.
0: port 0 (AHB) allocated
1: port 1 (AHB) allocated
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.
1: channel executed **once** for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13 **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half-transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DRAINFIFO:** empty FIFO
This bit is write only. Writing 0 has no impact.
Writing 1 to RESET in this register causes the hardware to deassert this DRAINFIFO bit, whatever is written into this DRAINFIFO. Else:
Software must write 1 in order to drain the channel FIFO on a suspended channel.
If the software concurrently writes 1 to DRAINFIFO and 1 to SUSP and 0 to reset, the hardware suspends the channel and drains the FIFO by popping out the residual FIFO bytes to the destination (see the programming sequence in *Figure 105*).
0: Write: no action
1: Write: drain FIFO after having suspended the channel

Bit 2 **SUSP:** suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel (channel with an ongoing GPDMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 103*.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.

Bit 1 **RESET:** reset

This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP, DRAINFIFO and EN bits (whatever is written receptively in bit 3 and bit 2 and bit 0).

The reset is effective when the channel is in steady state, meaning one of the following:

- active channel in suspended state (GPDMA_CxSR.SUSPF = 1, GPDMA_CxSR.IDLEF = GPDMA_CxCR.EN = 1 and GPDMA_CxSR.DRAININGF = 0)
- channel in disabled state (GPDMA_CxSR.IDLEF = 1 and GPDMA_CxCR.EN = 0).

After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 104*).

0: no channel reset

1: channel reset

Bit 0 **EN:** enable

Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:

this bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: write: ignored, read: channel disabled

1: write: enable channel, read: channel enabled

13.8.8 GPDMA channel x transfer register 1 (GPDMA_CxTR1)

Address offset: 0x90 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x in GPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	DAP	Res.	Res.	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]	
	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SAP	SBX	PAM[1:0]		Res.	SBL_1[5:0]						SINC	Res.	SDW_LOG2[1:0]	
	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **DAP**: destination allocated port

This bit is used to allocate the master port for the destination transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **DHX**: destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word:

0: no halfword-based exchanged within word

1: the two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0:no byte-based exchange within half-word

1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: destination incrementing burst

0: fixed burst

1: contiguously incremented burst

The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: A destination burst transfer must have an aligned address with its data width (start address GPDMA_CxDAR[2:0] and if present address offset GPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **SAP**: source allocated port

This bit is used to allocate the master port for the source transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: source byte exchange within the unaligned half-word of each source word

If the source data width is shorter than a word, this bit is ignored.

If the source data width is a word:

0:no byte-based exchange within the unaligned half-word of each source word

1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.

Condition: PAM_1

00: source data is transferred as right aligned, padded with 0s up to the destination data width

01: source data is transferred as right aligned, sign extended up to the destination data width

10-11: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

Condition: PAM_2

00: source data is transferred as right aligned, left-truncated down to the destination data width

01: source data is transferred as left-aligned, right-truncated down to the destination data width

10-11: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Note: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: source incrementing burst
0: fixed burst
1: contiguously incremented burst
The source address, pointed by GPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: binary logarithm of the source data width of a burst in bytes
00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued
A source burst transfer must have an aligned address with its data width (start address GPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.
Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

13.8.9 GPDMA channel x transfer register 2 (GPDMA_CxTR2)

Address offset: 0x94 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x. This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	Res.	TRIGSEL[5:0]					
rw	rw					rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	DREQ	SWREQ	Res.	REQSEL[7:0]							
rw	rw		rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half-transfer complete events generation.

00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half-transfer event is generated.

01: channel x (x = 0 to 11), same as 00, channel x (x =12 to 15), at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0). The complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half-transfer event is generated.

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half-transfer event is generated at the half of the LLI data transfer The LLI data transfer is a block transfer or a 2D/repeated block transfer for channel x (x =12 to 15), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half-transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half-transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]**: trigger event input selection

These bits select the trigger event input of the GPDMA transfer (as per *Section 13.3.6*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x (x = 12 to 15): same, each block also if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x (x = 0 to 11): same as 00; channel x (x = 12 to 15): at 2D/repeated block level: the first burst read of the 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. LLI data transfer is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger:

– If the peripheral is the source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is the destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and one trigger hit.

As shown in *Figure 120: Trigger hit, memorization, and overrun waveform*, the GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10). The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled. After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Transferring a next LLI_{n+1} that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 13.3.1 for the list of the implemented channels with this feature).

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in GPDMA control mode. The GPDMA is programmed with GPDMA_CxTR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The GPDMA block transfer can be early completed by the peripheral itself (see *Section 13.3.5* for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (GPDMA_CxBR1.BRC[10:0] must be set to 0)

- the peripheral must be set as the source of the transfer (DREQ = 0).

- data packing to a wider destination width is not supported (if destination width > source data width, GPDMA_CxTR1.PAM[1] must be set to 0).

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 13.3.3*).

Bit 10 **DREQ**: destination hardware request

This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)

1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (GPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: software request

This bit is internally taken into account when GPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[7:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[7:0] is ignored.

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **REQSEL[7:0]**: GPDMA hardware request selection

These bits are ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1(software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 13.3.3*.

Caution: The user must not assign a same input hardware request (same REQSEL[7:0] value) to different active GPDMA channels (GPDMA_CxCR.EN = 1 and GPDMA_CxTR2.SWREQ = 0 for these channels). GPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

13.8.10 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated with the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

13.8.11 GPDMA channel x alternate block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: at the end of a block transfer, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxBR2.BRDAO to the current GPDMA_CxDAR value (current destination address)

1: at the end of a block transfer, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRDAO from the current GPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), GPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the GPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: at the end of a block transfer, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxBR2.BRSAO to the current GPDMA_CxSAR value (current source address)

1: at the end of a block transfer, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRSAO from the current GPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), GPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the GPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

– If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.
– If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
– if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
– if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated with the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

13.8.12 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: source address

This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (GPDMA_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.SBL_1[5:0] and GPDMA_CxTR1.SDW_LOG2[1:0]

– the additional source incremented/decremented offset value as programmed by GPDMA_CxBR1.SDEC and GPDMA_CxTR3.SAO[12:0].

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15). additional block repeat source incremented/decremented offset value as programmed by GPDMA_CxBR1.BRSDEC and GPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

13.8.13 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: 0xA0 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0].

– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 12 to 15), the additional block repeat destination incremented/decremented offset value as programmed by GPDMA_CxBR1.BRDDEC and GPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

13.8.14 GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: destination address offset increment

The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: source address offset increment

The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size, and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

13.8.15 GPDMA channel x block register 2 (GPDMA_CxBR2)

Address offset: 0xA8 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRDDEC) the current destination address (GPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRSDEC) the current source address (GPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

13.8.16 GPDMA channel x linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

LA[15:2]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.
0: no GPDMA_CxTR1 update
1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.
0: no GPDMA_CxTR2 update
1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.
0: no GPDMA_CxSAR update
1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory

This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.

0: no GPDMA_CxDAR update

1: GPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory

This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.

0: no GPDMA_CxLLR update

1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure

If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.

Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).

Caution: The user must program this pointer not to exceed the 64-Kbyte addressable space defined by the link base address register GPDMA_CxLBAR. The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

13.8.17 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

LA[15:2]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.

0: no GPDMA_CxTR1 update

1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.

0: no GPDMA_CxTR2 update

1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.

0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)

1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.

0: no GPDMA_CxSAR update

1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0:no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bit 26 **UT3**: Update GPDMA_CxTR3 from memory
This bit controls the update of GPDMA_CxTR3 from the memory during the link transfer.
0: no GPDMA_CxTR3 update
1: GPDMA_CxTR3 update

Bit 25 **UB2**: Update GPDMA_CxBR2 from memory
This bit controls the update of GPDMA_CxBR2 from the memory during the link transfer.
0: no GPDMA_CxBR2 update
1: GPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).

Caution: The user must program this pointer not to exceed the 64-Kbyte addressable space defined by the link base address register GPDMA_CxLBAR. The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

13.8.18 GPDMA register map

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

14 Neural-ART accelerator™ (NPU)

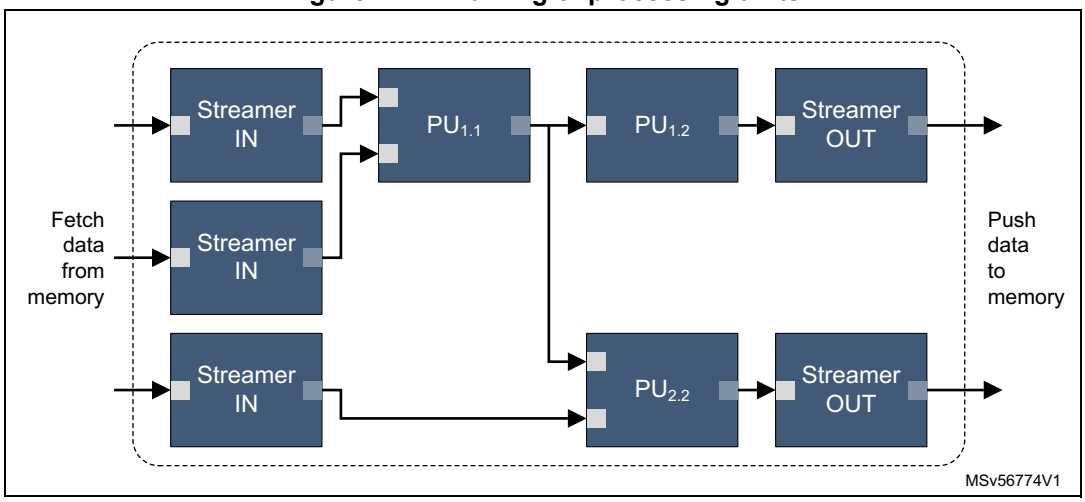
14.1 NPU introduction

Neural-ART accelerator is a branded family of design-time parametric and runtime reconfigurable neural processing unit (NPU) cores. These cores are specifically designed to accelerate (in area-constrained embedded and IoT devices) the inference execution of a wide range of quantized convolutional neural network (CNN) models.

Figure 123. Stream processing engine

Stream processing

The ST stream processing technology allows the creation of on-demand performance- and area-tailored instances to address artificial intelligence (AI) applications, from the lowest to the highest end class.



The ST stream processing technology is deemed far more flexible than a hardware data path, and more power-efficient than an on-chip memory bus. The core is a configurable data flow fabric, also known as stream switch, which can be programmed at runtime to create arbitrary virtual chains of processing units (PUs), implementing the sequence of operations to execute. Multiple chains can be active at the same time, provided there are enough available hardware resources.

In the virtual chains, data flow unidirectionally from one PU to the other, hence a processing chain cannot be faster than the slowest element in the chain. A back pressure mechanism controls the data flow in a virtual chain, and data streams can be easily forked or joined to feed multiple destinations, enabling multicasting, context switching, and filtering.

Chaining as many accelerators as possible in a single virtual chain reduces the number of useless and power consuming transfers from/to memory, thus reducing the overall memory traffic and the power consumption.

The resulting IP communicates with the rest of the system through stream engine units. These are smart half-DMAs that can read, and write the data to/from external memory to transfer from/to the IP internal buffers. Although not primarily intended for that, memory-to-memory transfers are possible, connecting two stream engines back to back.

Figure 124. Chaining of processing units

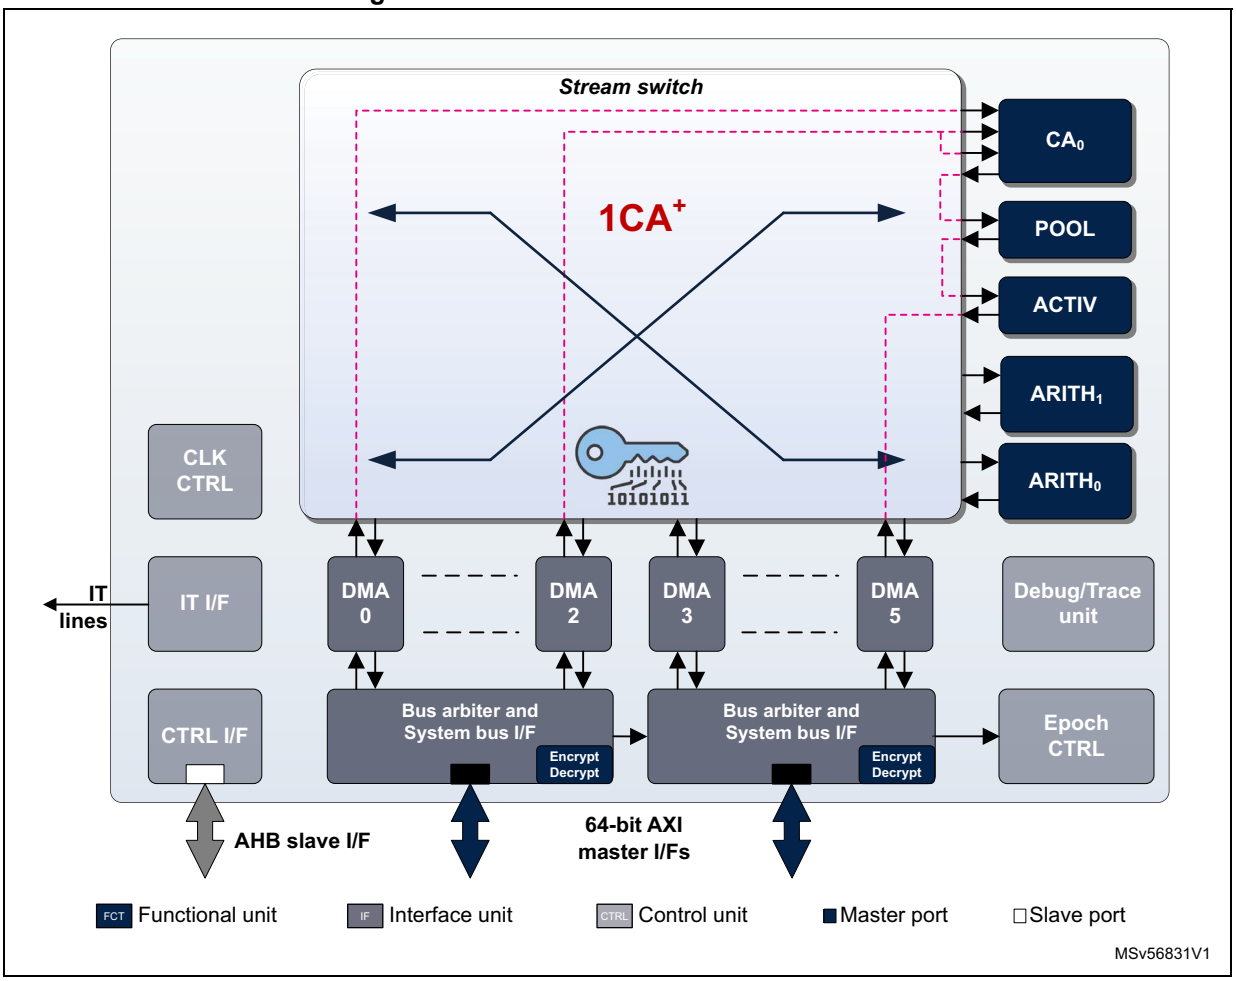
Epoch definition

The execution of CNN models is organized into indivisible processing sequences called epochs. A hardware epoch is defined by the sequence that starts with the configuration of the NPU by the host CPU, and ends with an interrupt sent back to the CPU. The host CPU can then trigger another hardware epoch or execute some software computing for the layers not accelerated by the hardware.

14.2 NPU implementation

The Neural-ART 11 NPU uses a 1CA configuration with the functional units listed in *Table 105*.

Table 105. Neural-ART 11 NPU configuration



Count	Unit	Description
1	STRSWITCH	Central data stream switch
1	CONVACC	*Convolutional accelerator*
1	POOL	*Pooling unit*
1	ACTIV	*Activation unit*
2	ARITH	*Arithmetic unit* for scalar arithmetic operators
6	STRENG	*Stream engines*, with embedded cipher
2	BUSIF	64-bit AXI interface
1	EPOCH	*Epoch controller*
1	DEBUG	Debug controller
-	SERVICES	Configuration network, Clock and reset manager, Interrupt controller

14.3 NPU functional description

14.3.1 NPU block diagram

The internal organization of the NPU is shown in *Figure 125*.

Figure 125. Neural-ART 11 NPU accelerator

When the NPU is configured and started, it autonomously fetches data from the external memory to feed its internal dynamically interconnected processing units. Similarly, the result of the operation sequence is flushed to the external memory.

Inputs/sources can be the activations/features, but also parameters, such as weights and biases constant data hosted in a memory-mapped nonvolatile memory. When the data-stream processing pipes are configured and started, the settings cannot be modified until the end-of-transfer event notifications of all DMA-outs and sinks.

14.3.2 NPU pins and internal signals

The NPU has no external connections.

Table 106. NPU internal signals

Signal name	Signal type	Comment
npu_clk	Input	Main clock
npu_rstn	Input	Reset
npu_host_int[3:0]	Output	Host interrupts
dbg_freeze_async	Input	Freeze in debug
ext_triggers_async[3:0]	Input	External synchronization triggers
trig_sig[7:0]	Output	Debug and trace triggers to CTI

14.3.3 Configuration network

Each of the functional units, whether accelerator or interface, has a configuration space made of a collection of configuration registers. These registers are accessible through the AHB interface. Their detailed description is out of the scope of the present document.

The NPU embeds a configuration network that provides host processor access to the configuration space of the different units in the Neural-ART core. This configuration network connects to the system backbone through a 32-bit AHB5-lite port. It supports a single 32-bit wide read and write transaction, with no pipelining nor outstanding transactions.

14.3.4 Clock/reset manager

The purpose of this unit is twofold:

1. Clock control

   The NPU uses a single functional clock provided by the RCC. This input clock is fed to the clock control unit from where it is gated and fed to the different units of the IP.

   The clock unit generates clocks not gated, and clocks gated by default that need to be enabled after reset.

   Clock gating is controlled by a configuration register bank, accessible via the configuration network, and programmed by the control code generated by the NPU compiler tool chain.

2. Reset control

   The NPU uses a single functional reset provided by the RCC. This reset signal is synchronized inside the IP and fed to the different functional units.

   Setting the clear bit in the control configuration register triggers a global NPU reset.

14.3.5 Stream link

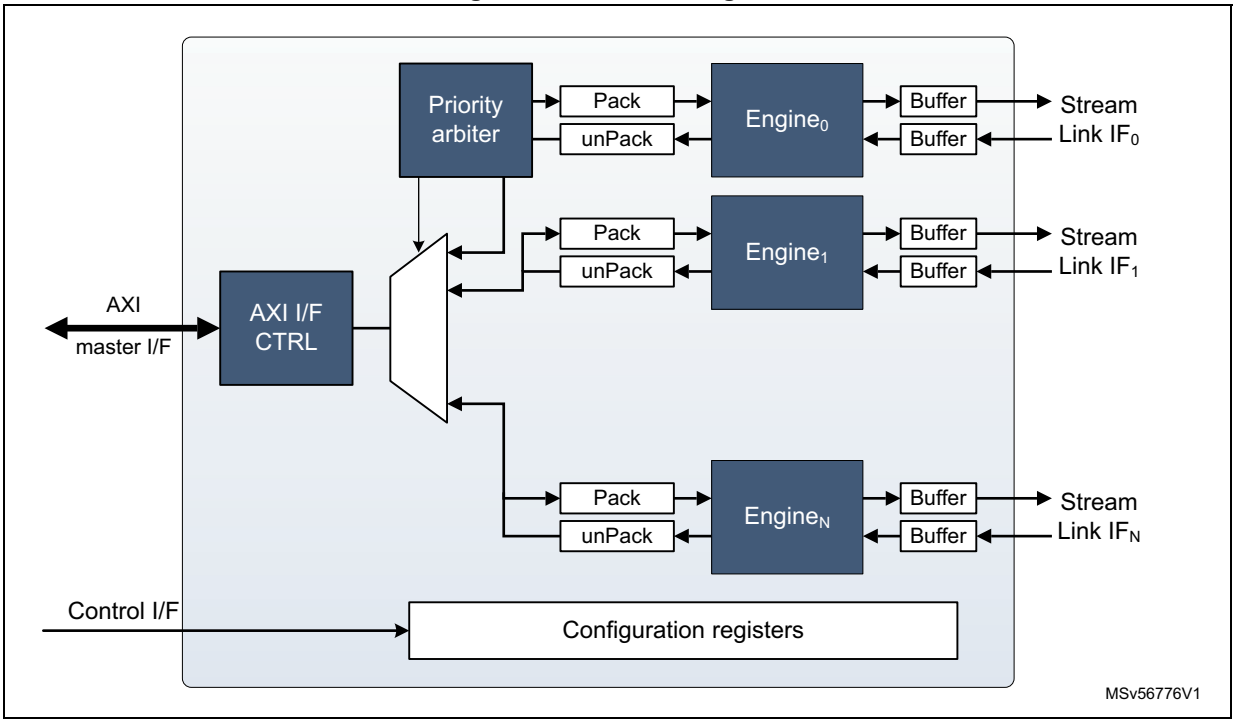
A stream link is a unidirectional interconnection to transport data streams from accelerator units, stream engines, and interfaces to the stream switch and vice versa.

The stream consists of data, messages, or commands, and additional signaling information.

- Data are transported over three 8-bit wide data channels that are either handled individually or can be interpreted as a single 24-bit data value.
- Transported data can use different formats. A raster scan data stream allows the automatic detection of the geometrical dimensions of the received feature data tensor (width and height). A raw data format requires to program additional parameters to handle correctly the received data stream.
- Signaling information is used to identify valid information on the stream link. It indicates the type and format of information transported, and whether this is the first or the last data transmitted.

14.3.6 Stream switch

This switch dynamically connects output stream link ports to input stream link ports, depending on the configuration data written to the configuration registers.



All input stream link ports can forward their data streams to one or multiple (multicast) output ports at the same time, allowing replication of the data stream.

Two stream links can be connected to a single output port of the switch. In this case, the output data are managed using a time-division context switch approach.

14.3.7 Stream engines

These engines manage the transfer from the system to the processing units and vice versa.

Figure 126. Stream engines

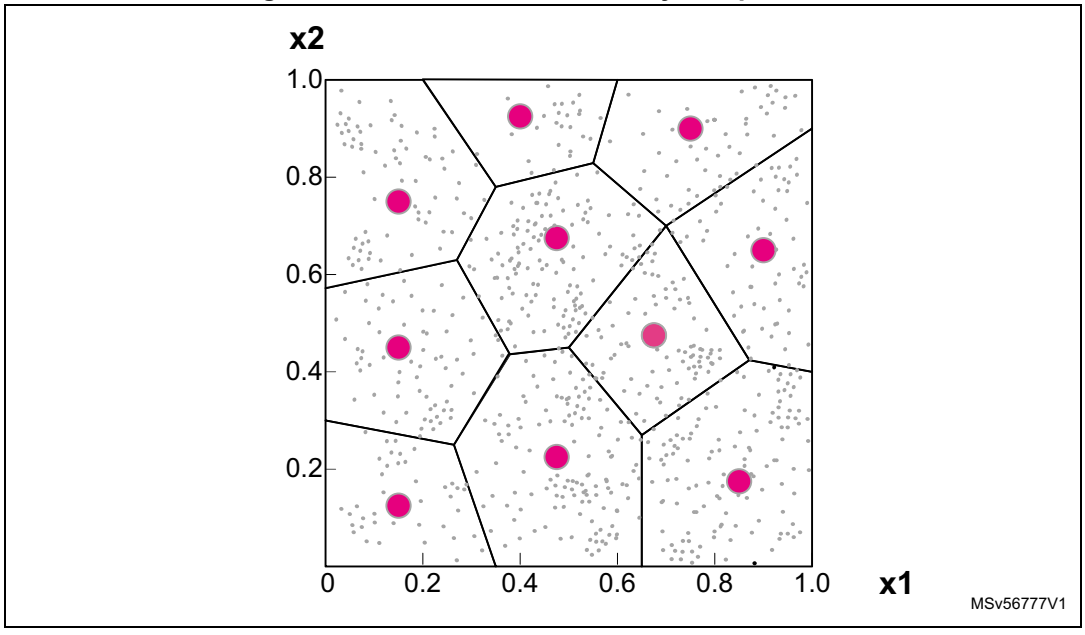
A stream engine connects to the stream switch by one input and one output stream link.

The stream engine offers a high configurability on read/write memory patterns:

- 2D and 3D data representations
- Gap management (interleaving)
- High flexibility of data format (size, rounding, subsampling or resampling, MSB or LSB alignment with sign extension).

Linked lists are supported.

14.3.8 Encryption/Decryption unit



A low overhead/latency encryption/decryption unit based on Keccak-p[200] SHA-3 algorithm cipher, with a programmable number of rounds, is integrated in the bus interface, and can be shared between the different stream engines. It supports both weights and activation decryption and encryption.

14.3.9 Decompression unit

This unit supports on-the-fly decoding for scalar quantized data associated with kernels weights (with arbitrary quantization function), and decoding of vector quantized groups of weights.

An n-dimensional space can be described in a lossy way, by subdividing it into subvolumes, each described by its centroid. The subvolumes are obtained to minimize a predefined distortion function. The whole signal space can be represented with huge savings in terms of storage, as it is possible to represent the space of interest using only centroid values.

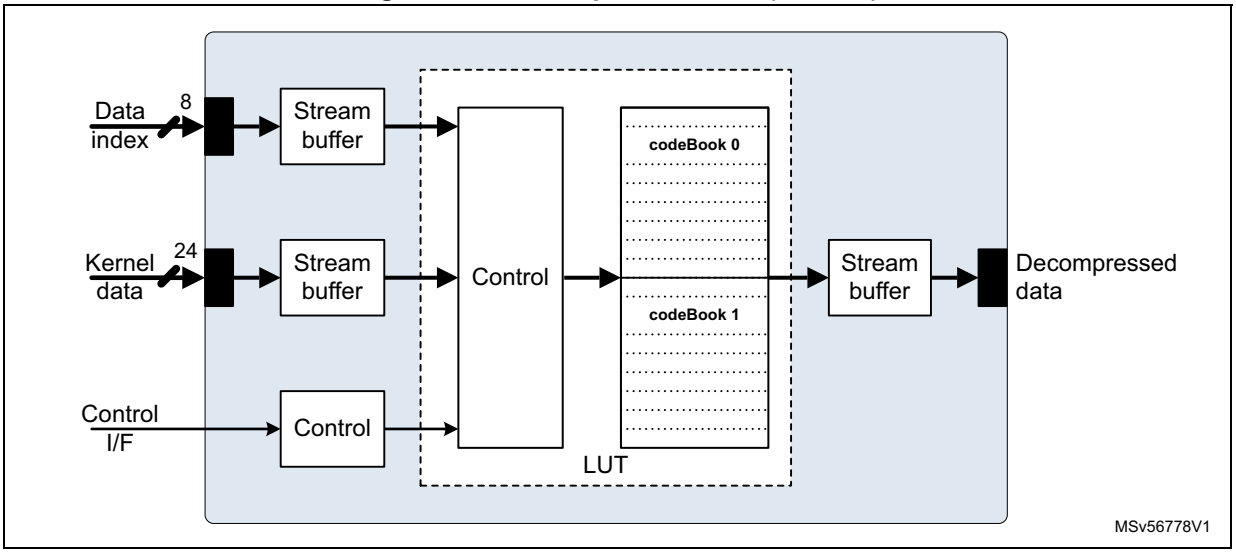


Figure 127. Two dimensional lossy compression

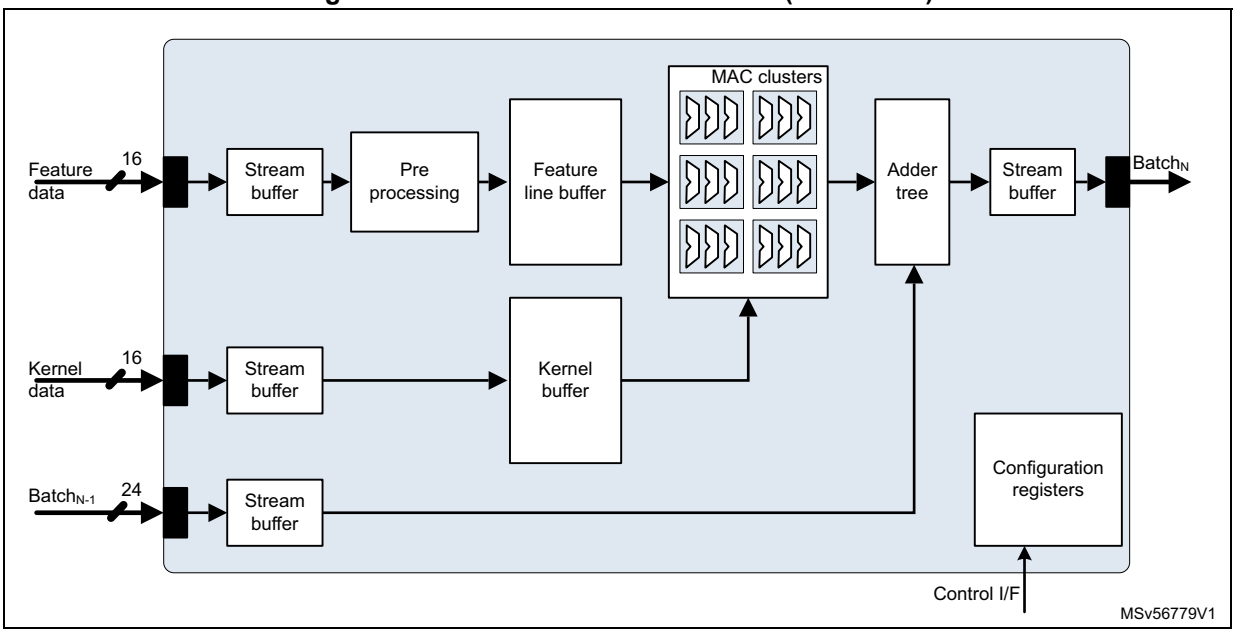
Quantization functions and/or vector quantizer code books (CB) are defined with an offline tool part of the NPU compiler toolchain. The encoder maps the input range into a finite range of rational values, called the code book. Any value stored by the CB is called a code

vector. A code vector is made by up to eight code words. Each code book can store up to 256 code vectors (CV).

Figure 128. Decompression unit (DECUN)



The decompression unit connects to the stream switch by two input stream links and one output stream link.

- iSL_0: receives the 8-bit indexes to decompress the data.
- iSL_1: receives the data to write in the code book, sent as raw data.

14.3.10 Convolutional accelerator

This is the core of the NPU. It implements clusters of multiply-accumulate (MAC) engines supporting fixed-point acceleration of the 3x3 convolutions used by many of the neural network models. It can be configured as 16- or 8-bit MACs, depending on which fixed-point precision for kernels and feature data is considered sufficient.

Figure 129. Convolutional accelerator (CONVACC)

The convolution accelerator connects to the stream switch by three input stream links and one output stream link.

- iSL_0: receives the feature data as 8- or 16-bit raster scan or raw data. Data go through a bit rate adaptation stream buffer and is then transmitted to the feature data preprocessing unit before it is stored in the feature line buffer.
- iSL_1: receives the kernel data as 8- or 16-bit raster scan or raw data.
- oSL: provides convolution results as 8- or 16-bit raster scan or raw data stream, with up to 24-bit wide signed data values.
- iSL_2: can receive intermediate 24-bit signed accumulator values to be accumulated with the convolution results.

Each convolution accelerator supports signed or unsigned arithmetic. It includes eighteen 16-bit MAC units grouped as six clusters of three MAC units. Each MAC performs a single 16x16-, two 16x8-, or four 8x8-bit multiply accumulate operation, which sums up to a maximum of 18 16x16-, 36 16x8-, or 72 8x8-bit multiply accumulate operations per clock cycle and per convolution accelerator unit.

The preprocessing unit implements the following sequence:

1. Format detection: determines if the data is raster scan or raw
2. Shift/round/saturation
3. HOR/VER cropping
4. Zero frame generation: on-the-fly extend the feature tensor structure.
5. Iteration control: simplifies the iterative processing of kernels larger than the 3x3 natively supported by the convolutional accelerator.

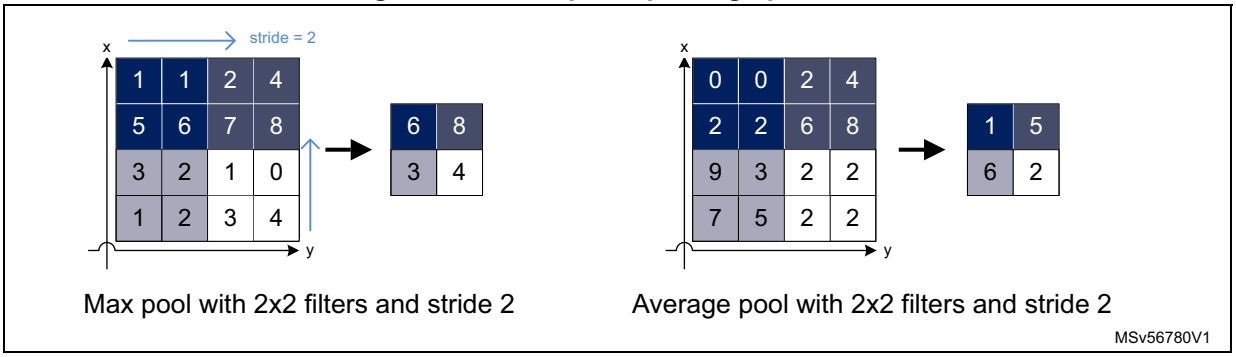
14.3.11 Pooling unit

This unit supports pooling operations like local 2D windowed (MxN) min, max, average pooling, as well as global max, min, or average pooling.

Supported features include:

- Native pooling windows of dimensions up to 3x3
- Horizontal and vertical strides ranging from 1 to 15
- Batch size ranging from 1 to 8
- Left, right, and top padding ranging from 0 to 7
- Bottom padding, depending on the window height

Figure 130. Example of pooling operations



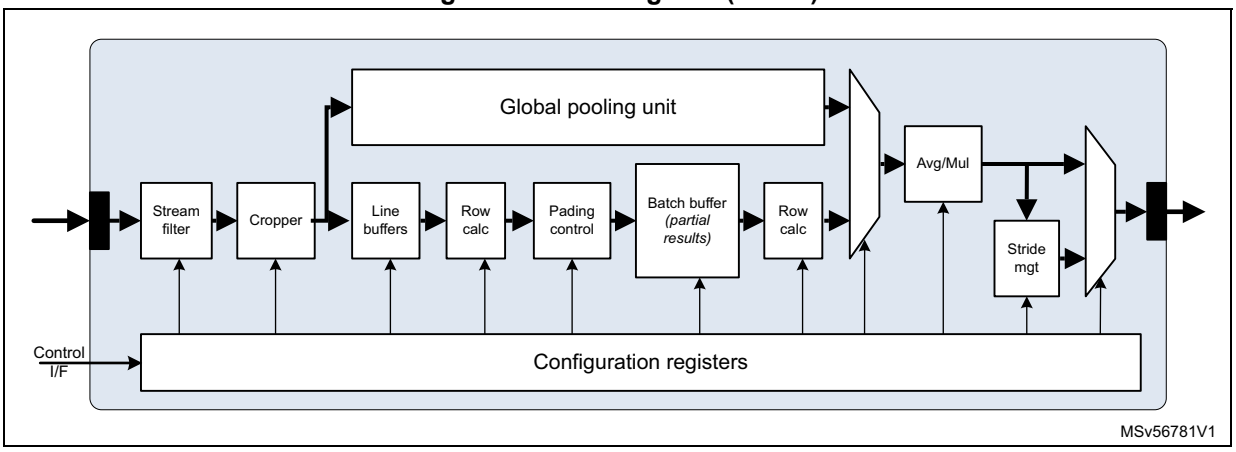


Figure 131. Pooling unit (POOL)

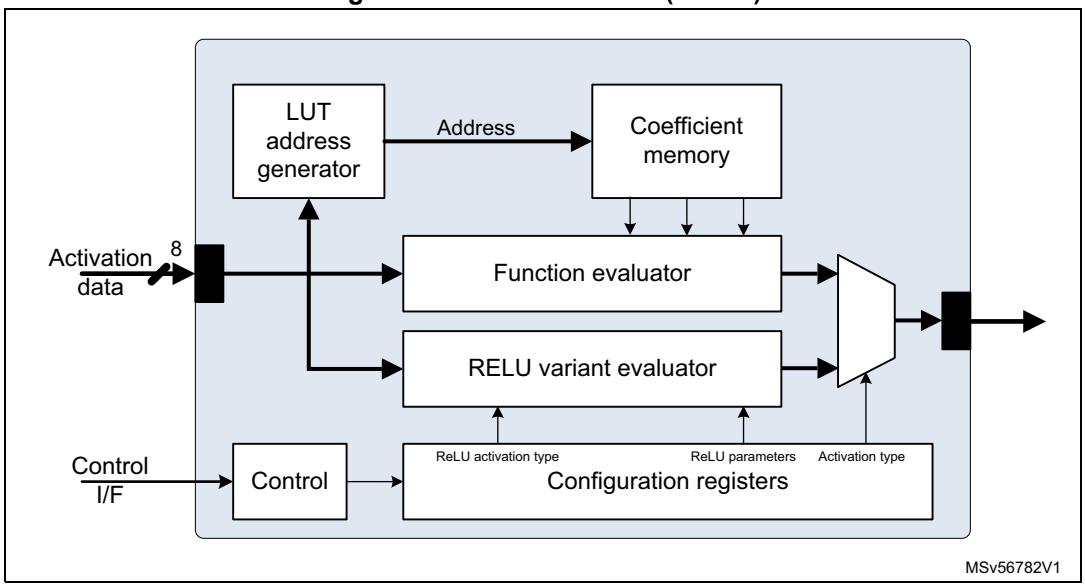


The pooling unit connects to the stream switch by one input and one output stream link:

- iSL_0: receives the activation input values as raster scan or raw data. Input is saturated to 16-bit.
- oSL: produces the pooled output as raw data.

14.3.12 Activation unit

This unit implements the activation functions associated with convolutional neural networks. It provides a dedicated path to compute ReLU-like activations such as plain, parametric, and thresholded ReLUs. There is also a generic function evaluator using a second-degree piece-wise polynomial approximation ($y = ax^2 + bx + c$ or $y = (ax + b) * x + c$). It uses a hierarchical uniform segmentation scheme to implement the evaluator.

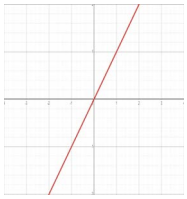
Figure 132. Activation unit (ACTIV)

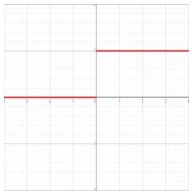
The unit connects to the stream switch by one input stream link and one output stream link.

- iSL_0: receives the activation input values as raster scan or raw data. Input is saturated to 16-bit.
- oSL: produces the result output as raw data.

Table 107 provides examples of usual activation functions.

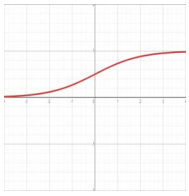
Table 107. Activation functions example

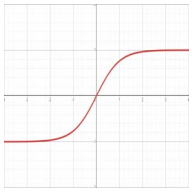


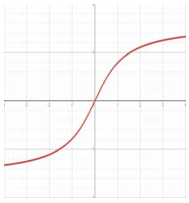


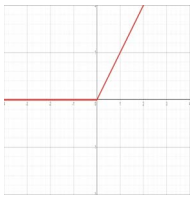
Function	Plot	Equation	Derivative
Identity		$f(x) = x$	$f(x) = 1$
Binary step		$f(x) = \begin{cases} 0 & \text{for } x < 0 \\ 1 & \text{for } x \geq 0 \end{cases}$	$f'(x) = \begin{cases} 0 & \text{for } x \neq 0 \\ \infty & \text{for } x = 0 \end{cases}$

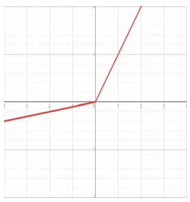
Table 107. Activation functions example (continued)

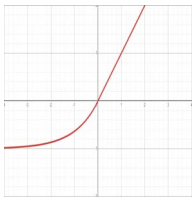


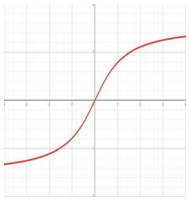










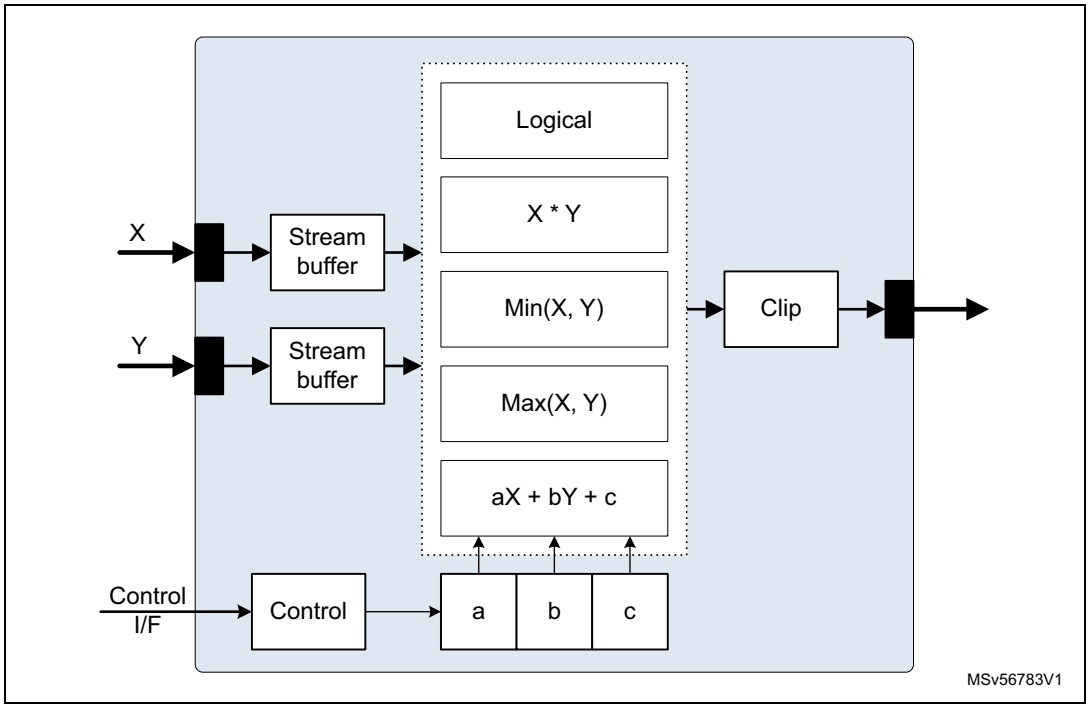


Function	Plot	Equation	Derivative
Logistic		$f(x) = \frac{1}{1+e^{-x}}$	$f'(x) = f(x)(1-f(x))$
Hyperbolic tangent		$f(x) = \tanh(x) = \left(\frac{2}{1+e^{-2x}} - 1\right)$	$f'(x) = 1-f(x)^2$
Arctan		$f(x) = \operatorname{atan}(x)$	$f'(x) = \frac{1}{x^2+1}$
Rectified linear unit (ReLU)		$f(x) = \begin{cases} 0 & \text{for } x < 0 \\ x & \text{for } x \geq 0 \end{cases}$	$f'(x) = \begin{cases} 0 & \text{for } x < 0 \\ 1 & \text{for } x \geq 0 \end{cases}$
Parametric rectified linear unit (PReLU)		$f(x) = \begin{cases} ax & \text{for } x < 0 \\ x & \text{for } x \geq 0 \end{cases}$	$f'(x) = \begin{cases} a & \text{for } x < 0 \\ 1 & \text{for } x \geq 0 \end{cases}$
Exponential linear unit (ELU)		$f(x) = \begin{cases} a(e^x - 1) & \text{for } x < 0 \\ x & \text{for } x \geq 0 \end{cases}$	$f'(x) = \begin{cases} f(x) + a & \text{for } x < 0 \\ 1 & \text{for } x \geq 0 \end{cases}$

Table 107. Activation functions example (continued)

Function	Plot	Equation	Derivative
SoftPlus		$f(x) = \ln(1 + e^x)$	$f'(x) = \frac{1}{1 + e^{-x}}$

14.3.13 Arithmetic unit



The arithmetic unit can handle outputs coming directly from the convolution accelerators. The main function is aX + bY+ c, where X and Y are input data streams, supplied via two input stream link interfaces and a, b and c are constants that are either vectors or scalars, which are preloaded into an internal memory via the configuration interface.

The arithmetic unit can be configured to perform other operations:

- x * y;
- MIN(x,y), MAX(x,y)
- Logical {AND, OR, NOT(X)}
- Bitwise {AND, OR, XOR, NOT(x)}
- Comparison operations like =, <, ≤, >, ≥
- Math operations like ABS(x), SIGN(x), and CLIP(x) with the 16-bit signed clip ranges supplied by the a coeff (min) and c coeff (max)

Based on the choice and type of coefficients, the unit can also perform element-wise operations like x - y, x + y, and similar ones.

Figure 133. Arithmetic unit (ARITH)

This unit connects to the stream switch by two input stream links and one output stream link.

- $iSL_{0,1}$: receives the input values, denoted X & Y, as raster scan or raw data. Input is saturated to 16-bit.
- oSL: produces the result output as raw data.

14.3.14 Reconfigurable buffer

The amount of data to process is usually divided using channel-wise data segmentation strategies. The data are then organized in execution epochs and channel data blocks along the three spatial dimensions. Data blocks are created considering the number of channels and the size of the incoming data. The partial data coming out from the different data blocks must then be reorganized and used in the next processing.

The reconfigurable buffer takes and stores the input data before making them available to the following units, which is useful to avoid deadlocks.

14.3.15 Epoch controller

This controller makes the NPU operation independent from the host CPU, which just provides a pointer to a 64-bit aligned “binary blob” placed in a memory space accessible through the AXI IF. The binary blob can be encrypted.

The core of the epoch controller is an FSM that decodes the control microinstructions, to appropriately configure all the processing units involved in the model execution using direct access to the NPU internal configuration bus.

The synchronization with the NPU is interrupt-based. An available step-by-step mode allows the execution of one microinstruction at a time. The execution is triggered by a write in a dedicated bit in the IRQ register.

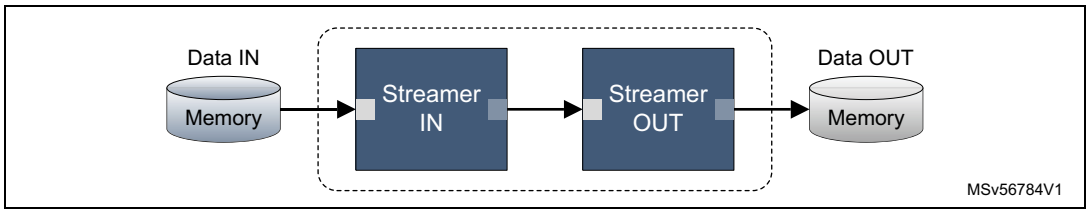
The controller frees the AHB control bus for other uses, and improves the performance through a faster NPU programming. The binary blob is fetched through the AXI interface, which provides a larger bandwidth than the AHB. The direct access to the internal configuration bus allows bypassing all the bus external structure, where transactions from the host processor need to pass through.

14.3.16 Interrupt controller

Functional units can generate level-sensitive, active high, interrupts. These are collected by the interrupt controller, routed to four master interrupt lines, and forwarded to the host CPU.

When a master interrupt fires, the host CPU must read the INTREG register to identify the source of the current interrupt signaling. Interrupt routing to the four master interrupt lines and selective enabling are controlled by the INTORMSK and INTANDMSK mask registers, which have as many bits as interrupt sources.

- INTORMSK: an interrupt is forwarded if any of the unmasked interrupts is active.
- INTANDMSK: an interrupt is forwarded if all the unmasked interrupts are active.



14.4 Configuration examples

The following figures illustrate typical examples of streaming processing supported by the Neural-ART 11 NPU.

14.4.1 DMA transfer

The simplest possible chain involves one input streamer and one output streamer connected back-to-back, which (although not primarily intended for that) configures the NPU as a high-bandwidth DMA.

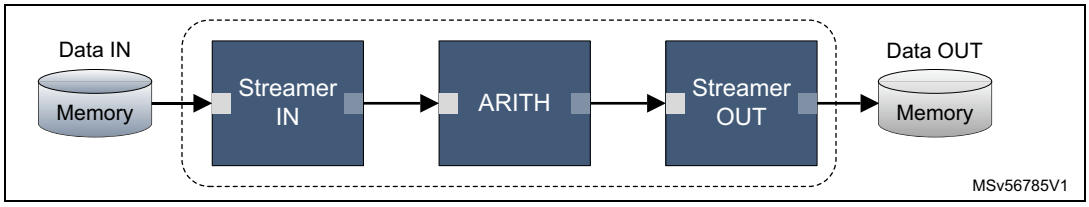


Figure 134. Memory to memory transfer

14.4.2 Simple processing

The simplest processing chain involves one input streamer and one output streamer, with one processing unit in between.

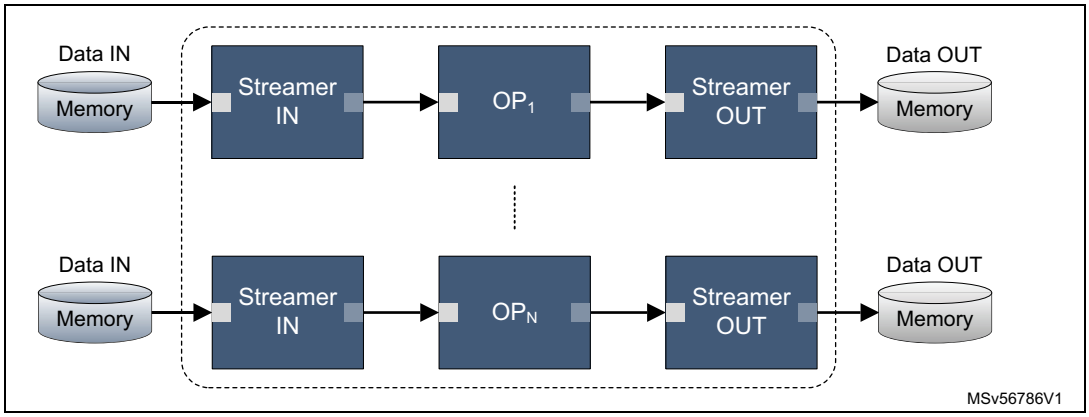

Figure 135. Simple processing

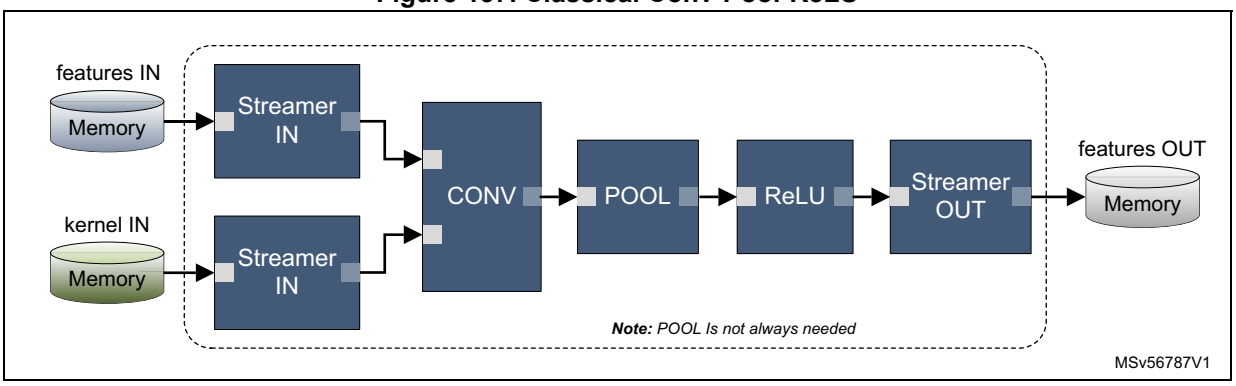
14.4.3 Multiple processing

Implements several independent simple processing chains, like the one in *Figure 135*.

Figure 136. Multiple processing



The number of independent chains is limited by the available hardware resources. It cannot exceed half the number of available stream engines, that is, three pairs of stream engines on Neural-ART 11, thus three chains.

14.4.4 Conv-Pool-ReLU

The virtual chain implementing the classical Conv-Pool-ReLU processing is illustrated in *Figure 137*.

Figure 137. Classical Conv-Pool-ReLU

14.5 Address space

The configuration bus address mapping depends on the specific NPU instance configuration. Each of the functional units has a 4-Kbyte configuration space, which yields a 128-Kbyte configuration space for the total IP, organized as shown in *Table 108*.

Table 108. Neural-ART 11 functional units memory base addresses(1)

Offset	Unit	Description
0x0000	CLKCTRL	Clock and reset manager
0x1000	INTCTRL	Interrupt controller
0x2000	BUSIF0	Bus interface 0
0x3000	BUSIF1	Bus interface 1
0x4000	STRSWITCH	Stream switch
0x5000	STRENG0	Stream engine 0
0x6000	STRENG1	Stream engine 1
0x7000	STRENG2	Stream engine 2
0x8000	STRENG3	Stream engine 3
0x9000	STRENG4	Stream engine 4
0xA000	STRENG5	Stream engine 5
0xB000	CONVACC0	Convolutional accelerator unit 0
0xC000	ACTIV0	Activation unit 0
0xD000	ARITH0	Arithmetic unit 0
0xE000	ARITH1	Arithmetic unit 1
0xF000	POOL0	Pooling unit 0
0x10000	EPOCHCTRL0	Epoch controller 0
0x11000	DEBUG0	Debug and trace unit 0

1. The base address is the offset relative to the first address location of the Neural-ART core, defined at integration level. Refer to the memory map.

15 Nested vectored interrupt controller (NVIC)

15.1 NVIC features

The NVIC includes the following features:

- Up to 170 maskable interrupt channels for STM32H7xxx (not including the 10 interrupt lines of Cortex®-M7 with FPU
- 16 programmable priority levels (4 bits of interrupt priority are used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late-arriving interrupts.

All interrupts, including the core exceptions, are managed by the NVIC.

For more information on exceptions and NVIC programming, refer to PM0253 programming manual for Cortex®-M7.

15.1.1 SysTick

The Cortex®-M7 contains a 24 bit down counter, which can be used as a system timer. The counter is loaded with the RELOAD value programmed in the SYST_RVR register. When enabled, by setting the ENABLE bit in the SYST_CSR register, the counter value decrements every cycle of the SysTick clock. When the counter reaches zero, it is automatically reloaded with the RELOAD value, and generates a SysTick interrupt to the NVIC on IRQ input # -1.

The SysTick clock can be selected by software from either the CPU clock (sys_cpu_ck), or the CPU clock divided by 8, according to the CLK_SOURCE bit in the SYST_CSR register (see *Table 109*).

Table 109. SysTick clock selection

CLK_SOURCE	SysTick clock
0	sys_cpu_ck/8
1	sys_cpu_ck

The value of the SysTick calibration register (SYST_CALIB) is fixed to 1000 (0x3E8). To generate a 1 ms timebase whatever the CPU clock frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- If the SysTick clock source is the CPU clock (sys_cpu_ck):

$$\text{reload value} = (F_{CPU} \times \text{SYST_CALIB}) - 1$$

- If the SysTick clock source is sys_cpu_ck/8:

$$\text{reload value} = ((F_{CPU} / 8) \times \text{SYST_CALIB}) - 1$$

  Where F_{CPU} refers to the CPU clock frequency expressed in MHz.

For example, to obtain a timebase of 1 ms when the SysTick clock source is the CPU clock running at 400 MHz:

$$\text{reload value} = (400 \times \text{SYST_CALIB}) - 1 = 0\text{x}61\text{A}7\text{F}$$

Note: SYST_CALIB has no effect on the SysTick clock frequency. It is provided for informational purposes only.

15.1.2 Interrupt and exception vectors

The exception vectors connected to the NVIC are the following: Reset, NMI, HardFault, MemManage, BusFault, UsageFault, SVCall, DebugMonitor, PendSV, SysTick.

Table 110. NVIC(1)

NVIC position	Priority	Type of priority	Acronym	Description	Address offset
-	-	-	-	Reserved	0x0000 0000
-	1	fixed	Reset	Reset	0x0000 0004
-14	2	fixed	NMI	Non maskable interrupt. The RCC Clock Security System (HSE CSS) is linked to the NMI vector.	0x0000 0008
-13	3	fixed	HardFault	All class of fault	0x0000 000C
-12	4	settable	MemManage	Memory management	0x0000 0010
-11	5	settable	BusFault	Pre-fetch fault, memory access fault	0x0000 0014

1. When different signals are connected to the same NVIC interrupt line, they are OR-ed.

16 Extended interrupt and event controller (EXTI)

The extended interrupt and event controller (EXTI) manages wake-up through configurable and direct event inputs. It provides wake-up requests to the power control, and generates interrupt requests to the CPU NVIC and events to the CPU event input.

The EXTI wake-up requests allow the system to be woken up from stop mode, and the CPU to be woken up from CStop mode.

Both the interrupt request and event request generation can also be used in run modes.

16.1 EXTI main features

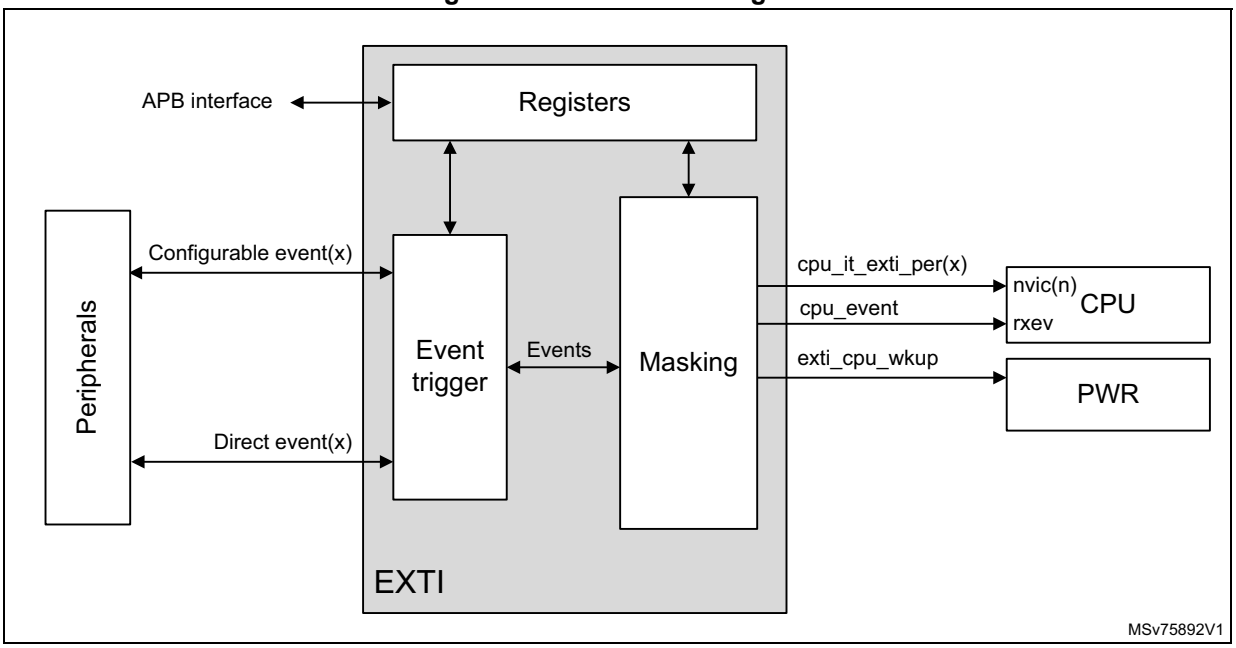
The EXTI main features are as follows:

- All event inputs allow the CPU to wake up and to generate a CPU interrupt and/or CPU event

The asynchronous event inputs are classified in two groups:

- Configurable events (signals from I/Os or peripherals able to generate a pulse) that feature:
  - Selectable active trigger edge
  - Interrupt pending status register bit
  - Individual interrupt and event generation mask
  - Software trigger possibility
- Direct events (interrupt and wake-up sources from other peripherals, requiring to be cleared in the peripheral) that feature:
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI (the interrupt pending status is provided by the peripheral generating the event)
  - Individual interrupt and event generation mask
  - No software trigger possibility.

16.2 EXTI block diagram



As shown in *Figure 138*, the EXTI consists of a register block accessed via an APB interface, an event input trigger block, and a masking block.

The register block contains all EXTI registers.

The event input trigger block provides event input edge triggering logic.

The masking block provides the event input distribution to the different wake-up, interrupt and event outputs, and their masking.

Figure 138. EXTI block diagram

16.2.1 EXTI connections between peripherals and CPU

The peripherals able to generate wake-up events when the system is in Stop mode or the CPU is in CStop mode are connected to an EXTI configurable event input or direct event input:

- Peripheral signals that generate a pulse are connected to an EXTI configurable event input. For these events, the EXTI provides a CPU status pending bit that has to be cleared.
- Peripheral interrupt and wake-up sources that have to be cleared in the peripheral are connected to an EXTI direct event input. There is no CPU status pending bit within the EXTI. The interrupt or wake-up is cleared by the CPU in the peripheral.

The CPU interrupts are connected to their respective CPU NVIC, and, similarly, the CPU event is connected to the CPU rxev input.

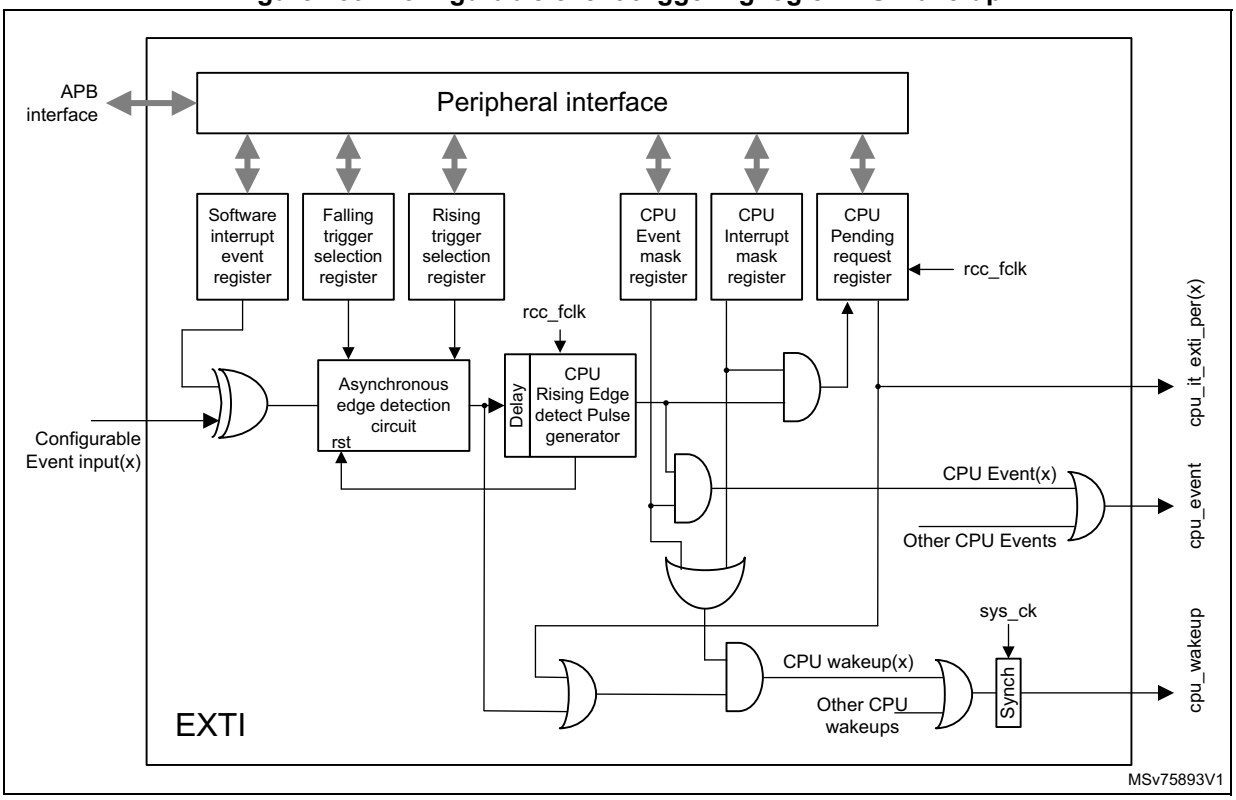
The EXTI wake-up signals are connected to the PWR block, and are used to wake up the CPU.

16.3 EXTI functional description

Depending on the EXTI event input type and wake-up target(s), different logic implementations are used. The applicable features are controlled from register bits:

- Active trigger edge enable, by *EXTI rising trigger selection register 1 (EXTI_RTSR1)*, *EXTI rising trigger selection register 2 (EXTI_RTSR2)*, *EXTI rising trigger selection register 3 (EXTI_RTSR3)*, and *EXTI falling trigger selection register 1 (EXTI_FTSR1)*, *EXTI falling trigger selection register 2 (EXTI_FTSR2)*, *EXTI falling trigger selection register 3 (EXTI_FTSR3)*
- Software trigger, by *EXTI software interrupt event register 1 (EXTI_SWIER1)*, *EXTI software interrupt event register 2 (EXTI_SWIER2)*, *EXTI software interrupt event register 3 (EXTI_SWIER3)*
- CPU interrupt enable, by *EXTI interrupt mask register 1 (EXTI_IMR1)*, *EXTI interrupt mask register 2 (EXTI_IMR2)*, *EXTI interrupt mask register 3 (EXTI_IMR3)*
- CPU event enable, by *EXTI event mask register 1 (EXTI_EMR1)*, *EXTI event mask register 2 (EXTI_EMR2)*, *EXTI event mask register 3 (EXTI_EMR3)*

Table 111. EXTI event input configurations and register control(1)



Event input type	Wake-up target(s)	Logic implementation	EXTI_RTSR	EXTI_FTSR	EXTI_SWIER	EXTI_IMR	EXTI_EMR
Configurable	CPU	Configurable event input, CPU wake-up logic	X	X	X	X	X
Direct	CPU	Direct event input, CPU wake-up logic	-	-	-	X	X

1. X indicates that functionality is available.

16.3.1 EXTI configurable event input - CPU wake-up

Figure 139 is a detailed representation of the logic associated with configurable event inputs which always wake up the CPU.

Figure 139. Configurable event triggering logic CPU wake-up

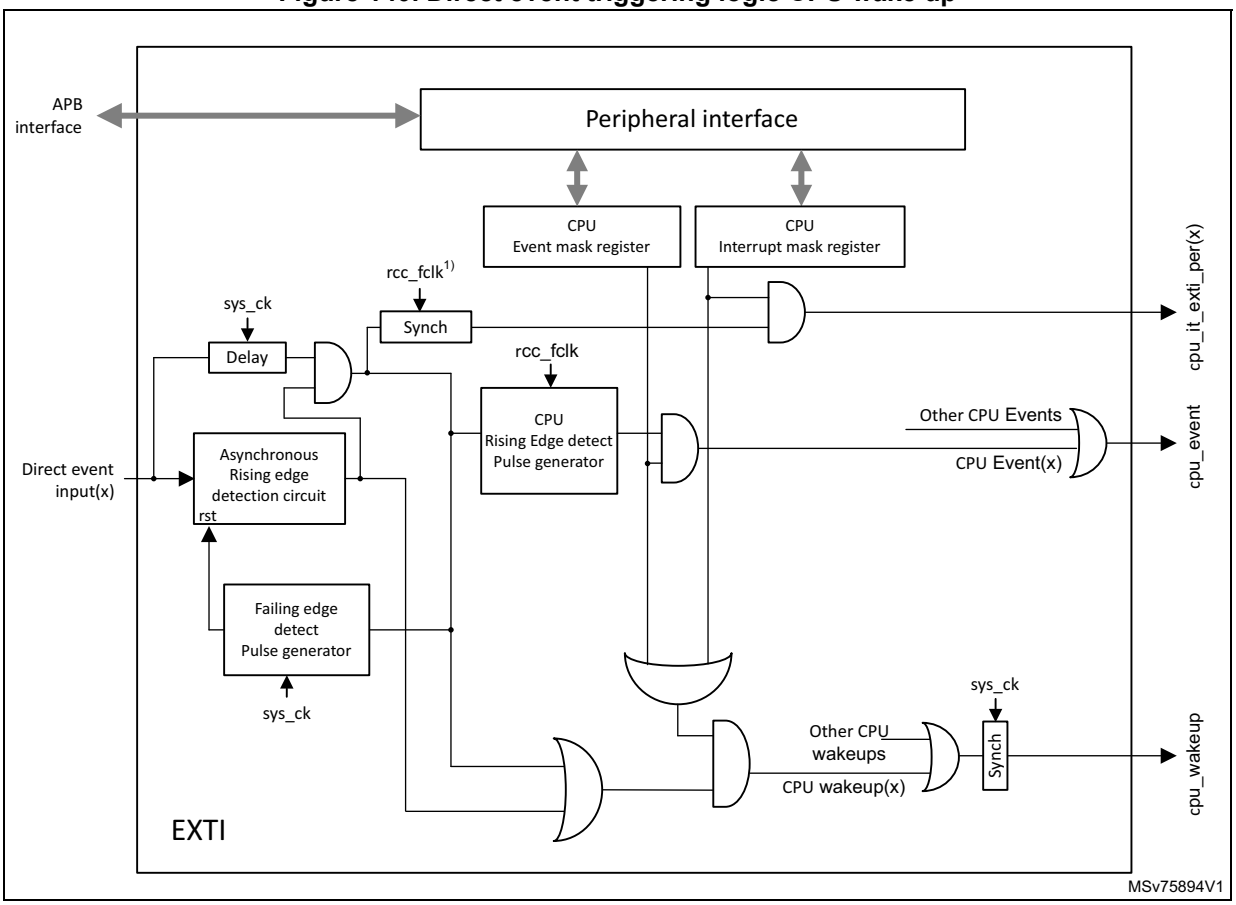
The software interrupt event register allows the system to trigger configurable events by software by writing the *EXTI software interrupt event register 1 (EXTI_SWIER1)*, *EXTI software interrupt event register 2 (EXTI_SWIER2)* and *EXTI software interrupt event register 3 (EXTI_SWIER3)*.

The rising edge *EXTI rising trigger selection register 1 (EXTI_RTSR1)*, *EXTI rising trigger selection register 2 (EXTI_RTSR2)*, *EXTI rising trigger selection register 3 (EXTI_RTSR3)*, and falling edge *EXTI falling trigger selection register 1 (EXTI_FTSR1)*, *EXTI falling trigger selection register 2 (EXTI_FTSR2)*, *EXTI falling trigger selection register 3 (EXTI_FTSR3)* selection registers allow the system to enable and select the configurable event active trigger edge or both edges.

The device features dedicated interrupt mask registers, namely *EXTI interrupt mask register 1 (EXTI_IMR1)*, *EXTI interrupt mask register 2 (EXTI_IMR2)*, and *EXTI interrupt mask register 3 (EXTI_IMR3)*, together with *EXTI pending register 1 (EXTI_PR1)*, *EXTI pending register 2 (EXTI_PR2)* and *EXTI pending register 3 (EXTI_PR3)* configurable event request pending registers. The pending register bit is only set for an unmasked interrupt. Each event generates an individual interrupt to the CPU NVIC. The configurable event interrupts need to be acknowledged (reset) by software in the EXTI_PRn register.

The device features dedicated event mask registers, that is, *EXTI event mask register 1 (EXTI_EMR1)*, *EXTI event mask register 2 (EXTI_EMR2)*, and *EXTI event mask register 3 (EXTI_EMR3)*. The enabled event then generates an event on the CPU. All events for a CPU are OR-ed together into a single CPU event signal. The CPU pending register (EXTI_PRn) is not set for an unmasked CPU event.

When a CPU interrupt or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the CPU clock is woken up before the asynchronous edge detection circuit is reset.



Note: A detected configurable event, enabled by the CPU, is only cleared when the CPU wakes up.

16.3.2 EXTI direct event input - CPU wake up

Figure 140 is a detailed representation of the logic associated with direct event inputs waking up the CPU.

Direct events only provide CPU interrupt enable and CPU event enable functionality.

Figure 140. Direct event triggering logic CPU wake up

1. The CPU interrupt for asynchronous direct event inputs (peripheral wake-up signals) is synchronized with the CPU clock. The synchronous direct event inputs (peripheral interrupt signals), after the asynchronous edge detection, are directly sent to the CPU interrupt without resynchronization.

16.4 EXTI event input mapping

For the 16 GPIO event inputs, the associated IOPORT pin has to be selected in the SBS register SBS_EXTICRn. The same pin from each IOPORT maps to the corresponding EXTI event input.

The wake-up capabilities of each event input are detailed in *Table 112*. An event input can wake up the CPU.

The EXTI event inputs with a connection to the CPU NVIC are indicated in the “Connection to NVIC” column. For the EXTI events not having a connection to the NVIC, the peripheral interrupt is directly connected to the NVIC in parallel with the connection to the EXTI.

All EXTI event inputs are OR-ed together and connected to the CPU event input (rxev).

Table 112. EXTI event input mapping

Event input	Source	Event input type	Connection to NVIC

1. PVD and AVD signals are OR-ed together on the same EXTI event input.

16.5 EXTI functional behavior

The direct event inputs are enabled in the respective peripheral generating the event. The configurable events are enabled by enabling at least one of the trigger edges.

An event only wakes up the CPU when the event-associated CPU interrupt is unmasked and/or the CPU event is unmasked.

Table 113. Masking functionality

CPU		Configurable event inputs PRx bits of EXTI_PR	CPU		
Interrupt enable MRx bits of EXTI_IMR	Event enable MRx bits of EXTI_EMR		Interrupt	Event	Wake-up
0	0	No	Masked	Masked	Masked
0	1	No	Masked	Yes	Yes
1	0	Status latched	Yes	Masked	Yes
1	1	Status latched	Yes	Yes	Yes

For configurable event inputs, when the enabled edge(s) occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending PRx bit in EXTI_PR is set and the CPU interrupt signal is activated. EXTI_PR PRx pending bit must be cleared by software writing it to 1. This clears the CPU interrupt.

For direct event inputs, when enabled in the associated peripheral, an event request is generated on the rising edge only. There is no corresponding CPU pending bit. When the associated CPU interrupt is unmasked the corresponding CPU interrupt signal is activated.

The CPU event has to be unmasked to generate an event. When the enabled edge(s) occur on the event input, a CPU event pulse is generated. There is no CPU event pending bit.

Both a CPU interrupt and a CPU event may be enabled on the same event input. They both trigger the same event input condition(s).

For the configurable event inputs, an event input request can be generated by software when writing a 1 in the software interrupt/event register EXTI_SWIER.

16.5.1 EXTI CPU interrupt procedure

- Unmask the event input interrupt by setting the corresponding mask bits in the EXTI_IMR register.
- For configurable event inputs, enable the event input by setting either one or both corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- Enable the associated interrupt source in the CPU NVIC or use the SEVONPEND, so that an interrupt coming from the CPU interrupt signal is detectable by the CPU after a WFI/WFE instruction.
  - For configurable event inputs the associated EXTI pending bit needs to be cleared.

16.5.2 EXTI CPU event procedure

- Unmask the event input by setting the corresponding mask bits of the EXTI_EMR register.
- For configurable event inputs, enable the event input by setting either one or both corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- The CPU event signal is detected by the CPU after a WFE instruction.
  - For configurable event inputs there is no EXTI pending bit to clear.

16.5.3 EXTI CPU wake-up procedure

- Unmask the event input by setting at least one of the corresponding mask bits in the EXTI_IMR and/or EXTI_EMR registers. The CPU wake-up is generated at the same time as the unmasked CPU interrupt and/or CPU event.
- For configurable event inputs, enable the event input by setting either one or both corresponding trigger edge enable bits in the EXTI_RTSR and EXTI_FTSR registers.
- Direct events automatically generate a CPU wake-up.

16.5.4 EXTI software interrupt/event trigger procedure

Any of the configurable event inputs can be triggered from the software interrupt/event register (the associated CPU interrupt and/or CPU event must be enabled by their respective procedure).

- Enable the event input by setting at least one of the corresponding edge trigger bits in the EXTI_RTSR and/or EXTI_FTSR registers.
- Unmask the software interrupt/event trigger by setting at least one of the corresponding mask bits in the EXTI_IMR and/or EXTI_EMR registers.
- Trigger the software interrupt/event by writing 1 to the corresponding bit in the EXTI_SWIER register.
- The event input may be disabled by clearing the EXTI_RTSR and EXTI_FTSR register bits.

Note: An edge on the configurable event input also triggers an interrupt/event.

16.6 EXTI registers

The registers can only be accessed with a 32-bit (word). A byte or half-word cannot be read or written.

16.6.1 EXTI rising trigger selection register 1 (EXTI_RTSR1)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **RTi:** Rising trigger event configuration bit of configurable event input i (i = 21 to 0)(1)

0: Rising trigger disabled (for event and interrupt) for input line i

1: Rising trigger enabled (for event and interrupt) for input line i

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs while the register is being written, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

16.6.2 EXTI falling trigger selection register 1 (EXTI_FTSR1)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw												rw		

Bits 31:28 **SWi:** Software interrupt on event i (i = 63 to 60)
This bitfield always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line i. This bit is auto cleared by hardware.

Bits 27:20 Reserved, must be kept at reset value.

Bit 19 **SW51:** Software interrupt on event 51
This bitfield always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line 51. This bit is auto cleared by hardware.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **SW49:** Software interrupt on event 49
This bitfield always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line 49. This bit is auto cleared by hardware.

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **SW46:** Software interrupt on event 46
This bitfield always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line 46. This bit is auto cleared by hardware.

Bits 13:3 Reserved, must be kept at reset value.

Bit 2 **SW34:** Software interrupt on event 34
This bitfield always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line 34. This bit is auto cleared by hardware.

Bits 1:0 Reserved, must be kept at reset value.

16.6.7 EXTI rising trigger selection register 3 (EXTI_RTSR3)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RT71	RT70	RT69	RT68	Res.	Res.	Res.	Res.
								rw	rw	rw	rw				

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **RTi:** Rising trigger event configuration bit of configurable event input i (i = 71 to 68)(1)

0: Rising trigger disabled (for event and interrupt) for input line i

1: Rising trigger enabled (for event and interrupt) for input line i

Bits 3:0 Reserved, must be kept at reset value.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs while the register is being written, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

16.6.8 EXTI falling trigger selection register 3 (EXTI_FTSR3)

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT71	FT70	FT69	FT68	Res.	Res.	Res.	Res.
								rw	rw	rw	rw				

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **FTi:** Falling trigger event configuration bit of configurable event input i (i = 71 to 68)(1)

0: Falling trigger disabled (for event and interrupt) for input line i

1: Falling trigger enabled (for event and interrupt) for input line i

Bits 3:0 Reserved, must be kept at reset value.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs while the register is being written, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

16.6.9 EXTI software interrupt event register 3 (EXTI_SWIER3)

Address offset: 0x48

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SW71	SW70	SW69	SW68	Res.	Res.	Res.	Res.
								rw	rw	rw	rw				

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **SWi:** Software interrupt on event i (i = 71 to 68)
Always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line i. This bit is auto cleared by HW.

Bits 3:0 Reserved, must be kept at reset value.

16.6.10 EXTI interrupt mask register 1 (EXTI_IMR1)

Address offset: 0x80

Reset value: 0xFFC0 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 **IMi:** CPU interrupt mask on event input i (i = 31 to 22)(1)
0: Interrupt request from line x is masked
1: Interrupt request from line x is unmasked

Bits 21:0 **IMi:** CPU interrupt mask on event input i (i = 21 to 0)(2)
0: Interrupt request from line x is masked
1: Interrupt request from line x is unmasked

1. The reset value for direct event inputs is set to 1 in order to enable the interrupt by default.
2. The reset value for configurable event inputs is set to 0 in order to disable the interrupt by default.

16.6.11 EXTI event mask register 1 (EXTI_EMR1)

Address offset: 0x84

Reset value: 0x0000 0000

	rc_w1												rc_w1		

Bits 31:28 **PRi:** Configurable event input i pending (i = 63 to 60)
0: No trigger request occurred
1: Selected trigger request occurred
This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bits 27:20 Reserved, must be kept at reset value.

Bit 19 **PR51:** Configurable event input 51 pending bit
0: No trigger request occurred
1: selected trigger request occurred
This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PR49:** Configurable event input 49 pending bit
0: No trigger request occurred
1: selected trigger request occurred
This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **PR46:** Configurable event input 46 pending bit
0: No trigger request occurred
1: selected trigger request occurred
This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bits 13:3 Reserved, must be kept at reset value.

Bit 2 **PR34:** Configurable event input 34 pending bit
0: No trigger request occurred
1: selected trigger request occurred
This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bits 1:0 Reserved, must be kept at reset value.

16.6.16 EXTI interrupt mask register 3 (EXTI_IMR3)

Address offset: 0xA0

Reset value: 0x0000 3F0F

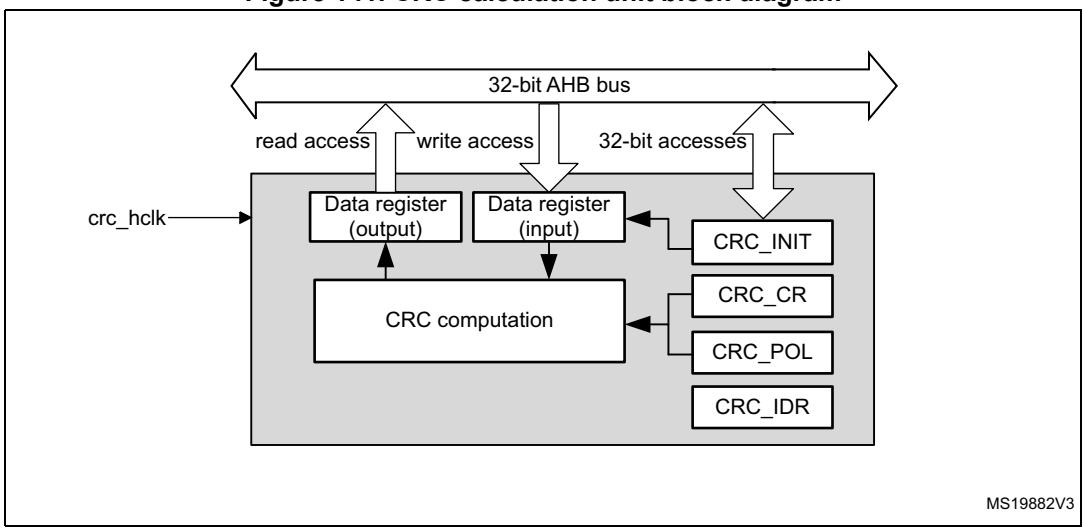
17 Cyclic redundancy check calculation unit (CRC)

17.1 CRC introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.



17.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-,16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility options on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes

17.3 CRC functional description

17.3.1 CRC block diagram

Figure 141. CRC calculation unit block diagram

17.3.2 CRC internal signals

Table 115. CRC internal input/output signals

Signal name	Signal type	Description
crc_hclk	Digital input	AHB clock

17.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. When the RTYPE_IN bit is set in CRC_CR, non-word accesses to CRC_DR register are ignored. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on input data width:

- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait-states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register. If RTYPE_IN bit is set in this register, the input reversing operation can be performed with a byte or half-word granularity, but not with single bit granularity.

For example, with RTYPE_IN cleared, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte (REV_IN[1:0] = 01)
- 0xD458B23C with bit-reversal done by half-word (REV_IN[1:0] = 10)
- 0xB23CD458 with bit-reversal done on the full word (REV_IN[1:0] = 11)

With RTYPE_IN set, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x3C4D1A2B with half-word reversal done by word (REV_IN[1:0] = 01)
- 0x4D3C2B1A with byte-reversal done by word (REV_IN[1:0] = 10)

The output data can also be reversed by setting the REV_OUT[1:0] bits in the CRC_CR register. If RTYPE_OUT is set in this register, the output reversing operation is performed with a byte or half-word granularity, but not with single bit granularity.

With RTYPE_OUT cleared, the operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

With RTYPE_OUT set, 0x11223344 output data are converted as:

- 0x33441122 with half-word reversal done by word (REV_IN[1:0] = 01)
- 0x44332211 with byte-reversal done by word (REV_IN[1:0] = 10)

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC 7-, 8-, 16-, and 32-bit calculations. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7-, 8-, 16-, or 32-bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

Note: The type of an even polynomial is $X+X^2+..+X^n$, while the type of an odd polynomial is $1+X+X^2+..+X^n$.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

17.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes when RTYPE bit is cleared in CRC_CR. When RTYPE is set, only word accesses are allowed. For the other registers only 32-bit accesses are allowed.

17.4.1 CRC data register (CRC_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DR[31:0]:** Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

17.4.2 CRC independent data register (CRC_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IDR[31:0]**: General-purpose 32-bit data register bits

These bits can be used as a temporary storage location for four bytes.

This register is not affected by CRC resets generated by the RESET bit in the CRC_CR register

17.4.3 CRC control register (CRC_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	RTYPE_OUT	RTYPE_IN	REV_OUT[1:0]		REV_IN[1:0]		POLYSIZE[1:0]		Res.	Res.	RESET
					rw	rw	rw	rw	rw	rw	rw	rw			rs

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **RTYPE_OUT**: Reverse type output
This bit controls the reversal granularity of the output data.
0: Bit level output
1: Byte or half-word level output

Bit 9 **RTYPE_IN**: Reverse type input
This bit controls the reversal granularity of the input data.
0: Bit level input
1: Byte or half-word level input

Bits 8:7 **REV_OUT[1:0]**: Reverse output data
This bitfield controls the reversal of the bit order of the output data.
00: Bit order not affected (RTYPE_OUT = 0 or 1)
01: Bit-reversed output format (RTYPE_OUT = 0) or half-word reversal done by word (RTYPE_OUT = 1)
10: Bit order not affected (RTYPE_OUT = 0) or byte reversal done by word (RTYPE_OUT = 1)
11: Bit order not affected (RTYPE_OUT = 0 or 1)

Bits 6:5 **REV_IN[1:0]**: Reverse input data
This bitfield controls the reversal of the bit order of the input data
00: Bit order not affected (RTYPE_IN = 0 or 1)
01: Bit reversal done by byte (RTYPE_IN = 0) or half-word reversal done by word (RTYPE_IN = 1)
10: Bit reversal done by half-word (RTYPE_IN = 0) or byte reversal done by word (RTYPE_IN = 1)
11: Bit reversal done by word (RTYPE_IN = 0) or bit order is not affected (RTYPE_IN = 1)

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size

These bits control the size of the polynomial.

00: 32 bit polynomial

01: 16 bit polynomial

10: 8 bit polynomial

11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit

This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware.

17.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_INIT[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_INIT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CRC_INIT[31:0]**: Programmable initial CRC value

This register is used to write the CRC initial value.

17.4.5 CRC polynomial (CRC_POL)

Address offset: 0x14

Reset value: 0x04C1 1DB7

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
POL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
POL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **POL[31:0]**: Programmable polynomial

This register is used to write the coefficients of the polynomial to be used for CRC calculation.

If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

17.4.6 CRC register map

Table 116. CRC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

18 CORDIC coprocessor (CORDIC)

18.1 CORDIC introduction

The CORDIC coprocessor provides hardware acceleration of mathematical functions (mainly trigonometric ones) commonly used in motor control, metering, signal processing, and many other applications.

It speeds up the calculation of these functions compared to a software implementation, making possible the use of a lower operating frequency, or freeing up processor cycles to perform other tasks.

18.2 CORDIC main features

- 24-bit CORDIC rotation engine
- Circular and Hyperbolic modes
- Rotation and Vectoring modes
- Functions: sine, cosine, sinh, cosh, atan, atanh, phase, modulus, square root, natural logarithm
- Programmable precision
- Low latency AHB slave interface
- Results can be read as soon as ready, without polling or interrupt
- DMA read and write channels
- Multiple register read/write by DMA

18.3 CORDIC functional description

18.3.1 General description

The CORDIC is a cost-efficient successive approximation algorithm for evaluating trigonometric and hyperbolic functions.

In trigonometric (circular) mode, the sine and cosine of an angle θ are determined by rotating the unit vector [1, 0] through decreasing angles until the cumulative sum of the rotation angles equals the input angle θ. The x and y cartesian components of the rotated vector then correspond, respectively, to the cosine and sine of θ. Inversely, the angle of a vector [x, y] corresponding to arctangent (y / x), is determined by rotating [x, y] through successively decreasing angles to obtain the unit vector [1, 0]. The cumulative sum of the rotation angles gives the angle of the original vector.

The CORDIC algorithm can also be used for calculating hyperbolic functions (sinh, cosh, atanh), by replacing the successive circular rotations by steps along a hyperbole.

Other functions can be derived from the basic functions described above.

18.3.2 CORDIC functions

The first step when using the coprocessor is to select the required function, by programming the FUNC field of the CORDIC_CR register.

Table 117 lists the functions supported by the CORDIC coprocessor.

Table 117. CORDIC functions

Function	Primary argument (ARG1)	Secondary argument (ARG2)	Primary result (RES1)	Secondary result (RES2)
Cosine	angle θ	modulus m	$m \cdot \cos\theta$	$m \cdot \sin\theta$
Sine	angle θ	modulus m	$m \cdot \sin\theta$	$m \cdot \cos\theta$
Phase	x	y	atan2(y,x)	$\sqrt{x^2+y^2}$
Modulus	x	y	$\sqrt{x^2+y^2}$	atan2(y,x)
Arctangent	x	none	atan x	none
Hyperbolic cosine	x	none	cosh x	sinh x
Hyperbolic sine	x	none	sinh x	cosh x
Hyperbolic arctangent	x	none	atanh x	none
Natural logarithm	x	none	ln x	none
Square root	x	none	$\sqrt{x}$	none

Several functions take two input arguments (ARG1 and ARG2), and some generate two results (RES1 and RES2) simultaneously. This is a side-effect of the algorithm and means that only one operation is needed to obtain two values. This is the case, for example, when performing polar-to-rectangular conversion: sin θ also generates cos θ, and cos θ also generates sin θ. Similarly for rectangular-to-polar conversion (phase(x,y), modulus(x,y)) and for hyperbolic functions (cosh θ, sinh θ).

Note: The exponential function, exp x, can be obtained as the sum of sinh x and cosh x. Furthermore, base N logarithms, $\log_N x$, can be derived by multiplying ln x by a constant K, where K = 1/ln N.

For certain functions (atan, log, sqrt) a scaling factor (see *Section 18.3.4*) can be applied to extend the range beyond the maximum [-1, 1] supported by the q1.31 fixed point format. The scaling factor must be set to 0 for all other circular functions, and to 1 for hyperbolic functions.

Cosine

Table 118. Cosine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m • cos θ	[-1, 1]

Table 118. Cosine parameters (continued)

Parameter	Description	Range
RES2	m • sin θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the cosine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the sine of the angle, multiplied by the modulus.

Sine

Table 119. Sine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m • sin θ	[-1, 1]
RES2	m • cos θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the sine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the sine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.

Phase

Table 120. Phase parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Phase angle θ in radians, divided by π	[-1, 1]

Table 120. Phase parameters (continued)

Parameter	Description	Range
RES2	Modulus m	[0, 1]
SCALE	Not applicable	0

This function calculates the phase angle in the range -π to π of a vector **v** = [x y] (also known as atan2(y,x). It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the phase angle θ of the vector **v**. RES1 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

The secondary result, RES2, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES2 is saturated to 1.

Modulus

Table 121. Modulus parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Modulus m	[0, 1]
RES2	Phase angle θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the magnitude, or modulus, of a vector **v** = [x y]. It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES1 is saturated to 1.

The secondary result, RES2, is the phase angle θ of the vector **v**. RES2 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

Arctangent

Table 122. Arctangent parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-1, 1]
ARG2	Not applicable	-
RES1	2^{-n} • atan x, in radians, divided by p	[-1, 1]
RES2	Not applicable	-
SCALE	n	[0 7]

This function calculates the arctangent, or inverse tangent, of the input argument x.

The primary argument, ARG1, is the input value, x = tan θ. If |x| > 1, a scaling factor of 2^{-n} must be applied in software such that $-1 < x \cdot 2^{-n} < 1$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the scale factor n must be programmed in the SCALE parameter.

Note that the maximum input value allowed is tan θ = 128, which corresponds to an angle θ = 89.55 degrees. For |x| > 128, a software method must be used to find atan x.

The secondary argument, ARG2, is unused.

The primary result, RES1, is the angle θ = atan x. RES1 must be multiplied by $2^n \cdot \pi$ to obtain the angle in radians.

The secondary result, RES2, is unused.

Hyperbolic cosine

Table 123. Hyperbolic cosine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \cosh x$	[0.5 0.846]
RES2	$2^{-n} \cdot \sinh x$	[-0.683 0.683]
SCALE	n	1

This function calculates the hyperbolic cosine of a hyperbolic angle x. It can also be used to calculate the exponential functions $e^x = \cosh x + \sinh x$, and $e^{-x} = \cosh x - \sinh x$.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. Since the minimum value of cosh x is 1, which is beyond the range of the q1.31 format, a scaling factor of 2^{-n} must be applied in software. The factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic cosine, cosh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic sine, sinh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic sine

Table 124. Hyperbolic sine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559, 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \sinh x$	[-0.683, 0.683]
RES2	$2^{-n} \cdot \cosh x$	[0.5, 0.846]
SCALE	n	1

This function calculates the hyperbolic sine of a hyperbolic angle x. It can also be used to calculate the exponential functions e^x = cosh x + sinh x, and e^{-x} = cosh x- sinh x.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. For all input values, a scaling factor of 2^{-n} must be applied in software, where n = 1. The scaled value x • 0.5 is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic sine, sinh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic cosine, cosh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic arctangent

Table 125. Hyperbolic arctangent parameters

Parameter	Description	Range
ARG1	$x \bullet 2^{-n}$	[-0.403 0.403]
ARG2	Not applicable	-
RES1	$2^{-n} \bullet$atanh x	[-0.559 0.559]
RES2	Not applicable	-
SCALE	n	1

This function calculates the hyperbolic arctangent of the input argument x.

The primary argument is the input value x. Only values of x in the -0.806 to +0.806 range are supported. The value x must be scaled by a factor 2^{-n}, where n = 1. The scaled value

x • 0.5 is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result is the hyperbolic arctangent, atanh x. RES1 must be multiplied by 2 to obtain the correct value.

The secondary result is not used.

Natural logarithm

Table 126. Natural logarithm parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.054 0.875]
ARG2	Not applicable	-
RES1	$2^{-(n+1)}.\ln x$	[-0.279 0.137]
RES2	Not applicable	-
SCALE	n	[1 4]

This function calculates the natural logarithm of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.107 to 9.35 are supported. The value x must be scaled by a factor 2^{-n}, such that $x < 2^{-n} < 1-2^{-n}$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 127 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 127. Natural log scaling factors and corresponding ranges

n	x range	ARG1 range
1	$0.107 \le x < 1$	$0.0535 \le ARG1 < 0.5$
2	$1 \le x < 3$	$0.25 \le ARG1 < 0.75$
3	$3 \le x < 7$	$0.375 \le ARG1 < 0.875$
4	$7 \le x \le 9.35$	$0.4375 \le ARG1 < 0.584$

The secondary argument is not used.

The primary result is the natural logarithm, ln x. RES1 must be multiplied by $2^{(n+1)}$ to obtain the correct value.

The secondary result is not used.

Square root

Table 128. Square root parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.027 0.875]
ARG2	Not applicable	-
RES1	$2^{-n}\sqrt{x}$	[0.04 1]
RES2	Not applicable	-
SCALE	n	[0 2]

This function calculates the square root of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.027 to 2.34 are supported. The value x must be scaled by a factor 2^{-n}, such that $x \cdot 2^{-n} < (1 - 2^{(-n-2)})$.

The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 129 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 129. Square root scaling factors and corresponding ranges

n	x range	ARG1 range
0	$0.027 \leq x < 0.75$	$0.027 \leq ARG1 < 0.75$
1	$0.75 \leq x < 1.75$	$0.375 \leq ARG1 < 0.875$
2	$1.75 \leq x \leq 2.341$	$0.4375 \leq ARG1 \leq 0.585$

The secondary argument is not used.

The primary result is the square root of x. RES1 must be multiplied by 2^n to obtain the correct value.

The secondary result is not used.

18.3.3 Fixed point representation

The CORDIC operates in fixed point signed integer format. Input and output values can be either q1.31 or q1.15.

In q1.31 format, numbers are represented by one sign bit and 31 fractional bits (binary decimal places). The numeric range is therefore -1 (0x80000000) to $1 - 2^{-31}$ (0x7FFFFFFF).

In q1.15 format, the numeric range is 1 (0x8000) to $1 - 2^{-15}$ (0x7FFF). This format has the advantage that two input arguments can be packed into a single 32-bit write, and two results can be fetched in one 32-bit read.

18.3.4 Scaling factor

Several of the functions listed in *Section 18.3.2* specify a scaling factor, SCALE. This allows the function input range to be extended to cover the full range of values supported by the CORDIC, without saturating the input, output, or internal registers. If the scaling factor is

required, it must be calculated by software and programmed into the SCALE field of the CORDIC_CSR register. The input arguments must be scaled accordingly before programming the scaled values in the CORDIC_WDATA register. The scaling must also be undone on the results read from the CORDIC_RDATA register.

Note: The scaling factor entails a loss of precision due to truncation of the scaled value.

18.3.5 Precision

The precision of the result is dependent on the number of CORDIC iterations. The algorithm converges at a constant rate of one binary digit per iteration for trigonometric functions (sine, cosine, phase, modulus), see *Figure 142*.

For hyperbolic functions (hyperbolic sine, hyperbolic cosine, natural logarithm), the convergence rate is less constant due to the peculiarities of the CORDIC algorithm (see *Figure 143*). The square root function converges at roughly twice the speed of the hyperbolic functions (see *Figure 144*).

Figure 142. CORDIC convergence for trigonometric functions

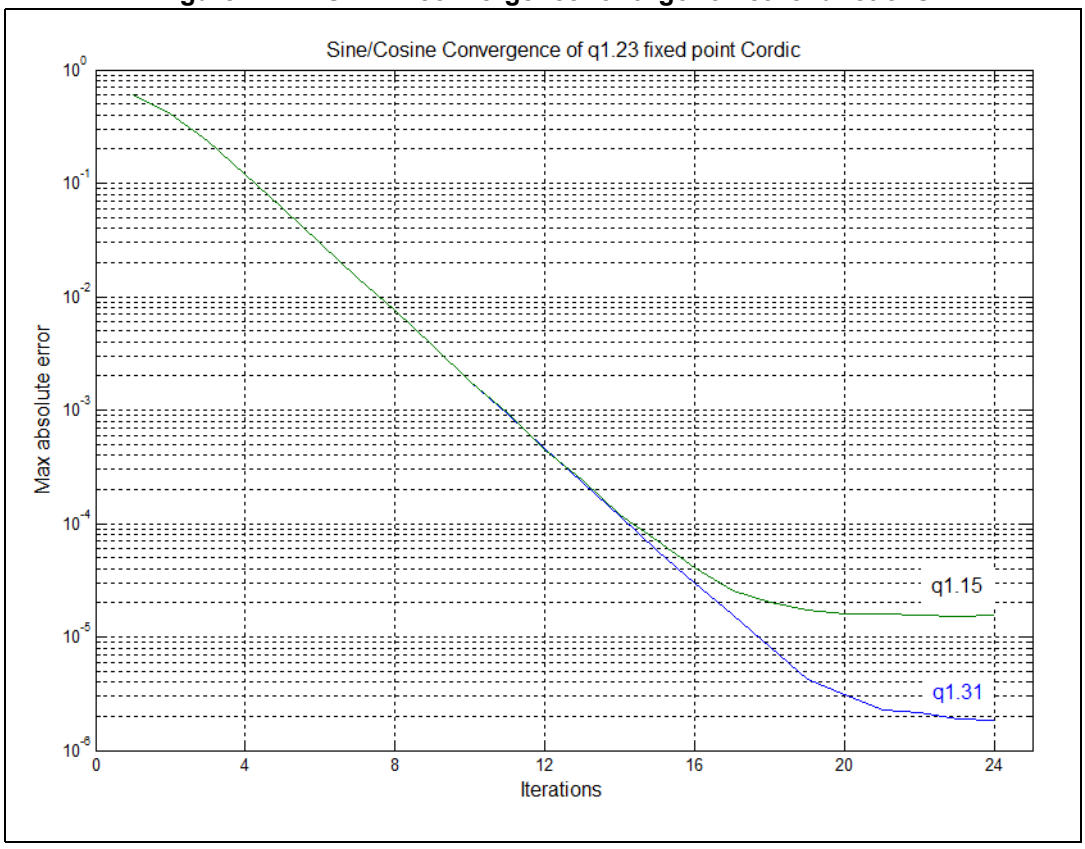

Figure 143. CORDIC convergence for hyperbolic functions

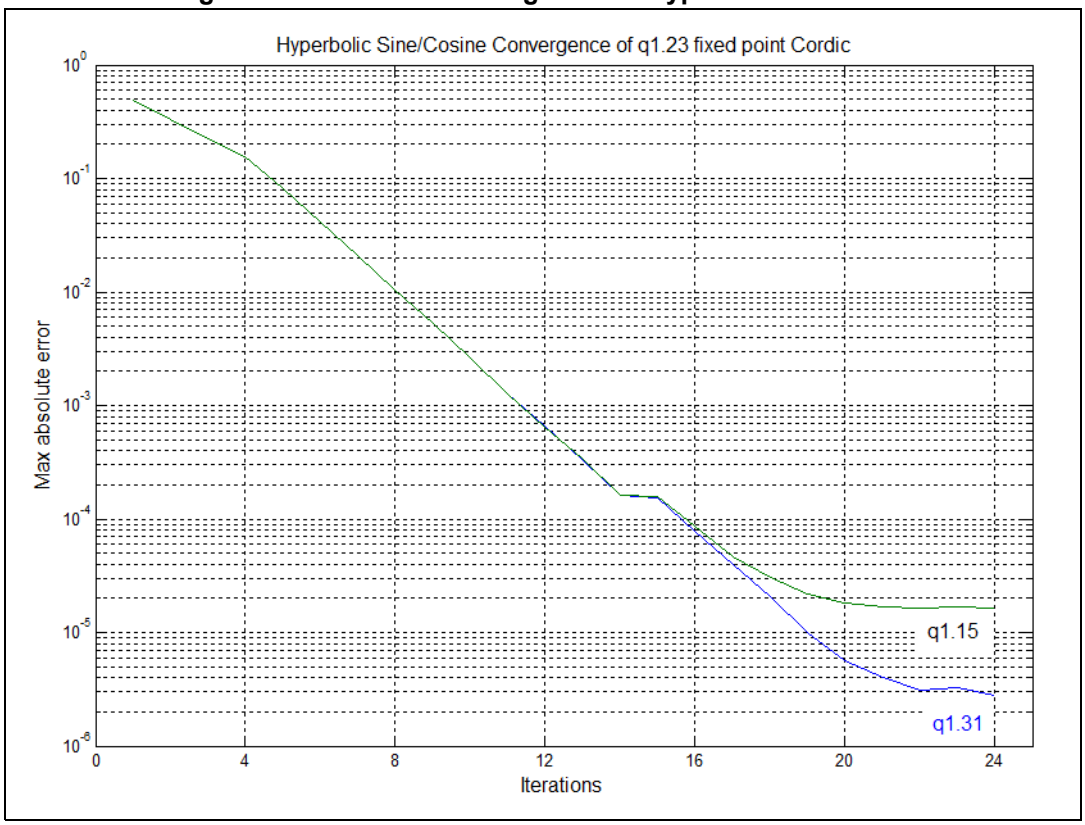

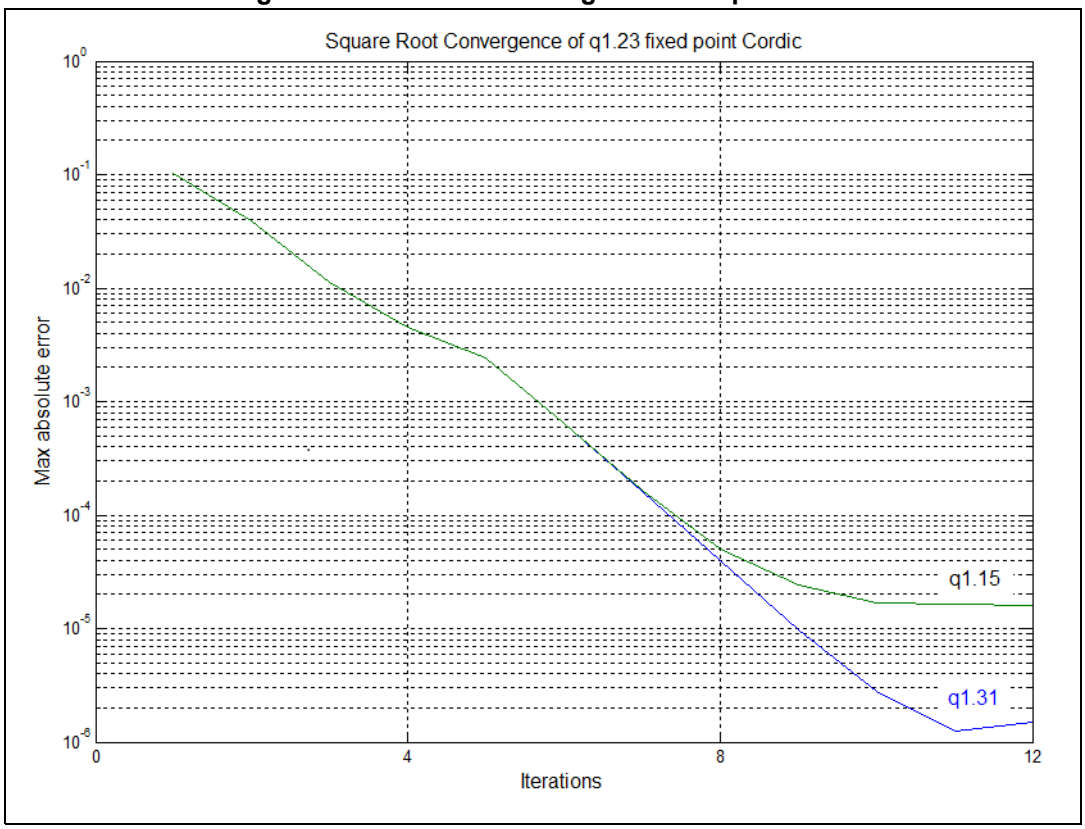

Figure 144. CORDIC convergence for square root

Note: The convergence rate decreases as the quantization error starts to become significant.

The CORDIC can perform four iterations per clock cycle. For each function, the maximum error remaining after every four iterations is shown in *Table 130*, together with the number of clock cycles required to reach that precision. From this table, the desired number of cycles can be determined and programmed in the PRECISION field of the CORDIC_CR register. The coprocessor stops as soon as the programmed number of iterations is completed, and the result can be read immediately.

Table 130. Precision vs. number of iterations

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sin, Cos, Phase(2), Mod, Atan(4)	4	1	2^{-3}	2^{-3}
	8	2	2^{-7}	2^{-7}
	12	3	2^{-11}	2^{-11}
	16	4	2^{-15}	2^{-15}
	20	5	2^{-18}	2^{-16}
	24	6	2^{-19}	2^{-16}

Table 130. Precision vs. number of iterations (continued)

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sinh, Cosh, Atanh, Ln(3)	4	1	2^{-2}	2^{-2}
	8	2	2^{-6}	2^{-6}
	12	3	2^{-10}	2^{-10}
	16	4	2^{-13}	2^{-13}
	20	5	2^{-17}	2^{-15}
	24	6	2^{-18}	2^{-15}
Sqrt(4)	4	1	2^{-7}	2^{-7}
	8	2	2^{-14}	2^{-14}
	12	3	2^{-19}	2^{-15}

1. Max residual error is the maximum error remaining after the given number of iterations, compared to the identical calculation performed in double precision floating point. An additional rounding error may be incurred, of up to 2^{-16} for q15 format or 2^{-20} for q31 format.
2. For modulus > 0.5. The achievable precision reduces proportionally to the magnitude of the modulus, as quantization error becomes significant.
3. SCALE = 1. If a higher scaling factor is used, the achievable precision is reduced proportionally.
4. SCALE = 0. If a higher scaling factor is used, the achievable precision is reduced proportionally.

18.3.6 Zero-overhead mode

The fastest way to use the coprocessor is to preprogram the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable.

The calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished), a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to reprogram the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument (ARG1) must be written first, followed by the secondary argument (ARG2). If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

Note: ARG2 is set to +1 (0x7FFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.

Once the calculation starts, any attempt to read the CORDIC_RDATA register inserts bus wait-states until the calculation is completed, before returning the result. It is then possible for the software to write the input and immediately read the result without polling to see if it is valid. Alternatively, the processor can wait for the appropriate number of clock cycles before reading the result. This time can be used to program the CORDIC_CSR register for the next calculation, and prepare the next input data, if needed. The CORDIC_CSR register can be reprogrammed while a calculation is in progress, without affecting the result of the ongoing calculation. In the same way, the CORDIC_WDATA register can be updated with the next argument(s) once the previous ones have been taken into account. The next arguments and settings remain pending until the previous calculation has completed.

When a calculation is finished, the result(s) can be read from the CORDIC_RDATA register. If two 32-bit results are expected (NRES = 1, RESSIZE = 0), the primary result (RES1) is read out first, followed by the secondary result (RES2). If only one 32-bit result is expected (NRES = 0, RESSIZE = 0), then RES1 is output on the first read.

If 16-bit results are expected (RESSIZE = 1), a single read to CORDIC_RDATA fetches both results packed into a 32-bit word. RES1 is in the lower half-word, and RES2 in the upper half-word. In this case, it is recommended to program NRES = 0. IF NRES = 1, a second read of CORDIC_RDATA must be performed to free up the CORDIC for the next operation. The data from this second read must be discarded.

The next calculation starts when the expected number of results has been read, provided the expected number of arguments has been written. This means that at any time, there can be a calculation in progress, or waiting for the results to be read, and an operation pending. Any further access to CORDIC_WDATA while an operation is pending cancels it and overwrites the data.

The following sequence summarizes the use of the CORDIC_IP in zero-overhead mode:

1. Program the CORDIC_CSR register with the appropriate settings
2. Program the argument(s) for the first calculation in the CORDIC_WDATA register. This launches the first calculation.
3. If needed, update the CORDIC_CSR register settings for the next calculation.
4. Program the argument(s) for the next calculation in the CORDIC_WDATA register.
5. Read the result(s) from the CORDIC_RDATA register. This triggers the next calculation.
6. Go to step *3*.

18.3.7 Polling mode

When a new result is available in the CORDIC_RDATA register, the RRDY flag is set in the CORDIC_CSR register. The flag can be polled by reading the register. It is reset by reading the CORDIC_RDATA register (once or twice, depending on the NRES field of the CORDIC_CSR register).

Polling the RRDY flag takes slightly longer than reading the CORDIC_RDATA register directly, since the result is not read as soon as it is available. The processor and bus interface are not stalled while reading the CORDIC_CSR register, so this mode may be of interest if stalling the processor is not acceptable (for example, if low latency interrupts must be serviced).

18.3.8 Interrupt mode

By setting the interrupt enable (IE) bit in the CORDIC_CSR register, an interrupt is generated whenever the RRDY flag is set. The interrupt is cleared when the flag is reset.

This mode allows the result of the calculation to be read under interrupt service routine, and hence given a priority relative to other tasks. However, it is slower than directly reading the result, or polling the flag, due to the interrupt handling delays.

18.3.9 DMA mode

If the DMA write enable (DMAWEN) bit is set in the CORDIC_CSR register, and no operation is pending, a DMA write channel request is generated. The DMA controller can transfer a primary input argument (ARG1) from memory into the CORDIC_WDATA register. Writing into the register deasserts the DMA request. If NARGS = 1 in the CORDIC_CSR register, a second DMA write channel request is generated to transfer the secondary input argument (ARG2) into the CORDIC_WDATA register. When all input arguments have been written, and any ongoing calculation has been completed (by reading the results), a new calculation is started and another DMA write channel request is generated.

If the DMA read enable (DMAREN) bit is set in the CORDIC_CSR register, the RRDY flag going active generates a DMA read channel request. The DMA controller can then transfer the primary result (RES1) from the CORDIC_RDATA register to memory. Reading the register deasserts the DMA request. If NRES = 1 in the CORDIC_CSR register, a second DMA request is generated to read out the secondary result (RES2). When all results have been read, the RRDY flag is deasserted.

The DMA read and write channels can be enabled separately. If both channels are enabled, the CORDIC can autonomously perform repeated calculations on a buffer of data without processor intervention. This allows the processor to perform other tasks. The DMA controller is operating in memory-to-peripheral mode for the write channel, and peripheral-to-memory mode for the read channel. The sequence is started by the processor setting the DMAWEN flag, the DMA read and write requests are generated as fast as the CORDIC can process the data.

In some cases, the input data may be stored in memory, and the output is transferred at regular intervals to another peripheral, such as a digital-to-analog converter. In this case, the destination peripheral generates a DMA request each time it needs a new data. The DMA controller can directly fetch the next sample from the CORDIC_RDATA register (in this case the DMA controller is operating in memory-to-peripheral mode, even though the source is a peripheral register). The act of reading the result allows the CORDIC to start a new calculation, which in turn generates a DMA write channel request, and the DMA controller transfers the next input value to the CORDIC_WDATA register. The DMA write channel is enabled (DMAWEN = 1), but the read channel must not be enabled.

In a similar way, data coming from another peripheral, such as an ADC, can be transferred directly to the CORDIC_WDATA register (in peripheral-to-memory mode). The DMA write channel must not be enabled. The CORDIC processes the input data and generates a DMA read request when complete, if DMAREN = 1. The DMA controller then transfers the result from CORDIC_RDATA register to memory (peripheral-to-memory mode).

Note: No DMA request is generated to program the CORDIC_CSR register. DMA mode is therefore useful only when repeatedly performing the same function with the same settings. The scale factor cannot be changed during a series of DMA transfers.

Note: Each DMA request must be acknowledged, as a result of the DMA performing an access to the CORDIC_WDATA or CORDIC_RDATA register. If an extraneous access to the relevant register occurs before this, the acknowledge is asserted prematurely, and may block the DMA channel. Therefore, when the DMA read channel is enabled, CPU access to the CORDIC_RDATA register must be avoided. Similarly, the processor must avoid accessing the CORDIC_WDATA register when the DMA write channel is enabled.

18.4 CORDIC registers

The CORDIC registers can be accessed only in 32-bit word format

18.4.1 CORDIC control/status register (CORDIC_CSR)

Address offset: 0x00

Reset value: 0x0000 0050

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARG SIZE	RES SIZE	N ARGS	NRES	DMA WEN	DMA REN	IEN
r									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SCALE[2:0]			PRECISION[3:0]				FUNC[3:0]			
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **RRDY**: Result ready flag

0: No new data in output register

1: CORDIC_RDATA register contains new data.

This bit is set by hardware when a CORDIC operation completes. It is reset by hardware when the CORDIC_RDATA register is read (NRES+1) times.

When this bit is set, if the IEN bit is also set, the CORDIC interrupt is asserted. If the DMAREN bit is set, a DMA read channel request is generated. While this bit is set, no new calculation is started.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 **ARGSIZE**: Width of input data

0: 32-bit

1: 16-bit

ARGSIZE selects the number of bits used to represent input data.

If 32-bit data is selected, the CORDIC_WDATA register expects arguments in q1.31 format.

If 16-bit data is selected, the CORDIC_WDATA register expects arguments in q1.15 format. The primary argument (ARG1) is written to the least significant half-word, and the secondary argument (ARG2) to the most significant half-word.

Bit 21 **RESSIZE**: Width of output data

0: 32-bit

1: 16-bit

RESSIZE selects the number of bits used to represent output data.

If 32-bit data is selected, the CORDIC_RDATA register contains results in q1.31 format.

If 16-bit data is selected, the least significant half-word of CORDIC_RDATA contains the primary result (RES1) in q1.15 format, and the most significant half-word contains the secondary result (RES2), also in q1.15 format.

Bit 20 **NARGS**: Number of arguments expected by the CORDIC_WDATA register

0: Only one 32-bit write (or two 16-bit values if ARGSIZE = 1) is needed for the next calculation.

1: Two 32-bit values must be written to the CORDIC_WDATA register to trigger the next calculation.

Reads return the current state of the bit.

Bit 19 **NRES**: Number of results in the CORDIC_RDATA register

0: Only one 32-bit value (or two 16-bit values if RESSIZE = 1) is transferred to the CORDIC_RDATA register on completion of the next calculation. One read from CORDIC_RDATA resets the RRDY flag.

1: Two 32-bit values are transferred to the CORDIC_RDATA register on completion of the next calculation. Two reads from CORDIC_RDATA are necessary to reset the RRDY flag.

Reads return the current state of the bit.

Bit 18 **DMAWEN**: Enable DMA write channel

0: Disabled. No DMA write requests are generated.

1: Enabled. Requests are generated on the DMA write channel whenever no operation is pending

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 17 **DMAREN**: Enable DMA read channel

0: Disabled. No DMA read requests are generated.

1: Enabled. Requests are generated on the DMA read channel whenever the RRDY flag is set.

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 16 **IEN**: Enable interrupt.

0: Disabled. No interrupt requests are generated.

1: Enabled. An interrupt request is generated whenever the RRDY flag is set.

This bit is set and cleared by software. A read returns the current state of the bit.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **SCALE[2:0]**: Scaling factor

The value of this field indicates the scaling factor applied to the arguments and/or results. A value n implies that the arguments have been multiplied by a factor 2^{-n}, and/or the results need to be multiplied by 2^{n}. Refer to *Section 18.3.2* for the applicability of the scaling factor for each function and the appropriate range.

Bits 7:4 **PRECISION[3:0]**: Precision required (number of iterations)

0: reserved

1 to 15: (Number of iterations)/4

To determine the number of iterations needed for a given accuracy refer to *Table 130*.

Note that for most functions, the recommended range for this field is 3 to 6.

Bits 3:0 **FUNC[3:0]**: Function

0: Cosine
1: Sine
2: Phase
3: Modulus
4: Arctangent
5: Hyperbolic cosine
6: Hyperbolic sine
7: Arctanh
8: Natural logarithm
9: Square root
10 to 15: Reserved

18.4.2 CORDIC argument register (CORDIC_WDATA)

Address offset: 0x04

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ARG[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARG[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **ARG[31:0]**: Function input arguments

This register is programmed with the input arguments for the function selected in the CORDIC_CSR register FUNC field.

If 32-bit format is selected (CORDIC_CSR.ARGSIZE = 0) and two input arguments are required (CORDIC_CSR.NARGS = 1), two successive writes are required to this register. The first writes the primary argument (ARG1), the second writes the secondary argument (ARG2).

If 32-bit format is selected and only one input argument is required (NARGS = 0), only one write is required to this register, containing the primary argument (ARG1).

If 16-bit format is selected (CORDIC_CSR.ARGSIZE = 1), one write to this register contains both arguments. The primary argument (ARG1) is in the lower half, ARG[15:0], and the secondary argument (ARG2) is in the upper half, ARG[31:16]. In this case, NARGS must be set to 0.

Refer to *Section 18.3.2* for the arguments required by each function, and their permitted range.

When the required number of arguments has been written, the CORDIC evaluates the function designated by CORDIC_CSR.FUNC using the supplied input arguments, provided any previous calculation has completed. If a calculation is ongoing, the ARG1 and ARG 2 values are held pending until the calculation is completed and the results read. During this time, a write to the register cancels the pending operation and overwrite the argument data.

18.4.3 CORDIC result register (CORDIC_RDATA)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RES[31:0]**: Function result

If 32-bit format is selected (CORDIC_CSR.RESSIZE = 0) and two output values are expected (CORDIC_CSR.NRES = 1), this register must be read twice when the RRDY flag is set. The first read fetches the primary result (RES1). The second read fetches the secondary result (RES2) and resets RRDY.

If 32-bit format is selected and only one output value is expected (NRES = 0), only one read of this register is required to fetch the primary result (RES1) and reset the RRDY flag.

If 16-bit format is selected (CORDIC_CSR.RESSIZE = 1), this register contains the primary result (RES1) in the lower half, RES[15:0], and the secondary result (RES2) in the upper half, RES[31:16]. In this case, NRES must be set to 0, and only one read performed.

A read from this register resets the RRDY flag in the CORDIC_CSR register.

18.4.4 CORDIC register map

Table 131. CORDIC register map and reset value

19 Filter math accelerator (FMAC)

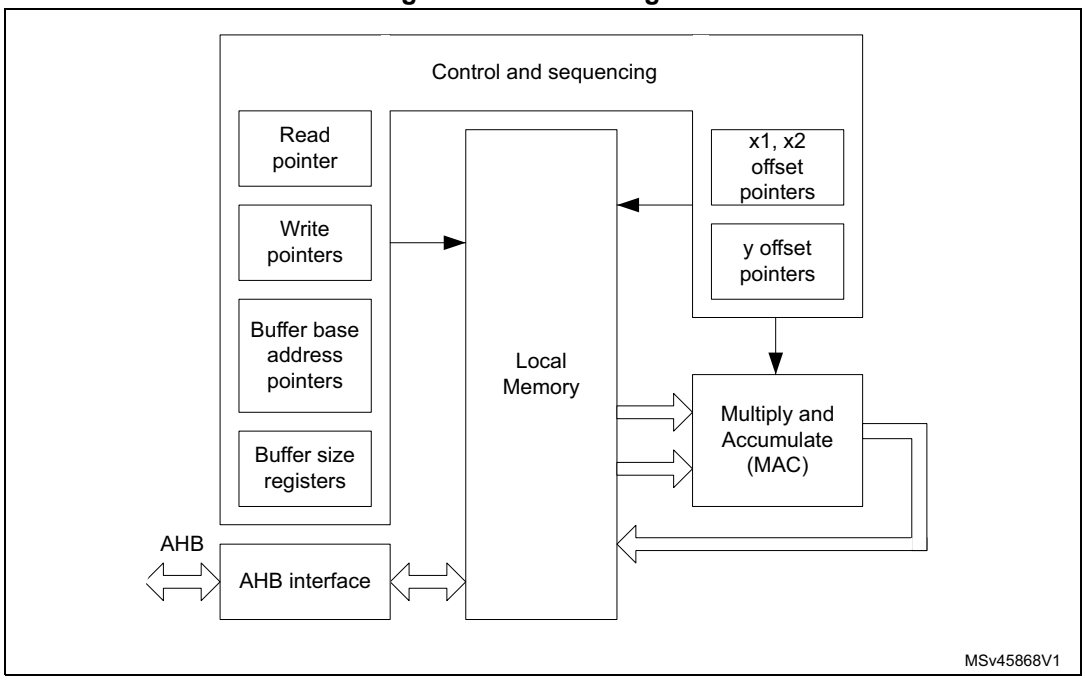
19.1 FMAC introduction

The filter math accelerator unit performs arithmetic operations on vectors. It comprises a multiplier/accumulator (MAC) unit, together with address generation logic which allows it to index vector elements held in local memory.

The unit includes support for circular buffers on input and output, which allows digital filters to be implemented. Both finite and infinite impulse response filters can be realized.

The unit allows frequent or lengthy filtering operations to be offloaded from the CPU, freeing up the processor for other tasks. In many cases it can accelerate such calculations compared to a software implementation, resulting in a speed-up of time critical tasks.

19.2 FMAC main features



- 16 x 16-bit multiplier
- 24 + 2-bit accumulator with addition and subtraction
- 16-bit input and output data
- 256 x 16-bit local memory
- Up to three areas can be defined in memory for data buffers (two input, one output), defined by programmable base address pointers and associated size registers
- Input and output buffers can be circular
- Filter functions: FIR, IIR (direct form 1)
- Vector functions: Dot product, convolution, correlation
- AHB slave interface
- DMA read and write data channels

19.3 FMAC functional description

19.3.1 General description

The FMAC is shown in *Figure 145*.

Figure 145. Block diagram

The unit is built around a fixed point multiplier and accumulator (MAC). The MAC can take two 16-bit input signed values from memory, multiply them together and add them to the contents of the accumulator. The address of the input values in memory is determined using a set of pointers. These pointers can be loaded, incremented, decremented or reset by the internal hardware. The pointer and MAC operations are controlled by a built-in sequencer in order to execute the requested operation.

To calculate a dot product, the two input vectors are loaded into the local memory by the processor or DMA controller, and the requested operation is selected and started. Each pair of input vector elements is fetched from memory, multiplied together and accumulated. When all the vector elements have been processed, the contents of the accumulator are stored in the local memory, from where they can be read out by the processor or DMA.

The finite impulse response (FIR) filter operation (also known as convolution) consists in repeatedly calculating the dot product of the coefficient vector and a vector of input samples, the latter being shifted by one sample delay, with the least recent sample being discarded and a new sample added, at each repetition.

The infinite impulse response (IIR) filter operation is the convolution of the feedback coefficients with the previous output samples, added to the result of the FIR convolution.

A more detailed description of the filter operations is given in *Section 19.3.6: Filter functions*.

19.3.2 Local memory and buffers

The unit contains a 256 x 16-bit read/write memory which is used for local storage:

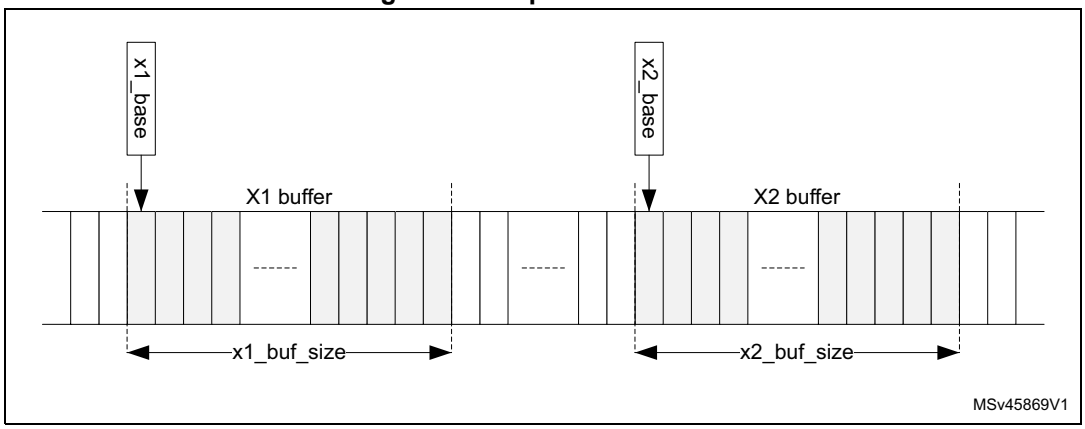
- Input values (the elements of the input vectors) are stored in two buffers, X1 and X2.
- Output values (the results of the operations) are stored in another buffer, Y.
- The locations and sizes of the buffers are designated as follows:
  - x1_base: the base address of the X1 buffer
  - x2_base: the base address of the X2 buffer
  - y_base: the base address of the Y buffer
  - x1_buf_size: the number of 16-bit addresses allocated to the X1 buffer
  - x2_buf_size: the number of 16-bit addresses allocated to the X2 buffer
  - y_buf_size: the number of 16-bit addresses allocated to the Y buffer.

These parameters are programmed in the corresponding registers when configuring the unit.

The CPU (or DMA controller) can initialize the contents of each buffer using the Initialization functions (*Section 19.3.5: Initialization functions*) and writing to the write data register. The data is transferred to the location within the target buffer indicated by a write pointer. After each new write, the write pointer is incremented. When the write pointer reaches the end of the allocated buffer space, it wraps back to the base address. This feature is used to load the elements of a vector prior to an operation, or to initialize a filter and load filter coefficients.

Buffer configuration

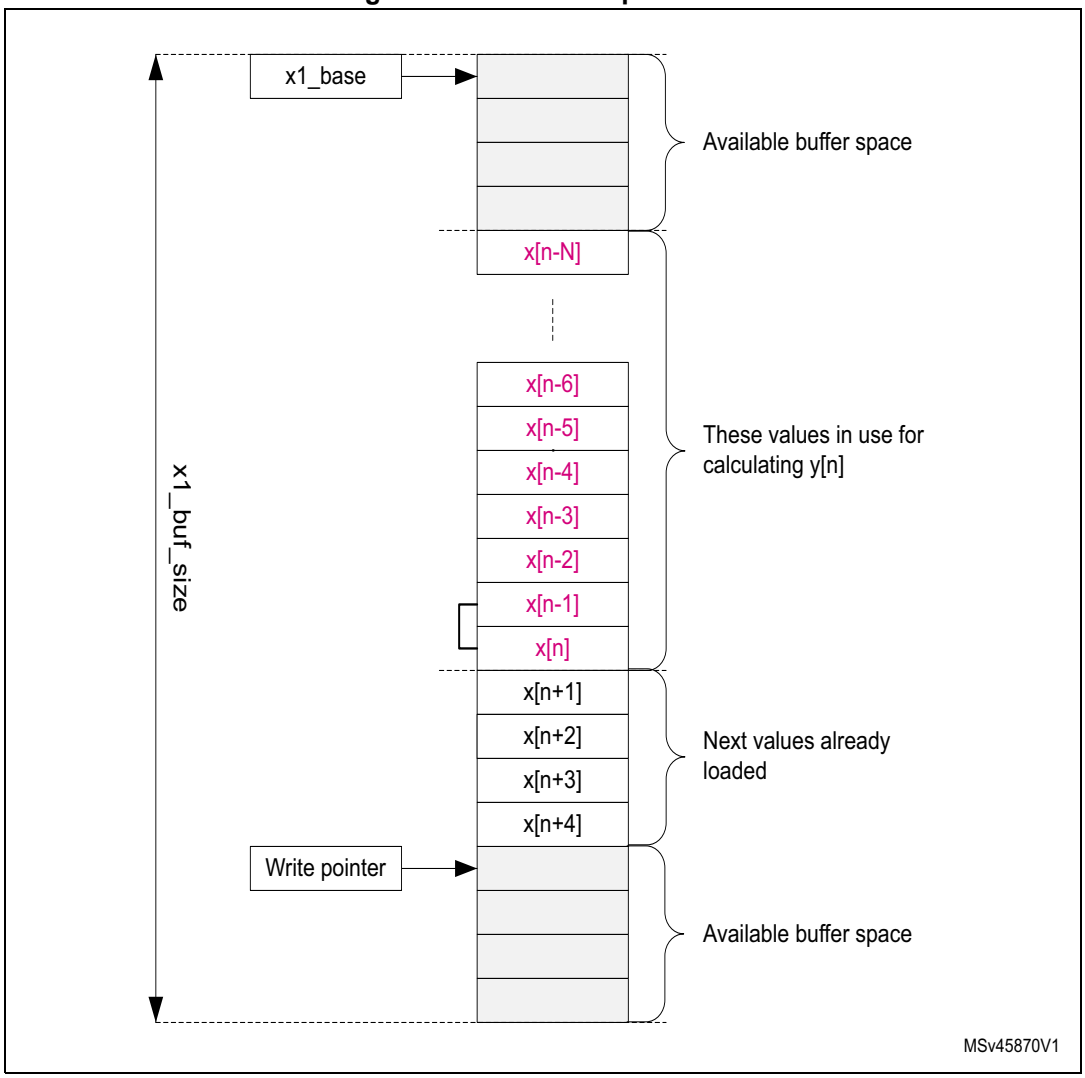
The buffer sizes and base address offsets must be configured in the X1, X2 and Y buffer configuration registers. For each function, the required buffer size is specified in the function description in *Section 19.3.6: Filter functions*. The base addresses can be chosen anywhere in internal memory, provided that all buffers fit within the internal memory address range (0x00 to 0xFF), that is, base address + buffer size must be less than 256.



There is no constraint on the size and location of the buffers (they can overlap or even coincide exactly). For filter functions it is recommended not to overlap buffers as this can lead to erroneous behavior.

When circular buffer operation is required, an optional “headroom”, d, can be added to the buffer size. Furthermore, a watermark level can be set, to regulate the CPU or DMA activity. The value of d and the watermark level must be chosen according to the application performance requirements. For maximum throughput, the input buffer must never go empty, so d must be somewhat greater than the watermark level, allowing for any interrupt or DMA latency. On the other hand, if the input data can not be provided as fast as the unit can process them, the buffer can be allowed to empty waiting for the next data to be written, so d can be equal to the watermark level (to ensure that no overflow occurs on the input).

19.3.3 Input buffers



The X1 and X2 buffers are used to store data for input to the MAC. Each multiplication takes a value from the X1 buffer and a value from the X2 buffer and multiplies them together. A pointer in the control unit generates the read address offset (relative to the buffer base address) for each value. The pointers are managed by hardware according to the current function.

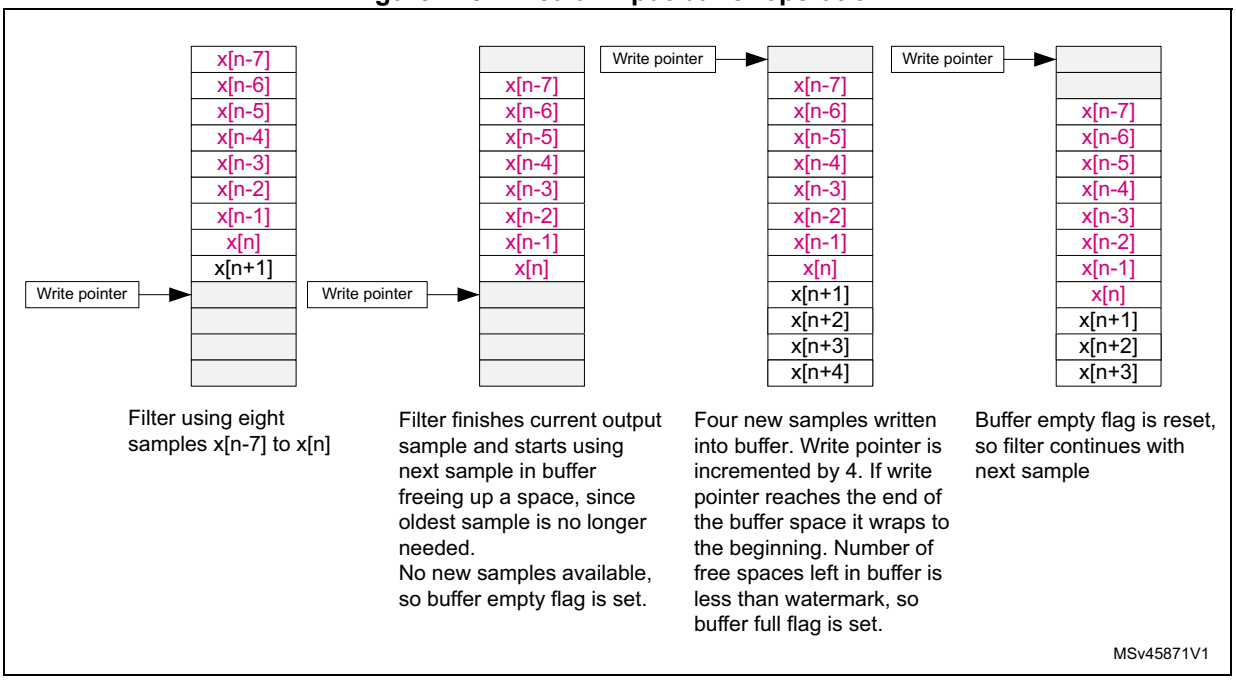
Figure 146. Input buffer areas

The X1 buffer can be used as a circular buffer, in which case new data are continually transferred into the input buffer whenever space is available. Pre-loading this buffer is optional for digital filters, since if no input samples have been written in the buffer when the operation is started, it is flagged as empty, which triggers the CPU or DMA to load new samples until there are enough to begin operation. Pre-loading is nevertheless useful in the case of a vector operation, that is, the input data is already available in system memory and circular operation is not required.

Figure 147. Circular input buffer

The X2 buffer can only be used in vector mode (that is not circular), and needs to be pre-loaded, except if the contents of the buffer do not change from one operation to the next. For filter functions, the X2 buffer is used to store the filter coefficients.

When operating as a circular buffer, the space allocated to the buffer (x1_buf_size) must generally be bigger than the number of elements in use for the current calculation, so that there are always new values available in the buffer. *Figure 147* illustrates the layout of the buffer for a filter operation. While calculating an output sample y[n], the unit uses a set of N+1 input samples, x[n-N] to x[n]. When this is finished, the unit starts the calculation of y[n+1], using the set of input samples x[n-N+1] to x[n+1]. The least-recent input sample, x[n-N], drops out of the input set, and a new sample, x[n+1], is added to it.



The processor, or DMA controller, must ensure that the new sample x[n+1] is available in the buffer space when required. If not, the buffer is flagged as empty, which stalls the execution of the unit until a new sample is added. No underflow condition is signaled on the X1 buffer.

Note: If the flow of samples is controlled by a timer or other peripheral such as an ADC, the buffer regularly goes empty, since the filter processes each new sample faster than the source can provide it. This is an essential feature of filter operation.

If the number of free spaces in the buffer is less than the watermark threshold programmed in the FULL_WM bitfield of the FMAC_X1BUFCFG register, the buffer is flagged as full. As long as the full flag is not set, interrupts are generated, if enabled, to request more data for the buffer. The watermark allows several data to be transferred under one interrupt, without danger of overflow. Nevertheless, if an overflow does occur, the OVFL error flag is set and the write data is ignored. The write pointer is not incremented in the event of an overflow.

The operation of the X1 buffer during a filtering operation is illustrated in *Figure 148*. This example shows an 8-tap FIR filter with a watermark set to four.

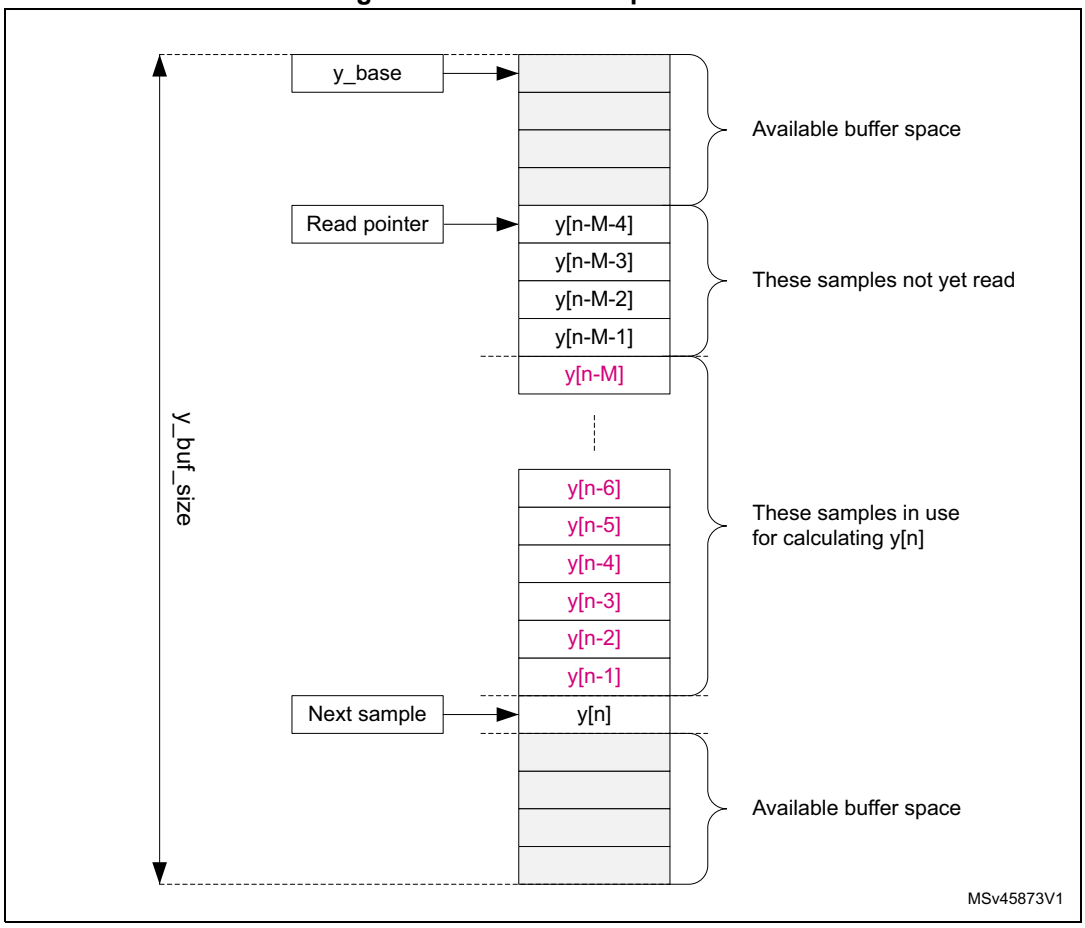


Figure 148. Circular input buffer operation

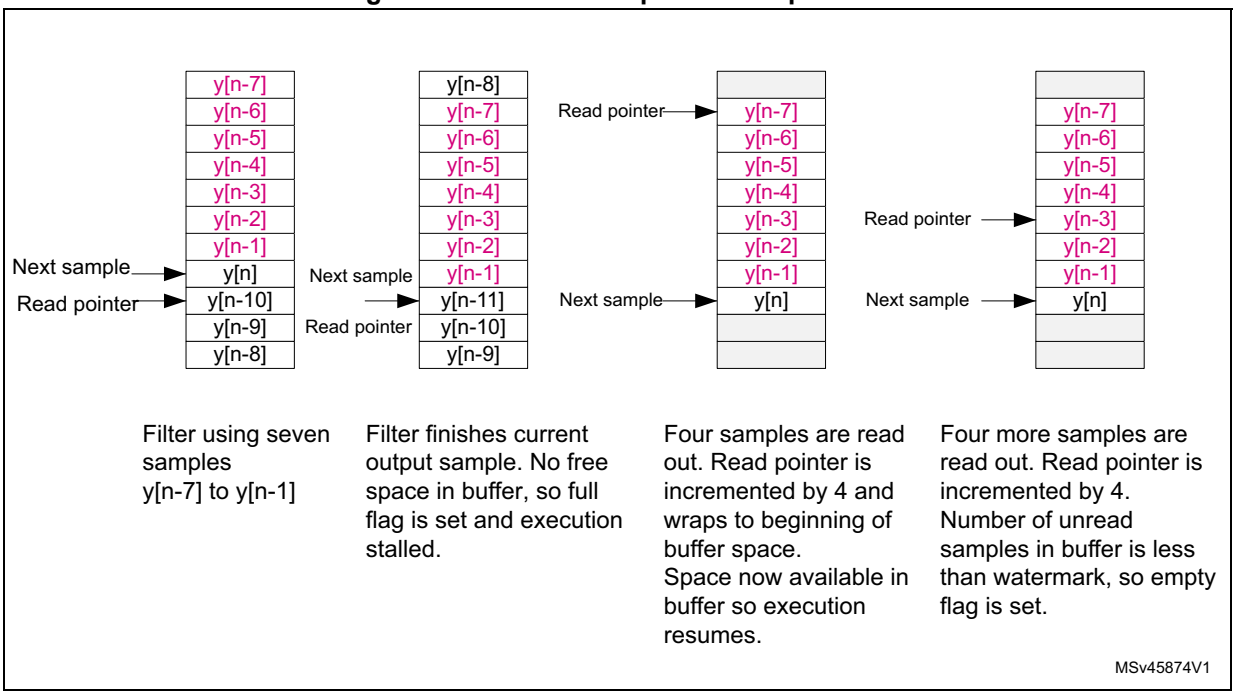
19.3.4 Output buffer

The Y (output) buffer is used to store the output of an accumulation. Each new output value is stored in the buffer until it is read by the processor or DMA controller. Each time a read access is made to the read data register, the read data is fetched from the address indicated by the read pointer. This pointer is incremented after each read, and wraps back to the base address when it reaches the end of the allocated Y buffer space.

Figure 149. Circular output buffer



The Y buffer can also operate as a circular buffer. If the address for the next output value is the same as that indicated by the read pointer (an unread sample), then the buffer is flagged as full and execution stalled until the sample is read.

In the case of IIR filters, the Y buffer is used to store the set of M previous output samples, y[n-M] to y[n-1], used for calculating the next output sample y[n]. Each time a new sample is added to the set, the least recent sample y[n-M] drops out.

If the number of unread data in the buffer is less than the watermark threshold programmed in the EMPTY_WM bitfield of the FMAC_YBUFCFG register, the buffer is flagged as empty. As long as the empty flag is not set, interrupts or DMA requests are generated, if enabled, to request reads from the buffer. The watermark allows several data to be transferred under one interrupt, without danger of underflow. Nevertheless, if an underflow does occur, the UNFL error flag is set. In this case, the read pointer is not incremented and the read operation returns the content of the memory at the read pointer address.

The operation of the Y buffer in circular mode is illustrated in *Figure 150*. This example shows a 7-tap IIR filter with a watermark set to four.

Figure 150. Circular output buffer operation

19.3.5 Initialization functions

The following functions initialize the FMAC unit. They are triggered by writing the appropriate value in the FUNC bitfield of the FMAC_PARAM register, with the START bit set. The P and Q bitfields must also contain the appropriate parameter values for each function as detailed below. The R bitfield is not used. When the function completes, the START bit is automatically reset by hardware.

During initialization, it is recommended that the DMA requests and interrupts be disabled. The transfer of data into the FMAC memory can be done by software or by memory-to-memory DMA transfers, since no flow control is required.

Load X1 buffer

This function pre-loads the X1 buffer with N values, starting from the address in X1_BASE. Successive writes to the FMAC_WDATA register load the write data into the X1 buffer and increment the write address. The write pointer points to the address X1_BASE + N when the function completes.

The function can be used to pre-load the buffer with the elements of a vector, or to initialize the input storage elements of a filter.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X1 buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

Load X2 buffer

This function pre-loads the X2 buffer with N + M values, starting from the address in X2_BASE. Successive writes to the FMAC_WDATA register load the write data into the X2 buffer and increment the write address.

The function can be used to pre-load the buffer with the elements of a vector, or the coefficients of a filter. In the case of an IIR, the N feed-forward and M feed-back coefficients are concatenated and loaded together into the X2 buffer. The total number of coefficients is equal to N + M. For an FIR, there are no feedback coefficients, so M = 0.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X2 buffer starting from address X2_BASE.
- The parameter Q contains the number of values, M, to be loaded into the X2 buffer starting from address X2_BASE + N.
- The parameter R is not used.

The function completes when N + M writes have been performed to the FMAC_WDATA register.

Load Y buffer

This function pre-loads the Y buffer with N values, starting from the address in Y_BASE. Successive writes to the FMAC_WDATA register load the write data into the Y buffer and increment the write address. The read pointer points to the address Y_BASE + N when the function completes.

The function can be used to pre-load the feedback storage elements of an IIR filter.

Parameters

- The parameter P contains the number of values to be loaded into the Y buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

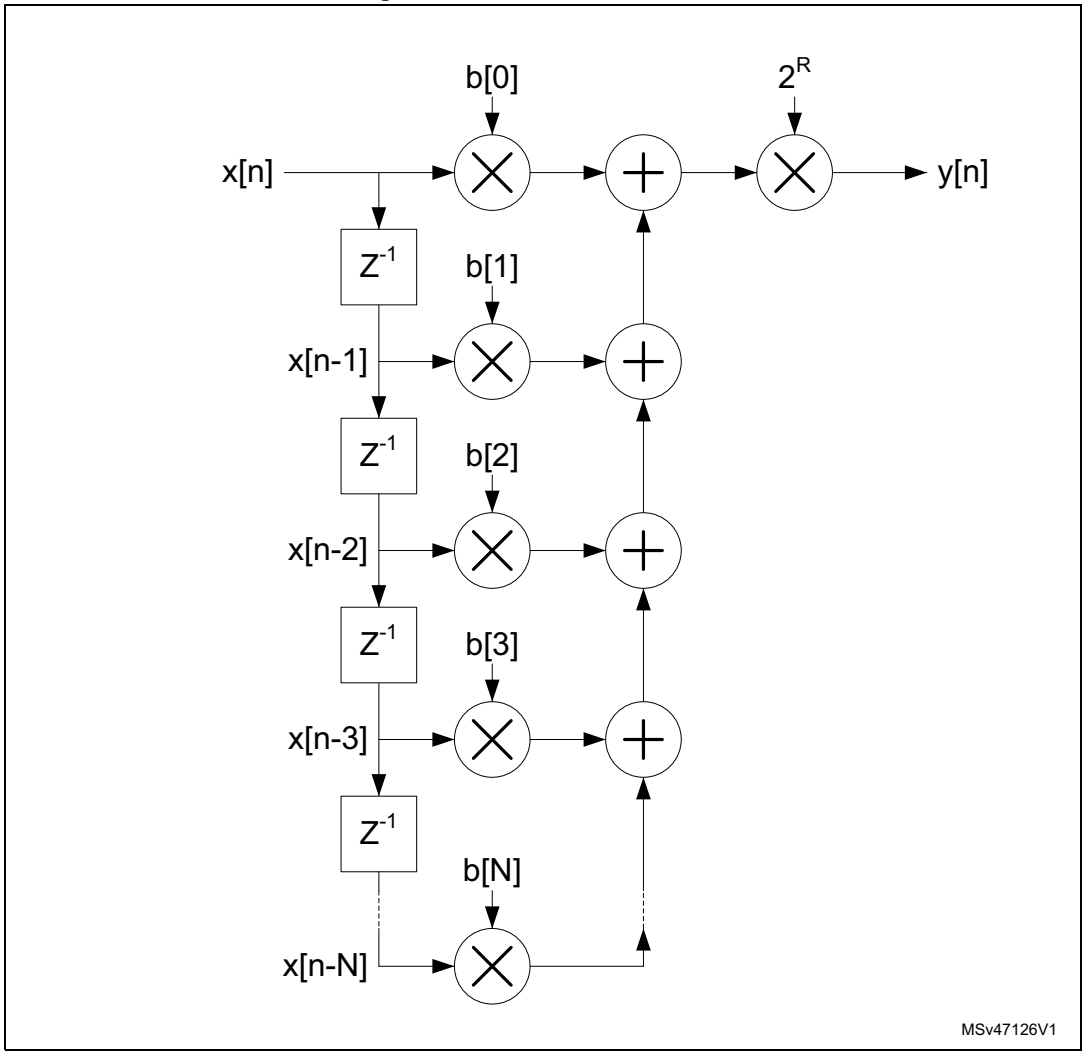
19.3.6 Filter functions

The following filter functions are supported by the FMAC unit. These functions are triggered by writing the corresponding value in the FUNC bitfield of the FMAC_PARAM register with the START bit set. The P, Q and R bitfields must also contain the appropriate parameter values for each function as detailed below. The filter functions continue to run until the START bit is reset by software.

Convolution (FIR filter)

Y = **B***__X__

$$y_n = 2^R \cdot \sum_{k=0}^{N} b_k x_{n-k}$$



This function performs a convolution of a vector **B** of length N+1 and a vector **X** of indefinite length. The elements of **Y** for incrementing values of n are calculated as the dot product,

$y_n = \underline{\mathbf{B}}.\underline{\mathbf{X}}_{\mathbf{n}}$, where $\underline{\mathbf{X}}_{\mathbf{n}} = [x_{n-N},...,x_n]$ is composed of the N+1 elements of **X** at indexes n - N to n.

This function corresponds to a finite impulse response (FIR) filter, where vector **B** contains the filter coefficients and vector **X** the sampled data.

The structure of the filter (direct form) is shown in *Figure 151*.

Figure 151. FIR filter structure

Note that the cross correlation vector can be calculated by reversing the order of the coefficient vector **B**.

Input:

- X1 buffer contains the elements of vector **X**. It is a circular buffer of length N + 1 + d.
- X2 buffer contains the elements of vector **B**. It is a fixed buffer of length N + 1.

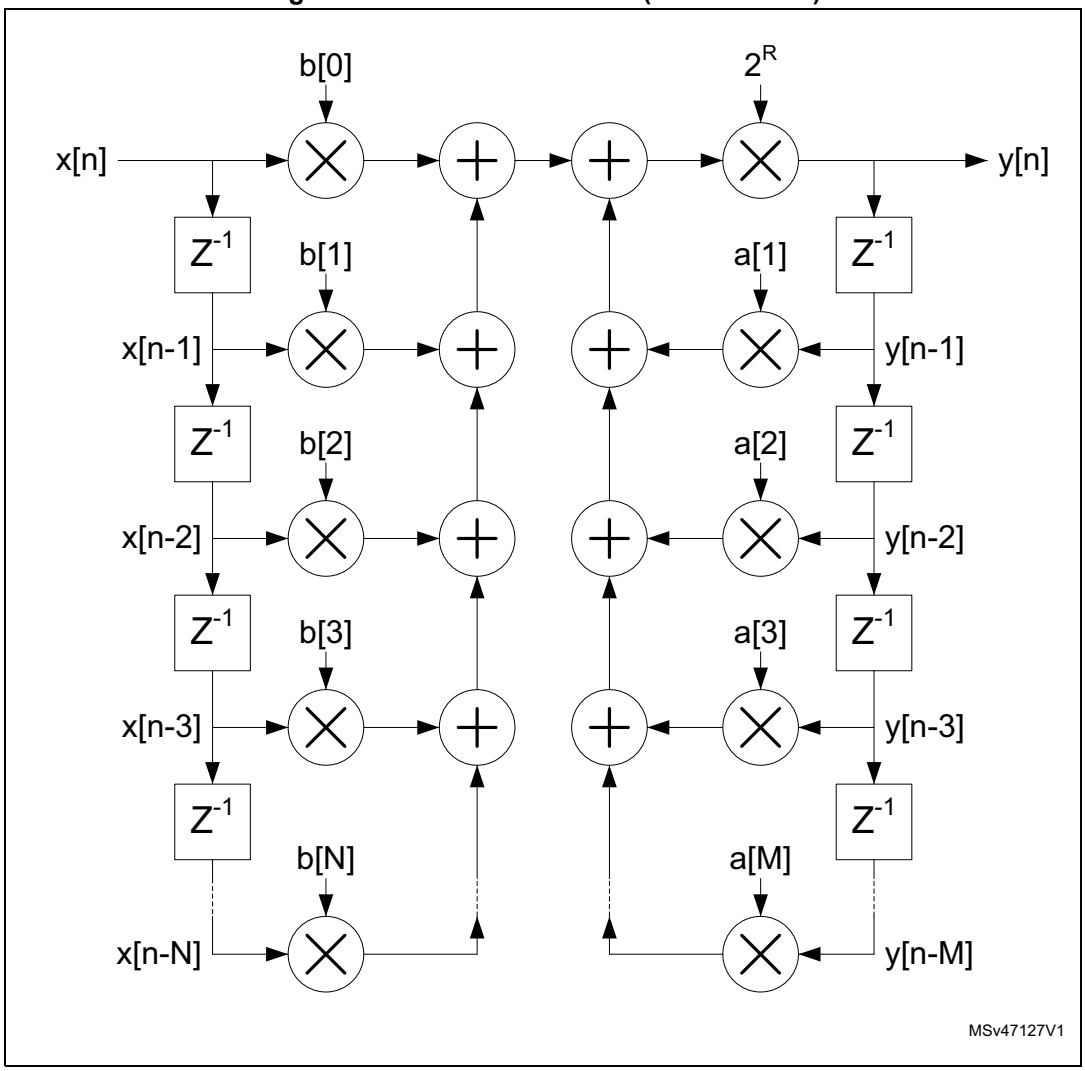
Output:

- Y buffer contains the output values, y_n. It is a circular buffer of length d.

Parameters:

- The parameter P contains the length, N+1, of the coefficient vector **B** in the range [2:127].
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by 2^R, where R is in the range [0:7]
- The parameter Q is not used.

The function completes when the START bit in the FMAC_PARAM register is reset by software.



IIR filter

Y = B*X+A*Y'

$$y_n = 2^R \cdot \left(\sum_{k=0}^{N} b_k x_{n-k} + \sum_{k=1}^{M} a_k y_{n-k} \right)$$

This function implements an infinite impulse response (IIR) filter. The filter output vector **Y** is the convolution of a coefficient vector **B** of length N+1 and a vector **X** of indefinite length, plus the convolution of the delayed output vector **Y'** with a second coefficient vector **A**, of length M. The elements of **Y** for incrementing values of n are calculated as y_n = **B**.$\mathbf{X_n}$ + **A**.$\mathbf{Y_{n-1}}$, where $\mathbf{X_n}$ = $[x_{n-N},...,x_n]$ comprises the N+1 elements of **X** at indexes n - N to n, while $\mathbf{Y_{n-1}}$ = $[y_{n-M},...,y_{n-1}]$ comprises the M elements of **Y** at indexes n - M to n - 1. The structure of the filter (direct form 1) is shown in *Figure 152*.

Figure 152. IIR filter structure (direct form 1)

Input:

- X1 buffer contains the elements of vector **X**. It is a circular buffer of length N + 1+ d.
- X2 buffer contains the elements of coefficient vectors **B** and **A** concatenated (b_0, b_1, b_2..., b_N, a_1, a_2, ..., a_M). It is a fixed buffer of length M+N+1.

Output:

- Y buffer contains the output values, y_n. It is a circular buffer of length M + d.

Parameters

- The parameter P contains the length, N + 1, of the coefficient vector **B** in the range [2:64].
- The parameter Q contains the length, M, of the coefficient vector **A** in the range [1:63].
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by 2^R, where R is in the range [0:7].

The function completes when the START bit in the FMAC_PARAM register is reset by software.

19.3.7 Fixed point representation

The FMAC operates in fixed point signed integer format. Input and output values are q1.15.

In q1.15 format, numbers are represented by one sign bit and 15 fractional bits (binary decimal places). The numeric range is therefore -1 (0x8000) to 1 - 2^{-15} (0x7FFF).

The accumulator has 26 bits, of which 22 are fractional and 4 are integer/sign (q4.22). This allows it to support partial accumulation sums in the range -8 (0x2000000) to +7.99999976 (0x1FFFFFF). A programmable gain from 0dB to 42dB in steps of 6dB can be applied at the output of the accumulator.

Note that the content of the accumulator is not saturated if the numeric range is exceeded. Partial sums whose value is greater than +7.99999976 or less than -8, wrap but this is harmless provided subsequent accumulations undo the wrapping. Nevertheless, the SAT flag in the FMAC_SR register is set if wrapping occurs, and generates an interrupt if the SATIEN bit is set in the FMAC_CR register. This helps in debugging the filter.

The data output by the accumulator can optionally be saturated, after application of the programmable gain, by setting the CLIPEN bit in the FMAC_CR register. If this bit is set, then any value which exceeds the numeric range of the q1.15 output, is set to 1 - 2^{-15} or -1, according to the sign. If clipping is not enabled, the unused accumulator bits after applying the gain is simply truncated.

19.3.8 Implementing FIR filters with the FMAC

The FMAC supports FIR filters of length N, where N is the number of taps or coefficients. The minimum local memory requirement for a FIR filter of length N is 2N + 1:

– N coefficients
– N input samples
– 1 output sample

Since the local memory size is 256, the maximum value for N is 127.

If maximum throughput is required, it may be necessary to allocate a small amount of extra space, d1 and d2, to the input and output sample buffers respectively, to ensure that the filter never stalls waiting for a new input sample, or waiting for the output sample to be read. In this case, the local memory requirement is 2N + d1 + d2.

The buffers must be configured as follows:

- X1_BUF_SIZE = N + d1;
- X2_BUF_SIZE = N;
- Y_BUF_SIZE = d2 (or 1 if no extra space is required)

The buffer base addresses can be allocated anywhere, but the X2 buffer must not overlap with the others, or else the coefficients are overwritten. An example configuration is:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = 2N + d1

However, if the memory space is limited, the X1 and Y buffer areas can be overlapped, such that each output sample takes the place of the oldest input sample, which is no longer required:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = N

In this case, Y_BUF_SIZE = X1_BUF_SIZE = N + d1, so that the buffers remain in sync.

Note: The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to $log_2(d1)$, otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to $log_2(d2)$.

The filter coefficients **must** be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. There is no point in pre-loading the Y buffer, since for the FIR filter there is no feedback path.

After configuring and initializing the buffers, the FMAC_CR register must be programmed according to the method used for writing and reading data to and from the FMAC memory.

Three methods are supported:

- Polling: No DMA request or Interrupt request is generated. Software must check that the X1_FULL flag is low before writing to WDATA, or that the Y_EMPTY flag is low before reading from RDATA.
- Interrupt: The interrupt request is asserted while the X1_FULL flag is low, for writes, or when the Y_EMPTY flag is low, for reads.
- DMA: DMA requests are asserted on the DMA write channel while the X1_FULL flag is low, and on the read channel while the Y_EMPTY flag is low.

Different methods can be used for read and for write. However it is not recommended to use both interrupts and DMA requests for the same operation[(a)]. The valid combinations are listed in *Table 132*.

Table 132. Valid combinations for read and write methods

WIEN	RIEN	DMAWEN	DMAREN	Write	Read
0	0	0	0	Polling	Polling
0	1	0	0	Polling	Interrupt
1	0	0	0	Interrupt	Polling
1	1	0	0	Interrupt	Interrupt
0	0	0	1	Polling	DMA
0	0	1	0	DMA	Polling
0	0	1	1	DMA	DMA
0	1	1	0	DMA	Interrupt
1	0	0	1	Interrupt	DMA

a. If both interrupts and DMA requests are enabled then only DMA must perform the transfer.

The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- FUNC = 8 (FIR filter);
- P = N (number of coefficients);
- Q = “Don’t care”;
- R = Gain;
- START = 1;

If less than N + d - 2^{FULL_WM} values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write 2^{FULL_WM} additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine must check the X1FULL flag after every 2^{FULL_WM} writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples).

When 2^{EMPTY_WM} output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read 2^{EMPTY_WM} samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine must check the YEMPTY flag after every 2^{EMPTY_WM} reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high.

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

19.3.9 Implementing IIR filters with the FMAC

The FMAC supports IIR filters of length N, where N is the number of feed-forward taps or coefficients. The number of feedback coefficients, M, can be any value from 1 to N-1. Only direct form 1 implementations can be realized, so filters designed for other forms need to be converted.

The minimum memory requirement for an IIR filter with N feed-forward coefficients and M feed-back coefficients is 2N + 2M:

- N + M coefficients
- N input samples
- M output samples

If M = N-1, then the maximum filter length that can be implemented is N = 64.

As for the FIR, for maximum throughput, a small amount of additional space, d1 and d2, is allowed in the input and output buffer size respectively, making the total memory requirement 2M + 2N + d1 + d2.

The buffers must be configured as follows:

- X1_BUF_SIZE = N + d1;
- X2_BUF_SIZE = N + M;
- Y_BUF_SIZE = M + d2;

The buffer base addresses can be allocated anywhere, but must not overlap. An example configuration is given below:

- X2_BASE = 0;
- X1_BASE = N + M;
- Y_BASE = 2N + M + d1;

Note: The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to $log_2(d1)$, otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to $log_2(d2)$.

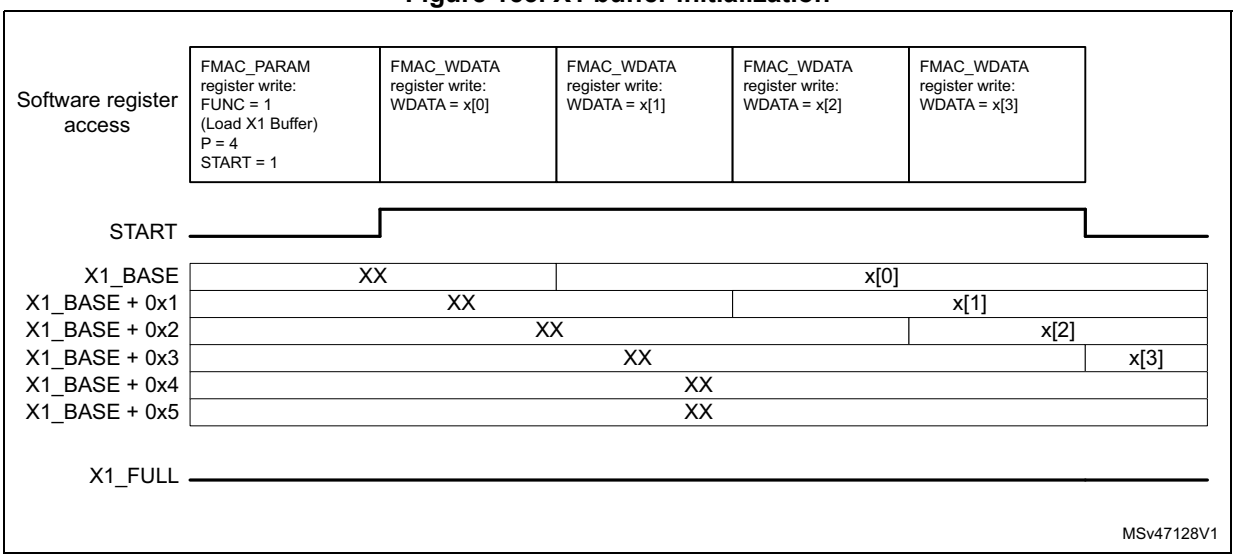
The filter coefficients (N feed-forward followed by M feedback) **must** be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. The Y buffer can optionally be pre-loaded with any number of values up to a maximum of M. This has the effect of initializing the feedback delay line.

After configuring the buffers, the FMAC_CR register must be programmed in the same way as for the FIR filter (see *Section 19.3.8: Implementing FIR filters with the FMAC*).

The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- FUNC = 9 (IIR filter);
- P = N (number of feed-forward coefficients);
- Q = M (number of feed-back coefficients);
- R = Gain;
- START = 1;

If less than N + d - 2^{FULL_WM} values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write 2^{FULL_WM} additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine must check the X1FULL flag after every 2^{FULL_WM} writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.



The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples). The first sample is calculated using the first N samples in the X1 buffer, and the first M samples in the Y buffer (whether or not they are preloaded. The first output sample is written into the Y buffer at Y_BASE + M.

When 2^{EMPTY_WM} new output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read 2^{EMPTY_WM} samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine must check the YEMPTY flag after every 2^{EMPTY_WM} reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

19.3.10 Examples of filter initialization

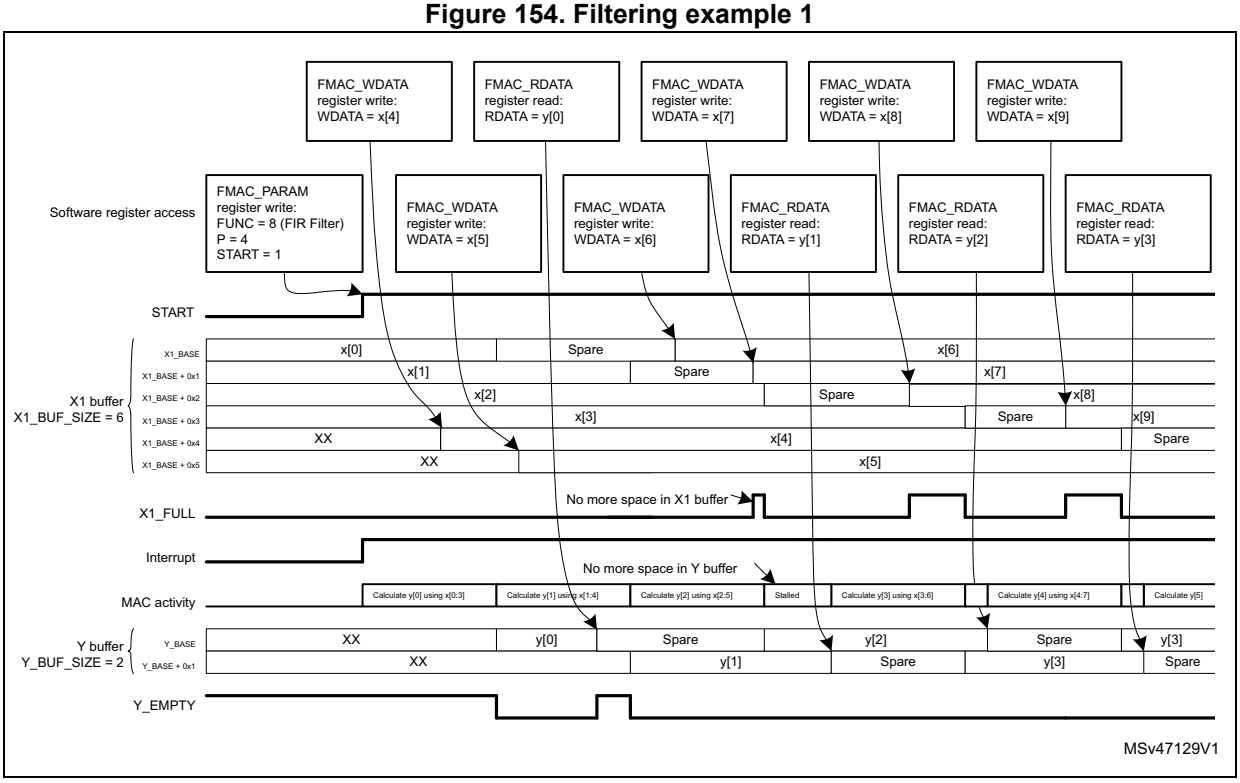


Figure 153. X1 buffer initialization

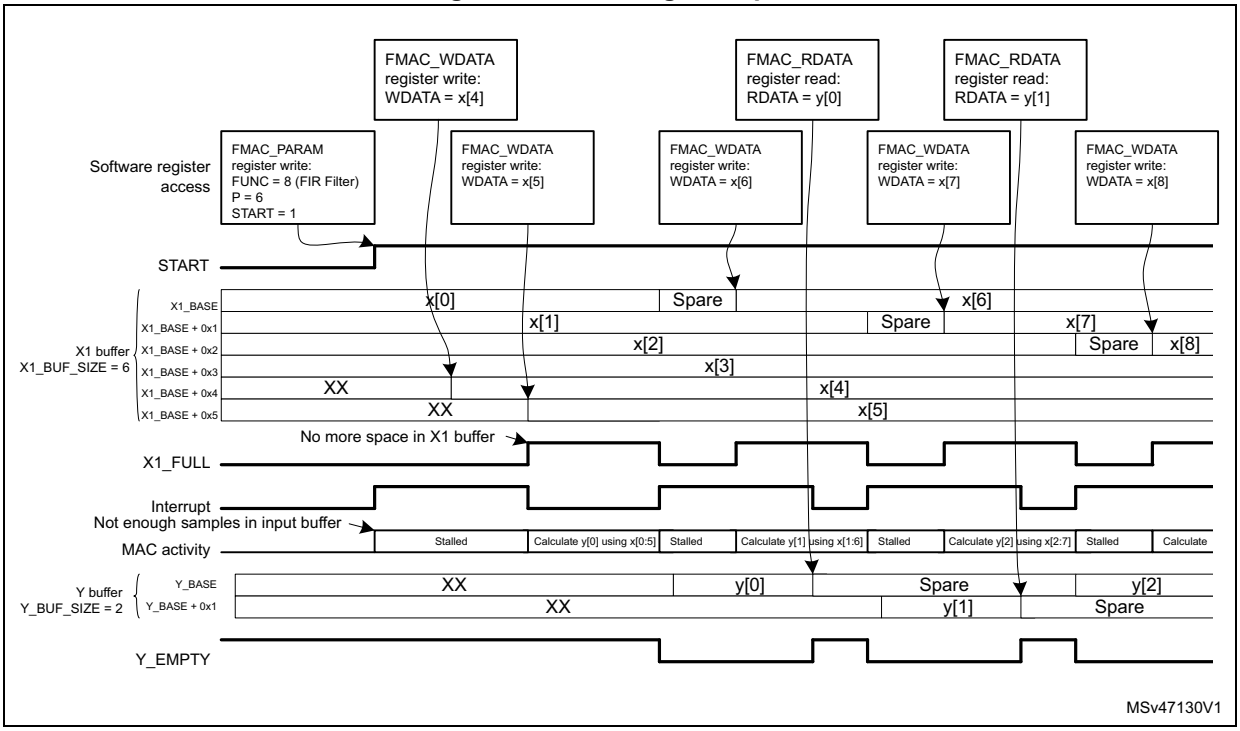
The example in *Figure 153* illustrates an X1 buffer pre-load with four samples (P = 4). The buffer size is six (X1_BUF_SIZE = 6). The initialization is launched by programming the FMAC_PARAM register with the START bit set. The four samples are then written to FMAC_WDATA, and transferred into local memory from X1_BASE onwards. The START bit resets after the fourth sample has been written. At this point, the X1 buffer contains the four samples, in order of writing, and the write pointer (next empty space) is at X1_BASE + 0x4.

19.3.11 Examples of filter operation

Figure 154. Filtering example 1

The example in *Figure 154* illustrates the beginning of a filter operation. The filter has four taps (P=4). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in *Figure 153*. So the filter starts calculating the first output sample, y[0], immediately after the START bit is set. Since the X1FULL flag is not set (due to two uninitialized spaces in the X1 buffer), the interrupt is asserted straight away, to request new data. The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer.



In the mean time, the FMAC finishes calculating the first output sample, y[0], and writes it into the Y buffer, causing the Y_EMPTY flag to go low. At the same time, the x[0] sample is discarded, as it is no longer required, freeing up its location in memory (at X1_BASE). The FMAC can immediately start work on the second output sample, y[1], since all the required input samples x[1:5] are present in the X1 buffer.

Since the Y_EMPTY flag is low, the interrupt remains active after the processor finishes writing x[5]. The processor reads y[0] from the FMAC_RDATA register, freeing up its location in the Y buffer. There are now no samples in the output buffer since y[1] is still being calculated, so the Y_EMPTY flag goes high. Nevertheless, the interrupt remains active, because there is still free space in the X1 buffer, which the processor next fills with x[6], and so on.

Note: In this example, the processor can fill the input buffer more quickly than the FMAC can process them, so the X1_full flag regularly goes active. However, it struggles to read the Y buffer fast enough, so the FMAC stalls regularly waiting for space to be freed up in the Y buffer. This means the filter is not executing at maximum throughput. The reason is that the

filter length is small and the processor relatively slow, in this example. So increasing the Y buffer size does not help.

Figure 155. Filtering example 2

The example in *Figure 155* illustrates the beginning of the same filter operation, but this time the filter has six taps (P=6). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in *Figure 153*. Because there are not enough samples in the input buffer, the X1FULL flag is not set, so the interrupt is asserted straight away, to request new data. The FMAC is stalled.

The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer. As soon as there are six unused samples in the X1 buffer, the X1_FULL flag goes active (since the buffer size is six), causing the interrupt to go inactive. The FMAC starts calculating the first output sample, y[0]. Since this requires all six input samples, there are no free spaces in the X1 buffer and so the X1_FULL flag remains active. Only when the FMAC finishes calculating y[0] and writes it into the Y buffer, can x[0] be discarded, freeing up a space in the X1 buffer, and deasserting X1_FULL. At the same time, the Y_EMPTY flag goes inactive. Both these flag states cause the interrupt to be asserted, requesting the processor to write a new input sample, first of all, and then read the output sample just calculated. The FMAC remains stalled until a new input sample is written.

In this example, the processor has to wait for the FMAC to finish calculating the current output sample, before it can write a new input sample, and therefore the X1 buffer regularly goes empty, stalling the FMAC. This can be avoided by allowing some extra space in the input buffer.

19.3.12 Filter design tips

The FMAC architecture imposes some constraints detailed below, on the design of digital filters.

1. Implementation of direct form 2, or transposed forms, is not efficient. Filters which have been designed for such forms must be converted to direct form 1.
2. Cascaded filters must either be combined into a single stage, or implemented as separate filters. In the latter case, multiple sets of filter coefficients can be pre-loaded into the memory, one set per stage, and only the X2_BASE address changed to select which set is used. The most efficient method of implementing a multi-stage filter is to pre-load a large X1 buffer with input samples, run the IIR filter function on it using the first stage coefficients, and store the output samples back in memory. Then change the X2_BASE pointer to point to the 2nd stage coefficients, and reload the input buffer with the output of the first stage (with a gain if required), before running the IIR function again. The procedure is repeated for all stages. Once the final stage samples have been transferred back into system memory, the input buffer can be loaded with the next set of input samples, and a new round of calculations started. Note that the N sample input buffer of each stage must be pre-loaded first of all with the N-1 last inputs from the previous round, plus one new sample, in order to keep continuity between each round. Similarly, the output buffer of each stage must be loaded with the last M samples from the previous round, for the same reason.
3. The use of direct form 1 for IIR designs can lead to large positive or negative partial sums in the accumulator, if for example a large step occurs on the input, or some of the filter coefficients' absolute values are >1. Since the accumulator is limited to 26 bits, the biggest value that it can handle without wrapping (changing sign) is 0x1FFFFFF positive or 0x2000000 negative. This corresponds to 3.99999988 and -4 respectively in q3.23 fixed point format. Wrapping does not represent a problem provided the wrapping is "undone" before the end of the accumulation. However this is not always the case when a filter is starting up and can lead to unexpected results. Consider pre-loading the output buffer with suitable values to avoid this.
4. The IIR filter has feed-forward (numerator) coefficients $[b_0, b_1, ..., b_{N-1}]$, and feed-back (denominator) coefficients $[1, a_1, ..., a_M]$. Many IIR filters require some of the denominator coefficients to have an absolute value greater than 1 to achieve a steep roll-off in the frequency response. Given that the coefficients are coded in fixed point q1.15 format, this is not possible. Nevertheless, by scaling the denominator coefficients by a factor 2^{-R}, such that $2^{-R}.[1, a_1, ..., a_M]$ are all less than 1, such filters can be implemented. However an inverse gain of 2^R must be applied at the output of the accumulator to compensate the scaling. This has an adverse effect on the signal-to-noise ratio.

19.4 FMAC registers

19.4.1 FMAC X1 buffer configuration register (FMAC_X1BUFCFG)

Address offset: 0x00

Reset value: 0x0000 0000

Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	FULL_WM[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
X1_BUF_SIZE[7:0]								X1_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **FULL_WM[1:0]**: Watermark for buffer full flag

Defines the threshold for setting the X1 buffer full flag when operating in circular mode. The flag is set if the number of free spaces in the buffer is less than 2^{FULL_WM}.

0: Threshold = 1

1: Threshold = 2

2: Threshold = 4

3: Threshold = 8

Setting a threshold greater than 1 allows several data to be transferred into the buffer under one interrupt.

Threshold must be set to 1 if DMA write requests are enabled (DMAWEN = 1 in FMAC_CR register).

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **X1_BUF_SIZE[7:0]**: Allocated size of X1 buffer in 16-bit words

The minimum buffer size is the number of feed-forward taps in the filter (+ the watermark threshold - 1).

Bits 7:0 **X1_BASE[7:0]**: Base address of X1 buffer

19.4.2 FMAC X2 buffer configuration register (FMAC_X2BUFCFG)

Address offset: 0x04

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
X2_BUF_SIZE[7:0]								X2_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **X2_BUF_SIZE[7:0]**: Size of X2 buffer in 16-bit words
This bitfield can not be modified when a function is ongoing (START = 1).

Bits 7:0 **X2_BASE[7:0]**: Base address of X2 buffer
The X2 buffer base address can be modified while START=1, for example to change coefficient values. The filter must be stalled when doing this, since changing the coefficients while a calculation is ongoing affects the result.

19.4.3 FMAC Y buffer configuration register (FMAC_YBUFCFG)

Address offset: 0x08

Reset value: 0x0000 0000

Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	EMPTY_WM[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Y_BUF_SIZE[7:0]								Y_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **EMPTY_WM[1:0]**: Watermark for buffer empty flag
Defines the threshold for setting the Y buffer empty flag when operating in circular mode. The flag is set if the number of unread values in the buffer is less than 2^{EMPTY_WM}.
0: Threshold = 1
1: Threshold = 2
2: Threshold = 4
3: Threshold = 8
Setting a threshold greater than 1 allows several data to be transferred from the buffer under one interrupt.
Threshold must be set to 1 if DMA read requests are enabled (DMAREN = 1 in FMAC_CR register).

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **Y_BUF_SIZE[7:0]**: Size of Y buffer in 16-bit words
For FIR filters, the minimum buffer size is 1 (+ the watermark threshold). For IIR filters the minimum buffer size is the number of feedback taps (+ the watermark threshold).

Bits 7:0 **Y_BASE[7:0]**: Base address of Y buffer

19.4.4 FMAC parameter register (FMAC_PARAM)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
START	FUNC[6:0]							R[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Q[7:0]								P[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **START**: Enable execution
0: Stop execution
1: Start execution
Setting this bit triggers the execution of the function selected in the FUNC bitfield. Resetting it by software stops any ongoing function. For initialization functions, this bit is reset by hardware.

Bits 30:24 **FUNC[6:0]**: Function
0: Reserved
1: Load X1 buffer
2: Load X2 buffer
3: Load Y buffer
4 to 7: Reserved
8: Convolution (FIR filter)
9: IIR filter (direct form 1)
10 to 127: Reserved
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 23:16 **R[7:0]**: Input parameter R.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 15:8 **Q[7:0]**: Input parameter Q.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 7:0 **P[7:0]**: Input parameter P.
The value of this parameter is dependent on the function
This bitfield can not be modified when a function is ongoing (START = 1)

19.4.5 FMAC control register (FMAC_CR)

Address offset: 0x10

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RESET
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CLIP EN	Res.	Res.	Res.	Res.	Res.	DMA WEN	DMA REN	Res.	Res.	Res.	SAT IEN	UNFL IEN	OVFL IEN	WIEN	RIEN
rw						rw	rw				rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RESET**: Reset FMAC unit

This resets the write and read pointers, the internal control logic, the FMAC_SR register and the FMAC_PARAM register, including the START bit if active. Other register settings are not affected. This bit is reset by hardware.

0: Reset inactive

1: Reset active

Bit 15 **CLIPEN**: Enable clipping

0: Clipping disabled. Values at the output of the accumulator which exceed the q1.15 range, wrap.

1: Clipping enabled. Values at the output of the accumulator which exceed the q1.15 range are saturated to the maximum positive or negative value (+1 or -1) according to the sign.

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **DMAWEN**: Enable DMA write channel requests

0: Disable. No DMA requests are generated

1: Enable. DMA requests are generated while the X1 buffer is not full.

This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

Bit 8 **DMAREN**: Enable DMA read channel requests

0: Disable. No DMA requests are generated

1: Enable. DMA requests are generated while the Y buffer is not empty.

This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SATIEN**: Enable saturation error interrupts

0: Disabled. No interrupts are generated upon saturation detection.

1: Enabled. An interrupt request is generated if the SAT flag is set

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 3 **UNFLIEN**: Enable underflow error interrupts

0: Disabled. No interrupts are generated upon underflow detection.

1: Enabled. An interrupt request is generated if the UNFL flag is set

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 2 **OVFLIEN**: Enable overflow error interrupts
0: Disabled. No interrupts are generated upon overflow detection.
1: Enabled. An interrupt request is generated if the OVFL flag is set
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 1 **WIEN**: Enable write interrupt
0: Disabled. No write interrupt requests are generated.
1: Enabled. An interrupt request is generated while the X1 buffer FULL flag is not set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 0 **RIEN**: Enable read interrupt
0: Disabled. No read interrupt requests are generated.
1: Enabled. An interrupt request is generated while the Y buffer EMPTY flag is not set.
This bit is set and cleared by software. A read returns the current state of the bit.

19.4.6 FMAC status register (FMAC_SR)

Address offset: 0x14

Reset value: 0x0000 0001

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SAT	UNFL	OVFL	Res.	Res.	Res.	Res.	Res.	Res.	X1 FULL	Y EMPTY
					r	r	r							r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **SAT**: Saturation error flag
Saturation occurs when the result of an accumulation exceeds the numeric range of the accumulator.
0: No saturation detected
1: Saturation detected. If the SATIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bit 9 **UNFL**: Underflow error flag
An underflow occurs when a read is made from FMAC_RDATA when no valid data is available in the Y buffer.
0: No underflow detected
1: Underflow detected. If the UNFLIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bit 8 **OVFL**: Overflow error flag
An overflow occurs when a write is made to FMAC_WDATA when no free space is available in the X1 buffer.
0: No overflow detected
1: Overflow detected. If the OVFLIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **X1FULL**: X1 buffer full flag

The buffer is flagged as full if the number of available spaces is less than the FULL_WM threshold. The number of available spaces is the difference between the write pointer and the least recent sample currently in use.

0: X1 buffer not full. If the WIEN bit is set, the interrupt request is asserted until the flag is set. If DMAWEN is set, DMA write channel requests are generated until the flag is set.

1: X1 buffer full.

This flag is set and cleared by hardware, or by a reset.

Note: after the last available space in the X1 buffer is filled there is a delay of 3 clock cycles before the X1FULL flag goes high. To avoid any risk of overflow it is recommended to insert a software delay after writing to the X1 buffer before reading the FMAC_SR. Alternatively, a FULL_WM threshold of 2 can be used.

Bit 0 **YEMPTY**: Y buffer empty flag

The buffer is flagged as empty if the number of unread data is less than the EMPTY_WM threshold. The number of unread data is the difference between the read pointer and the current output destination address.

0: Y buffer not empty. If the RIEN bit is set, the interrupt request is asserted until the flag is set. If DMAREN is set, DMA read channel requests are generated until the flag is set.

1: Y buffer empty.

This flag is set and cleared by hardware, or by a reset.

Note: after the last sample is read from the Y buffer there is a delay of 3 clock cycles before the YEMPTY flag goes high. To avoid any risk of underflow it is recommended to insert a software delay after reading from the Y buffer before reading the FMAC_SR. Alternatively, an EMPTY_WM threshold of 2 can be used.

19.4.7 FMAC write data register (FMAC_WDATA)

Address offset: 0x18

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WDATA[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **WDATA[15:0]**: Write data

When a write access to this register occurs, the write data are transferred to the address offset indicated by the write pointer. The pointer address is automatically incremented after each write access.

19.4.8 FMAC read data register (FMAC_RDATA)

Address offset: 0x1C

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RDATA[15:0]**: Read data

When a read access to this register occurs, the read data are the contents of the Y output buffer at the address offset indicated by the READ pointer. The pointer address is automatically incremented after each read access.

19.4.9 FMAC register map

Table 133.FMAC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

20 Hardware signal processor (HSP)

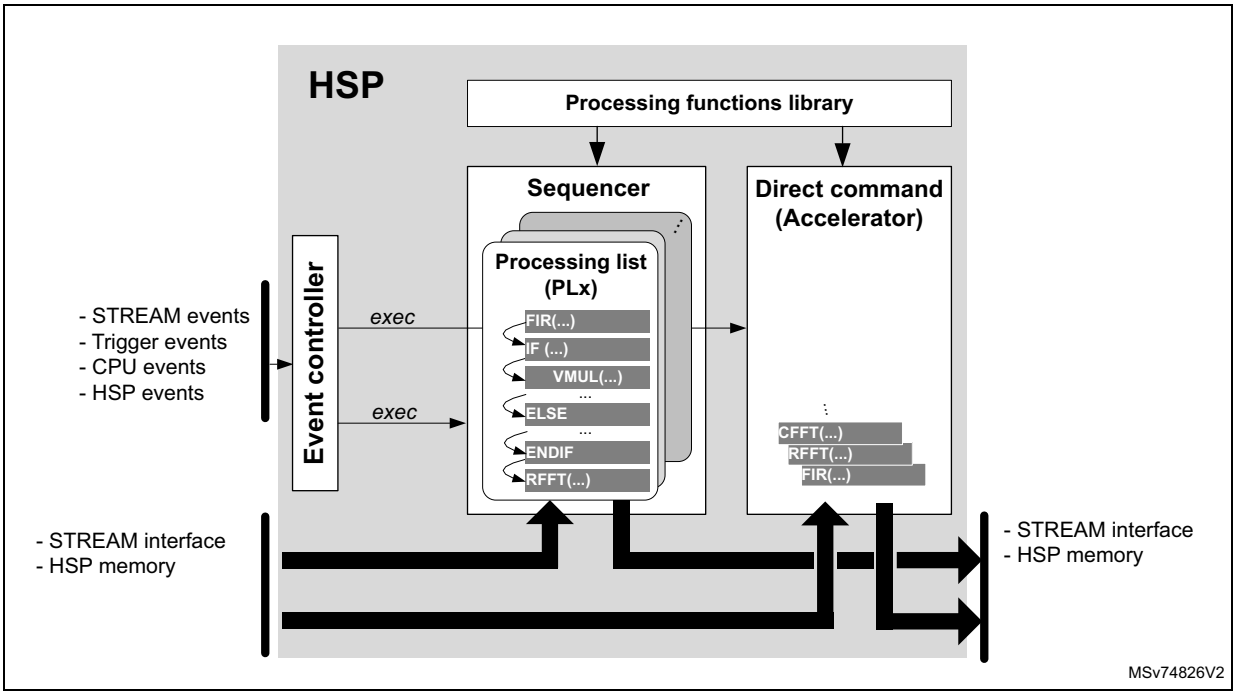
20.1 HSP introduction

The hardware signal processor (HSP) is a dedicated signal processor engine. It can offload and speed up operations initially handled by the CPU. It targets the following application areas:

- Control loops
- Metering
- Small convolutional neural networks
- General-purpose signal processing

The HSP is built around a dedicated high-performance signal processor engine (SPE) working in 32-bit floating point or 8-bit integer. The SPE runs the HSP microcode (also named firmware).

A part of the microcode (firmware) is embedded in a private ROM. This microcode provides optimized signal processing functions, named “processing functions”.



The HSP can perform sequences of operations autonomously. These sequences are called “processing lists”.

As shown in the figure below, the HSP proposes a sequencer to handle the processing lists, and a direct command interface for the accelerator function.

The peripherals connected to the event controller generate events according to their activity. These events are handled by the event controller, and the event having the highest priority activates a task. This task executes the recorded processing list. If other events are pending, the sequence is repeated when the execution of the current processing list is completed.

Each task can host a single processing list.

Figure 156. HSP functional view

The application can record up to 37 processing lists into the HSP during the runtime. A processing list represents an HSP task. The execution of processing lists is triggered by events. The event sources can be:

- STREAM interface
- Trigger signals
- Software triggers

The HSP offers the following bus interfaces:

- An AHB slave port interface giving access to the HSP control registers (SP0)
- An AHB slave port interface giving access to the HSP memories (SP1)

When the data to be processed are 16- or 32-bit integers, the HSP converts them into a 32-bit floating-point format before performing the required processing.

If the data are in 8-bit integer or 32-bit floating-point format, the HSP processes them directly.

Data exchange between the HSP and the application can be done in several ways:

- Using the BRAM as a shared memory
- Using the STREAM interface

After each processing task performed in 32-bit floating-point format, the HSP can provide the data either in floating-point or integer format. Processing performed using an 8-bit integer returns results in 8-bit integer format.

See the user manual *HSP processing functions on STM32 MCUs* (UM3360).

Finally, the HSP offers an interrupt interface allowing the application to receive interrupts from a wide variety of events.

20.2 HSP main features

- AHB slave interface for memories (SP1)
- AHB slave interface for register control (SP0)
- Rich set of signal processing commands (such as FFT, FIR, or IIR)
- Support of 2D convolution for neural networks
- Operations performed in floating-point single precision compliant with the IEEE-754 standard

  The HSP FPU is compliant with the IEEE-754 standard with the following limitations:
  - Denormals are flushed to zero.
  - Only round to the nearest is supported.
- Supported data formats:
  - Signed/unsigned 16-bit integer format
  - Signed/unsigned 32-bit integer format
  - 32-bit floating-point format
  - 8-bit integer (CNN functions)
- Trigger inputs
- Break generation
- STREAM interface
- Trigger outputs
- Interrupt services

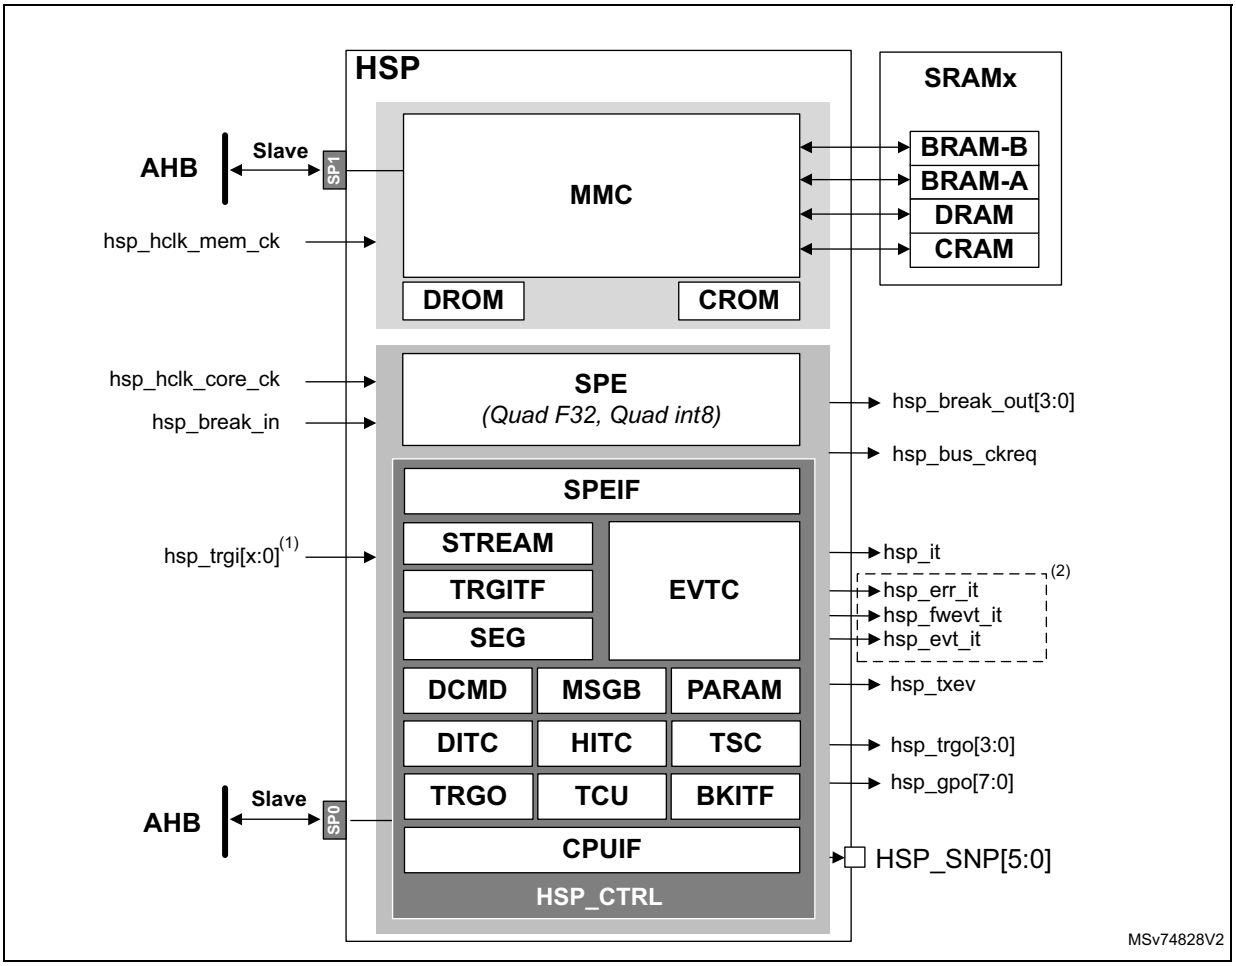
Targeted applications:

- Audio: speech capture
- Motor control
- Digital power
- Metering

20.3 HSP implementation

The table below details the set of features implemented into the product.

Table 134. HSP features for STM32H7Power(1)



Item	Values
SRAM instance containing the BRAM, CRAM and DRAM.	AHBSRAM3
CRAM size	20 Kbytes
DRAM size	12 Kbytes
BRAM size	32 Kbytes
Global interrupt (hsp_global_it)	X
Error interrupt (hsp_err_it)	-
Event interrupt (hsp_evt_it)	-
Firmware event interrupt (hsp_fwevt_it)	-
HSPDMA and STI function	-
Number of DMA channels	-
Number of DMA requests which can be connected to peripherals	-
Number of STIAP ports	-
Number of trigger inputs	20
Direct ADC interface function	-
Number of ADC interfaces	-
Maximum number of processing lists	37

1. ‘X’ = supported, ‘-’ = not supported.

20.4 HSP functional description

20.4.1 HSP block diagram

Figure 157. HSP block diagram

1. The number of trigger inputs depends on the product, see *Section 20.3: HSP implementation*.
2. These interrupt lines are not always externally connected, see *Section 20.3: HSP implementation*. However, all interrupt source signals are internally connected to the global interrupt signal (hsp_it), which is connected to the CPU interrupt controller on all products. Please see *Section 20.4.12: HSP interrupt controller (HITC)* for details.

20.4.2 HSP pins and internal signals

Table 135. HSP external pins

Pin name	Pin type	Comment
HSP_SNP[5:0]	Output	HSP outputs for debug and diagnostics

Table 136. HSP internal signals

Signal name	Signal type	Comment
hsp_hclk_mem_ck	Input	Bus clock input for memories
hsp_hclk_core_ck	Input	Bus clock input for HSP core
hsp_bus_ckreq	Output	Bus interface clock request output
hsp_break_out[3:0]	Output	HSP break output signals
hsp_break_in	Input	HSP break input signal
hsp_it	Output	HSP global interrupt
hsp_err_it(1)	Output	HSP error interrupt
hsp_evt_it(1)	Output	HSP event interrupt
hsp_fwevt_it(1)	Output	HSP firmware event interrupt
hsp_txev	Output	HSP direct command complete event.
hsp_trgi[x:0](2)	Input	HSP trigger input signals
hsp_trgo[3:0]	Output	HSP trigger output signals
hsp_gpo[7:0]	Output	HSP general-purpose output signals
hsp_dbgmcu_stp	Input	Halt request from DBGMCU (check DBG section to see if the feature is available)

1. This interrupt line is not always connected to the interrupt controller, see *Section 20.3: HSP implementation*.
2. The number of trigger input signals depends on the product, see *Section 20.3: HSP implementation*.

The table below shows how HSP trigger inputs are connected in the product.

Table 137.HSP trigger input connections for STM32H7Power

Input trigger names	Trigger sources
hsp_trgi0	GPDMA1 dma_chan_tc[15]
hsp_trgi1	GPDMA1 dma_chan_tc[14]
hsp_trgi2	GPDMA1 dma_chan_tc[13]
hsp_trgi3	GPDMA1 dma_chan_tc[12]
hsp_trgi4	EXTI0
hsp_trgi5	NPU host_int_3
hsp_trgi6	TIM1 TRGO
hsp_trgi7	TIM1 TRGO2
hsp_trgi8	TIM2 TRGO
hsp_trgi9	TIM3 TRGO
hsp_trgi10	TIM6_TRGO
hsp_trgi11	TIM7_TRGO
hsp_trgi12	TIM8_TRGO

Table 137.HSP trigger input connections for STM32H7Power (continued)

Input trigger names	Trigger sources
hsp_trgi13	TIM8_TRGO2

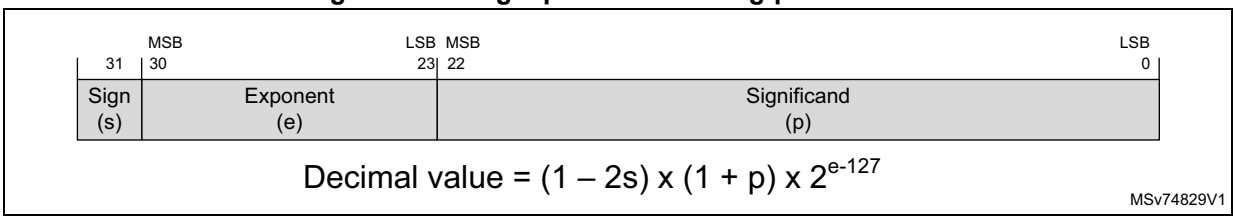
hsp_break_in	-

20.4.3 Floating-point format

The HSP is a powerful and flexible signal processing engine, able to perform operations on data located into its shared memory (BRAM).



The HSP can work by processing data blocks (vector) or sample per sample. The latter mode is particularly helpful for closed-loop control.

The HSP supports several kinds of data input formats: 8-, 16-, 32-bit integers, and 32-bit floating points. For simplification, this document refers to 32-bit floating points as “float32”. In the same way, signed 8-bit integers are named “int8”.

The SPE embedded into the HSP performs its computation in single-precision floating points (float32) or 8-bit integers (int8).

As defined by the IEEE-754 standard, the single-precision floating-point numbers are stored into the memory as shown in the figure below.

Figure 158. Single-precision floating-point format

The single precision floating-point number includes:

- A sign bit
- A significand part of 23 bits
- An exponent of 8 bits (-126 to + 127)

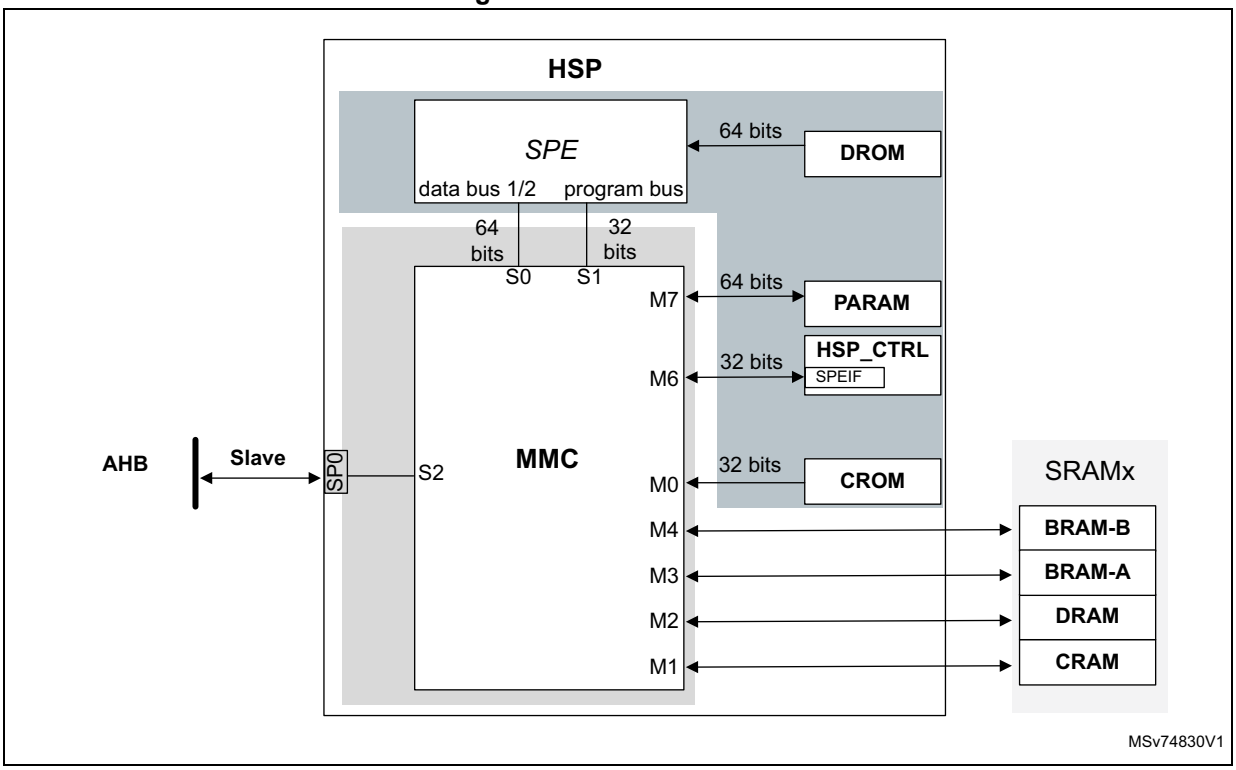
The first leading 1 bit of a normalized significand is “hidden”, or “implicit”, extending the significand to 24-bit precision.

Floating point greatly simplifies working with large numbers, up to about $\pm 3.4e^{38}$, and small numbers down to about $\pm 1.17e^{-38}$.

The HSP embeds the capability of converting integers into float32 and vice versa.

The HSP also supports integer 8-bit operations. They are dedicated to run convolutional neural networks. In this mode, the internal accumulator size is 32 bits to keep the best accuracy.

20.4.4 Memory management



A memory controller (MMC) manages the SRAM shared with the HSP. This SRAM can be used by the application like any other SRAM or dedicated to HSP activity when the HSP is activated (see *Section 20.3: HSP implementation* to check which SRAM is shared with the HSP on the product). This SRAM is split into five different sections when the application intends to use the HSP. The different sections are listed below:

- The code RAM (CRAM) section, containing the HSP firmware program, plug-ins, and processing lists
- The data RAM (DRAM) section, containing SPE sensitive data and processing list parameters
- The buffer RAM A (BRAM-A), RAM B (BRAM-B), and RAM-AB sections, containing the working data, filter coefficients, and filter states

In addition, the HSP embeds a code ROM and a data ROM:

- The code ROM (CROM) contains the generic signal processing functions library.
- The data ROM (DROM) contains constants, such as FFT coefficients.

Figure 159. MMC overview

Memory protection and sharing

The access to the memory shared with the HSP is controlled by the MMC (memory controller) block. After a system reset, this SRAM is available for the application, and can be used as a general-purpose SRAM.

Note: This SRAM can be enabled or disabled via an RCC control bit. Make sure it is enabled before using it.

The BRAM-A, BRAM-B, and BRAM-AB sections are always shared with the application and are generally used for data exchanges and working buffers.

The application can restrict the access to CRAM and DRAM sections with the CDRLCK[1:0] bitfield in the *HSP control register (HSP_CR)*. CRAM and DRAM access filtering works as follows:

- CDRLCK[1:0] = 0: read and write access through the AHB slave of CRAM and DRAM is allowed.
- CDRLCK[1:0] = 1: write access to CRAM and DRAM is not allowed. Any read access is allowed. Only an HSP reset can restore write access to these memories.
- CDRLCK[1:0] = 2 or 3: read and write access to CRAM and DRAM is not allowed. Only an HSP reset can restore read and write access to these memories.

An invalid application read access to a RAM protected by CDRLCK[1:0] returns 0. An invalid application write access to a RAM protected by CDRLCK[1:0] is ignored. In both cases, the ACCERRF and SAHBERR flags are set.

Accessing above BRAMAB_END (see *Figure 160*) also generates a bus error. The ACCERRF and SAHBERR flags are set as well.

See *Section 20.4.12: HSP interrupt controller (HITC)*.

The access restrictions programmed with CDRLCK[1:0] do not affect the SPE.

*Note: The application must first enable the **hsp_hclk_core_ck** (via the RCC) to change the value of CDRLCK[1:0]. Once CDRLCK[1:0] is updated, the **hsp_hclk_core_ck** can be disabled.*

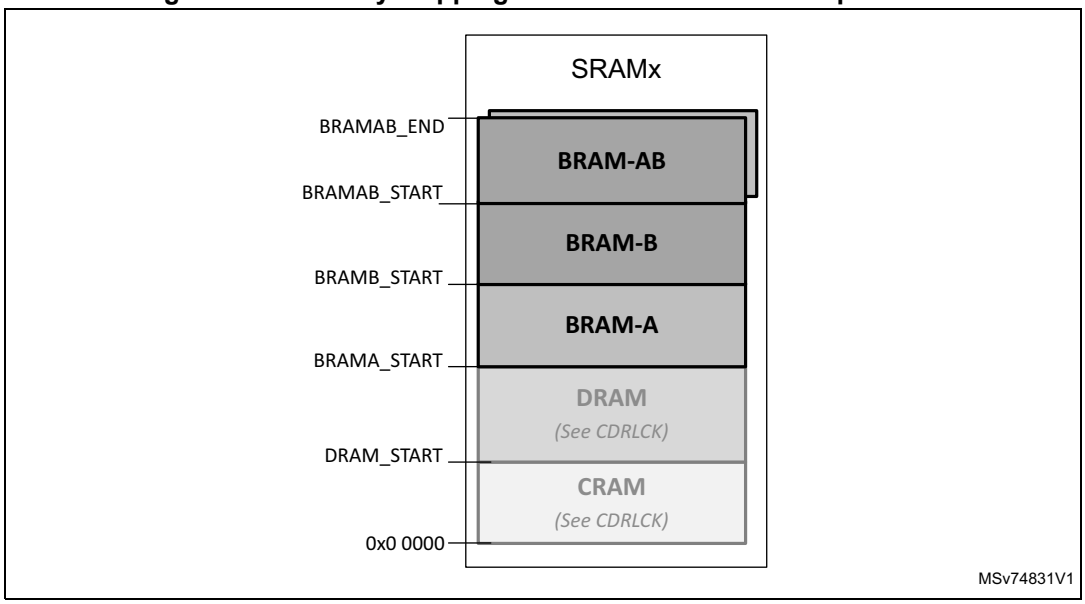
If the HSP was previously activated, it is recommended to reset the HSP before reusing the shared SRAM. The HSP reset is handled by the RCC.

Table 140 shows the address offset of each memory section. The BRAM is seen as two single ports, or like a dual port (BRAM-AB). Depending on the operations requested from the HSP, the application must use a dual-port BRAM or single-port BRAMs.

Table 140. Memory mapping seen from MMC AHB slave(1)

Section start/stop acronym	Generic address offset (bytes)
BRAMAB_END	BRAMAB_START + (BRAM_SIZE * 512) - 1
BRAMAB_START	BRAMB_START + BRAM_SIZE * 512
BRAMB_START	BRAMA_START + BRAM_SIZE * 512
BRAMA_START	DRAM_START+ DRAM_SIZE * 1024
DRAM_START	CRAM_SIZE * 1024
CRAM_START	0

1. CRAM_SIZE, DRAM_SIZE, and BRAM_SIZE represent the size, in Kbytes, of CRAM, DRAM, and BRAM respectively. Refer to section *Section 20.3: HSP implementation* for memory size.



As shown in *Figure 160*, the application sees the SRAM shared with the HSP as a contiguous memory block, with the capacity to restrict access to CRAM and DRAM blocks. When the HSP is enabled, the CPU can still access this SRAM, but the HSP also uses it.

For the HSP to run safely, it is recommended to write-protect CRAM and DRAM as soon as the application has loaded the main firmware code and its data into CRAM and DRAM.

The CPU can access:

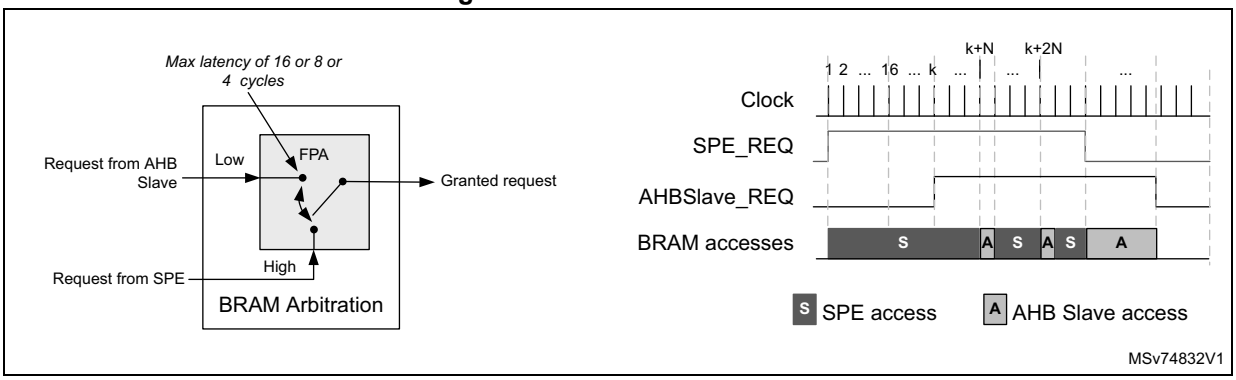
- BRAM-A, BRAM-B, and DRAM in 8, 16, or 32 bits (and in 64 bits, if the product supports it)
- CRAM in 8, 16, or 32 bits.

Figure 160. Memory mapping seen from the AHB slave port SP1

Memory resource arbitration

When the HSP is running, the BRAM-AB, BRAM-A, or BRAM-B can be accessed by the SPE or by the application through the AHB slave interface.

To keep the best SPE performances, the MMC arbiter gives the highest priority to the SPE. However, some processing done by the SPE can take 100% of the BRAM resource, preventing the other requesters from accessing the BRAM. To avoid this, the MMC ensures that if the application requests the BRAM resource, the resource is granted in the worst case after 16, 8, or 4 cycles. BARB[1:0] in the *HSP control register (HSP_CR)* allows the selection of one of these values.



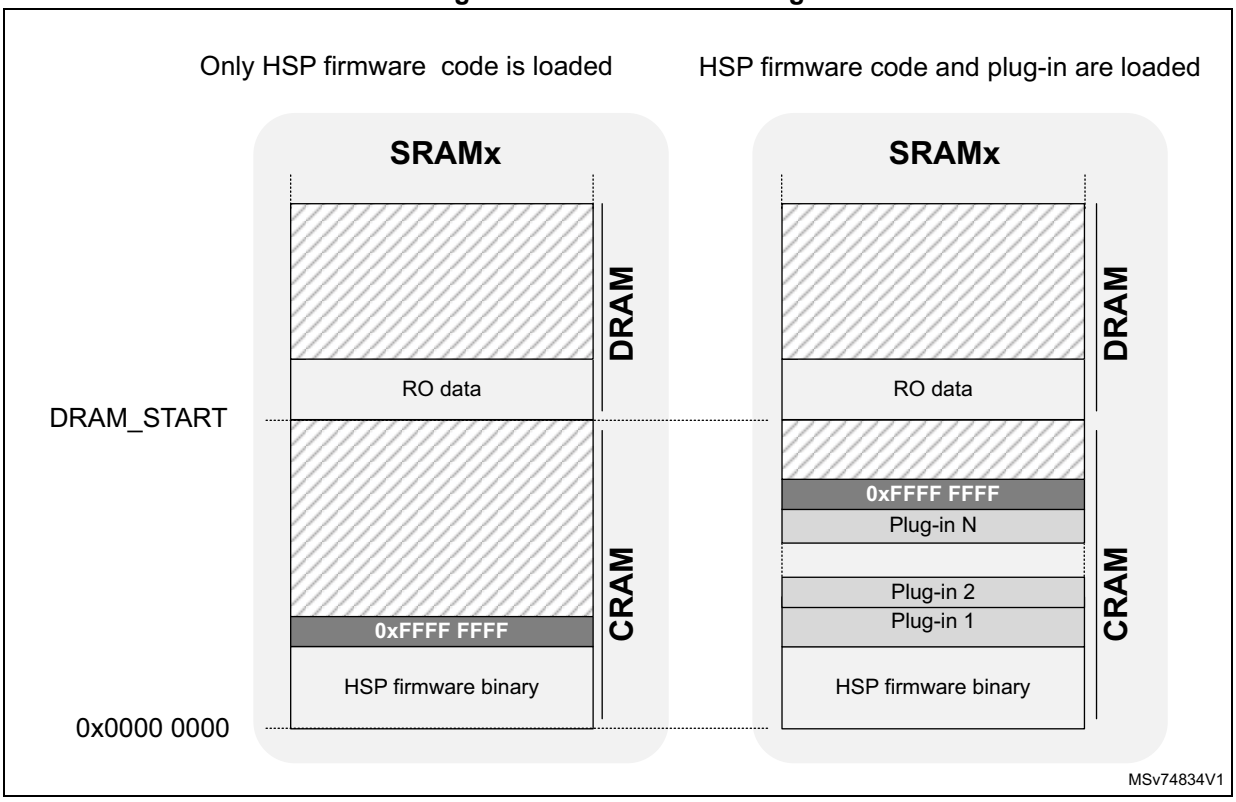
As shown in *Figure 161*, a fixed-priority arbiter (FPA) ensures that the request coming from the AHB slave interface is granted at most every 16, 8, or 4 cycles. This mechanism prevents important degradation of SPE performances.

The right part of the figure shows an arbitration example.

- The SPE occupies 100% of the BRAM bandwidth. After k clock periods, the AHB slave must access the BRAM-AB.
- After N cycles (k + N), the AHB slave can perform its transaction. N can be either 4, 8, or 16.

When the SPE no longer uses the BRAM, the AHB slave transactions are served immediately using the full bandwidth.

Figure 161. BRAM arbitration



20.4.5 HSP boot

Before running the HSP, the application must copy the HSP firmware code into the code RAM (CRAM) and data RAM (DRAM). Additionally, some applications can also request to copy plug-ins. Plug-ins are extra binary codes provided by STMicroelectronics and used to correct the limitations of existing processing functions, or to add new processing functions not included in the original product.

The binary files must be copied as shown in *Figure 162*:

- If no plug-ins are loaded, the application must write a termination word (0xFFFF FFFF) right after the copied binary code.
- If plug-ins must be added, they must be copied contiguous to the HSP firmware binary code, and the termination word must be added right after the last plug-in.

Figure 162. HSP code loading

Refer to *Section 20.3: HSP implementation* to find which SRAM instance contains BRAM, CRAM, and DRAM on the product, as well as the relative address offset.

The application must execute the sequence below to run the HSP properly:

1. Reset the HSP using the reset bit in the RCC.
2. Copy the HSP firmware binary code and the RO data into the CRAM and DRAM sections respectively. Copy plug-in binaries, if any, into the CRAM.
3. Enable the HSP core clock via the RCC.
4. If needed, protect CRAM and DRAM sections against accidental corruption via CDRLCK[1:0].
5. Set the BOOTEN bit to run the HSP. The HSP executes the code starting at the CRAM base address of the CRAM, and enters the HSPCFG state.

6. In HSPCFG state, the HSP firmware performs the following operations:
   a) Initialize the internal HSP subblocks. TSKLUT is also initialized to only allow the activation of the supervisor (PLSUP) or Direct Command Accelerator functions (PLDCMD).
   b) Copy the firmware versions and SPE into HSP_FWVERR and HSP_SPEVERR.
   c) Set BSTAT[3:0] to 1, indicating it is waiting for the FW_INIT command.
7. The HSP firmware is now ready to accept the FW_INIT command.
8. When the FW_INIT command is complete, the HSP firmware activates the plugin codes, if any. This phase sets BSTAT[3:0] to 8.
9. The HSP enters the RUN phase and the WFE state, and sets BSTAT[3:0] to 2. As soon as an enabled event is activated, the HSP exits the WFE state and goes to:
   a) PLRUN if the selected event is valid (meaning it is associated with an existing processing list). The HSP firmware executes the processing list corresponding to the selected event, and goes back to WFE.
   b) PLSUP if the selected event corresponds to the supervisor. The HSP firmware executes the command sent by the application and goes back to WFE. Processing lists are created in this mode.
   c) PLDCMD if a direct command is programmed via the DCMD block.
   d) PLFAIL if the selected event is not valid.

   In PLDCMD mode, the HSP firmware executes the command sent by the application and goes back to WFE.

   In PLFAIL, the HSP firmware sets the FWERRF bit, sets the firmware error code in FWERRN[9:0], and goes back to WFE.

If an error occurs during this initialization process, the HSP firmware goes to the CFGFAIL state. In the CFGFAIL state, BSTAT[3:0] is set to 9. To set the HSP firmware back to the HSPCFG state, the HSP must be reset through the RCC.

When the HSP firmware initialization is completed, the application can enable the events, which are supposed to trigger the programmed processing list.

BOOTEN, CDRLCK[1:0], and BSTAT[3:0] are located in the *HSP control register (HSP_CR)*.

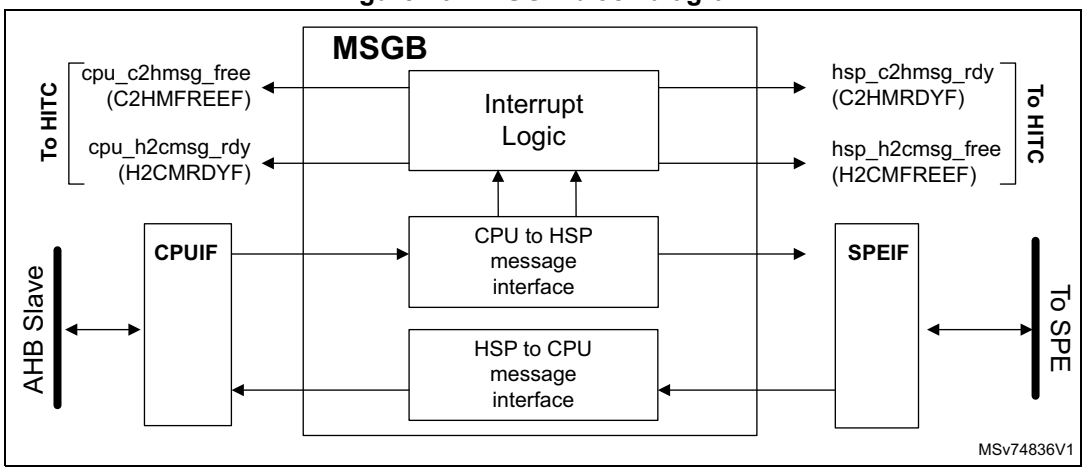
Figure 163. HSP start-up

The table below shows the different values BSTAT can take.

Table 141. BSTAT possible values

Conditions	BSTAT[3:0]
Information	
Default value after reset	0b0000
The HSP firmware started	0b0010
The HSP firmware waits for firmware initialization command (FW_INIT)	0b0001
The HSP firmware is in RUN phase	0b0011
The HSP firmware is recording a processing list	0b0100
Errors	
The HSP firmware is in CFGFAIL state	0b1100

20.4.6 Message box (MSGB)



The message box (MSGB) offers various services dedicated to the HSP firmware configuration.

The MSGB block contains an HSP-to-CPU and a CPU-to-HSP message interface with:

- Synchronization flags and interrupt capabilities
- Two payload registers

The MSGB is generally used with the *HSP parameter register x (HSP_PARAMRx)* to provide the message payload. Messages are used to configure the HSP firmware part, especially to record the processing list.

Figure 164. MSGB block diagram

CPU to HSP message interface

Using polling mode

When the CPU wants to send a message to the HSP, it has to do the following:

1. Read C2HSEM in the *HSP CPU-to-HSP semaphore register (HSP_C2HSEMR)*.
2. Wait until C2HSEM = 0, indicating that the previous message has been read by the HSP and a new message can be transferred.
3. Write a new value in the *HSP CPU-to-HSP message data register (HSP_C2HMSGDR)*.
4. Set C2HSEM.

On its side, the HSP does the following:

1. Read the C2HSEM bit.
2. Wait until C2HSEM = 1, indicating that a new message is available.
3. Read the C2HDATA.
4. Clear C2HSEM to indicate that the message has been read.

Using interrupt mode

The MSGB can generate interrupts to the CPU when the CPU-to-HSP mailbox is ready to receive a new message (through the C2HMFREEF flag).

The CPU must first enable the interrupts by executing the sequence below:

1. Clear the C2HMFREEF flag by setting C2HMFREEC in the *HSP events interrupt clear register (HSP_EVT_ICR)*.
2. Allow the C2HMFREEF flag to generate an interrupt by setting C2HMFREEIE in the *HSP events interrupt enable register (HSP_EVT_IER)*.

When an event interrupt occurs, the interrupt subroutine (ISR) must do the following:

1. Read the C2HMFREEF flag in the *HSP events interrupt status register (HSP_EVT_ISR)*.
2. If C2HMFREEF is set:
   - The CPU can clear this flag by setting C2HMFREEC.
   - The CPU can write a new message.
   - When the CPU wants to notify the HSP that a new message is available, C2HSEM must be set.

   The last two steps can be done outside the ISR.

HSP-to-CPU message interface

Using polling mode

When the HSP wants to send a message to the CPU, it does the following:

1. Read the H2CSEM flag.
2. Wait until H2CSEM = 0, indicating that the previous message has been read by the CPU and the content of HSP_SPE_H2CMSGDR can be overwritten.
3. Write the new value into C2HDATA.
4. Set H2CSEM.

On its side, the CPU does the following:

1. Read H2CSEM in the *HSP HSP-to-CPU semaphore register (HSP_H2CSEMR)*.
2. Wait until H2CSEM = 1, indicating that a new message is available.
3. Read the *HSP HSP-to-CPU message data register (HSP_H2CMSGDR)*.
4. Clear H2CSEM in the *HSP HSP-to-CPU semaphore register (HSP_H2CSEMR)* to indicate that the message has been read.

Note: Handling the MSGB in polling mode also sets H2CMRDYF and C2HMFREEF. Prior to using these flags, the software must clear them.

If the CPU and the HSP set and clear C2HSEM at the same time respectively, C2HSEM is cleared.

If the CPU and the HSP set and clear C2HSEM at the same time respectively, C2HSEM is cleared.

Using interrupt mode

The MSGB can generate interrupts to the CPU when a new message is available for the CPU (through the H2CMRDYF flag).

The CPU must first enable the interrupts by executing the sequence below:

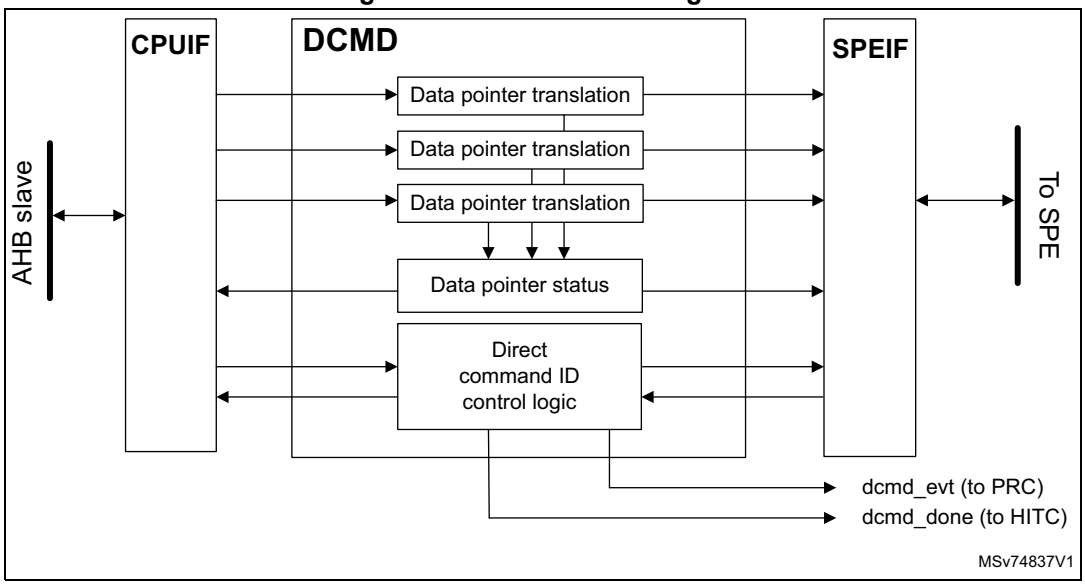
1. Clear the H2CMRDYF flag by setting the H2CMRDYC bit in the *HSP events interrupt clear register (HSP_EVT_ICR)*.
2. Allow the H2CMRDYF flag to generate an interrupt by setting the H2CMRDYIE bit in the *HSP events interrupt enable register (HSP_EVT_IER)*.

When an event interrupt occurs, the interrupt subroutine (ISR) must do the following:

1. Read the H2CMRDYF flag in the *HSP events interrupt status register (HSP_EVT_ISR)*.
2. If H2CMRDYF is set:
   - The CPU can clear this flag by setting H2CMRDYC.
   - The CPU can read the message.
   - When the CPU decides to free the message box, the H2CSEM bit must be cleared.

   The last two steps can be done outside the ISR.

20.4.7 Direct command interface (DCMD)



The direct command interface (DCMD) is dedicated to the execution of direct commands, reducing the command overhead in an efficient way. It is used for HSP accelerator mode. This block is controlled by the HSP with a PLDCMD dedicated processing list (refer to *Section 20.6.4: Executing direct commands (accelerator mode)*).

The DCMCD provides the following services:

- Direct command ID register, for triggering events
- Up to three data pointer interfaces
- Status flags

The DCMD is generally used with the *HSP parameter register x (HSP_PARAMRx)* to provide the parameters corresponding to the command that the application wants to execute.

Figure 165. DCMD block diagram

Prior to running a direct command, the SPE must perform the following preliminary operations:

1. Decode the command
2. Adapt the data pointer values
3. Execute the command

To reduce latency in command decoding, the DCMD block allows the SPE to start command decoding while the CPU is still providing the parameters.

By default, the DCMD block is enabled. DCMDDIS in the *HSP BUFF configuration register (HSP_BUFFCFGR)* controls the enabling and disabling of this function. This bit is write-once after an HSP reset. If the application wants to ensure that the DCMD cannot be accidentally disabled, it must clear DCMDDIS. If the application wants to disable the DCMD, DCMDDIS must be set.

The CPU can transmit the command ID to be executed by writing the command ID in the *HSP DCMD command ID register (HSP_DCMDIDR)*.

A write access to this register triggers two actions:

- It sets the DCBSY flag.
- It asserts the DCMD event (**dcmd_evt**).

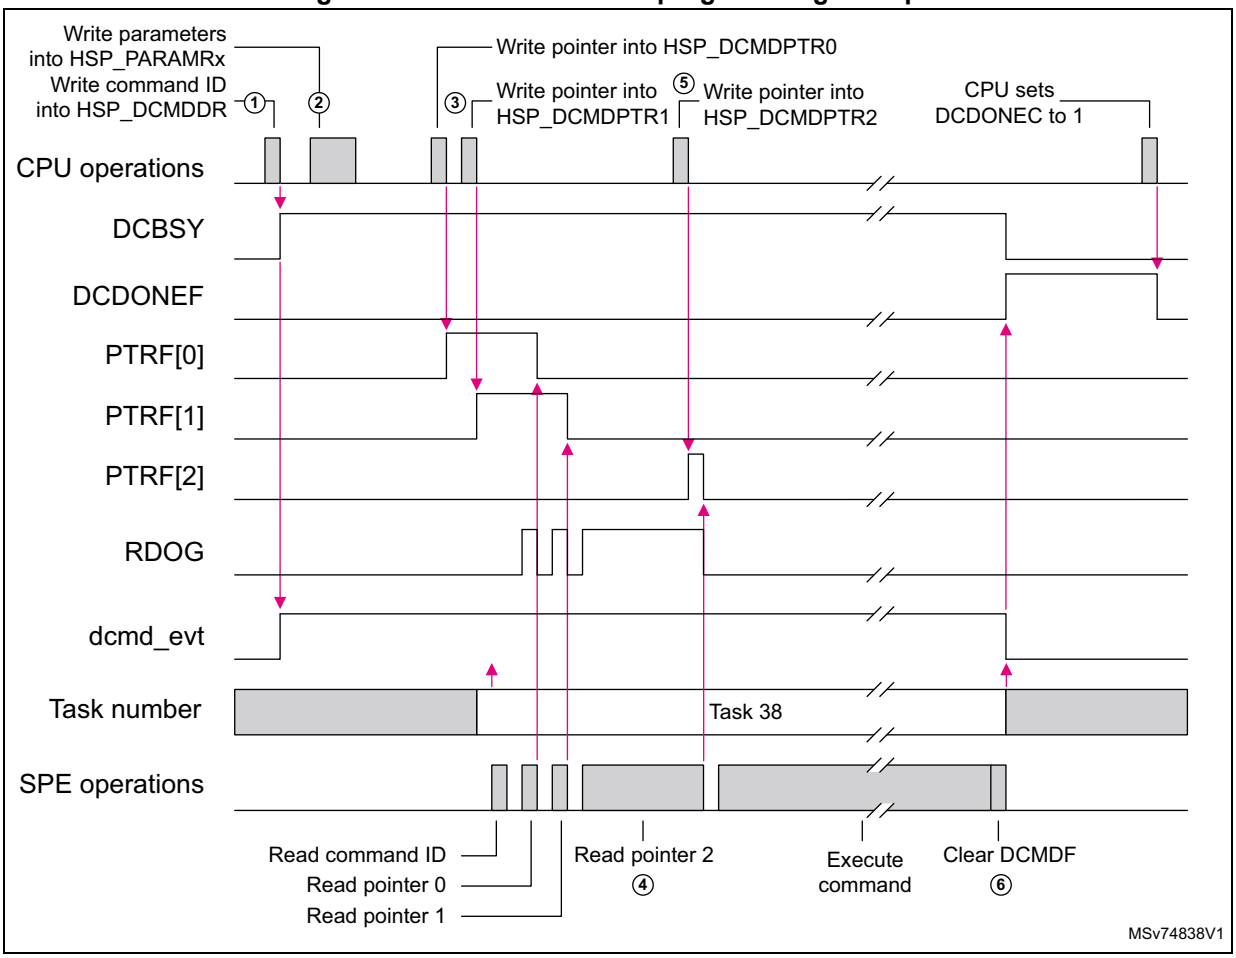
dcmd_evt triggers a processing list dedicated to the execution of direct commands. The number of this processing list is 38, and its priority is set to 26.

The DCBSY flag is cleared by the SPE when the direct command execution is completed.

The *HSP DCMD address pointer register x (HSP_DCMDPTRx)* allows the CPU to provide to the SPE the address pointers requested by the direct commands.

When the CPU writes an address pointer into one of the HSP_DCMDPTRx registers, the HSP hardware sets the corresponding PTRF[x] flag in the *HSP DCMD pointer status register (HSP_DCMDPTSR)*.

When the SPE reads this pointer, the DCMD hardware sets the corresponding PTRFx bit to zero. The DCMD also provides a bit (RDOG) indicating if the SPE is performing a read operation of one of the three data pointers. This bit can be used in a debug phase to check if the SPE is waiting for a data pointer value.



Note: If the SPE reads a pointer register not yet updated by the CPU, the SPE remains frozen on the read operation until the CPU has updated the corresponding pointer register.

The DCMD also offers the possibility to generate an interrupt when the DCBSY flag is cleared, meaning that the command has been completed. The interrupt is enabled by setting DCDONEIE in the *HSP events interrupt enable register (HSP_EVT_IER)*.

Figure 166 shows a typical example of a command programming sequence, and the behavior of the various signals. During an initialization sequence, the CPU is assumed to clear DCMDDIS.

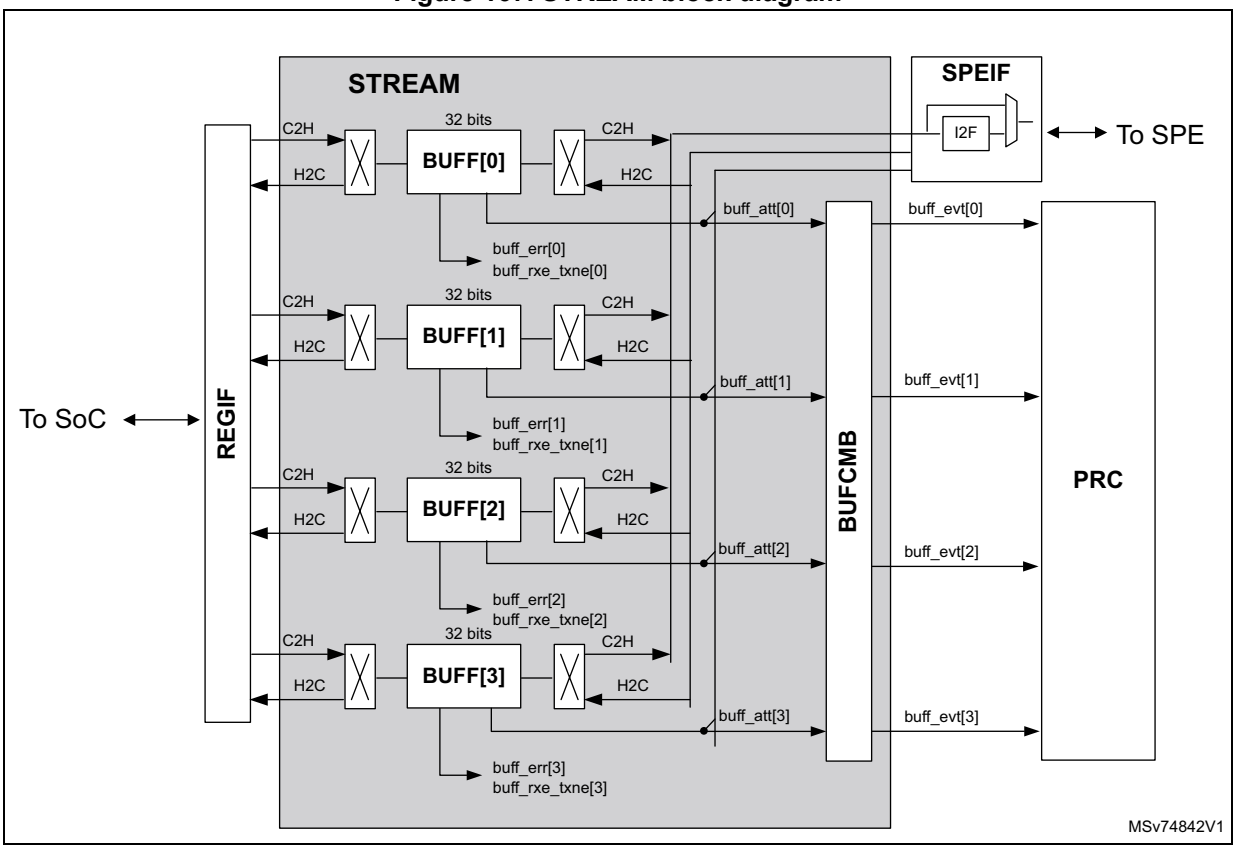
1. The CPU writes the command ID in the *HSP DCMD command ID register (HSP_DCMDIDR)*. The DCBSY and dcmd_evt are set (#1 in the figure).
2. The CPU writes data parameters in the *HSP parameter register x (HSP_PARAMRx)* (#2 in the figure).
3. The CPU starts to write the first two address pointers in the *HSP DCMD address pointer register x (HSP_DCMDPTRx)*. As soon as the EVTC allows it, task number 26 is activated (#3 in the figure).
4. The SPE first reads the command ID to check which command must be executed, and then starts to read the necessary address pointers. The first two address pointers are already available, but the SPE remains blocked for several cycles when reading the third pointer, because the CPU did not yet write it (#4 in the figure).
5. When the CPU writes the third pointer, the SPE gets it translated, and the command can be executed (#5 in the figure).
6. When the command execution is completed, the SPE clears the DCBSY flag. This action clears the dcmd_evt (#6 in the figure).
7. Finally, if DCDONEIE is set, an interrupt can be generated to inform that task execution has been completed. Then the CPU can clear the interrupt (and DCDONEF flag) by setting the clear bit (DCDONEC).

Figure 166. Direct command programming example

If the SPE reads a data pointer not written by the CPU, the SPE remains blocked in the reading operation. The SPE can no longer serve interrupts, nor enter debug mode. The SPE can exit this freeze state through one of the following actions:

- The application provides the expected data pointer.
- DCMDDIS is set (if possible). The SPE unfreezes, but executes a command with an invalid pointer, which could be unsafe.
- The HSP is reset.

The HSP also provides a signal event for the CPU named **hsp_txev,** indicating that the current direct command execution has been completed. Every time a direct command execution is completed, a single-cycle pulse is generated. DCMDEVEN in the *HSP control register (HSP_CR)* allows this function activation (see also *Section 20.4.12: HSP interrupt controller (HITC)*).



20.4.8 STREAM interface

The STREAM interface can be used if the application wants to trigger an HSP processing list when data are sent to or read from the STREAM interface. It allows the application to set up source- or sink-driven processing.

For example, a DAC associated with a DMA device can take its data from the STREAM interface. As soon as the STREAM interface is read by the DMA device, the SPE is advised and the associated processing list, recorded by the application during an initialization phase, is executed immediately. Typically, this processing list prepares the next sample for the DAC.

Conversely, an ADC associated with a DMA device can provide its data to the STREAM interface. As soon as the STREAM interface is written by the DMA device, the SPE is advised and the associated processing list, recorded by the application during an initialization phase, is executed immediately. Typically, this processing list processes the incoming sample and frees the STREAM interface for the next data.

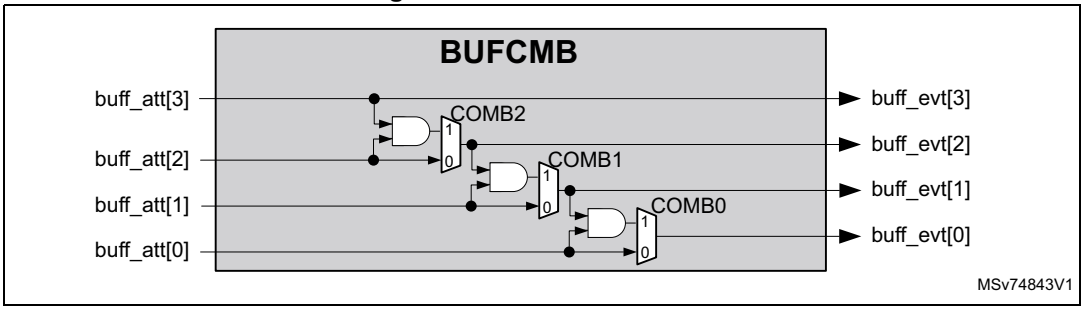
Figure 167. STREAM block diagram

The STREAM interface provides up to four data buffers of 32 bits. Each of them can be configured either in the CPU-to-HSP direction (C2H) or the HSP-to-CPU direction (H2C). Buffers configured in CPU-to-HSP direction are called C2HBUFF in this document, and buffers configured in HSP-to-CPU direction are called H2CBUFF.

These buffers can be accessed by the application through the *HSP BUFFx data register x (HSP_BUFFxDR)*.

The data provided by the CPU (C2H direction) can be converted to float32 automatically if the I2FEN bit in the *HSP BUFF configuration register (HSP_BUFFCFGR)* is set.

The conversion from integer to float32 only works for the following input formats:



- Signed integers up to 32 bits. The sign extension must always be performed up to 32 bits. The accuracy of a signed 32-bit integer is reduced to 24 bits due to the float32 format.
- Unsigned integers up to 31 bits. Bit 31 must be cleared. The accuracy is limited to 24 bits due to the float32 format.

The STREAM buffers configured in the C2H direction assert the **buff_att** signal when a data is written into a STREAM buffer by the application. The **buff_att** signal remains active as long as the SPE does not read the corresponding STREAM buffer.

The STREAM buffers configured in the H2C direction assert the **buff_att** signal when they are empty. The **buff_att** event signal remains active as long as the SPE does not write data into the corresponding STREAM buffer.

The BUFCMB block adds additional flexibility by combining the **buff_att**[x] signals to generate the buffer events (**buff_evt**[x]). The BUFCMB allows the generation of the **buff_evt**[x] event, when the corresponding **buff_att**[x] signal is activated or when both **buff_att**[x] and **buff_att**[x+1] signals are activated. The BUFCMB is configured in the *HSP BUFF configuration register (HSP_BUFFCFGR)*.

Figure 168. BUFCMB details

The table below lists some of the possible configurations:

Table 142. BUFFCMB programming examples

COMB2	COMB1	COMB0	-	Outputs
0	0	0	→	**buff_evt**[x] generated when **buff_att**[x] is activated
1	0	1	→	**buff_evt**[0] generated when **buff_att**[0] & **buff_att**[1] are activated **buff_evt**[1] generated when **buff_att**[1] is activated **buff_evt**[2] generated when **buff_att**[2] & **buff_att**[3] are activated **buff_evt**[3] generated when **buff_att**[3] is activated

Table 142. BUFFCMB programming examples (continued)

COMB2	COMB1	COMB0	-	Outputs
0	1	1	→	**buff_evt**[0] generated when **buff_att**[0] & **buff_att**[1] & **buff_att**[2] are activated **buff_evt**[1] generated when **buff_att**[1] & **buff_att**[2] are activated **buff_evt**[2] generated when **buff_att**[2] is activated **buff_evt**[3] generated when **buff_att**[3] is activated
1	1	1	→	**buff_evt**[0] generated when **buff_att**[0] & **buff_att**[1] &...& **buff_att**[3] are activated **buff_evt**[1] generated when **buff_att**[1] & **buff_att**[2] & **buff_att**[3] are activated **buff_evt**[2] generated when **buff_att**[2] & **buff_att**[3] are activated **buff_evt**[3] generated when **buff_att**[3] is activated

The CPU can configure the buffer directions and the BUFCMB with the *HSP BUFF configuration register (HSP_BUFFCFGR)*.

The STREAM interface is activated by setting STREAMEN in the *HSP BUFF configuration register (HSP_BUFFCFGR)*. When STREAMEN is set, it is no longer possible to change the buffer direction, nor to modify the BUFFCMB configuration.

Note: Clearing STREAMEN resets the STREAM block, and all pending buffer events are cleared. Any write access operation to the STREAM buffers is ignored, and read access returns the last data.

The STREAM interface generates an error signal for each buffer and the error signals **buff_err**[3:0] are asserted:

- If new data are written into a buffer configured in the C2H direction while the previous data have not been read by the SPE, an overrun error is detected. The new data are written, and the previous ones are lost.
- If a buffer configured in the H2C direction is read by the CPU while the SPE did not have time to write the new data, an underrun error is detected. In this case, the CPU reads the previous data.

These error signals activate the B[3:0]ERRF flags in the *HSP error interrupt status register (HSP_ERR_ISR)*. An interrupt to the CPU can be generated if the corresponding interrupt enable flag is set.

The STREAM interface also generates buffer status signals (**buff_rxe_txne**[3:0]). These signals set the corresponding B[3:0]EVTF in the *HSP events interrupt status register (HSP_EVT_ISR)* in each of the following conditions:

- If the corresponding C2H buffer is empty
- If the corresponding H2C buffer is not empty

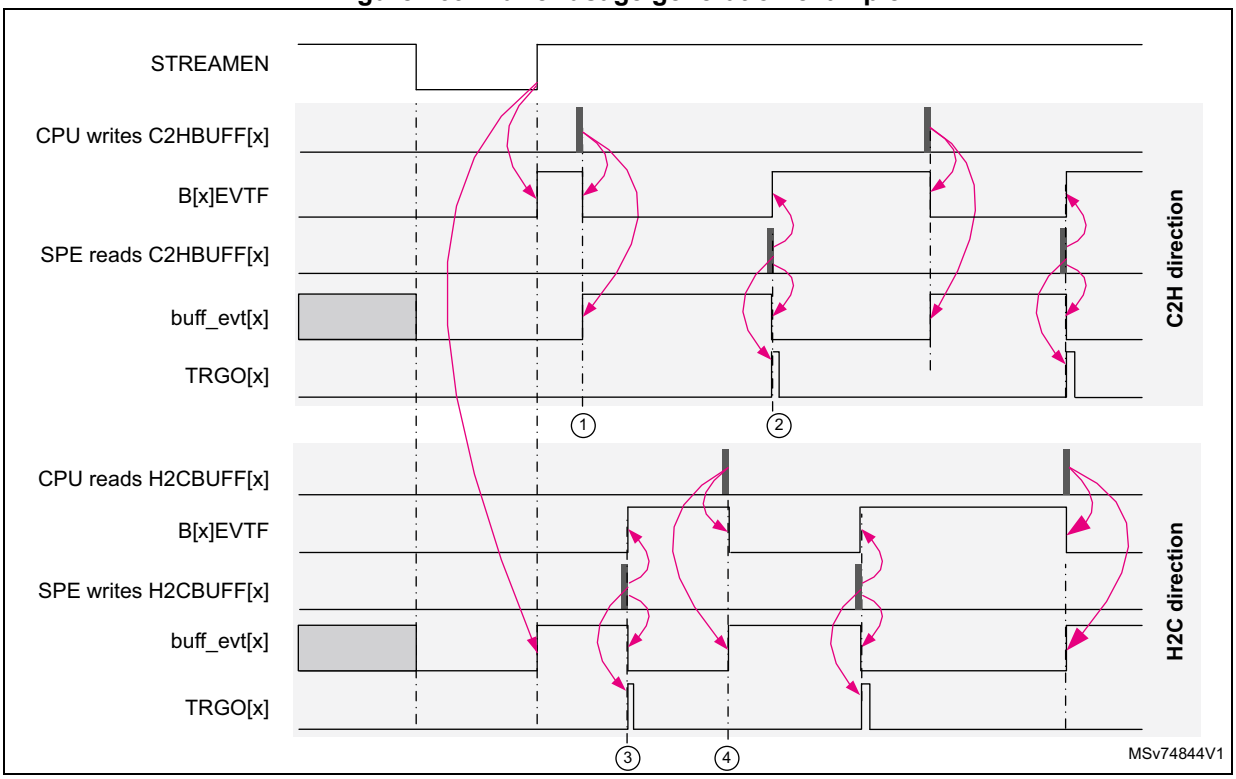
An interrupt to the CPU can be generated if the corresponding interrupt enable flag is set.

buff_att[x] signals are also provided to the TRGO to generate a trigger pulse on **hsp_trgo**[x] if the SPE reads a C2H buffer, or writes into the H2C buffer.

Figure 169 shows how buff_evt[x], BxEVTF, buff_evt[y], ByEVTF, and TRGO (when enabled) behave in the case of C2H and H2C buffers, when BUFCMB is configured with its

default values (bypass). When STREAMEN is cleared, the complete STREAM interface is reset and the **buff_evt**[x] and **buff_rxe_txne**[x] signals return to 0.

Case where BUFF[x] is set in the C2H direction:



1. As soon as STREAMEN is set, B[x]EVTF goes high, indicating that BUFF[x] is empty.
2. When the CPU writes into a BUFF[x], the B[x]EVTF flag goes back to 0 and **buff_evt**[x] is activated, requesting SPE processing (#1 in the figure).
3. When the SPE reads BUFF[x], the B[x]EVTF flag is set again, **buff_evt**[x] is released, and a TRGO[x] pulse is generated if selected for the STREAM buffer (#2 in the figure).

Case where BUFF[x] is set in the H2C direction:

1. As soon as STREAMEN is set, the **buff_evt**[y] signal goes high, requesting SPE activation.
2. When the SPE writes BUFF[x], the B[x]EVTF flag is set, **buff_evt**[x] is released, and a TRGO[y] pulse is generated if selected for the STREAM buffer (#3 in the figure).
3. When the CPU reads BUFF[x], the B[x]EVTF flag goes back to 0 and **buff_evt**[x] is activated, requesting SPE processing (#4 in the figure).

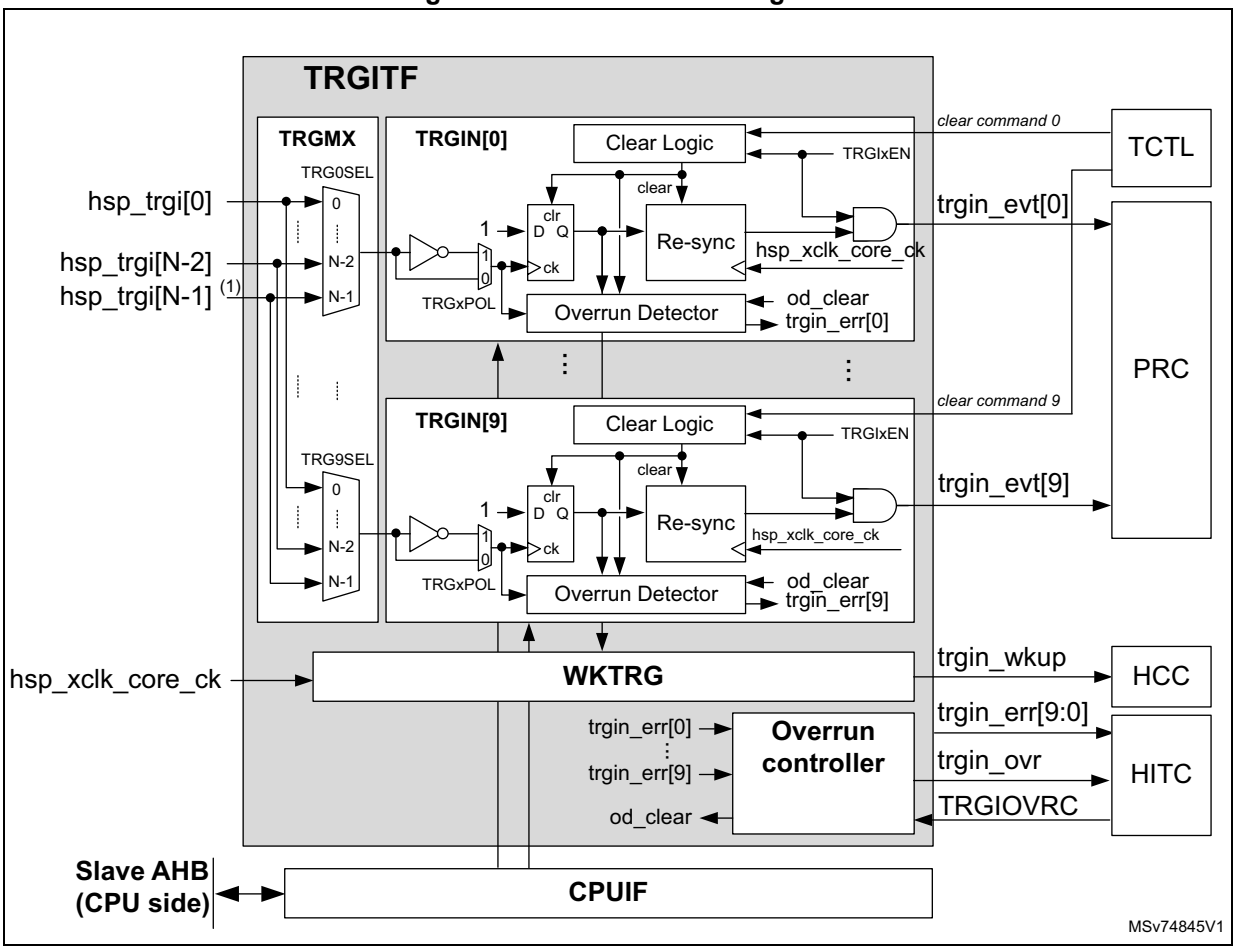
When the SPE writes into a BUFF[x], the **buff_evt**[y] flag goes back to 0, and a TRGO[x] pulse is generated if it is selected for the STREAM buffer (#1 in the figure).

Figure 169. Buffer usage generation example

20.4.9 Trigger input interface (TRGITF)

The HSP embeds up to 10 trigger input blocks, named TRGINx. Each TRGINx receives a trigger input signal from TRGMX. For each TRGINx, the application can select any trigger input signal, and program the activation of an event on a rising or falling edge of the selected signal.

TRGINx blocks can be configured through the *HSP TRGIN configuration register (HSP_TRGINCFGR)*, *HSP TRGIN input selection register 0 (HSP_TRGINSELR0)*, *HSP TRGIN input selection register 1 (HSP_TRGINSELR1)*, and *HSP TRGIN input selection register 2 (HSP_TRGINSELR2)*.



Each trigger interface can be independently enabled through the *HSP BUFF configuration register (HSP_BUFFCFGR)*.

The TRGIN blocks perform the following functions:

- Selecting the rising or falling edge sensitivity to generate an event.
- Storing a transition, even if this transition is faster than the EVTC internal clock.
- Performing the clock domain crossing.
- Storing the event until it is taken into account by the priority encoder.

The pending events are automatically cleared by the TCTL block when the SPE starts the corresponding processing.

Figure 170. TRGITF block diagram

1. The number of trigger inputs depends on the product (see *Section 20.3: HSP implementation*).

The TRGMX block allows the application to route any trigger input to any TRGIN interface.

The WKTRG block allows the detection of an enabled pending event even if the TRGITF is not clocked. This signal is used for autonomous functions or to wake up the product if needed.

Note: When TRGIxEN are cleared, the corresponding TRGIN logic is maintained to reset, avoiding the storage of a spurious transition, for example when the polarity is changed. The overrun detector and pending event are also reset when TRGIxEN is cleared.

It is recommended to change the polarity bit and the signal source selection when the corresponding TRGIxEN bit is cleared.

TRGIN overrun detection

Each TRGIN block has an overrun detector checking if a new trigger event occurred while the previous one was not yet taken into account by the SPE. The overrun detector sets the **trgin_err**[x] signal when an overrun is detected. The overrun controller generates the **trgin_ovr** signal, setting the TRGIOVRF flag. If the TRGIOVRIE bit is set, an interrupt is generated to the CPU. The application can check which TRGIN block causes the overrun by reading TRGIERR[9:0] in the *HSP error information register (HSP_ERRINFR)*. When the

application clears the TRGIOVRF flag through the TRGIOVRC bit, all overrun detectors are reset.

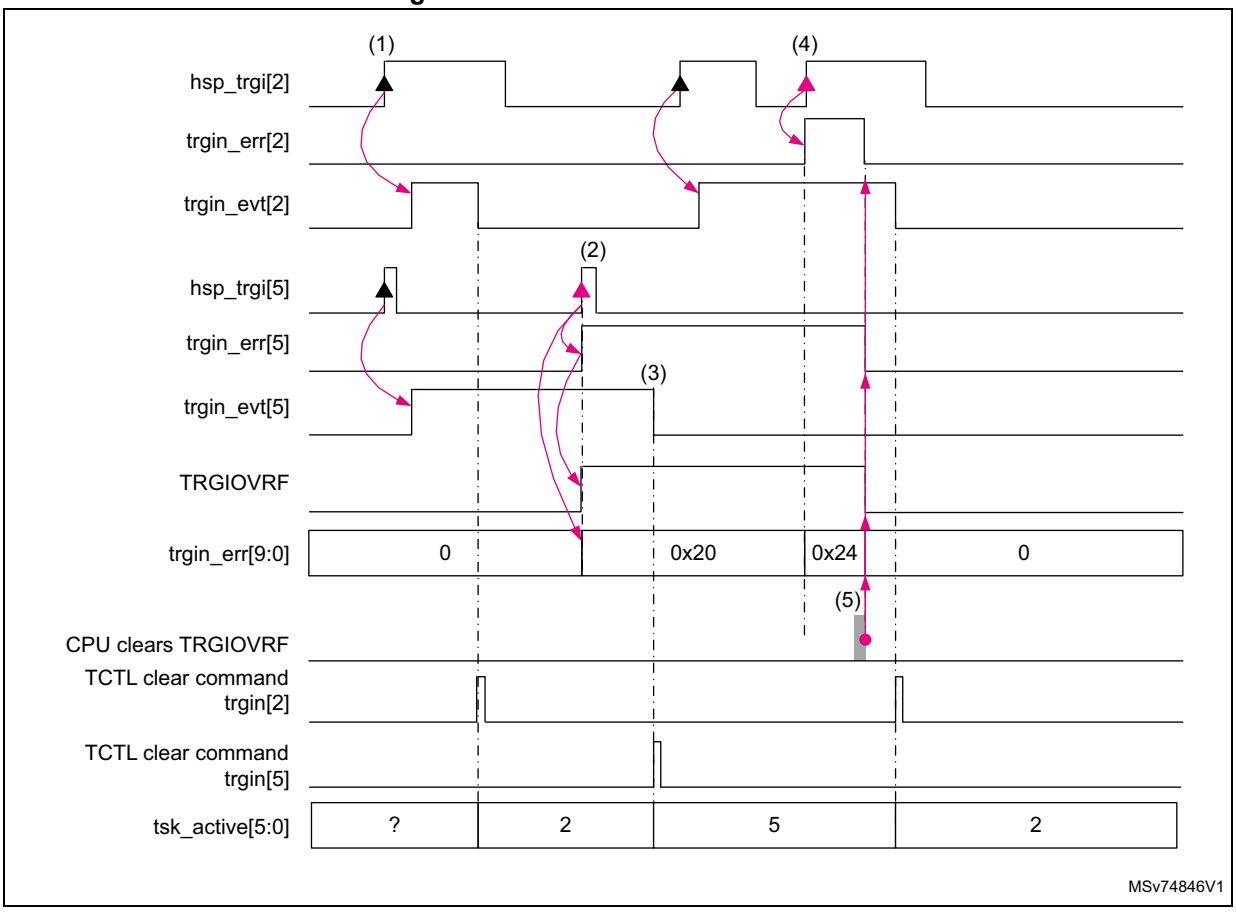
See *Section 20.4.12: HSP interrupt controller (HITC)*.

*Note: The overrun function does not work when **hsp_hclk_core_ck** is not present.*

Figure 171 shows a case of overrun detection, using two TRGIN inputs. In the example, **trgin_evt**[2] activates the task number 2, and **trgin_evt**[5] activates the task number 5.

hsp_trgi[2] and **hsp_trgi**[5] receive an event at the same time (#1 in the figure). **trgin_evt**[2] and **trgin_evt**[5] are activated. In the example, a higher priority is given to **trgin_evt**[2], which is executed as soon as the SPE is available. **tsk_active**[5:0] indicates that task number 2 is in execution.

While the **trgin_evt**[5] event is pending, a second trigger is detected in the **hsp_trgi**[5] input, causing an overrun error (#2 in the figure). The flag TRGIOVRF is set, and **trgin_err**[9:0] is set to 0x20 (bit 5 set). An interrupt can be activated for the application.



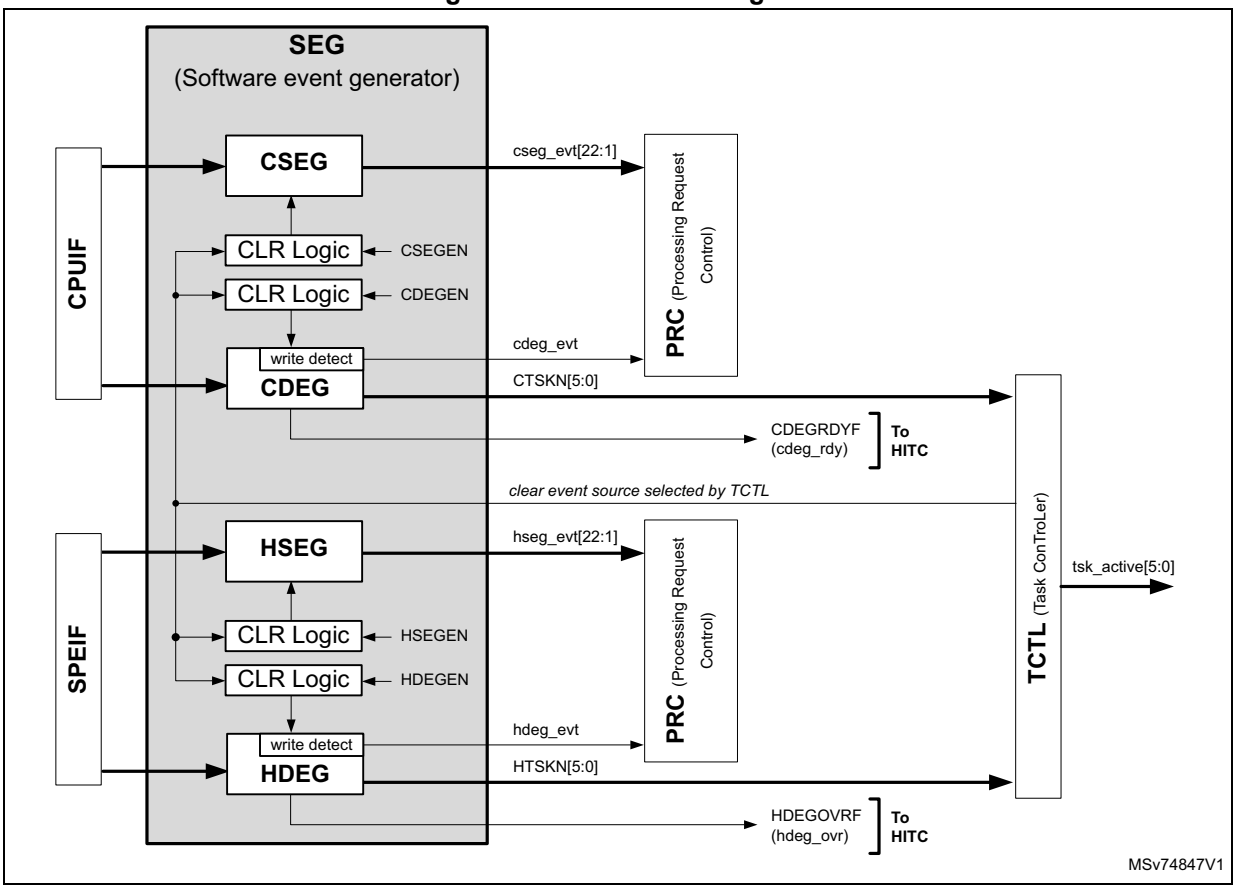
The SPE completed task number 2, and the HSP can serve the pending request from **trgin_evt**[5]. Task 5 is activated (#3 in the figure).

The **hsp_trgi**[2] receives two new triggers, the first one activates **trgin_evt**[2] and the second one activates the overrun error (#4 in the figure). The TRGIOVRF was already set, and the **trgin_err**[9:0] value is updated to 0x24 (bits 5 and 2 set).

The application reads **trgin_err**[9:0] and clears TRGIOVRF (#5 in the figure). **trgin_err**[x], TRGIOVRF, and **trgin_err**[9:0] are reset. When the SPE completes task 5, the pending event is served and task 2 is executed again.

Note: Two events have been lost due to overrun.

Figure 171. TRGIN overrun detection



20.4.10 Software events generator (SEG)

The CPU can trigger events:

- By using the event lines shared with STREAM and TRGITF, through the CPU shared event generator (CSEG) block.
- By using the dedicated event line input 27 through the CPU-dedicated event generator (CDEG) block.

Similarly, the SPE can trigger events either by using the HSEG, or by using the dedicated event line input 0 through the HDEG block.

Figure 172. SEG block diagram

Generating events with CSEG

The CSEG allows the CPU to reuse events not allocated to a peripheral interface, such as STREAM or TRGITF.

For event inputs 1 to 22, the CPU can select the CSEG as the event generator. This is done through the EVTxSRC field for each event input x.

Then, with a simple write access request to the *HSP CPU shared event generator register (HSP_CSEGR)*, the CPU can trigger one or several events.

The priority encoder of the HSP handles all the activated events according to their priority. The software can check which event is processed by reading back HSP_CSEGR.

Prior to generating an event, the application must enable the CSEG interface by setting CSEGEN in the *HSP BUFF configuration register (HSP_BUFFCFGR)*. When CSEGEN is cleared, the CSEG block is reset and all pending events (**cseg_evt**[x]) are cleared.

Note: There is no protection against overrun situations; the application must ensure that CSEVTx is cleared before setting it again.

For example, if the application wants to activate the event N, it must follow this sequence:

1. Wait for CSEVT[N] = 0. If CSEVT[N] = 1, it means that the HSP did not yet consider the previous request.
2. When CSEVT[N] = 0, set it.

The CSEG block can also be used by the application for debugging purposes, by forcing the execution of a task connected to STREAM or TRGITF. It also allows the CPU to generate events with a high priority level if necessary.

Generating events with CDEG

The CDEG allows the application to trigger any of the 38 tasks through the **cdeg_evt** event.

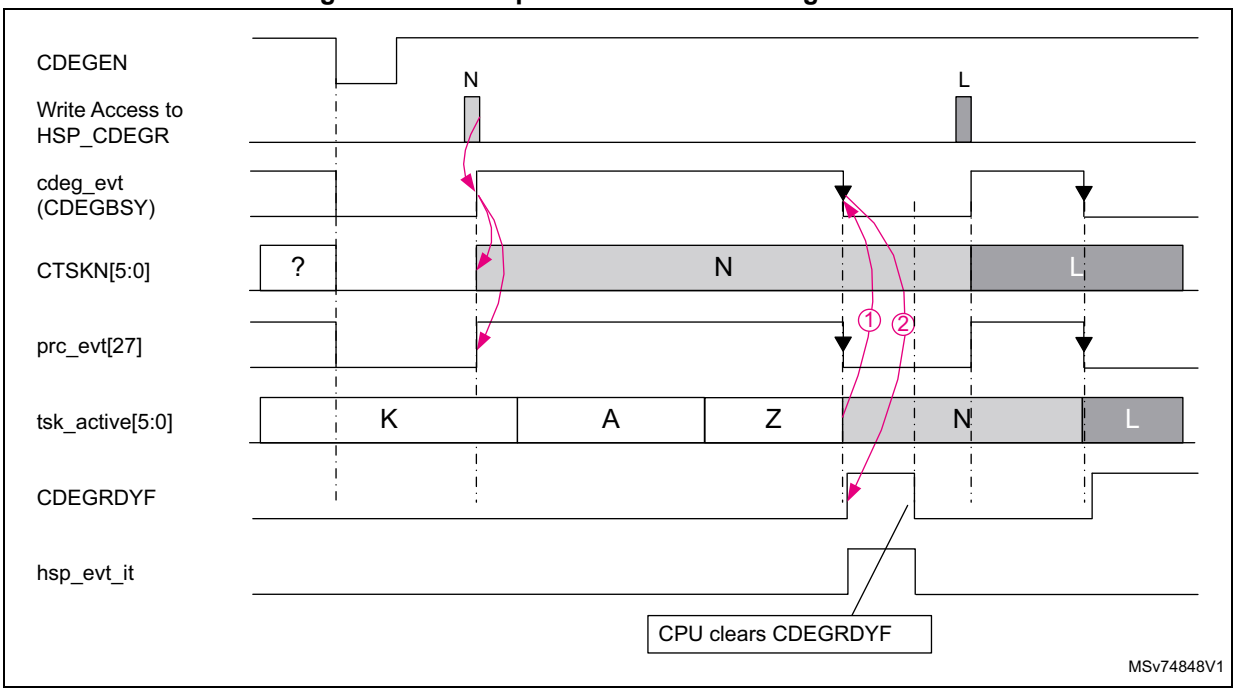
The CDEG allows one event to be posted at a time: the CPU needs to wait until the previous event has been taken into account before activating a new event.

*Note: The **cdeg_evt** event is routed to the input number 27 of the priority encoder (PE) having the lowest priority.*

Prior to generating events, the application must enable the CDEG interface by setting CDEGEN in the *HSP BUFF configuration register (HSP_BUFFCFGR)*. When CDEGEN is set to 0, the DSEG block is reset, and **cdeg_evt** is cleared.

To generate a dedicated event, the CPU must do the following:

1. Wait until the CDEGBSY bit is cleared.
2. Write the task number to execute (0 to 38) in CTSKN[5:0].



When the CPU writes in the *HSP CPU dedicated event generation register (HSP_CDEGR)*, the **prc_evt**[27] event is asserted, and CDEGBSY is set. The CDEG block can also generate an interrupt when the current CTSKN[5:0] is taken into account by the HSP.

Figure 173 shows a basic example. The CPU writes in HSP_CDEGR and CTSKN[5:0] is set to N. The write operation in this register sets the **cdeg_evt** signal and CDEGBSY flag. **cdeg_evt** is routed to **prc_evt**[27]. When the task controller is able to serve the task associated with **prc_evt**[27], the **cdeg_evt** signal and CDEGBSY flag are cleared by the TCTL (#1 in the figure), and the CDEGRDYF flag is set, asserting an HSP interrupt if the corresponding interrupt enable control bit is set (#2 in the figure). The CDEG block is ready to accept a new request.

*Note: CDEGRDYF is set when a transition from 1 to 0 is detected on the **cdeg_evt** signal.*

CTSKN[5:0] and CDEGBSY are located in the *HSP CPU dedicated event generation register (HSP_CDEGR)*, and CDEGRDYF is located in the *HSP events interrupt status register (HSP_EVT_ISR)*.

Figure 173. Example of dedicated event generation

Generating events with HSEG

The HSP shared event generator (HSEG) allows the SPE to reuse events not allocated to a peripheral interface, such as STREAM or TRGITF.

The HSEG block is very similar to the CSEG, but it is dedicated to SPE usage.

Generating events with HDEG

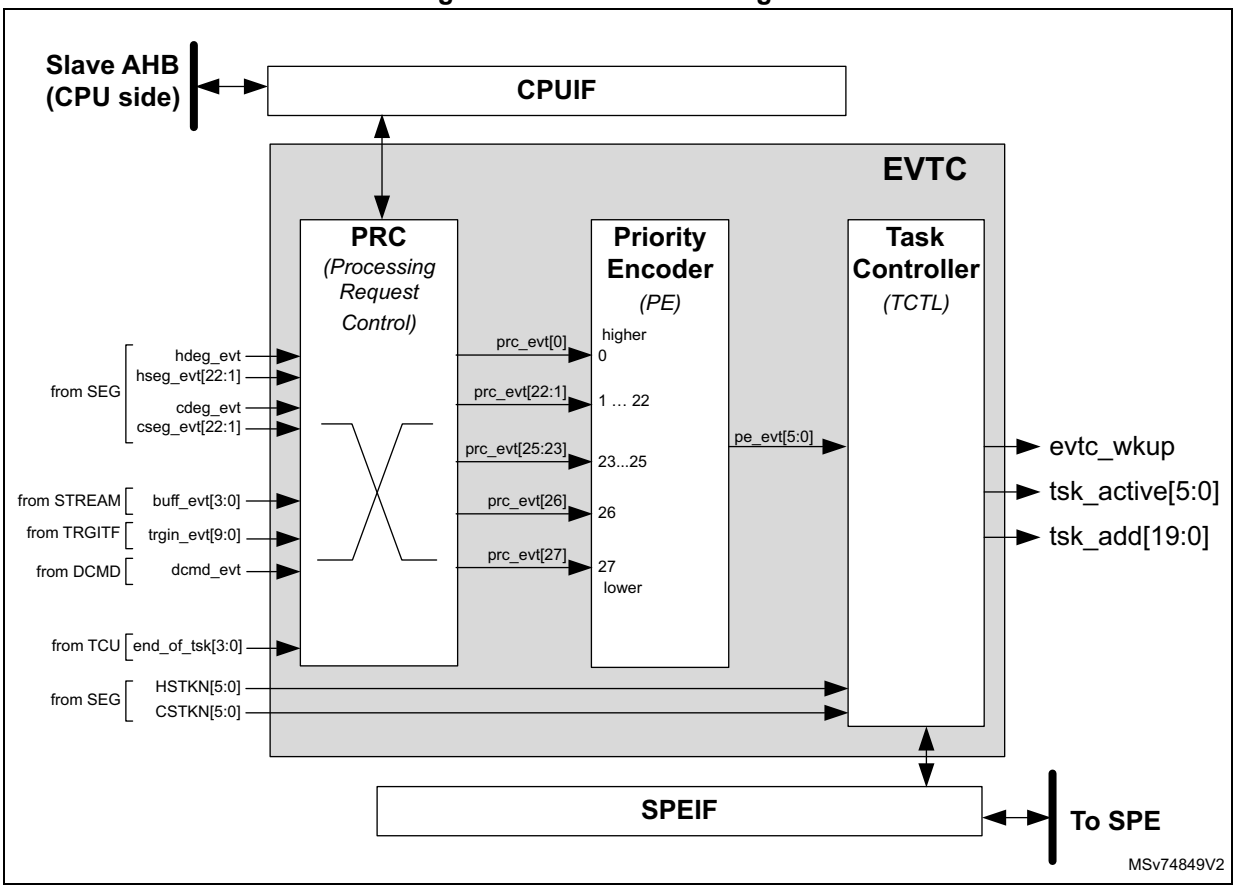
The HSP dedicated event generator (HDEG) allows the SPE firmware to trigger any of the 38 tasks using the event 0.

The HDEG block is similar to the CDEG, but it is dedicated to SPE usage.

20.4.11 Event controller (EVTC)

The event controller (EVTC) collects the events generated by the various HSP internal peripherals and reconditions them. The event with the highest priority activates the corresponding task, which executes the recorded processing list.

- Handle the STREAM interface.
- Handle the trigger inputs.
- Collect application events.
- Select the event having the highest priority.
- Ask the SPE to execute the processing list associated with the selected event.



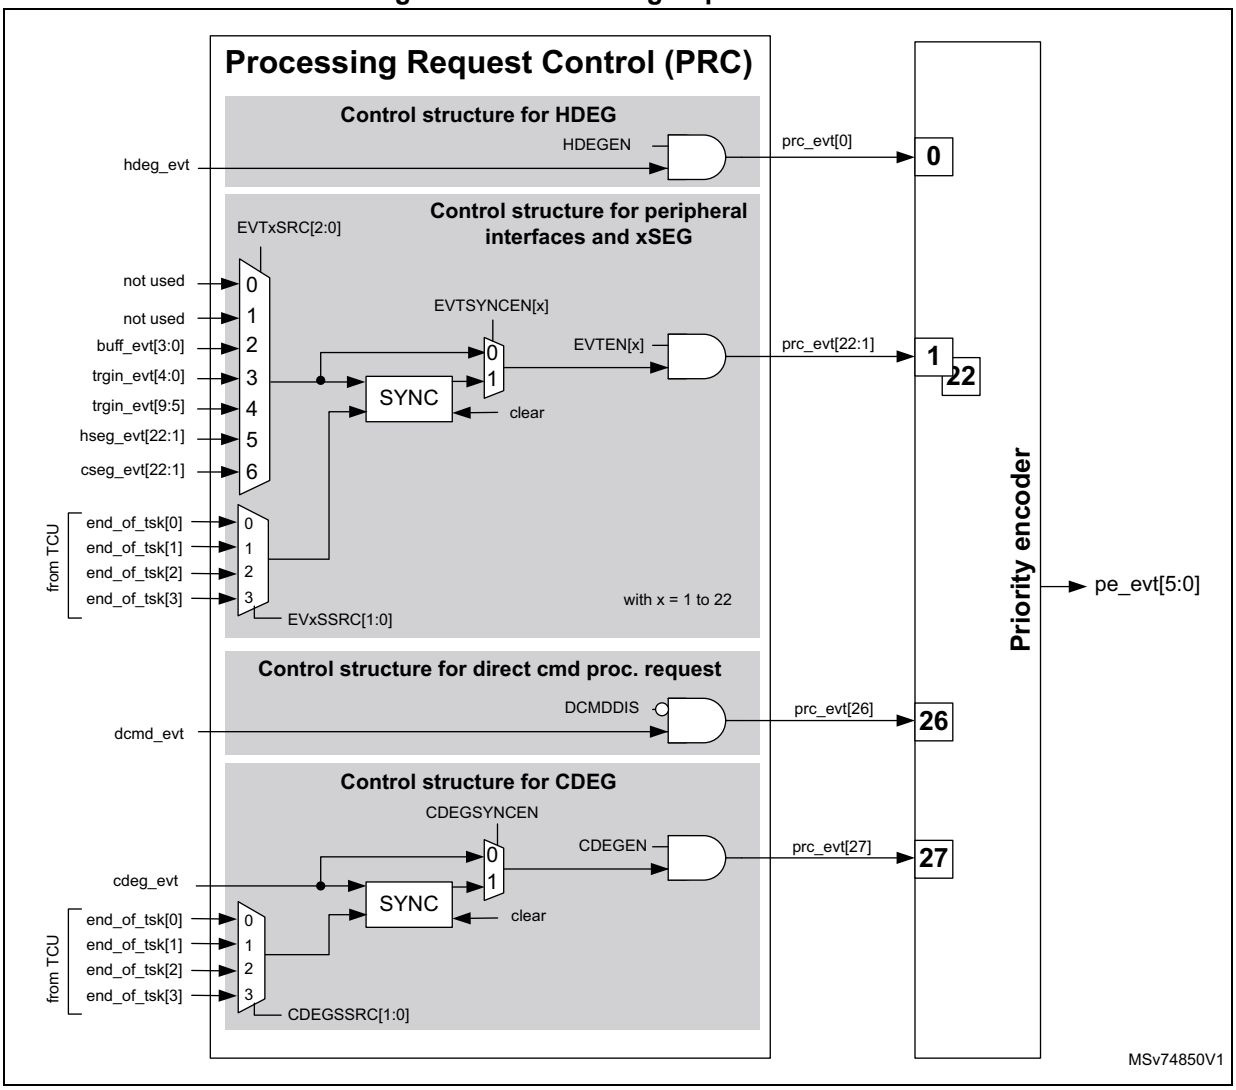
The execution of a processing list can be triggered by several sources:

- The CPU: up to 38 tasks can be triggered by software.
- The SPE: up to 38 tasks can be triggered by firmware.

- Trigger input lines (**hsp_trgi**[X:0]):
  - Triggers from various device peripherals, such as timers, ADCs, DACs, and ADF/MDF
  - Up to 20 trigger inputs are available.
- The STREAM interface:
  - Allows any peripheral to trigger a processing list.
  - Has up to four buffers are available.

The EVTC is configured mainly by the application CPU through the AHB slave interface.

Figure 174. EVTC block diagram



Processing request control (PRC)

For each input of the priority encoder, the processing request control (PRC) is in charge:

- Of selecting the request source that triggers a task through the EVTSRC[2:0]R registers.
- Of enabling and disabling the synchronization option with the *HSP event synchronization enable register (HSP_ESYNCENR)*.
- Of enabling and disabling the generation of the processing request with the *HSP event enable register (HSP_EVTENR)*.

Figure 175 shows the processing request control details for each type of inputs. Most of the inputs have a processing request source selector, a synchronizer, and a processing request enable.

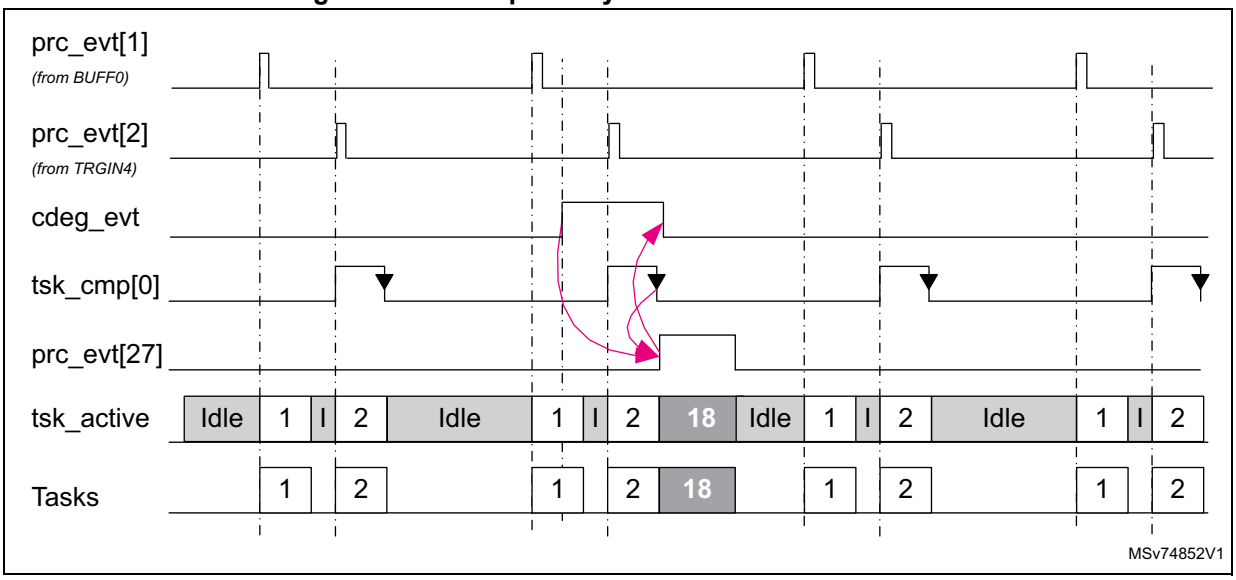


Figure 175. Processing request control

The synchronization mechanism allows the application to delay the activation of an event until the completion of a specific task.

Figure 176 shows an example of the synchronization usage. Tasks 1 and 2 are running at a regular time interval, and their execution must not be delayed. From time to time, the application needs to run an additional task (18 in the figure), for example, to update dynamic parameters. The application does not want to delay the execution of tasks 1 and 2 due to task 18 execution, so it decides to run task 18 right after task 2, because the time interval between the end of task 2 and the start of task 1 allows it. The application sets TSKCMP0[5:0] to 2 to resynchronize the pending **cdeg_evt** event with the end of the execution of task 2.

Figure 176. Example of synchronization mechanism

The table below shows which event can be connected for each priority encoder input, and thus which processing task number is activated (**tsk_active**[5:0]).

Table 143. Trigger sources versus priority and task number(1)

EVTxSRC[2:0] position(2)							Priority or prc_evt[x]	-	Processing task activated
0	1	2	3	4	5	6

1. BUFF[y] represents the events **buff_evt**[y],
   BUFF[y] represents the events **buff_evt**[y],
   TRGIN[y] represents the events **trgin_evt**[y],
   HSEG[y] represents the events **hseg_evt**[y],
   CSEG[y] represents the events **cseg_evt**[y],
2. With x = 1 to 22.

The following table shows a different view: for each event source, the possible priority levels are shown.

Table 144. Trigger sources versus priority and task number(1)(2)

Event sources	Possible priority levels	-	Event sources	Possible priority levels
BUFF[0]	1, 5, 9, 13, 17, 21	→	BUFF[1]	2, 6, 10, 14, 18, 22
BUFF[2]	3, 7, 11, 15, 19	→	BUFF[3]	4, 8, 12, 16, 20
TRGIN[0]	3, 8, 13, 18	→	TRGIN[1]	4, 9, 14, 19
TRGIN[2]	5, 10, 15, 20	→	TRGIN[3]	1, 6, 11, 16, 21
TRGIN[4]	2, 7, 12, 17, 22	→	TRGIN[5]	3, 8, 13, 18
TRGIN[6]	4, 9, 14, 19	→	TRGIN[7]	5, 10, 15, 20
TRGIN[8]	1, 6, 11, 16, 21	→	TRGIN[9]	2, 7, 12, 17, 22
HDEG	0	→	HSEG	1 to 22
CDEG	27	→	CSEG	1 to 22
DCMD	26	→	-	-

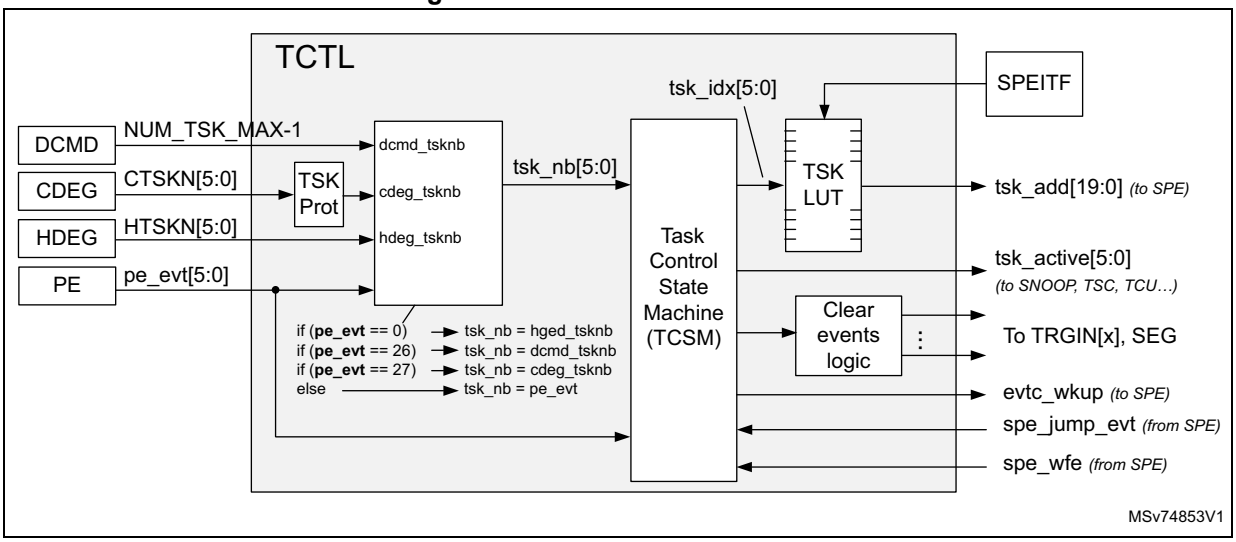
1. The HDEG priority is fixed at 0 but can run any task number. The CDEG behaves similarly but has a priority fixed at 27.
2. BUFF[y] represents the events **buff_evt**[y]
   TRGIN[y] represents the events **trgin_evt**[y]
   HSEG[y] represents the events **hseg_evt**[y]
   CSEG[y] represents the events **cseg_evt**[y]

Priority encoder (PE) and task controller (TCTL)

The priority encoder defines which event has the highest priority when several events are requesting the execution of processing lists.

The event priority is fixed. The event having the highest priority is the event connected to input 0 of the PE (dedicated to the SPE). The event having the lowest priority is the event connected to input 27.

When no event is pending, **pe_evt**[5:0], and **tsk_active**[5:0] are equal to 0x3F, and the SPE remains in “wait for event” (WFE).



The TCTL generates the task number to be executed (**tsk_nb**[5:0]), according to the output provided by the priority encoder (**pe_evt**[5:0] signal):

- If the output of the priority encoder corresponds to the event number 0 (**pe_evt**[5:0] = 0), the TCTL activates the task number given by HTSKN[5:0]. This field is updated by the SPE when the SPE requests the execution of a specific processing list through the HDEG interface.
- If the output of the priority encoder corresponds to the event number 27 (**pe_evt**[5:0] = 27), then the TCTL activates the task number given by CTSKN[5:0]. This field is provided by the CPU when it requested the execution of a specific processing list through the CDEG interface. Note that a specific protection mechanism prevents having a task number higher than 39. If CTSKN is higher than 37, the task number is forced to 39.
- If the output of the priority encoder corresponds to the event number 26 (**pe_evt**[5:0] = 26), the TCTL activates task number 38. This task is reserved for direct command handling.
- Finally, if the output of the priority encoder provides other values, the TCTL consider it as a task number.

When **tsk_nb**[5:0] becomes different from 0x3F, the TCSM block latches the value of the task to be executed (**tsk_active**[5:0]). The active task value is used as an index to read a look-up table (TSKLUT), which contains the address of the task (or processing list) to be executed by the SPE. The TSKLUT is updated by the SPE. Finally, the TCTL asserts the **evtc_wkup** signal to inform the SPE that a task needs to be executed.

The TCTL is also responsible for clearing TRGINx, SEG, and DCMD events when they are taken into account. When the SPE starts the execution of the selected task, **spe_wfe** goes to zero, and several cycles later the SPE generates a pulse (on **spe_jump_evt**), indicating that the processing list address has been taken into account, and can be updated for the next task to process. In addition, the TCTL generates an error if the SPE does not activate **spe_jump_evt** in the expected time window.

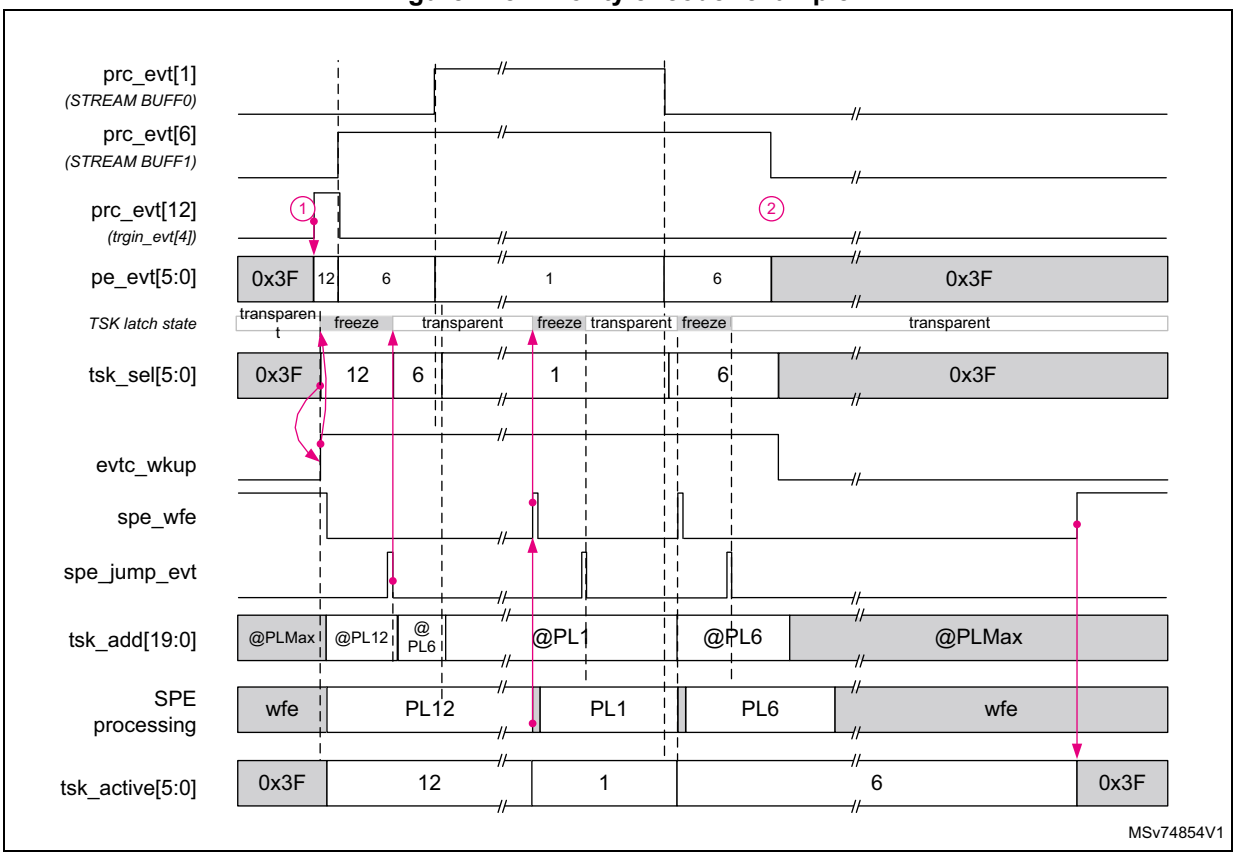
Figure 177. Task controller details

The task having the highest number (task number 39) is dedicated to the SPE firmware and indicates that an unexpected task number has been activated (PLFAIL). The SPE firmware activates the FWERRF flag with the error code described in *Table 145: Firmware error number*. An interrupt is generated to the application if enabled.

When no event is pending, the first event to become active is selected. If several events are waiting for a task completion by the SPE, the event having the highest priority is selected when the SPE acknowledges completion of the previous task.

In the example below, initially there are no pending events and the SPE is in WFE. **tsk_active**[5:0] has a default value output of 0x3F. The **evtc_wkup** signal is inactive, and the output of **tsk_add**[19:0] is the address of the maximum task number supported by the product (see *Section 20.3: HSP implementation*).

As no event is pending, the first active event is the first served. As soon as **prc_evt**[12] becomes active (**trgin_evt**[4]), the priority encoder detects that an event is pending, and immediately updates its output **pe_evt**[5:0] (#1 in the figure). The PESM sees that **pe_evt**[5:0] is no longer equal to the default value, latches **pe_evt**[5:0], asserts **evtc_wkup,** and clears the selected event source if the event is generated by TRGINx, CDEG, HDEG, CSEG, or HSEG.



The **pe_evt**[5:0] output is continuously changing according to the event activity.

The SPE exits from WFE (indicated by the clearing of the **spe_wfe** signal) and executes the processing list given at the address **tsk_add**[19:0] (@PL12 in the figure below). The SPE informs the EVTC that **tsk_add**[19:0] can be unfrozen by sending a pulse on **spe_jump_evt** when it branches to the address defined by **tsk_add**[19:0]. The EVTC can select the next processing list to execute while PL12 is under execution. When the execution of PL12 is complete, the SPE attempts to go to WFE, and the signal **spe_wfe** goes to 1 for one cycle. The rising edge of **spe_wfe** indicates to the ETVC that **tsk_add**[19:0] must be frozen again. The PESM latches **pe_evt**[5:0] and keeps **evtc_wkup** activated. In the example, BUFF0 (**prc_evt**[1]) is selected because at the end of the processing of PL12, **prc_evt**[1] has the highest priority.

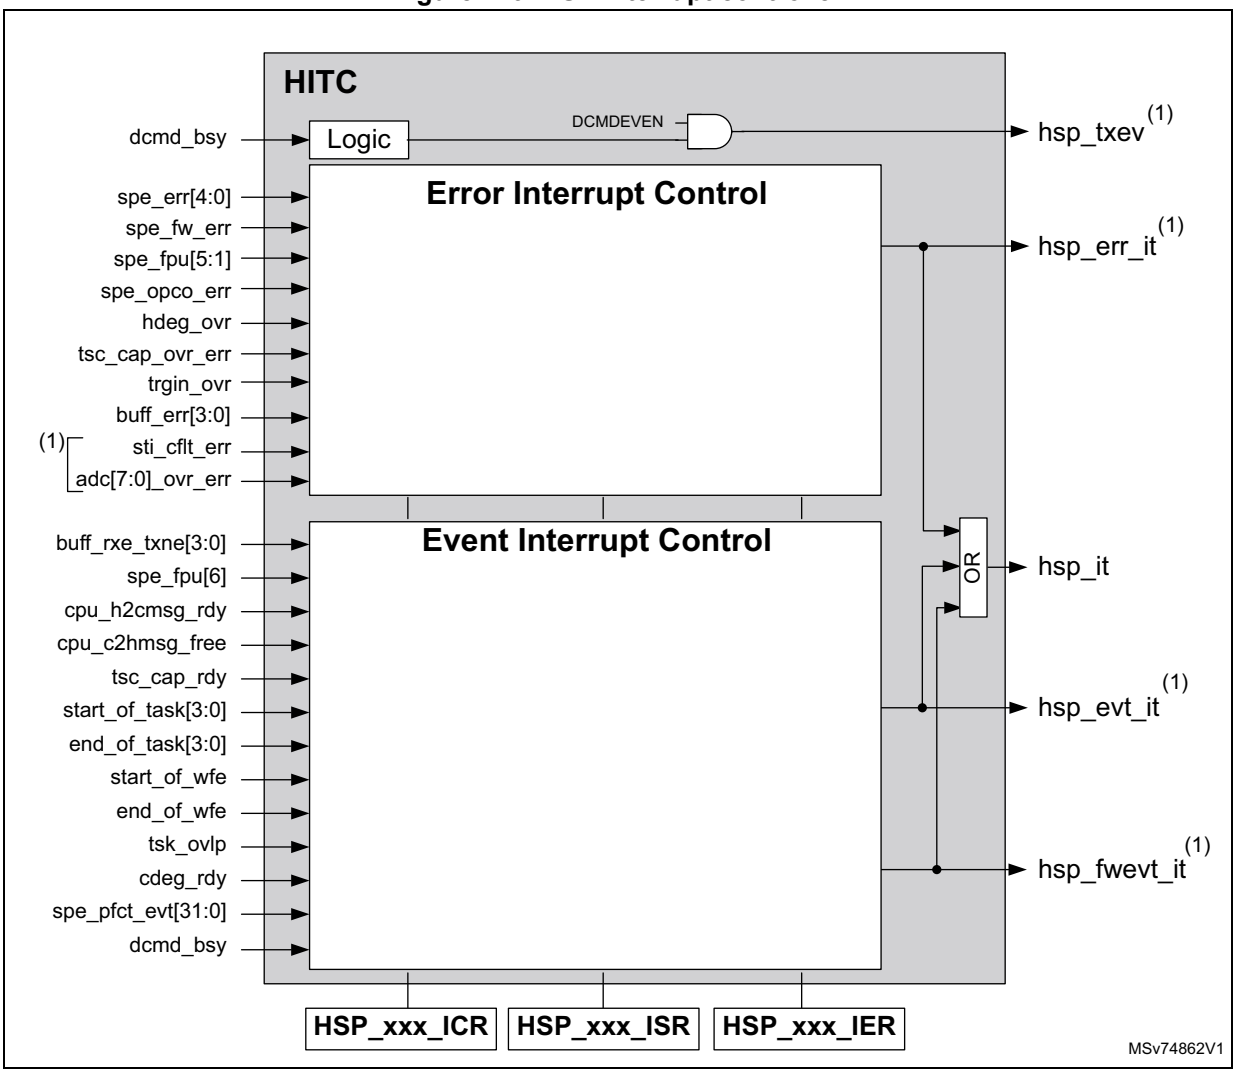
Seeing **evtc_wkup** still active, the SPE processes PL1. When the SPE completes the execution of the PL1 processing list, it can branch to the execution of PL6.

The **prc_evt**[1] and **prc_evt**[6] are cleared when the SPE reads the corresponding buffer. When the SPE acknowledges **prc_evt**[6] (#2 in the figure), there are no processing requests. The PESM clears **evtc_wkup**. SPE completes the processing of PL6 and goes to WFE.

Figure 178. Priority encoder example

The EVTC monitors the delay between the moment the SPE exits from WFE and the moment it jumps to the execution of the corresponding task. If there is no jump to the selected processing list when the SPE exits from WFE, the EVTC remains frozen. The application is notified of this abnormal behavior by the assertion of the SCHERRF flag. To recover from this situation, the HSP must be reset through the RCC.

The execution of a task cannot be interrupted by another task.



If an enabled event occurs while a task is in execution, the event remains pending until the corresponding task is executed by the SPE.

If several enabled events occur at the same time, the priority encoder defines which must be served first.

20.4.12 HSP interrupt controller (HITC)

The HSP interrupt controller collects events and flags generated by the various parts of the HSP, and generates interrupts to the application processor and to the SPE.

Figure 179. HSP interrupt controller

1. The signals and blocks related to these signals are not always present (see *Section 20.3: HSP implementation*).

Four interrupt lines are provided to the application processor:

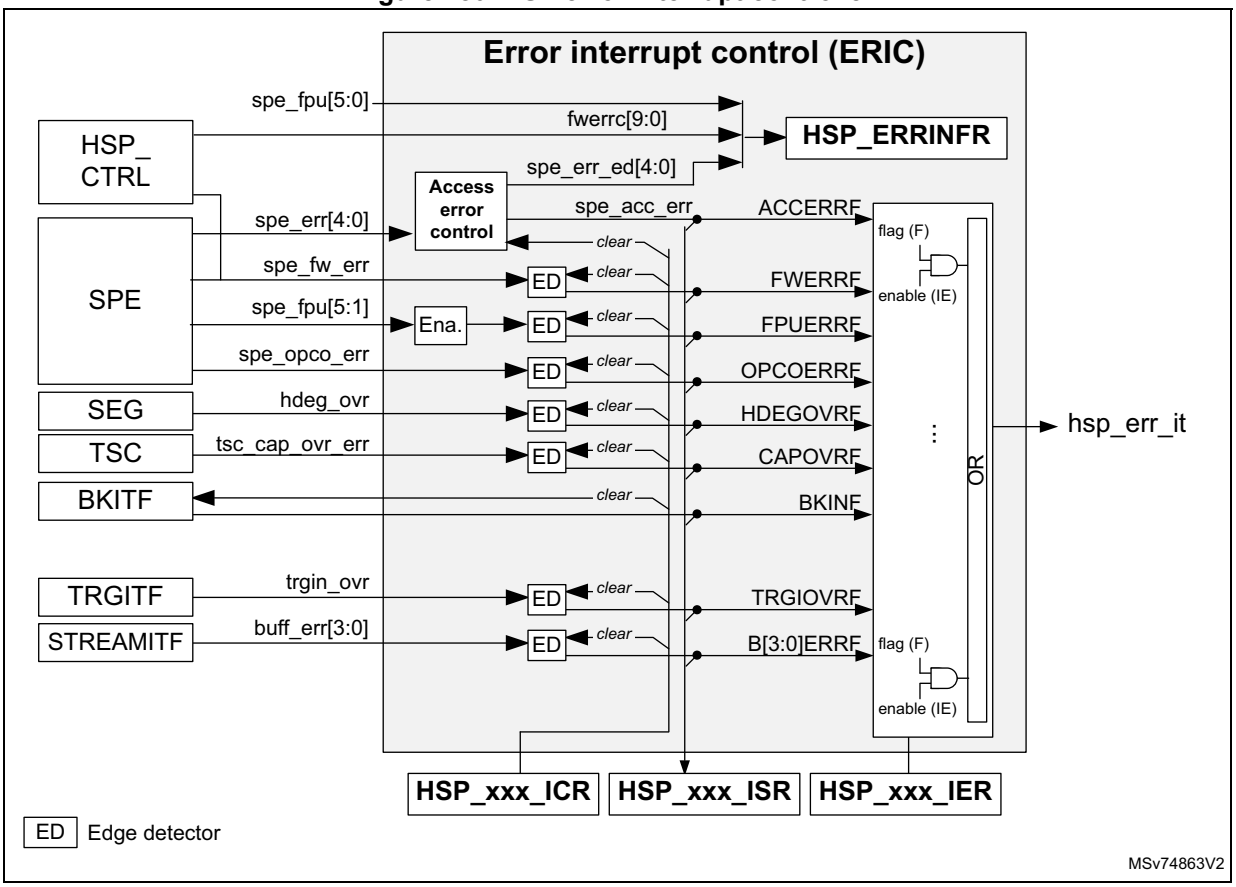
- An interrupt line handling errors (**hsp_err_it**)
- An interrupt line handling various hardware events (**hsp_evt_it**)
- An interrupt line handling events generated by the SPE processing (**hsp_fwevt_it**)
- A global interrupt is asserted when one of the previous interrupts is asserted (**hsp_it**)

In addition, the HITC provides a dedicated event output (hsp_txev) able to exit the CPU from a WFE state when a direct command execution is completed. There is no need to acknowledge this event. It can be enabled with DCMDEVEN in the *HSP control register (HSP_CR)*.

The HITC contains several flags, which can be read and cleared at any time by the application. These flags can also generate an interrupt if the corresponding interrupt enables have been set.

The application can enable the interrupts through the *HSP error interrupt enable register (HSP_ERR_IER)*, *HSP events interrupt enable register (HSP_EVT_IER)*, and *HSP processing event interrupt enable register (HSP_PFCTEVT_IER)*.

The application can check the status flags through the *HSP error interrupt status register (HSP_ERR_ISR)*, *HSP events interrupt status register (HSP_EVT_ISR)*, and *HSP processing event interrupt status register (HSP_PFCTEVT_ISR)*.



The application can clear the interrupt sources through the *HSP error interrupt clear register (HSP_ERR_ICR)*, *HSP events interrupt clear register (HSP_EVT_ICR)*, and *HSP processing event interrupt clear register (HSP_PFCTEVT_ICR)*.

For additional information on the interrupt root cause, refer to the *HSP error information register (HSP_ERRINFR)*.

Description of error flags

This section lists all event sources capable of asserting the error and global interrupt lines.

Figure 180. HSP error interrupt controller.

Floating point unit error (FPUERRF)

The FPUERRF flag reports floating-point exceptions. This flag is activated when one of the following events occurs: UDFLOW, OVFLOW, DIVZERO, INVALID, or DENORM.

In addition, the *HSP error information register (HSP_ERRINFR)* shows the value of these five exceptions at any time, plus the INEXACT exception.

The six FPU exception signals are generated by the SPE. The meaning of the exceptions is the following:

- **INEXACT**: generated when an operation produces a result that does not fit into its intended destination. The result had to be altered by rounding it off to fit. This exception does not set the flag FPUERRF.

  Examples: $1 + 2^{-25}$ is rounded to 1 with the INEXACT flag activated,

  2.0/3.0 provides inexact rounding as well.
- **UDFLOW**: generated when an operation produces a result closer to 0 than what is supported by the float32. This exception sets the flag FPUERRF if UDFIE is set.
- **OVFLOW**: generated when the largest representable finite number is exceeded in magnitude by what would have been the rounded floating-point result with the exponent range unbounded. This exception sets the flag FPUERRF if OVFIE is set. Example: $2^{127} * 4$ yields an overflow.
- **DIVZERO**: generated when a division by zero is performed. This exception sets the flag FPUERRF if DBZIE is set.
- **INVALID**: generated when an operation produces a result outside of the float32 domain (such as the square root of a negative number or 0/0). This exception sets the flag FPUERRF if INVIE is set.
- **DENORM**: generated when a denormal number is detected. When denormal numbers are detected, they are replaced by 0. This exception sets the flag FPUERRF if DENORMIE is set.

The FPUERRF flag and the information bits UDFLOW, OVFLOW, DIVZERO, INVALID, DENORM, and INEXACT are cleared when FPUERRC is set.

Note: It is possible to freeze HSP execution upon assertion of the FPUERRF flag through the BKITF (see Section 20.4.19: Break interface (BKITF)).

Access error (ACCERRF)

The HSP indicates that an access error occurred by setting ACCERRF. Several conditions can lead to an access error and the *HSP error information register (HSP_ERRINFR)* gives additional information on the root cause. The meaning of the flags present in HSP_ERRINFR is described below:

- CMERR: CRAM/CROM error

  When this flag is set, it means that the SPE fetches or performs load and store operations outside the CRAM/CROM memory range.
- DMERR: BRAM/DRAM error:

  When set, it means that the SPE performs load and store operations outside the BRAM/DRAM memory range.

- MAHBERR internal AHB master error:

  When set, it means that the HSP_CTRL is not properly accessed. This error typically occurs if the SPE performs a wrong access operation to HSP_CTRL.
- SAHBERR slave AHB error:

  When set, it means one of the following:
  - The device tried to access an invalid memory space.
  - The device attempted to write in the CRAM/DRAM memory while it was protected by CDRLCK[1:0].
  - The device performed a nonsupported access operation through the slave AHB interface, such as an access operation not aligned on 32-bit data.

    No error is reported if the device reads or writes into a nonexiting register located in the valid address range of the HSP. When an access operation is not valid, the slave AHB interface always responds to the request with data (in this case 0).

    Invalid read access operations return 0. Invalid write access operations are ignored.

    Accessing above BRAMAB_END (see *Figure 160*) also generates a bus error.

Note: It is possible to freeze HSP execution upon assertion of the ACCERRF flag through BKITF (see Section 20.4.19: Break interface (BKITF)).

Firmware errors (FWERRF)

This flag is activated when the SPE firmware code reported error situations. When the SPE meets an error condition, during the code execution, not covered by hardware error flags, the flag FWERRF is activated and FWERRN[9:0] in the *HSP firmware error register (HSP_FWERR)* is updated.

Note: FWERRN[9:0] is only cleared when the HSP is reset. It always contains the last error code reported by the SPE firmware. Every time the firmware updates the error code, FWERRF is activated, generating a new interrupt if FWERRIE is activated. FWERRF is cleared by the application by setting FWERRC.

Various conditions can lead to the activation of the firmware error flag and FWERRN[9:0] reports the error code detected by the SPE firmware (as detailed in the table below).

Table 145. Firmware error number

FWERRN[9:0] (1)	Error code description
0x000	No error reported, default value after reset
0x005 - 0x008	Reserved
0x009	An event requested the execution of an undefined processing list.
0x00A - 0x3FF	Reserved

1. FWERRN[9:0] is in the *HSP firmware error register (HSP_FWERR)*.

Scheduler errors (SCHERRF)

This flag is activated when the EVTC remains frozen due to an unexpected behavior of the SPE. More precisely, when the EVTC requests the SPE to execute a task, if the SPE responds OK but does not confirm the jump to the task address, the EVTC remains frozen. When this situation occurs, the SCHERRF flag is activated. The only way to recover from this situation is to reset the HSP.

Invalid OpCode error (OPCOERRF)

This flag is activated when the SPE detects an invalid opcode. The SPE executes a NOP for each invalid opcode detected.

Note: It is possible to freeze HSP execution upon assertion of the OPCOERRF flag through BKITF (see Section 20.4.19: Break interface (BKITF)).

STREAM error (B[3:0]ERRF)

For buffers configured in the C2H direction, this flag represents an overrun. For buffers configured in the H2C direction, it represents an underrun.

This flag is activated when new data are written in C2HBUFFx by the CPU, while the previous data have not yet been read. In this case, the new data are written in C2HBUFFx.

This flag is activated when H2CBUFFx is read by the CPU, while it is empty (HSP did not write any new data on time). In this case, the CPU reads the previous data.

TRGI overrun error (TRGIOVRF)

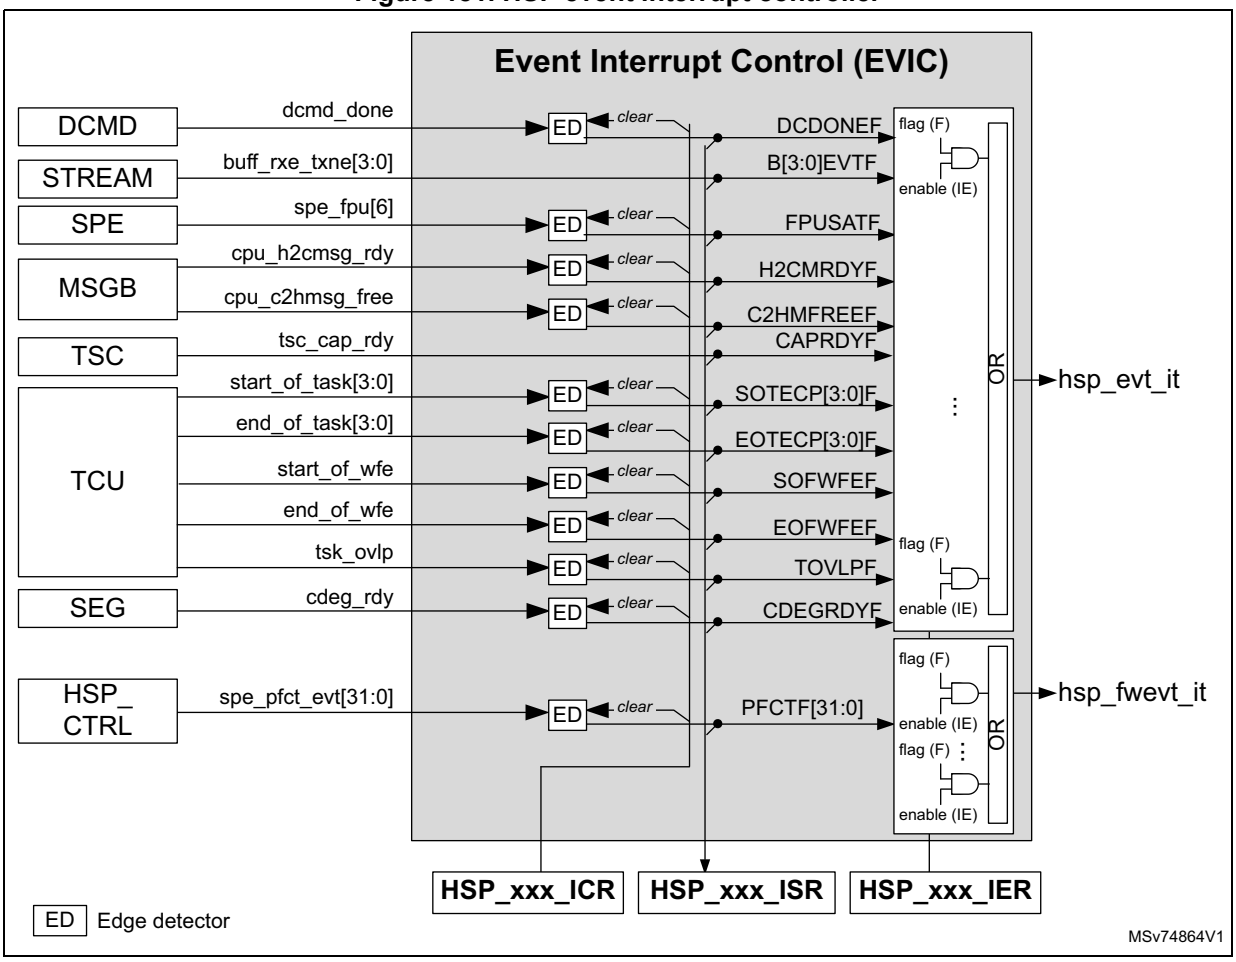
This flag is activated when a new event occurs while the previous event is still pending. The application can check which TRGIN interface generated the overrun through TRGIERR[9:0] in the *HSP error information register (HSP_ERRINFR)*.

HSP-dedicated event generator overrun error (HDEGOVRF)

This flag is set when the SPE posts a firmware event while the previous event has not yet been taken into account. The new event posted by the SPE is ignored.

Capture overrun error (CAPOVRF)

This flag is set when a new capture value must be written in HSP_CAPDR while the device has not yet read the previous one. In this case, the new capture value is dropped.



Break input (BKINF)

This flag indicates that the HSP receives a break input event. The SPE is frozen and an application action is needed to restart the HSP (see *Section 20.4.19: Break interface (BKITF)*).

Description of event flags

This section lists all the event sources capable of asserting the event and global interrupt lines.

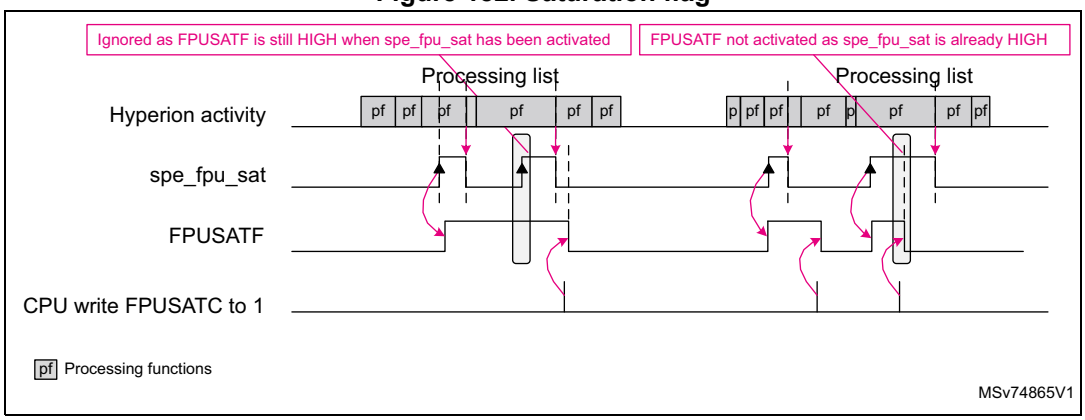
Figure 181. HSP event interrupt controller

CPU-dedicated event generator ready (CDEGRDYF)

It indicates if the execution of the previous event posted by the CPU into the CDEG block has been started. The CPU can use this information to post a new event.

STREAM buffer event (B[3:0]EVTF)

For buffers configured in the C2H direction, this flag indicates that the buffer is empty. For buffers configured in the H2C direction, this flag indicates that the buffer is not empty.



FPU saturation (FPUSATF)

This flag indicates that the FPU detected and performed a saturation of the signal.

As shown in the figure below, when a saturation is detected, the SPE sets the **spe_fpu_sat** signal. This signal remains set until the completion of the current processing function. The

FPUSATF flag is set when a rising edge on **spe_fpu_sat** is detected, and it is cleared when FPCSATC is set.

Figure 182. Saturation flag

Capture buffer ready (CAPRDYF)

It indicates that a new capture value is available in the *HSP data capture register (HSP_CAPDR)*.

Message box ready and free (H2CMRDYF, C2HMFREEF)

The H2CMRDYF flag indicates that a message is available for the CPU in the MSGB.

The C2HMFREEF flag indicates that the MSGB is free and the CPU can post a new message for the HSP.

Start/end of task event comparator (SOTECP[3:0]F, EOTECP[3:0]F)

SOTECPxF is set if the task selected by TSKCMPx is starting.

EOTECPxF is set if the task selected by TSKCMPx has just been completed.

Start/end of WFE state (EOFWFEF, SOFWFEF)

SOFWFEF is set when the SPE enters the WFE state.

EOFWFEF is set when the SPE exits the WFE state.

Task overlap (TOVLPF)

This flag is set when the execution of one of the tasks on the selected range has been delayed due to the execution of another task (see *Section 20.4.14: Task comparator unit (TCU)*).

Direct command done flag (DCDONEF)

This flag is set when the execution of the current direct command is completed. More precisely, it is set when the DCBSY flag transitions from 1 to 0 (see *Section 20.4.7: Direct command interface (DCMD)*).

Processing function flags (PFCTF[31:0])

These flags are activated by the processing functions, several of which use flags.

The table below gives a summary of all interrupts that the application can use.

Table 146. HSP interrupt requests

Interrupt acronym[1]		Interrupt event	Event Flags	Enable control bits	Interrupt clear method	Exit Sleep	Exit Stop and Standby
HSP	HSP_ERR[2]	C2HBUFF[3:0] overrun or H2CBUFF[3:0] underrun	B[3:0]ERRF	B[3:0]ERRIE	Write 1 in B[3:0]ERRC	Yes	No
		HDEG event overflow	HDEGOVRF	HDEGOVRIE	Write 1 in HDEGOVRC	Yes	No
		Access error	ACCERRF	ACCERRIE	Write 1 in ACCERRC	Yes	No
		SPE invalid opcode	OPCOERRF	OPCOERRIE	Write 1 in OPCOERRC	Yes	No
		SPE arithmetic error	FPUERRF	FPUERRIE	Write 1 in FPUERRC	Yes	No
		Capture register overflow	CAPOVRF	CAPOVRIE	Write 1 in CAPOVRC	Yes	No
		SPE firmware errors	FWERRF	FWERRIE	Write 1 in FWERRC	Yes	No
		Scheduler error	SCHERRF	SCHERRIE	Write 1 in SCHERRC	Yes	No
		Break input activated.	BKINF	BKINIE	Write 1 in BKINC	Yes	No
		Task overlap detection	TOVLPF	TOVLPIE	Write 1 in TOVLPC	Yes	No
	HSP_EVT[2]	C2HBUFF[3:0] empty or H2CBUFF[3:0] not empty	B[3:0]EVTF	B[3:0]EVTIE	Write or read HSP_BUFFxDR	Yes	No
		Capture buffer ready flag	CAPRDYF	CAPRDYIE	Read HSP_CAPDR	Yes	No
		Message ready for CPU	H2CMRDYF	H2CMRDYIE	Write 1 in H2CMRDYC	Yes	No
		Message box to HSP free	C2HMFREEF	C2HMFREEIE	Write 1 in C2HMFREEC	Yes	No
		Saturation from FPU	FPUSATF	FPUSATIE	Write 1 in FPUSATC	Yes	No
		Start of task 0 to 3	SOTECP[3:0]F	SOTECP[3:0]IE	Write 1 in SOTECP[3:0]C	Yes	No
		End of task 0 to 3	EOTECP[3:0]F	EOTECP[3:0]IE	Write 1 in EOTECP[3:0]C	Yes	No
		Start of WFE	SOFWFEF	SOTWFEIE	Write 1 in SOTWFEC	Yes	No
		End of WFE	EOFWFEF	EOFWFEIE	Write 1 in EOTWFEC	Yes	No
		Direct command busy	DCDONEF	DCDONEIE	Write 1 in DCDONEC	Yes	No
		CPU dedicated event generator ready	CDEGRDYF	CDEGRDYIE	Write 1 in CDEGRDYC	Yes	No
	HSP_FWEVT[2]	Processing functions flags	PFCTF[31:0]	PFCTIE[31:0]	Write 1 in PFCTC[31:0]	Yes	No

1. HSP_ERR is generated by the **hsp_err_it** signal; HSP_EVT is generated by the **hsp_evt_it** signal; HSP_FWEVT is generated by the **hsp_fwevt_it** signal; HSP_GLOB is generated by the **hsp_it** signal.
2. This interrupt line is not always connected to the interrupt controller (see *Section 20.3: HSP implementation*).

20.4.13 HSP reset and clocking

The HSP MMC block is reset by the product system reset.

The other HSP blocks, including the SPE, are also reset by the product system reset, but can also be reset by the application through a reset control bit in the RCC.

When the application resets the HSP with the RCC control bit, the following conditions must be satisfied:

- There are no ongoing transactions through its AHB slave interface.
- The SPE no longer performs transactions through its bus interfaces.

The HSP offers a mechanism to ensure that the SPEhas stopped all transactions before a reset. The application must ensure that transactions through its AHB slave interface are stopped.

The application must follow this sequence to set the HSP to a safe state before resetting it with the RCC control bit:

1. Clear the HSP_EVTENR register.
2. In the HSP_ITFENR register, set the DCMDDIS bit and clear all others.
3. Set RSTREQ in HSP_CR.
4. Wait for RSTOK = 1 in HSP_CR.

   This bit must go high after 1 ms at most after an RSTREQ assertion. A timeout must control if this delay elapsed.

   If RSTOK is set, the application can reset the HSP safely through the RCC reset control bits, by executing the following sequence:

   a) Disable the HSP clock (**hsp_hclk_core_ck**).

   b) Set the HSP reset bit to 1.

   c) Clear the HSP reset bit.

   d) Enable the HSP clocks.

   If the timeout elapsed before RSTOK is set, it cannot be ensured that resetting the HSP does not disturb the activity of other components of the product.

HSP clocking

The HSP works with two clocks that are synchronous to the interconnect clock:

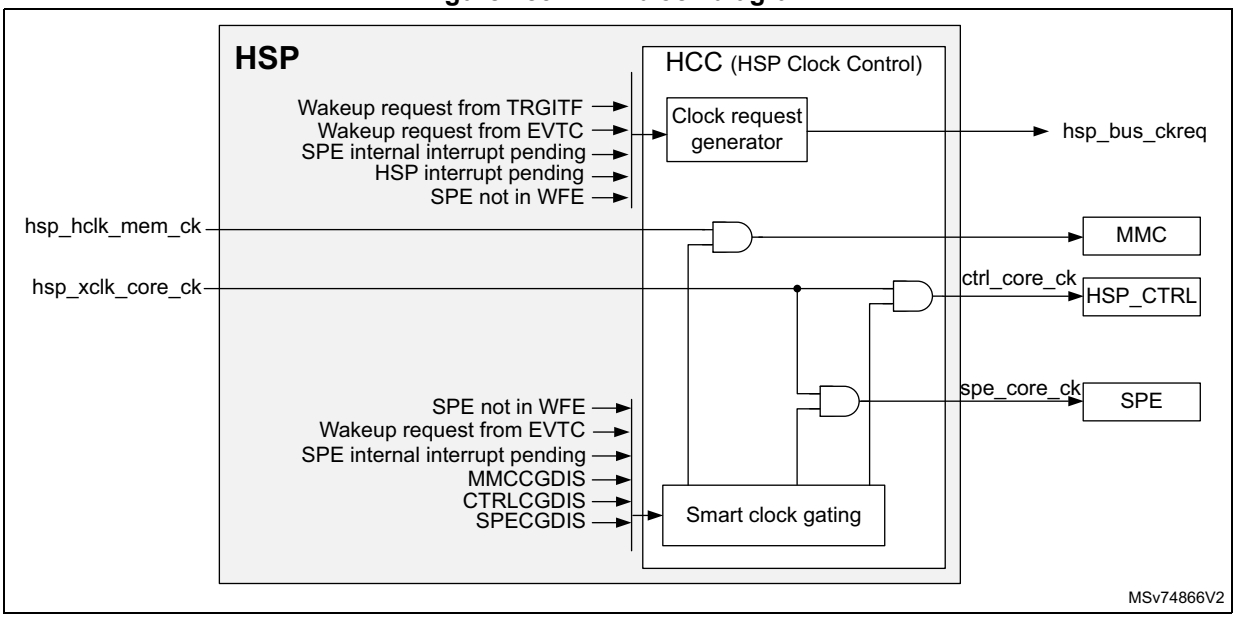
- **hsp_hclk_mem_ck:** clock for the memory components and associated logic

  This clock allows the application to use the SRAM4 as additional memory even when the HSP is disabled.
- **hsp_hclk_core_ck:** clock for the remaining parts of the HSP, including the SPE

When the HSP is disabled or not used (BOOTEN = 0), the CPU must provide **hsp_hclk_mem_ck** to access the SRAM4.

When the application wants to use the HSP, the CPU must provide **hsp_hclk_mem_ck** and **hsp_hclk_core_ck**.

The clock generation is controlled through the RCC.



Smart clock gating

The HSP performs a local clock gating to reduce power consumption. This smart clock gating is activated by default, but can be disabled by CTRLCGDIS, SPECGDIS and MMCCGDIS in the *HSP control register (HSP_CR)*.

- When CTRLCGDIS is cleared, parts of the HSP_CTRL block are not clocked when they are inactive.
- When MMCCGDIS is cleared, the MMC block is not clocked when there is no memory access.
- When SPECGDIS is cleared, the SPE is not clocked in WFE.

Setting one of these bits forces the clocking of the corresponding block.

Figure 183. HCC block diagram

The HSP can request the bus clock (with the **hsp_bus_ckreq** signal) when needed.

In addition, the HSP can detect a TRGIN event, even if **hsp_hclk_mem_ck** and **hsp_hclk_core_ck** clocks are not provided by the product.

See the low-power capability table “Functionalities depending on the working mode” in the PWR section of the product to check if the bus clock request is supported.

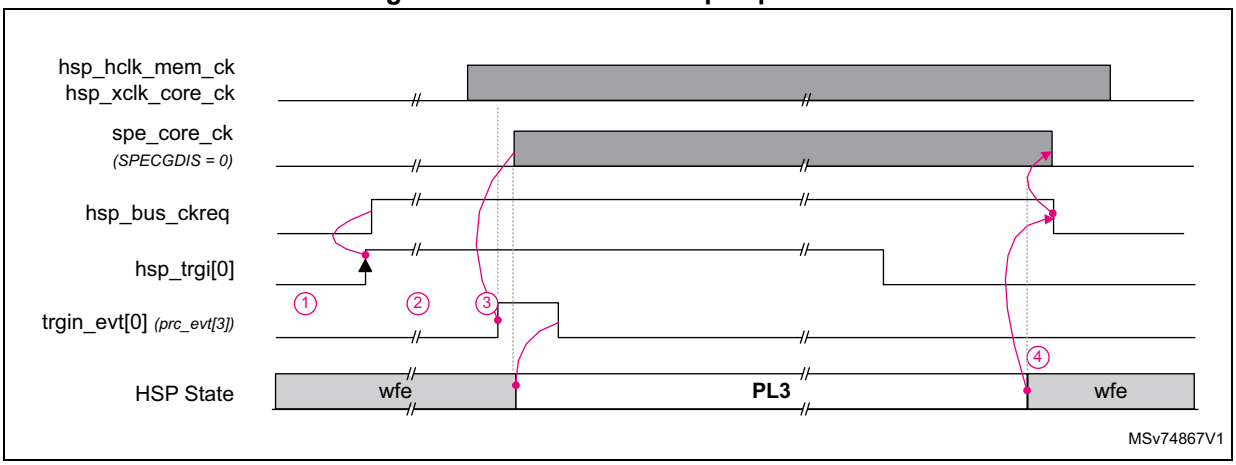


Figure 184 shows a wake-up example using TRGITF.

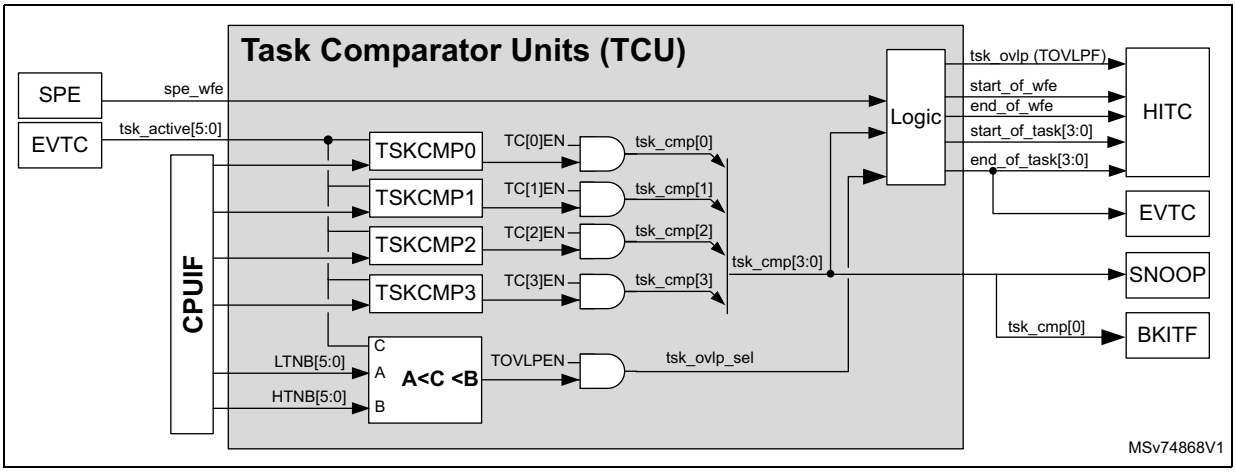
1. Before the trigger event occurs, the HSP is not clocked at all (#1 in the figure).
2. As soon as the **hsp_trgi**[0] active edge is detected asynchronously, the HSP asserts the **hsp_bus_ckreq** signal. After a setup delay generally due to the startup of the

oscillator providing the clock, the RCC provides a bus clock, but the **spe_core_ck** remains gated (#2 in the figure).

3. Using the bus clock, the EVTC can generate **trgin_evt**[0] and wakes up the SPE. **spe_core_ck** is enabled to allow the SPE to process processing list PL3 (#3 in the figure).
4. **hsp_bus_ckreq** is maintained active until the SPE turns back to WFE. The **spe_core_ck** clock is gated as well (#4 in the figure).

Figure 184. TRGITF wake-up capabilities

20.4.14 Task comparator unit (TCU)



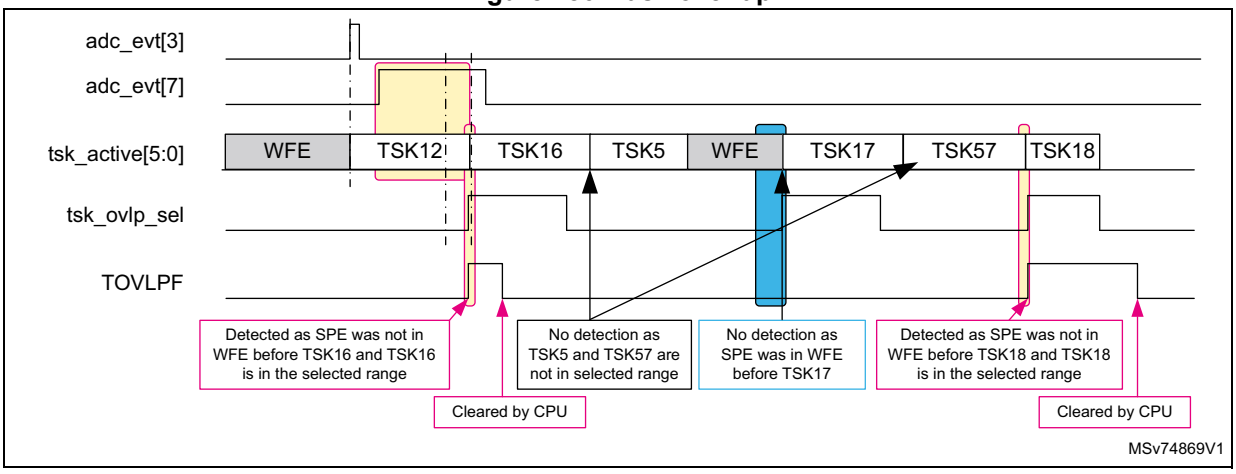
The TCU offers several services based on the task active value (tsk_active[5:0]) provided by the EVTC.

The TSKCMP[3:0] comparator enables the following features controlled through the *HSP task comparator unit register (HSP_TCUCFGR)*:

- Synchronize the generation of an event with the completion of a selected task.
- Generate an interrupt when the execution of a specific task starts or stops, or when the SPE goes to WFE.
- Route comparator outputs to I/Os (with HSP_SNP[5:0] I/Os) for debugging or tuning purposes, to check the duration of a task or for task sequencing.

The TCU can also be used to detect if there are task overlap situations. This function informs the application that the execution of several tasks does not occur at the expected time, because the HSP was performing another task. In some applications, this may inform the application that scheduling behaves in an unexpected way.

Figure 185. TCU block diagram



A task overlap situation is detected if between the end of execution of the previous task and the start of the next task, the SPE remains only one clock cycle to WFE. This means that when the previous task execution was completed, there was a request to execute another task. If the delayed task is not in the selected group, the detection is not activated.

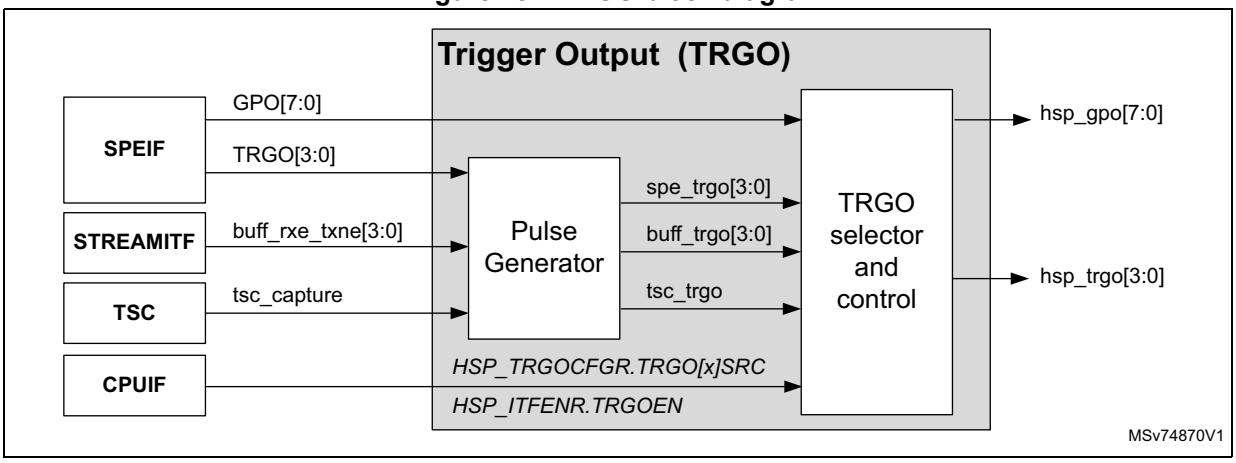
The application can define a group of tasks where the overlap situation must be reported; the group range can go from task number 1 to task number 39.

In the figure below, HTNB is set to 19, and LTNB is set to 15, to restrict the test overlap check to tasks 16, 17, and 18. The tasks 16, 5, 57, and 18 have been delayed, but only the delay of tasks 16 and 18 are reported.

Figure 186. Task overlap

Note: In some cases, it is normal to have task overlap situations: for example, when the SPE triggers a new task, or when a task is synchronized with the completion of another task. Selecting a limited group of tasks where the overlap must be checked reduces the risk of having spurious generation of the task overlap event.

To activate the task overlap function, the application must do the following:



1. Select the range of tasks where the overlap condition must be checked, by initializing HTNB[5:0] and LTNB[5:0] in the *HSP task overlap control register (HSP_TOVLPCR)* to the range boundary.
2. Set the TOVLPIE control bit if an interrupt is requested from the CPU.
3. Set TOVLPEN in the *HSP task overlap control register (HSP_TOVLPCR)*.

20.4.15 Trigger outputs (TRGO)

The HSP offers the possibility to generate trigger pulses on up to four trigger outputs (**hsp_trgo**[3:0]). The pulse width is one **hsp_hclk_core_ck** period.

It is also possible for the application to control the level of eight GPOs (**hsp_gpo**[7:0]) using dedicated processing functions.

Figure 187. TRGO block diagram

The TRGO is enabled with TRGOEN in the *HSP interface enable register (HSP_ITFENR)*. When TRGOEN=0, it is not possible to generate trigger pulses on **hsp_trgo**[3:0], nor to change the level of **hsp_gpo**[7:0].

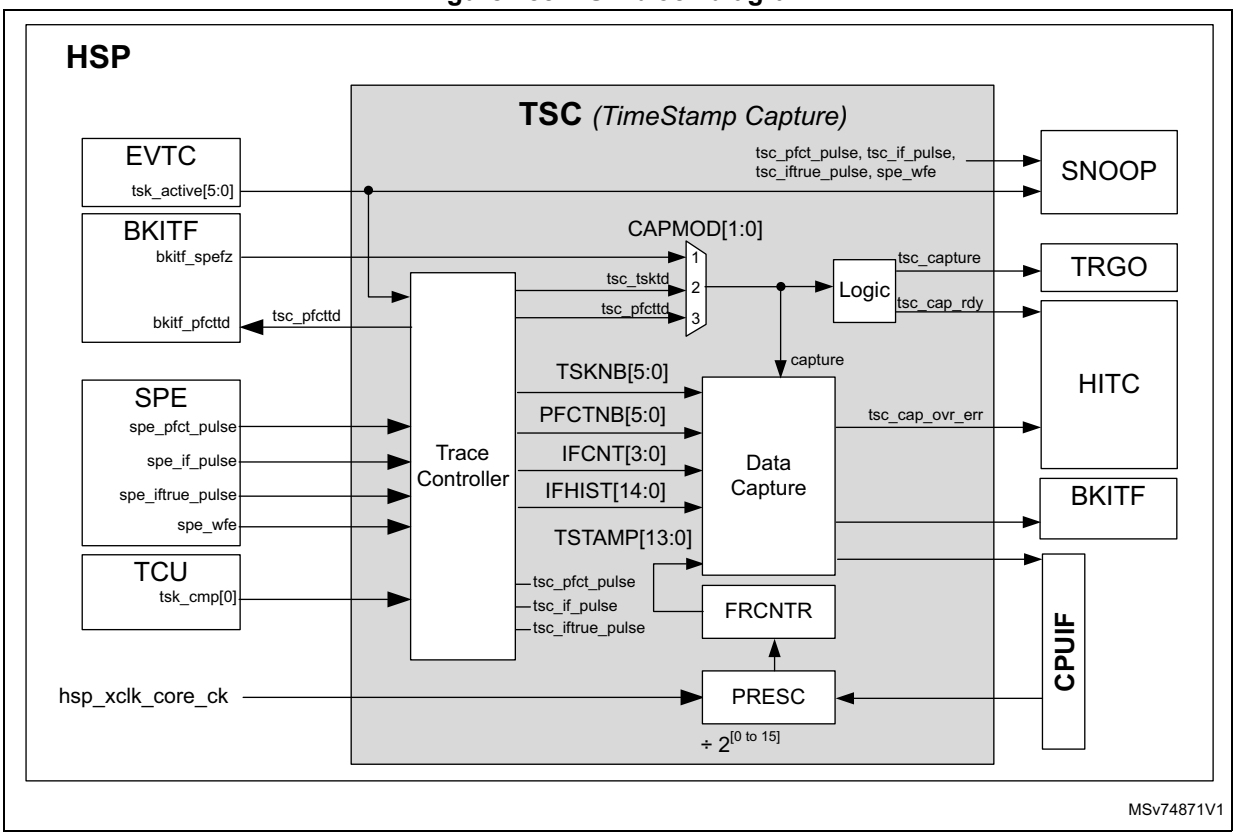
A selector allows the application to define the trigger source for one of the four trigger outputs, using the *HSP TRGO configuration register (HSP_TRGOCFGR)*.

The table below lists the possible trigger sources.

Table 147. List of trigger sources

Trigger source	Description
TRGO[3:0]	The SPE can generate a trigger pulse by setting one of those 4 bits.
buff_rxe_txne[3:0]	A trigger pulse is generated in the corresponding trigger output (**buff_trgo**[3:0]), every time C2HBUFF[3:0] is ready to accept a new data from the CPU, or every time H2CBUFF[3:0] contains a data for the CPU.
tsc_capture	A trigger pulse generated every time a new capture data is available,

The trigger output can typically be used to trigger an automatic data transfer using a DMA device. For example:



- When a pulse is generated from the **tsc_capture** event, the DMA device can read the *HSP data capture register (HSP_CAPDR)* and write it into a circular buffer, storing the scheduling history automatically.
- If a buffer configured in the C2H direction generates a pulse trigger, the DMA device can automatically write the next data to process in the *HSP BUFFx data register x (HSP_BUFFxDR)*. The SPE is informed that a new sample is available on one of the Rx buffers.
- If a buffer configured in the H2C direction generates a pulse trigger, the DMA device can automatically read the corresponding Tx buffer through the *HSP BUFFx data register x (HSP_BUFFxDR)*. The SPE is informed that a Tx buffer is available and a new sample can be written in the corresponding Tx buffer.

20.4.16 Time-stamp capture (TSC)

To ease the processing tuning and the debug, the HSP offers the possibility to capture a time-stamp, the task number, the processing function number, and other helpful information, using three different capture modes:

- Task capture mode: a capture is done every time the activated task number changes.
- Processing function capture mode: a capture is done every time the processing function number changes.
- Break capture mode: a capture is done every time the SPE breaks.

Figure 188. TSC block diagram

The TSC mainly contains a trace controller, a data capture function, and a free-running counter.

The data capture function consists of storing information concerning SPE activity in the HSP_CAPDR register.

The data capture function can be controlled with CAPMOD[1:0]:

- When CAPMOD[1:0] = 0, the capture function is disabled. The capture events are ignored. The complete capture function is no longer clocked.
- When CAPMOD[1:0] = 1, a capture is performed every time the SPE breaks (**bkitf_spefz**).
- When CAPMOD[1:0] = 2, a capture is performed every time the processing list number changes (**tsk_active**[5:0]).
- When CAPMOD[1:0] = 3, a capture is performed every time the processing function number changes (**tsc_pfctnb**[5:0]).

The SPE provides several signals to ease the debugging:

- spe_pfct_pulse signal generates a pulse when the SPE starts the execution of a processing function.
- spe_if_pulse signal generates a pulse when a conditional function is executed.
- spe_iftrue_pulse signal generates a pulse if the conditional function result is true.
- spe_wfe signal indicates if the SPE is in WFE.

All these signals are visible through the SNOOP block (see *Section 20.4.18: Snoop function (SNOOP)*).

The TSC trace controller reconditions the signals received from the SPE, TCU, and EVTC and provides the following services:

- Counting the processing function inside a processing list (tsc_pfctnb[5:0]). This counter is reset every time the SPE goes back to WFE. When this counter reaches 63, on the next processing function it wraps around to 0 and continues counting.
- Generating a signal indicating when the execution of a new processing function starts. This signal (tsc_pfcttd) can be used to freeze the SPE every time the execution of a new processing function starts.

  It can also be used to generate a capture event and thus monitor the execution of processing functions.

  In addition, it is possible to generate the tsc_pfcttd signal only during the execution of a specific task number. This can be done by using the output of TSKCMP0 (tsk_comp[0]) as the filter signal. This filtering function can be controlled through the TSKFLT bit.
- Counting the number of conditional functions the SPE has performed since the previous execution of a processing function (IFCNT[3:0]). This counter is reset when a new processing function is executed, or when the SPE goes to WFE.
- Providing a comparison history of conditional functions since the previous execution of a processing function (IFHIST[14:0]). For example, if three conditional functions have been executed since the previous execution of a processing function.
  - IFHIST[0] contains 1 if the comparison of the first conditional function was true.
  - IFHIST[1] contains the comparison result of the second conditional function.
  - IFHIST[2] contains the comparison result of the third conditional function.

  IFHIST and IFCNT are stored in the capture register only when the next processing function is executed and if CAPMOD[1:0] = 3.

- Reformat the spe_pfct_pulse, spe_if_pulse, and spe_iftrue_pulse signals for the SNOOP block. Each signal is stretched to a minimum pulse width of five hsp_hclk_core_ck periods.

The figure below shows a simplified block diagram of the trace controller.

Figure 189. Trace controller block diagram

The TSC also provides a clock prescaler (PRESC[4:0]) cascaded with a 14-bit free-running counter (FRCNTR). The prescaler uses the HSP core clock as its timebase (**hsp_hclk_core_ck**). The PRESC[4:0] offers a 15-bit dynamic range, allowing the application to adjust the time granularity according to the desired trace.

The free-running counter and prescaler are enabled with the FRCNTEN bit.

When FRCNTEN is cleared, PRESC[4:0] and FRCNTR are reset, and no longer clocked. To change the prescaler value safely (PRESC[4:0]), the application must first clear FRCNTEN.

When a capture event occurs, the TSC stores the value of various signals in the HSP_CAPDR register:

- Timestamp (TSTAMP[13:0])
- Processing list number (TSKNB[5:0])
- Processing function number (PFCTNB[5:0])
- Number of conditional functions executed since the previous processing function (IFCNF[3:0])
- Comparison of the status history for each conditional function (IFHIST[14:0])

The TSC offers two data capture formats for more flexibility. This format is selected through the FRCNTEN bit.

- When FRCNTEN is cleared, the time-stamp function is disabled, and HSP_CAPDR contains:
  - The processing list number (TSKNB[5:0])
  - The processing function number (PFCTNB[5:0])
  - The conditional function counter (IFCNT[3:0])
  - The conditional function comparison status history (IFHIST[14:0])
- When FRCNTEN is set, the timestamp function is enabled, and HSP_CAPDR contains:
  - The timestamp (TSTAMP[13:0])
  - The processing list number (TSKNB[5:0])
  - The conditional function counter (IFCNT[3:0])
  - A reduced set of the conditional functions comparison status history (IFHIST[7:0])

Note: Having 15 bits for IFHIST allows keeping the history of up to 15 consecutive conditional functions. Having 8 bits for IFHIST keeps the history of up to 8 consecutive conditional functions.

When a capture occurs, the HSP performs the following actions:

- The parameters listed above are stored into the capture register (HSP_CAPDR).
- The flag CAPRDYF is activated (with the **tsc_cap_rdy** signal) to inform the CPU that the capture register has been updated.
- A capture event signal is sent to the TRGO to generate a trigger pulse (see *Section 20.4.15: Trigger outputs (TRGO)*).

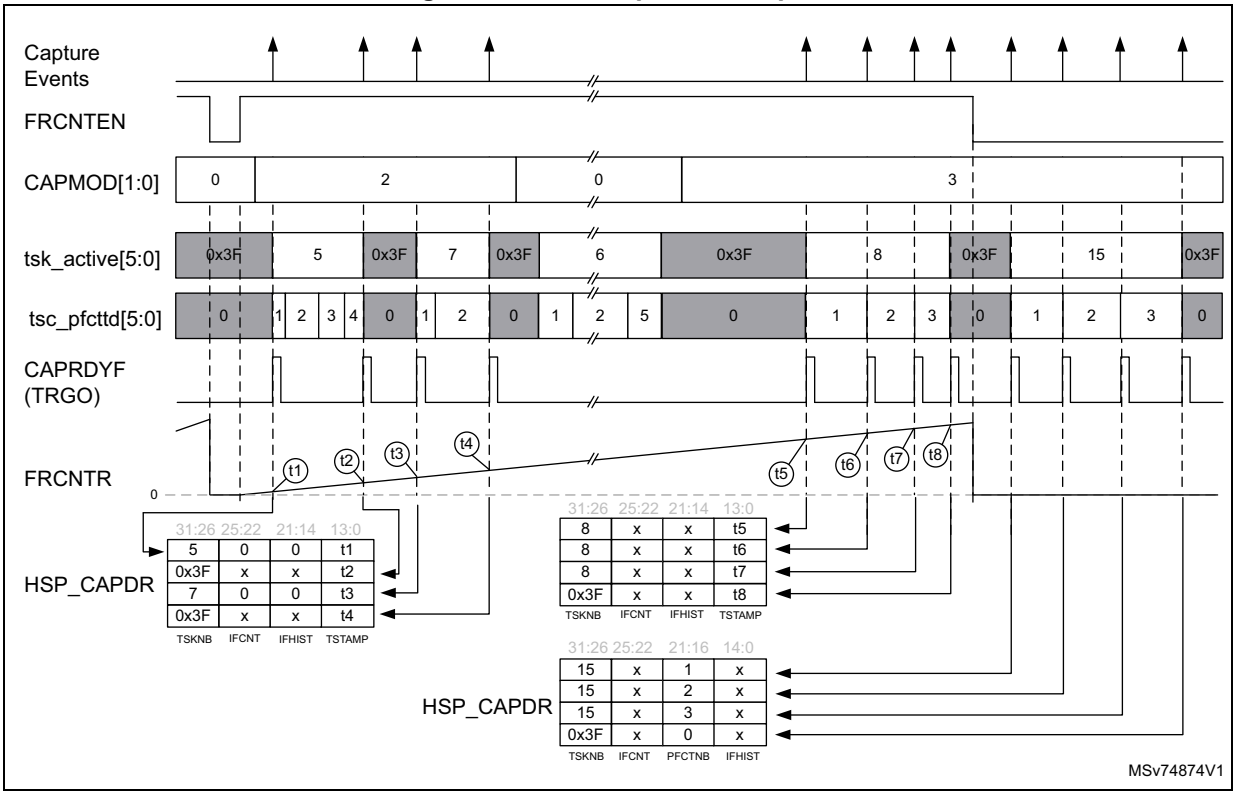
PRESC[4:0], FRCNTEN, TSKFLT, and CAPMOD[1:0] are located in the *HSP capture control register (HSP_CAPCR)*.

*Note: PFCTNB[5:0] (**tsc_pfctnb**[5:0]) represents the number of processing functions since the start of the current task. This value is incremented every time a processing function is executed. When the capture event is due to a change of TSKNB[5:0] (**tsk_active**[5:0]), PFCTNB is equal to 0.*

*The **tsc_pfctnb**[5:0] is also available on I/Os with the SNOOP function.*

Figure 190 shows how the TSC works, and which kinds of information can be captured.

Initially, the free-running counter is enabled and CAPMOD is cleared, indicating that the capture is disabled. Then the application clears and sets FRCNTEN to restart the free-running counter.



When CAPMOD is set to 2, the TSC stores all transitions of the task number in HSP_CAPCR. The CAPRDYF flag is set every time data are ready in HSP_CAPCR, and cleared when the application reads data. In this mode, IFCNT and IFHYST are not meaningful. When CAPMOD = 2, PFCTNB is cleared.

Later, CAPMOD is cleared and the free-running counter is still working, but the capture interface is disabled.

Next, CAPMOD is set to 3, with FRCNTEN = 1, allowing the TSC to store all processing function transitions with an associated timestamp in HSP_CAPCR. In this case, the amount of captured data may be important. In some cases, an overrun may occur. In this mode, IFCNT and IFHIST are updated according to the content of the processing list.

Finally, if FRCNTEN is cleared, the HSP_CAPDR format is changed and the timestamp is no longer present, but the depth of IFHIST is increased and PFCTNB is added.

Figure 190. TSC capture example 1

Note: IF CAPMOD is set to 2 before the boot of the SPE (BOOTEN = 1), the TSC captures an event, even when the SPE goes to WFE for the first time.

When TSKNB[5:0] = 0x3F and PFCTNB[5:0] = 0, it means that the SPE is in WFE.

When two processing lists are spaced by only one cycle in WFE, the WFE state (event indicating the end of the processing list) is not recorded in HSP_CAPDR, avoiding the generation of a probable overrun situation.

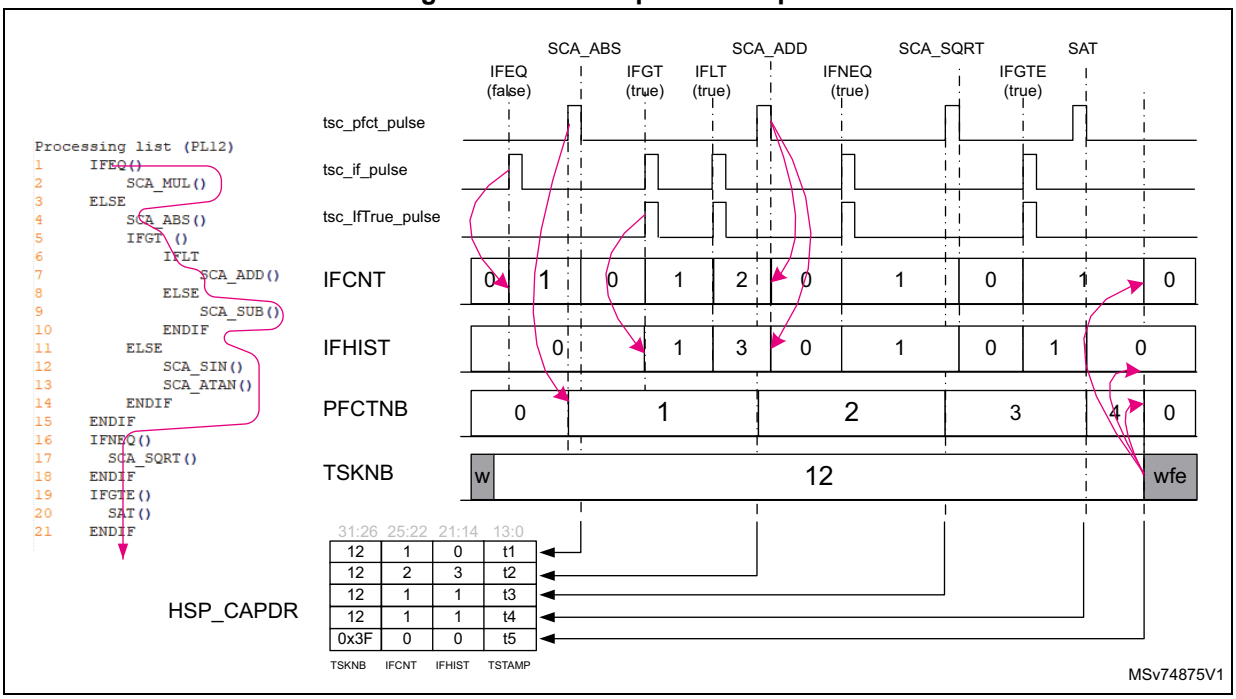


Figure 191 details the case where CAPMOD is set to 3, with a processing list containing conditional functions.

The left side of *Figure 191* shows the (simplified) processing list to be traced, with the red line indicating what has been executed. Processing functions in lines 2, 9, 12, and 13 are not executed.

The first record in HSP_CAPDR shows that one conditional function has been executed before this record. Using the processing list code, the application can deduce that the IFEQ comparison result is false (IFHIST[1] = 0). The ELSE part is then executed, and this first record corresponds to SCA_ABS.

The second record in HSP_CAPDR, at t2, shows that two conditional functions have been executed since t1. Using the processing list code, the application can deduce that after executing SCA_ABS, the IFGT comparison result was true (IFHIST[0] = 1). The ELSE part has not been executed. This is also confirmed by the true IFLT comparison result (IFHIST[1] = 1). The record at t2 corresponds to SCA_ADD, and so on.

Figure 191. TSC capture example 2

If the capture register needs to be written with a new record while the application did not yet read the previous value:

- The TSC activates the overrun flag (CAPOVRF).
- The TSC does not overwrite the capture register. The previous unread value is not corrupted.
- The TSC does not generate a capture event for the TRGO.

The TSC also provides CAPRDYF, asserted when a data is available in the HSP_CAPDR register. This flag is automatically cleared when the CPU reads HSP_CAPDR.

If CAPRDYIE is set in the *HSP events interrupt enable register (HSP_EVT_IER)*, an interrupt can be generated to the CPU.

Note: A TRGO signal can be generated as well. Depending on the product, it allows using the device DMA to read HSP_CAPDR (see Section 20.4.15: Trigger outputs (TRGO)).

Application example: catching the SPE state in case of SPE break

The application must follow this programming sequence:

1. Clear FRCNTEN.
2. Clear CAPMOD[1:0].
3. In the BKITF, enable all sources that are able to freeze the SPE.
4. Set CAPMOD[1:0].

This configuration can be helpful if the application wants to log field issues and identify what the SPE was doing when a break event occurred. The timestamp is not enabled in this example.

Application example: capturing processing function timestamps

The application must follow the programming sequence below:

- If the application intends to generate capture events only for processing functions located in a specific task:
  a) In the TCU, write the task number where the trace must be done in TSKCMP0[5:0] in the *HSP task comparator unit register (HSP_TCUCFGR)*.
  b) Enable the task comparator 0 by setting TC0EN in HSP_TCUCFGR.
  c) In BKITF, set TSKFLT.
- If the application intends to generate capture events every time a new processing function is executed, clear TSKFLT in the BKITF block. It is not necessary to program the TCU block.
- Prevent the processing function transition detector to break the SPE by setting SSEN = 0.
- In the TSC:
  – Clear FRCNTEN.
  – Clear CAPMOD[1:0].
  – Set the PRESC[4:0] to the desired value.
  – Set FRCNTEN.
  – Select the processing functions capture mode (CAPMOD[1:0] = 0b11).

The application can read the captured values in several ways:

- In polling mode, by waiting for CAPRDYF = 1, then reading HSP_CAPDR. This method is simple but not flexible and requests CPU load.
- In interrupt mode, by setting CAPRDYIE to allow the HSP to generate an interrupt every time new data are available. This is a simple and flexible method, but requests CPU load.
- Program the HSP to generate an event on one of the **hsp_trgo**[x] signals. This can be done by setting TRGO0SRC[1:0] to 3, for example, to use the **hsp_trgo_out**[3] signal. Depending on the product capabilities, the **hsp_trgo**[x] signals are connected to the trigger inputs of the device DMA, allowing it to read HSP_CAPDR every time a new timestamp is available. This method is the most efficient for the CPU loading but also for real time.

Note: Performing captures of processing function transitions may cause real-time issues, depending on the traced processing function. The execution time of some processing functions can be down to 10 ***hsp_hclk_core_ck*** *cycles, causing potential overrun if HSP_CAPDR is not read on time.*

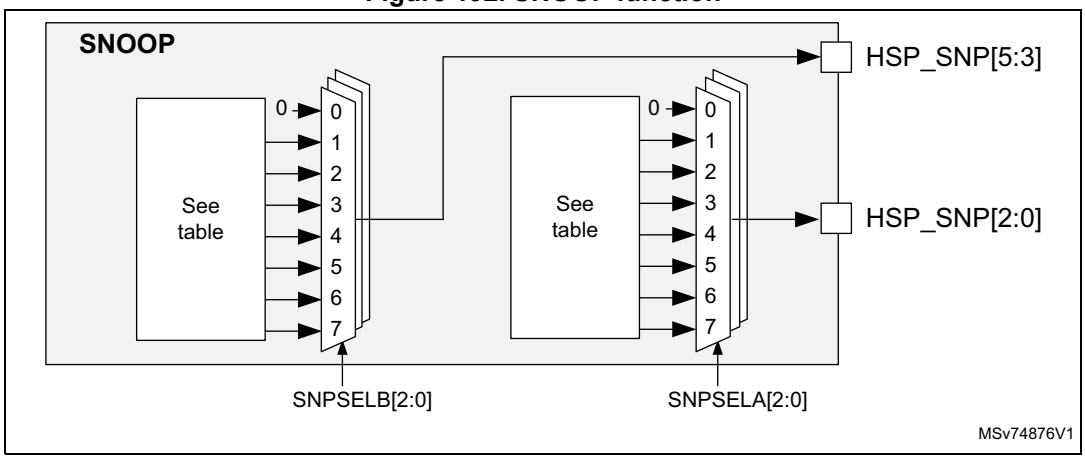
Warning: When CAPMOD[1:0] must be modified, it is recommended to clear it before setting it to the desired value.

20.4.17 BRAM conflict counter

The BRAM can be accessed by the following masters:

- SPE
- SoC master devices via HSP slave port SP1

The priority is given to the SPE, but the application may want to check if access requests to the BRAM-A, BRAM-B, or BRAM-AB suffer from contentions, reducing the overall performance. For this purpose, the HSP offers a 32-bit conflict counter incremented every time the MMC detects a contention on BRAM access.



This feature can be enabled or disabled through CCNTREN in the *HSP capture control register (HSP_CAPCR)*. The conflict counter is reset when CCNTREN is disabled.

The conflict counter value can be read at any moment through the *HSP conflict counter register (HSP_CCNTR)*.

20.4.18 Snoop function (SNOOP)

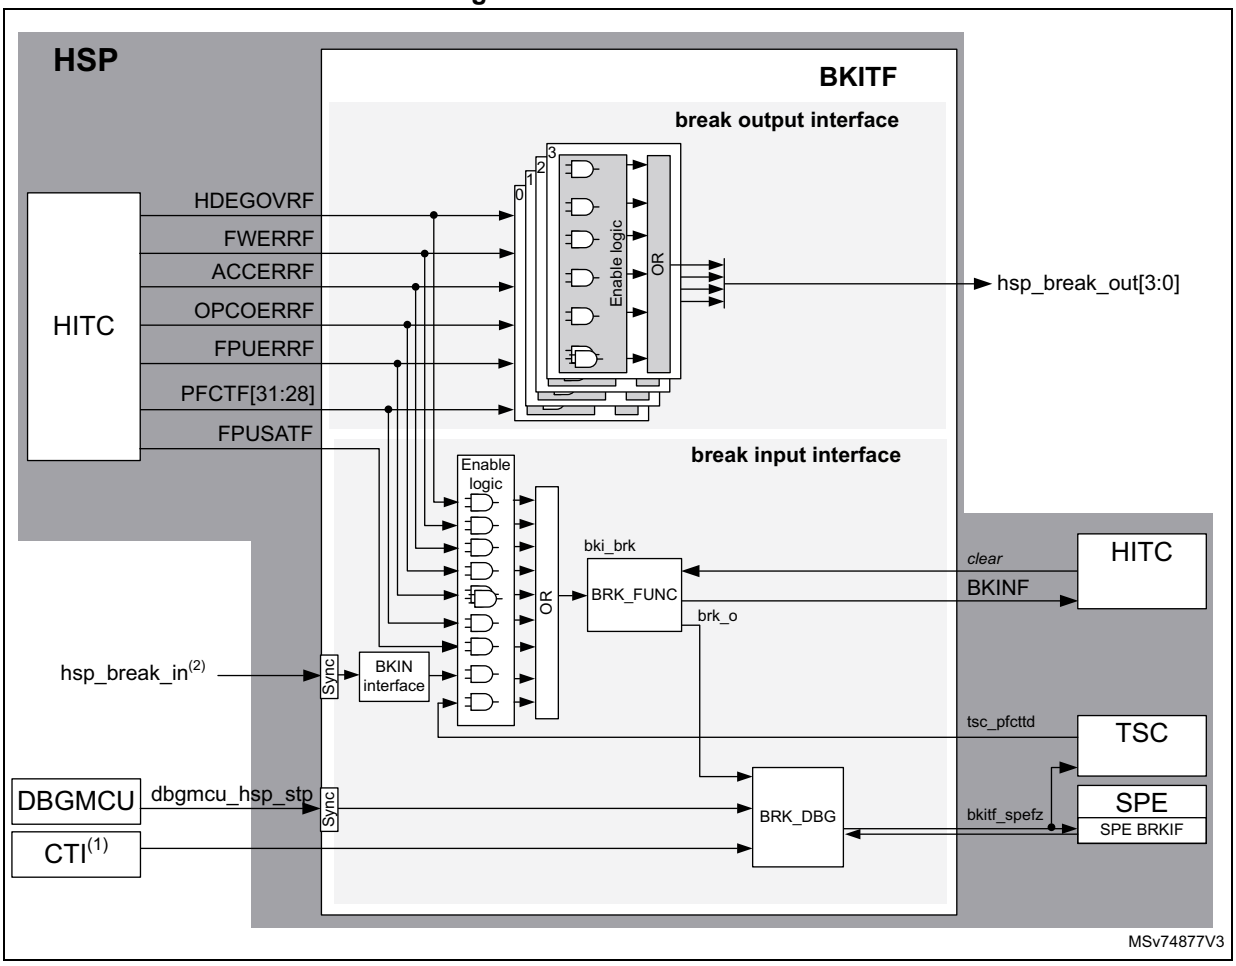
The HSP offers the possibility to observe key signals to ease application tuning. The application can select which set of signals can be observed on the HSP_SNP[5:0] pads through SNPSELB[2:0] and SNPSELA[2:0] in the *HSP SNOOP register (HSP_SNPR)*.

Figure 192. SNOOP function

The table below shows the signal that can be observed through pads.

Table 148. Snoop signal selection

SNPSELx[2:0]	HSP_SNP[5]	HSP_SNP[4]	HSP_SNP[3]	HSP_SNP[2]	HSP_SNP[1]	HSP_SNP[0]
	SNPSELB[2:0]			SNPSELA[2:0]		
0	Disabled	Disabled	Disabled	Disabled	Disabled	Disabled
1	tsk_active[5]	tsk_active[4]	tsk_active[3]	tsk_active[2]	tsk_active[1]	tsk_active[0]
2	prc_evt[25]	prc_evt[24]	prc_evt[23]	-	-	-
3	dcmd_evt	cdeg_evt	hdeg_evt	trgin_evt[0]	buff_evt[0]	adc_evt[0]
4	tsc_pfctnb[5]	tsc_pfctnb[4]	tsc_pfctnb[3]	tsc_pfctnb[2]	tsc_pfctnb[1]	tsc_pfctnb[0]
5	-	-	tsk_cmp[3]	tsk_cmp[2]	tsk_cmp[1]	tsk_cmp[0]
6	tsc_call_pulse	tsc_if_pulse	tsc_iftrue_pulse	evtc_wkup	spe_jump_evt	spe_wfe
7	pe_evt[5]	pe_evt[4]	pe_evt[3]	pe_evt[2]	pe_evt[1]	pe_evt[0]



20.4.19 Break interface (BKITF)

The HSP offers a break output interface, providing up to four break output signals (**hsp_brk_out**[3:0]). These signals can be used by the application to stop sensitive peripherals when a critical issue is detected in the HSP.

The HSP also offers a break input interface allowing the application to freeze the SPE in case of internal errors or errors reported by an external block through **hsp_break_in**. When the SPE breaks, it is possible to store in a capture register which processing list the HSP was executing, as well as a timestamp.

In addition, the BKITF allows the step-by-step processing list execution with the processing function granularity for debugging purposes.

Figure 193. Break interface

1. CTI is not present in all products (refer to *Section 20.3: HSP implementation*).
2. hsp_break_in is not always connected; refer to *Table 139: HSP break connections on STM32H7Power* for more details.

HSP break output interface

For each break output signal, it is possible to select one or several flags as the source. The table below lists the possible sources for the break output interface. The control bits listed in the table must be set to allow the corresponding flag to generate a break signal.

Table 149. Flags and signal sources for break function

Source	Description	Control(1)
ACCERRF	Access error flag	ACCEREN
FPUERRF	FPU Computation errors	FPUEREN
OPCOERRF	Illegal operating code	OPCEREN
PFCTF[31:28]	Flags set by processing function (application dependent)	PFCT[31:28]EN
HDEGOVRF	Dedicated software event generator error	HDEGOVEN
FWERRF	Firmware errors	FWEREN
FPUSATF	FPU saturation flag	FSATEN

1. These bits are in the *HSP break output configuration register x (HSP_BKOxCFGR)*.

Note: These flags are asserted by the HSP or firmware code, and cleared by the application (see Table 146: HSP interrupt requests).

The **hsp_break_out**[x] signal is set when at least one of the enabled sources is activated, and goes back to 0 when all enabled sources are inactive.

HSP break input interface

The break input interface can be used to:

- Freeze the SPE
- Generate capture events to the TSC

The freeze of the SPE can be activated by various sources:

- Several error status flags
- A break input signal
- A start of the end of execution of processing functions
- A request from the DBGMCU
- A request from CTI (if available in the product)

Table 150 lists the possible sources for the break input interface. The control bits must be set to allow the corresponding flag to generate a break signal. These control bits are in the *HSP break input configuration register (HSP_BKICFGR)*.

Note: The BKINF flag is not asserted by all available break sources.

Table 150. Flags and signal sources for break input and debug functions

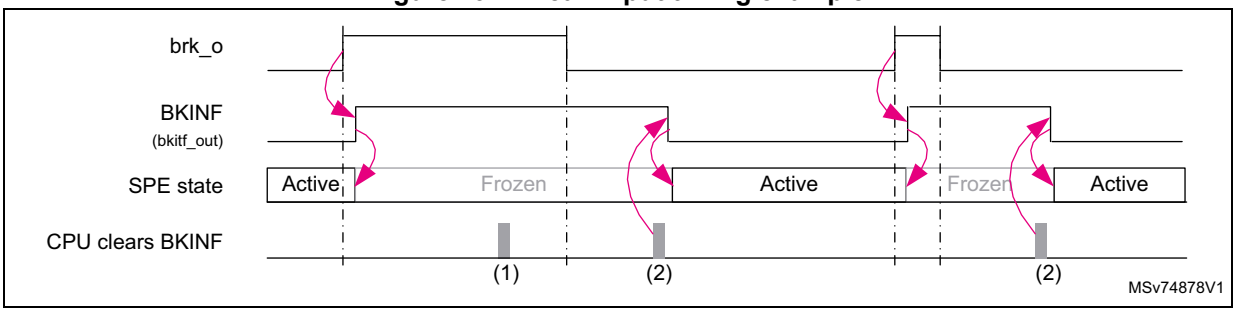
Break sources	Description	HSP control (1)	Affected flag	Affected functions
ACCERRF	Access error flag	ACCEREN	BKINF	SPE freeze
FPUERRF	FPU Computation errors	FPUEREN		
OPCOERRF	Illegal operating code	OPCEREN		
PFCTF[31:28]	Flags set by processing functions	PFCT[31:28]EN		
HDEGOVRF	Dedicated software event generator error	HDEGOVEN		
FWERRF	Firmware errors	FWEREN		
FPUSATF	FPU saturation flag	FSATEN		
tsc_pfctdt	Processing function transition detection	SSEN		
DBGMCU	HSP freeze when CPU breaks	-(2)	-	SPE freeze
CTI	CoreSight CTI	-		

1. These bits are located in the *HSP break input configuration register (HSP_BKICFGR)*, except for DBGMCU and CTI sources.
2. DBGMCU has a bit to control this function (see the DEBUG section of the reference manual).

The SPE freeze is controlled by the **bkitf_spefz** signal. When **bkitf_spefz** is asserted, the SPE immediately stops fetching code and remains frozen. The HSP_CTRL is still accessible, allowing the application to access all HSP registers and memories (conditioned by the REGLCK bit).

The SPE can resume the execution if all enabled break sources are inactive and the corresponding flags are cleared.

In addition, the moment the SPE is frozen, a capture event is sent to the TSC to store the time-stamp, the task number, and the processing function number.



If the break is generated by BRK_FUNC, the BKINF is asserted as well. As shown in *Figure 194*, when the application resets the BKINF flag, if the break condition is still present at the input, the BKINF flag is not reset (#1 in the figure). If the break condition is no longer present, the CPU can clear the BKINF flag, and the SPE can resume the execution (#2 in the figure).

When the SPE is in break, the application can decide on one of the following actions:

- Resume the SPE execution: the application clears all enabled break sources and clears the BKINF (by setting BKINC).
- Restart the complete application: the application maintains the SPE frozen by not resetting the BKINF and performs an HSP reset through the RCC control bits.

The break input function is configured through the *HSP break input configuration register (HSP_BKICFGR)*.

Figure 194. Break input timing example

20.5 Debug

The HSP offers the following debug options:

- Freeze the SPE according to some error status flags.

  This can be helpful to find the processing function that is causing the error (see *Application example: SPE freeze on specific error conditions*).
- Freeze the SPE every time the SPE starts the execution of a new processing function (see *Application example: SPE step-by-step debug*).
- Capture a timestamp every time a new processing function is executed (see *Application example: capturing processing function timestamps*).
- Freeze the SPE when the CPU is halted by using a control bit located in the DBGMCU block.

Application example: SPE freeze on specific error conditions

This feature can be used in applications requesting the SPE to stop immediately in case of errors inside or outside the HSP. It can also be used for debugging purposes, to find the processing function generating an unexpected error, for example.

To use this function, the HSP must be programmed as follows:

- Define which flags or signals generate an SPE break (see *Table 150: Flags and signal sources for break input and debug functions*).
- If CAPMOD[1:0] of the TSC block is set to 0b01, when the SPE breaks, the application finds the timestamp, the last task, and the processing function number in the HSP_CAPDR register.

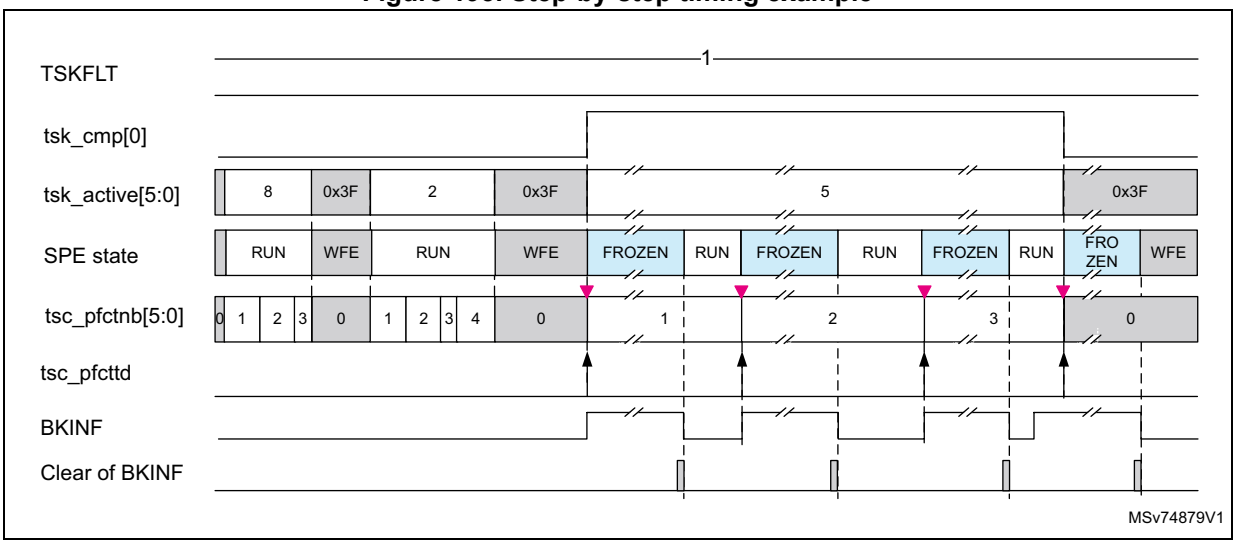
When the SPE breaks due to error detection, the application can decide:

- To resume the SPE execution.
- To restart the complete application.

Application example: SPE step-by-step debug

This feature can be helpful for debugging purposes to analyze data buffers after the execution of each processing function. It is possible to perform this step-by-step debugging only for processing functions located in a specific task, or for any processing function.

To use this feature, the HSP must be programmed as follows:



- If the application intends to break the SPE only when a specific task is executed:
  - In the TCU, write the task number where the step-by-step feature must be activated in TSKCMP0[5:0] of the *HSP task comparator unit register (HSP_TCUCFGR)* and enable the task comparator by setting TC0EN in HSP_TCUCFGR.
  - Set the TSKFLT bit of the HSP_CAPCR register.
- If the application intends to break the SPE every time a new processing function is executed, clear TSKFLT. No need to program the TCU block.
- Allows the step-by-step feature to break the SPE by setting SSEN = 1.
- If the capture mode of the TSC is configured to perform a capture every time the SPE is frozen (CAPMOD[1:0] = 0b01), when the SPE breaks, the application finds the task under execution, the processing function number, and a timestamp in HSP_CAPDR.

When the SPE is in break, the application can check buffer contents and resume the SPE execution. To resume the SPE execution, the application must clear the BKINF flag by setting BKINC in the *HSP error interrupt clear register (HSP_ERR_ICR)*. If additional flags or signals are able to generate a break, all enabled sources must be cleared to resume the SPE.

The CPU can be broken when the SPE breaks (see *Section 20.5.1: Register protection*).

In the figure below, TSKCMP0[5:0] is set to 5. The SPE runs normally until it starts the execution of task number 5. At the start of the execution of task number 5, the SPE breaks, allowing the application to dump the data before execution of processing function number 1. Then the application clears the BKINF flag, and the SPE executes processing function number 1 and breaks again at the start of processing function number 2, allowing the application to dump data, and so on.

Figure 195. Step-by-step timing example

20.5.1 Register protection

The HSP embeds some hardware protection to prevent unexpected changes to register contents when the HSP is activated. *Table 151* shows the list of write-protected and unprotected fields. The register protection is mainly handled by the REGLCK bit.

Note: When the application sets the REGLCK bit, it is no longer possible to clear it by writing this bit to 0. The HSP must be reset.

Table 151. List of locked fields

Register	Unprotected fields	Write-protected fields	Write protection condition
HSP control register (HSP_CR)	BOOTEN REGLCK RSTREQ SPECGDIS MMCCGDIS CTRLCGDIS DCMDEVEN	-	BOOTEN = 1
HSP event enable register (HSP_EVTENR)	-	All	REGLCK = 1
HSP event synchronization enable register (HSP_ESYNCENR)	-	All	REGLCK = 1
HSP event synchronization source register 0 (HSP_ESYNC0SRCR) *HSP event synchronization source register 1 (HSP_ESYNC1SRCR)* *HSP event synchronization source register 2 (HSP_ESYNC2SRCR)*	-	All	REGLCK = 1 or EVTENx = 1
HSP event source register 0 (HSP_EVTSRC0R) *HSP event source register 1 (HSP_EVTSRC1R)* *HSP event source register 2 (HSP_EVTSRC2R)*	-	All	REGLCK = 1 or EVTENx = 1
HSP BUFF configuration register (HSP_BUFFCFGR)	-	All	REGLCK = 1
HSP BUFF configuration register (HSP_BUFFCFGR)	-	All	REGLCK = 1 or BUFFEN = 1
HSP TRGIN configuration register (HSP_TRGINCFGR) *HSP TRGIN input selection register 0 (HSP_TRGINSELR0)* *HSP TRGIN input selection register 1 (HSP_TRGINSELR1)* *HSP TRGIN input selection register 2 (HSP_TRGINSELR2)*	-	All	REGLCK=1 or TRGIxEN = 1
HSP TRGO configuration register (HSP_TRGOCFGR)	-	All	REGLCK = 1 or TRGOEN = 1
HSP task comparator unit register (HSP_TCUCFGR)	-	All	REGLCK = 1
HSP task overlap control register (HSP_TOVLPCR)	-	All	REGLCK = 1
HSP break output configuration register x (HSP_BKOxCFGR)	-	All	REGLCK = 1
HSP break input configuration register (HSP_BKICFGR)	-	All	REGLCK = 1

20.6 HSP firmware description

The HSP is built around a dedicated high-performance signal processor engine (SPE) running the firmware embedded in the CROM and the CRAM. The CROM mainly contains a set of optimized signal processing functions (libraries), and the CRAM contains the scheduler part of the HSP.

These signal processing functions are called “processing functions”, and the application can record several lists of processing functions to be executed upon activation of specific events. These lists of processing functions are called “processing lists”.

Events generated by peripherals trigger tasks, and each task can contain a single processing list.

This section gives an overview of the way that the application can perform the various operations supported by the HSP, such as running a direct command or recording a processing list.

This document does not provide details on processing functions; refer to the user manual *HSP processing functions on STM32 MCUs* (UM3360).

20.6.1 Processing list mapping

Table 152 shows the processing list mapping. Processing lists 0 to 36 are dedicated to recording application processing lists.

Processing lists 37, 38, and 39 are built-in processing lists, not available to the application.

- The processing list number 37, named PLSUP, is responsible for several control tasks, such as recording processing lists.
- The processing list number 38, named PLDCMD, is used to run direct commands when the application wants to use the HSP in accelerator mode.
- The processing list number 39, named PLFAIL, is triggered every time the application tries to execute a processing list with a number higher than 38 or when the application wants to execute a nonexiting processing list.

The built-in processing lists cannot be modified by the application.

After an HSP reset, processing lists 0 to 36 are routed to PLFAIL, to handle the activation of non-exiting processing lists. Every time the application records a new processing list, the link to PLFAIL is replaced by the link to the new processing list.

Several blocks can trigger a processing list: TRGIN, STREAM, CSEG, HSEG, CDEG, HDEG, DCMD.

Table 152 shows that:

- Processing list number 0 can only be triggered by HDEG.
- Processing lists numbers 1 to 22 can be triggered by TRGIN, STREAM, CSEG, HSEG, CDEG, and HDEG.
- Processing lists numbers 23 to 36 can be triggered by CDEG and HDEG
- Processing list number 37 can be triggered by CDEG.
- Processing list number 38 can be triggered by DCMD.

CDEG always has the priority 27 (lowest); HDEG always has the priority 0 (highest); DCMD always has the priority 26.

TRGIN, STREAM, CSEG, and HSEG always have the priority of the processing number they are activating. For example, if STREAM is programmed to trigger processing list number 12, then its priority is 12.

Table 152. Processing list mapping

Peripheral generating events	-	Processing list number	Processing list usage
CDEG, HDEG	→	0	Application PL or jump to PLFAIL
TRGITF, STREAM, CSEG, HSEG, CDEG, HDEG	→	1	Application PL or jump to PLFAIL
	→	...	...
	→	22	Application PL or jump to PLFAIL
CDEG, HDEG	→	23	Application PL or jump to PLFAIL
	→	...	...
	→	36	Application PL or jump to PLFAIL
CDEG	→	37	PLSUP
DCMD	→	38	PLDCMD
-	→	39	PLFAIL

20.6.2 Sending commands to the HSP

The application must send commands to the HSP in the following cases:

- To complete the HSP initialization phase by sending the FW_INIT command.
- When a processing list must be programmed.
- When a direct command must be executed.
- When the application wants to erase all processing lists.

Sending the FW_INIT command

The firmware initialization command (FW_INIT) is sent only once during the initialization phase to give to the HSP firmware the base address of the BRAMAB, and to activate or not the performance monitor. This base address may differ from a product to another.

To send the FW_INIT command, the application must do the following:

1. Wait until the HSP is ready to accept the FW_INIT command, signified by BSTAT[3:0] = 1.
2. Send the FW_INIT command as follows:
   a) Check that MSGB is free (C2HSEM is cleared).
   b) Write the base address of BRAM-AB in HSP_PARAMR0. This address changes from one product to another, so the application needs to provide this information to the HSP.
   c) Clear HSP_PARAMR1 to disable the performance monitor, and set it to enable it.
   d) Write the command ID of the FW_INIT command in HSP_C2HMSGDR.
   e) Set C2HSEM.
3. Check for the completion of the command execution (H2CSEM is set).
4. Read the command status in HSP_H2CMSGDR. If the status differs from 0, the command has not been processed properly.
5. Clear H2CSEM.

Sending commands to the supervisor

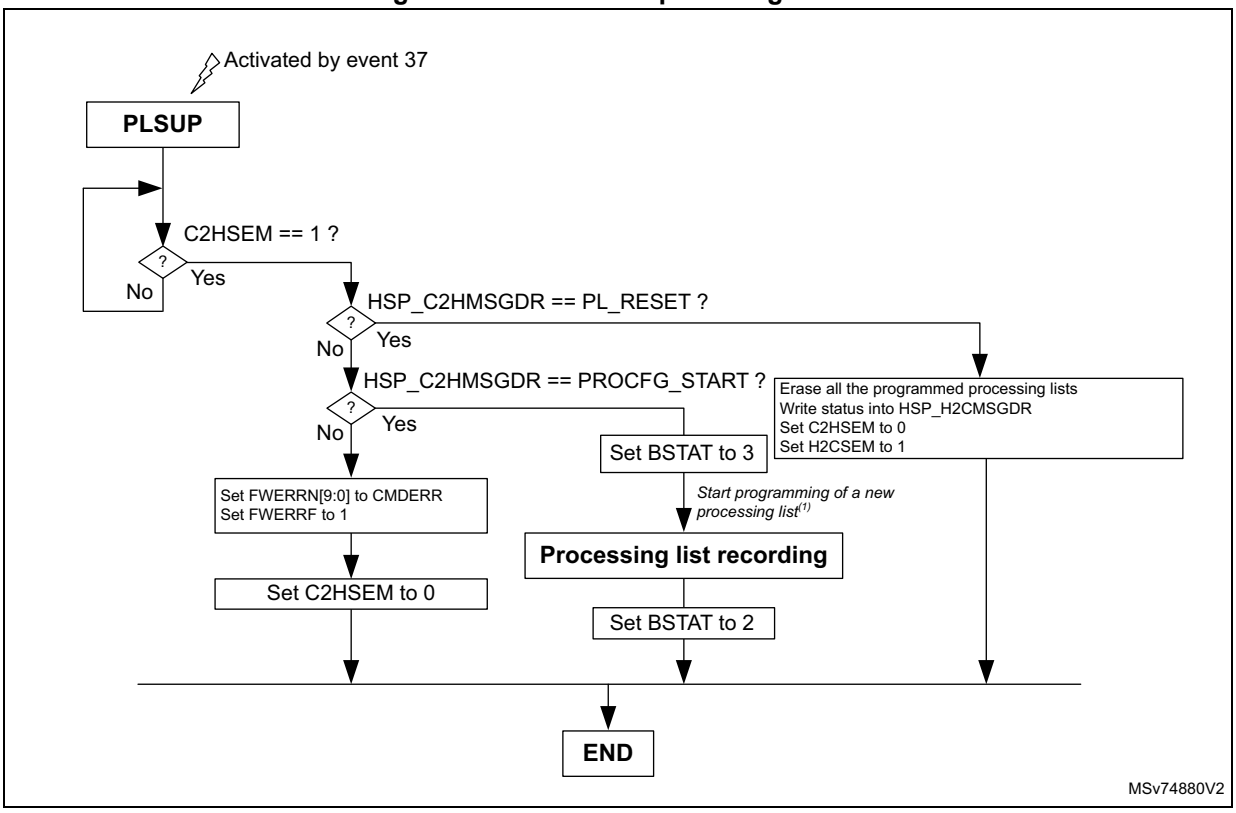
The PLSUP built-in processing list activates the supervisor function. The supervisor can be used to perform various tasks including the processing list recording. The supervisor can be activated at any moment by writing 37 in the *HSP CPU dedicated event generation register (HSP_CDEGR)*.

The supervisor event has the lowest priority. If it is activated while other active events are pending, it is served when all other events are served.

To send a command to the supervisor, the application must:

1. Activate the supervisor.
2. Use the MSGB and HSP_PARAMRx to send commands.

The recommended procedure to send a command to the supervisor is detailed below:



Sending a command to the supervisor

1. If not yet enabled, set CDEGEN in the HSP_IFTENR register.
2. Activate (if not done yet) the supervisor as follows:
   a) Check that CDEG is free (CDEGBSY is cleared).
   b) Write 37 in the HSP_CDEGR register.
3. Check that MSGB is free (C2HSEM is cleared).
4. Write the command parameters in the HSP_PARAMRx registers.
5. Write the command ID in the HSP_C2HMSGDR register.
6. Set C2HSEM in the HSP_C2HSEMR register.
7. Wait for the completion of the command execution (H2CSEM is set).
8. Read the HSP_H2CMSGDR register to get the command status.
9. Clear H2CSEM.

As shown in the figure below, the supervisor can perform the following operations:

- Erase all existing processing lists.
- Program new processing lists.

Figure 196. PLSUP simplified algorithm

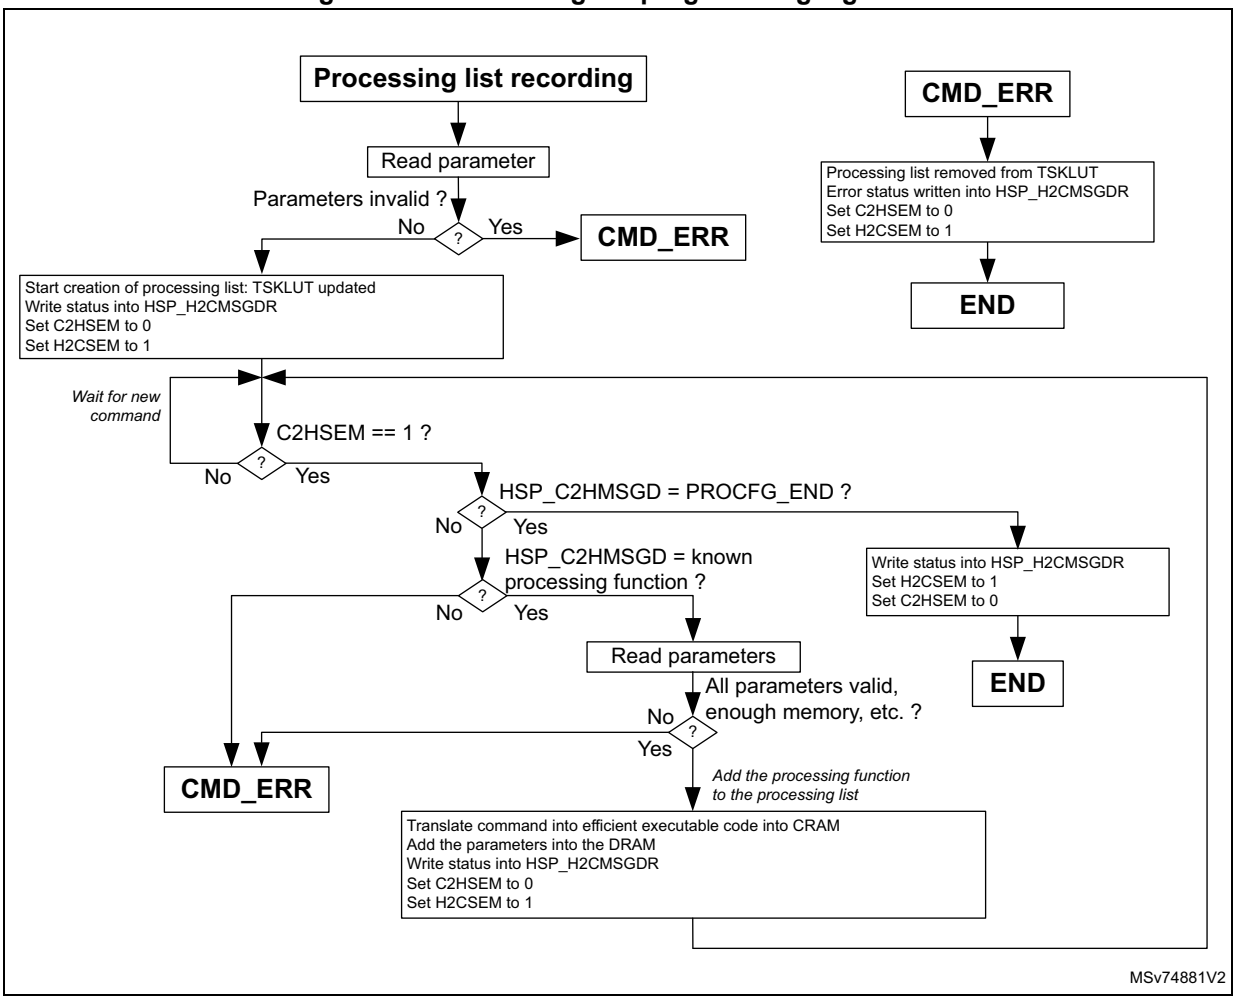
1. Refer to *Figure 197: Processing list programming algorithm*.

20.6.3 Recording processing lists

At any time, the application can add a new processing list to the HSP by activating the supervisor:

1. Send the PROCFG_START command as follows:
   a) Activate the supervisor by writing 37 in HSP_CDEGR (this action activates the supervisor, if not done yet).
   b) Check that C2HSEM is cleared.
   c) Write the processing list number in the HSP_PARAMR0 register.
   d) Write the PROCFG_START command ID in the HSP_C2HMSGDR register.
   e) Set C2HSEM in the HSP_C2HSEMR register.
   f) Wait for H2CSEM to be set, read the command status, and clear H2CSEM.
2. Send the command to record the first processing function as follows:
   a) Check that C2HSEM is cleared.
   b) Write the processing function parameters in the HSP_PARAMRx registers.
   c) Write the processing function command ID in the HSP_C2HMSGDR register.
   d) Set C2HSEM in the HSP_C2HSEMR register.
   e) Wait for H2CSEM to be set, read the command status, and clear H2CSEM.
3. Record the wanted sequence by sending commands as explained in step 2.
4. Write the PROCFG_END command to exit the supervisor:
   a) Check that C2HSEM is cleared.
   b) Write the PROCFG_END command ID in the HSP_C2HMSGDR register.
   c) Set C2HSEM in the HSP_C2HSEMR register.
   d) Wait for H2CSEM to be set, read the command status, and clear H2CSEM.

The number and format of each processing function parameter are described in the user manual *HSP processing functions on STM32 MCUs* (UM3360).



For each command, the HSP firmware sends back a status with HSP_H2CMSGDR.

Figure 197 shows the processing list recording sequence:

1. When the PROCFG_START command is recognized, the supervisor enters into this processing list programming sequencer.
2. BSTAT[3:0] indicates when the supervisor is programming a processing list.
3. When an error is detected, processing list programming is aborted. The processing list address is removed from TSKLUT. The command status reported by the command provides information about the error root cause.

As soon as a processing list is programmed, if its associated event is enabled, activated, and selected by the EVTC, the processing list is executed.

Figure 197. Processing list programming algorithm

20.6.4 Executing direct commands (accelerator mode)

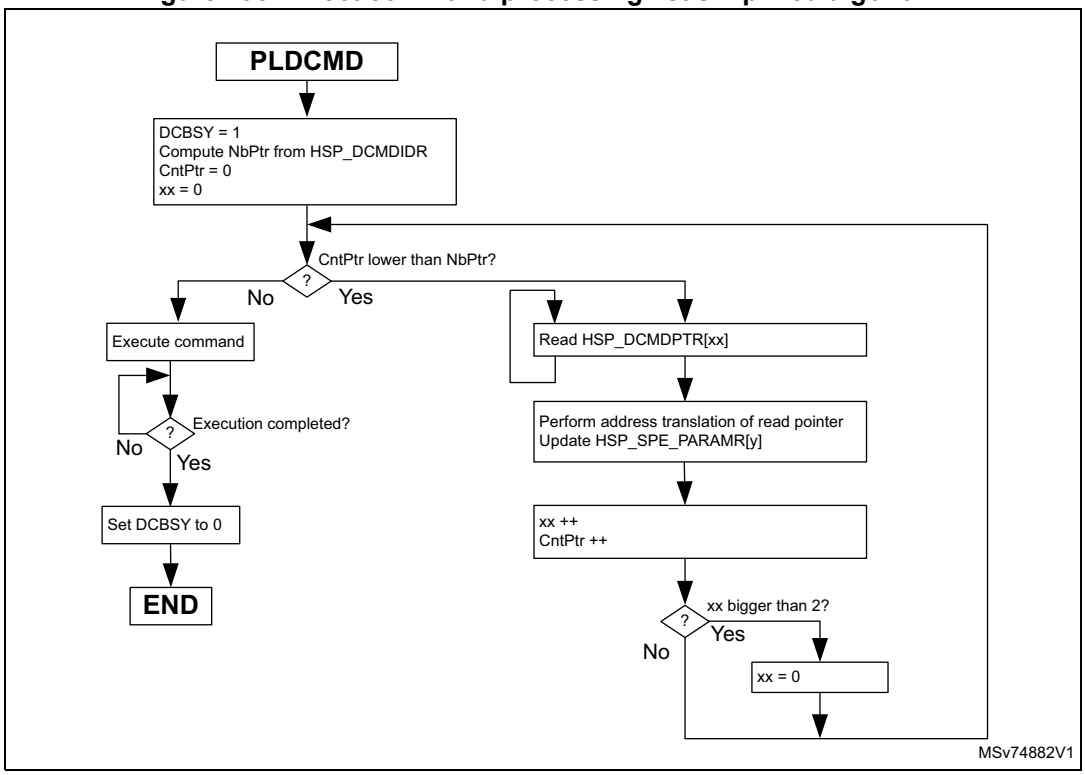
At any time, the application can ask the HSP to execute a processing function as a direct command. If the HSP is executing processing lists, the execution of the direct command is delayed until the EVTC grants the request.

The direct commands are mainly used to execute processing functions dedicated to vector operations. In addition, the processing functions executed in immediate mode can only work with data from BRAM.

The direct command execution is performed through the DCMD and HSP_PARAMRx registers.

The list below provides the recommended sequence to run a direct command. The number of arguments and pointers depend on the command executed (refer to the HSP firmware commands in the user manual *HSP processing functions on STM32 MCUs* (UM3360).

The DCMD block is enabled by default, but can be disabled:



1. Write the command ID of the command to be executed in th *HSP DCMD command ID register (HSP_DCMDIDR)*.
2. Write all parameters except the pointers in HSP_PARAMRx.

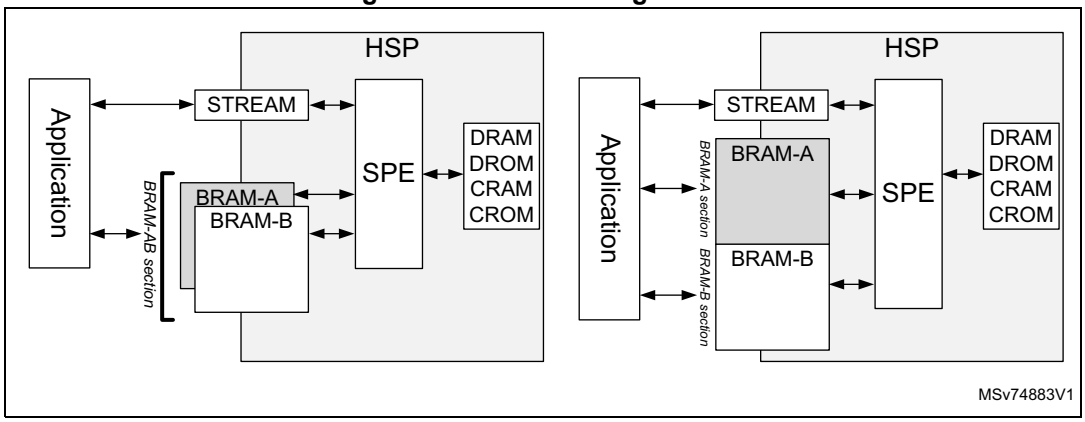
3. Write the first pointer in HSP_DCMDPTR0.
4. Write the second pointer in HSP_DCMDPTR1 (if needed).
5. Write the third pointer in HSP_DCMDPTR2 (if needed).
6. Write the fourth pointer as follows (if needed):
   a) Wait for PRTF0 = 0.
   b) Write the fourth pointer in HSP_DCMDPTR0.
7. Write the fifth pointer as follows (if needed):
   – Wait for PRTF1 = 0.
   – Write the fifth pointer in HSP_DCMDPTR1.
8. And so on
9. Wait for command completion by checking that DCBSY = 0.

Figure 198 describes the PLDCMD built-in processing function. The SPE is expecting from the CPU to program the HSP as described above. To reduce overhead, the PLDCMD task does not perform a lot of checks. The application must properly program the direct command interface.

Note: ST provides a set of functions making the HSP interface transparent for the user.

Figure 198. Direct command processing list simplified algorithm

20.6.5 Data buffer handling



The HSP working buffers are located in the BRAM. Data exchanges between the HSP and the application can use the following interfaces:

- BRAM-A, BRAM-B, or BRAM-AB
- STREAM

Depending on the executed processing function, sharing data through the BRAM must be done using the BRAM-AB section or the BRAM-A and BRAM-B sections. Refer to *Table 153: List of processing functions* for more details.

Using the BRAM-AB section means that the content of BRAM-A must be the same as BRAM-B.

Figure 199. Data sharing models

20.6.6 Performance monitoring

In addition to the TSC block, the HSP also offers a performance monitoring tool, allowing the application to measure the execution time of a processing list.

This function is activated by setting the HSP_PARAM1R register (PERFEN) during the execution of the FW_INIT command.

When activated, a cycle counter value can be read in the last DRAM location after the completion of each processing list. The value is given in HSP core clock cycles (**hsp_hclk_core_ck**). Note that the application cannot read this cycle counter if CDRLCK[1:0] is set to 3.

The cycle counter is cleared every time the HSP starts the execution of a processing list.

Note: The PL_RESET command also allows the enabling or disabling of the performance monitor.

20.6.7 Processing functions summary

The table below gives a summary of all commands that the application can use to program processing functions into processing lists, or to execute them as direct commands. All the commands are described in detail in the user manual *HSP processing functions on STM32 MCUs* (UM3360).

In the table below:

- The column “Type” indicates if the function can be executed immediately in accelerator mode (ACC) or included in a processing list (SEQ).
- The column “STREAM” indicates if input or output data can be taken from the STREAM interface: “Y” = yes, “y/n” = yes for sequencer and no for accelerator mode, “-” means no.
- The column “BRAM” indicates which BRAM section must be used to exchange data: “DP” means that the BRAM-AB section must be used, “SP” means that the BRAM-A, and/or BRAM-B sections must be used.

Table 153. List of processing functions

Processing function mnemonic	Description	Type	STREAM	BRAM
PROCFG_START	Starts the creation of a processing list	SEQ	-	-
PROCFG_END	Ends the creation of a processing list	SEQ	-	-
PL_RESET	Processing list reset	SEQ	-	-
Filter processing functions on real numbers				
BIQDF1_CASC	Cascaded biquad direct form 1 filtering	SEQ, ACC	y/n	DP
BIQDF2T_CASC	Cascaded biquad direct form 2 transposed filtering	SEQ, ACC	y/n	DP
FIR	Optimal FIR filtering	SEQ, ACC	y/n	DP
FIRDEC	FIR filtering with decimation	SEQ, ACC	-	DP
FIRLMS	FIR filtering with adaptive LMS algorithm	SEQ, ACC	y/n	DP
IIRDF1	Optimal IIR filtering using the direct form 1	SEQ, ACC	y/n	DP
IIR_LATTICE	IIR filtering using the Lattice form	SEQ, ACC	y/n	DP
IIR_3P3Z	3rd order IIR filter with saturation and gain adjust	SEQ	Y	DP
IIR_2P2Z	2nd order IIR filter with saturation and gain adjust	SEQ	Y	DP
FLTBANK	Frequency filtering using internal filter banks	SEQ, ACC	-	DP
CONV	Convolution between two vectors	SEQ, ACC	-	DP
CORR	Correlation between two vectors	SEQ, ACC	-	DP
GET_FLTSTATE	Gets the filter state for single stage filters	ACC	-	DP
GET_FLTSTATE_BIQ	Gets the filter state for biquads	ACC	-	DP
SET_FLTSTATE	Sets the filter state for single stage filters	ACC	-	DP
SET_FLTSTATE_BIQ	Sets the filter state for biquads	ACC	-	DP
RST_FLTSTATE	Resets the filter state.	ACC	-	-
Vector processing functions on real				
VECT_ABS	Element-wise absolute value	SEQ, ACC	-	DP
VECT_ABSMAX	Maximum absolute value of a vector	SEQ, ACC	-	DP

Table 153. List of processing functions (continued)

Processing function mnemonic	Description	Type	STREAM	BRAM
VECT_ADD	Element-wise addition	SEQ, ACC	-	DP
VECT_ATAN2	Element-wise arc tangent 2	SEQ, ACC	-	DP
VECT_AVG	Average value	SEQ, ACC	-	DP
VECT_COPY	Vector copy	SEQ, ACC	-	DP
VECT_COS	Element-wise cosine	SEQ, ACC	-	DP
VECT_DEC	Vector decimation	SEQ, ACC	-	DP
VECT_DIV	Element-wise division	SEQ, ACC	-	DP
VECT_DOTP	Dot product	SEQ, ACC	-	DP
VECT_EXP	Element-wise exponential	SEQ, ACC	-	DP
VECT_EXP10	Element-wise 10^x	SEQ, ACC	-	DP
VECT_FTOI	Conversion of float32 to 32-bit signed integers	SEQ, ACC	-	DP
VECT_FTOU	Conversion of float32 to 32-bit unsigned integers	SEQ, ACC	-	DP
VECT_ITOF	Conversion of signed 32-bit integers to float32	SEQ, ACC	-	DP
VECT_I24TOF	Conversion of signed 24-bit integers to float32	SEQ, ACC	-	DP
VECT_Q31TOF	Conversion of signed Q31 to float32	SEQ, ACC	-	DP
VECT_FTOQ31	Conversion of float32 to signed Q31	SEQ, ACC	-	DP
VECT_LN	Element-wise natural logarithm	SEQ, ACC	-	DP
VECT_LOG10	Element-wise logarithm base 10	SEQ, ACC	-	DP
VECT_MAX	Search for value and position of the biggest element	SEQ, ACC	-	DP
VECT_MIN	Search for value and position of the smallest element	SEQ, ACC	-	DP
VECT_MUL	Element-wise product	SEQ, ACC	-	DP
VECT_MULCOS	Element-wise product with a cosine	SEQ, ACC	-	DP
VECT_MULSIN	Element-wise product with a sinus	SEQ, ACC	-	DP
VECT_OFFSET	Adds an offset to each element	SEQ, ACC	y/n	DP
VECT_OFFSETI	Adds an immediate offset to each element	SEQ, ACC	-	DP
VECT_RMS	Root mean square value	SEQ, ACC	y/n	DP
VECT_SIN	Element-wise sinus	SEQ, ACC	-	DP
VECT_SINCOS	Element-wise sinus and cosine	SEQ, ACC	-	DP
VECT_SCALE	Multiplies each element by a value	SEQ, ACC	y/n	DP
VECT_SCALEI	Multiplies each element by an immediate value	SEQ, ACC	-	DP
VECT_SET	Sets a value to each element	SEQ, ACC	y/n	DP

Table 153. List of processing functions (continued)

Processing function mnemonic	Description	Type	STREAM	BRAM
VECT_SETI	Sets an immediate value to each element	SEQ, ACC	y/n	DP
VECT_SQRT	Element-wise square-root	SEQ, ACC	-	DP
VECT_SUB	Element-wise subtraction	SEQ, ACC	-	DP
VECT_UTOF	Conversion of unsigned 32-bit integer to float32	SEQ, ACC	-	DP
VECT_ZINS	Interpolation by inserting zeros	SEQ, ACC	-	DP
Processing functions operating on complex				
CMPLX_CONJ	Element-wise conjugate	SEQ, ACC	-	DP
CMPLX_DOTP	Dot product	SEQ, ACC	-	DP
CMPLX_MAG	Magnitude	SEQ, ACC	-	DP
CMPLX_MAGSQR	Magnitude squared	SEQ, ACC	-	DP
CMPLX_MUL	Element-wise product	SEQ, ACC	-	DP
CMPLX_MULEXP	Element-wise product with an exponential complex	SEQ, ACC	-	DP
CMPLX_RMUL	Element-wise product of a complex with a real vector	SEQ, ACC	-	DP
CMPLX_FTOQ15	Conversion of float32 to Q15 format	SEQ, ACC	-	DP
CMPLX_Q15TOF	Conversion of Q15 to float32 format	SEQ, ACC	-	DP
Scalar processing functions on real				
SCA_ABS	Absolute value	SEQ	Y	DP
SCA_ADD	Addition	SEQ	Y	DP
SCA_ATAN2	Arc tangent 2	SEQ	Y	DP
SCA_CNTCMP	Comparison to a threshold, with a counter	SEQ	-	DP
SCA_COS	Cosine	SEQ	Y	DP
SCA_CLARKE	Clarke transform	SEQ	-	DP
SCA_DIV	Division	SEQ	Y	DP
SCA_EXP	Exponential	SEQ	Y	DP
SCA_EXP10	10^x	SEQ	Y	DP
SCA_FATAN2	Low-precision Arc tangent 2	SEQ	Y	DP
SCA_FCOS	Low-precision cosine	SEQ	Y	DP
SCA_FSIN	Low-precision sinus	SEQ	Y	DP
SCA_FTOI	Conversion of a float32 to signed 32-bit integer	SEQ	-	DP
SCA_FTOQ31	Conversion of a float32 to Q31	SEQ	-	DP
SCA_FTOU	Conversion of a float32 to unsigned 32-bit integer	SEQ	-	DP

Table 153. List of processing functions (continued)

Processing function mnemonic	Description	Type	STREAM	BRAM
SCA_I24TOF	Conversion of a signed 24-bit integer to float32	SEQ	-	DP
SCA_ITOF	Conversion of a signed 32-bit integer to float32	SEQ	-	DP
SCA_Q31TOF	Conversion of a Q31 to float32	SEQ	-	DP
SCA_ICLARKE	Inverses Clarke transform	SEQ	-	DP
SCA_IPARK	Inverses Park transform	SEQ	Y	DP
SCA_LN	Natural logarithm	SEQ	Y	DP
SCA_LOG10	Logarithm base 10	SEQ	Y	DP
SCA_MUL	Product	SEQ	Y	DP
SCA_PARK	Park transform	SEQ	Y	DP
SCA_PID	PID operation	SEQ	Y	DP
SCA_RAMP	Performs a ramp-up or ramp-down	SEQ	-	DP
SCA_SIN	Sinus	SEQ	Y	DP
SCA_SINCOS	Sinus and cosine	SEQ	Y	DP
SCA_SET	Sets a value	SEQ	Y	DP
SCA_SQRT	Square-root	SEQ	Y	DP
SCA_SUB	Subtraction	SEQ	Y	DP
SCA_TOVECT	Builds a vector with consecutive scalar values	SEQ	Y	DP
SCA_UTOF	Conversion of unsigned 32-bit integer into float32	SEQ	Y	DP
Matrix processing functions on real				
MAT_ABS	Computes the absolute value of each element	SEQ, ACC	-	DP
MAT_ADD	Addition of two matrix	SEQ, ACC	-	DP
MAT_INV	Computes the inverse of a matrix	SEQ, ACC	-	DP
MAT_SUB	The subtraction of two matrix	SEQ, ACC	-	DP
MAT_MUL	The product of two matrix	SEQ, ACC	-	DP
MAT_OFFSET	Adds an offset to each element of a matrix	SEQ, ACC	y/n	DP
MAT_SCALE	Multiplies each element of a matrix by a scalar	SEQ, ACC	y/n	DP
MAT_TRANS	Transpose of a matrix	SEQ, ACC	-	DP
MAT_VECT2COL	Copies a vector to a matrix column	SEQ, ACC	-	DP
MAT_COL2VECT	Copies a matrix column into a vector	SEQ, ACC	-	DP
Transform processing functions				
RFFT	Real FFT transform	SEQ, ACC	-	DP
FFT	Complex or real FFT and IFFT transform	SEQ, ACC	-	DP
DCT	Discrete cosine transform type 2	SEQ, ACC	-	DP

Table 153. List of processing functions (continued)

Processing function mnemonic	Description	Type	STREAM	BRAM
Conditional processing functions				
IF_ELSE	IF-THEN-ELSE functions	SEQ	-	DP
LOOP	Loop function	SEQ	-	DP
Convolution processing functions				
CNN_CONV2D	2D convolution	ACC	-	SP
CNN_CONVDW	Depth-wise convolution	ACC	-	SP
CNN_CONVPW	Point-wise convolution	ACC	-	SP
CNN_FC	Fully connected layer	ACC	-	SP
CNN_POOL	Pooling layer	ACC	-	SP
Specific processing functions				
COMP	Compares a vector or scalar to two thresholds, and branch according to result.	SEQ	-	DP
MUL_WIN	Element-wise product with a window	SEQ	-	DP
SAT	Performs a saturation to each vector element, using a programmable MAX and MIN values.	SEQ	-	DP
SEND_EVENT	Triggers an event to the SPE.	SEQ	-	-
SET_FLAG	Sets flags to generate interrupt to the CPU.	SEQ	-	-
SET_GPO	Set GPO signals	SEQ	-	-
SET_TRGO	Sets TRGO signals.	SEQ	-	-
SET_BITS	Forces a specific field to a value.	SEQ	Y	DP
CHK_BITS	Checks values of a bitfield.	SEQ	Y	DP
WAIT_COND	Loops until condition is met.	SEQ	Y	DP

20.7 HSP registers

All HSP registers can be read in 8, 16, or 32 bits. All write operations must be performed in 32 bits.

20.7.1 HSP control register (HSP_CR)

Address offset: 0x000

Reset value: 0x0000 0000

This register is used to control several HSP functions such as HSP boot, register access protection, and smart clock gating.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BSTAT[3:0]				Res.	Res.	BARB[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	RSTOK	RSTREQ
r	r	r	r			rw	rw							r	rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REGLCK	CDRLCK[1:0]		DCMDEVEN	Res.	Res.	Res.	Res.	SPECGDIS	MMCCGDIS	Res.	CTRLCGDIS	Res.	Res.	Res.	BOOTEN
rs	rs	rs	rw					rw	rw		rw				rs

Bits 31:28 **BSTAT[3:0]**: Boot status

Set and cleared by the HSP. This bitfield shows the status of the boot sequence.
For possible values, refer to *Table 141: BSTAT possible values*.

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:24 **BARB[1:0]**: BRAM arbitration

Set and cleared by the CPU.
00: Max arbitration latency is 16 cycles. This setting gives 96% of the BRAM bandwidth to the SPE, when the SPE requests 100% of the BRAM bandwidth. (default after reset).
01: Max arbitration latency is 8 cycles. This setting gives 89% of the BRAM bandwidth to the SPE, when the SPE requests 100% of the BRAM bandwidth.
10: Max arbitration latency is 4 cycles. This setting gives 80% of the BRAM bandwidth to the SPE, when the SPE request 100% of the BRAM bandwidth.
11: Reserved

Note: This bitfield is write-protected when REGLCK = 1.

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **RSTOK**: Reset request accepted

Set by the HSP, cleared by hardware when the HSP is reset. This bit indicates to the CPU that the HSP can be safely reset.
0: The HSP is not yet set into a state which ensures a safe reset. The application must wait until this bit is set (default after reset).
1: The HSP can be safely reset.

Bit 16 **RSTREQ**: Reset request

Set by the CPU, cleared by hardware when the HSP is reset. Writing this bit to 0 has no effect. Read operation returns the effective value.
0: No HSP reset requested (default after reset)
1: HSP reset requested

Bit 15 **REGLCK**: Register write lock access control

Set by the CPU, cleared by hardware when the HSP is reset. Writing this bit to 0 has no effect. Read operation returns the effective value.

0: Registers are accessible by the CPU through the slave AHB interface (default after reset).

1: Selected registers are write-protected and the CPU cannot change the content.

Bits 14:13 **CDRLCK[1:0]**: CRAM and DRAM lock access control

Set by the CPU, cleared by hardware when the HSP is reset. Writing this bit to 0 has no effect. Read operation returns the effective value.

00: CRAM and DRAM are accessible for read and write operations (default after reset).

01: CRAM and DRAM are write protected, but can be read.

1x: CRAM and DRAM are read and write protected.

Bit 12 **DCMDEVEN**: Direct command event enable

Set and cleared by CPU. This bit is used to enable the generation of an event on hsp_txev signal every time the execution of a direct command is completed.

0: Event generation disabled (default after reset)

1: Event generation enabled

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **SPECGDIS**: SPE clock gating disable

Set and cleared by the CPU.

0: SPE clock gating enabled: SPE clocks are locally gated (default after reset).

1: SPE clock gating disabled: SPE clocks are not locally gated.

Bit 6 **MMCCGDIS**: MMC clock gating disable

Set and cleared by the CPU.

0: MMC clock gating enabled: MMC clocks are locally gated (default after reset).

1: MMC clock gating disabled: MMC clocks are not locally gated.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CTRLCGDIS**: HSP_CTRL clock gating disable

Set and cleared by the CPU.

0: HSP_CTRL clock gating enabled: HSP_CTRL clocks are locally gated (default after reset).

1: HSP_CTRL clock gating disabled: HSP_CTRL clocks are not locally gated.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **BOOTEN**: Boot enable control

Set by the CPU and cleared by an HSP reset.

This bit allows the HSP to boot. Writing this bit to 0 has no effect. Read operation returns the effective value.

0: The HSP is not allowed to boot (default after reset).

1: The HSP is allowed to boot, and the SPE executes the code located in the CRAM.

20.7.2 HSP CPU-to-HSP semaphore register (HSP_C2HSEMR)

Address offset: 0x040

Reset value: 0x0000 0000

This register is used by the CPU to synchronize the messages. This register can also be accessed by the SPE processor. When the CPU sets a bit to 1, it sets the corresponding bit. Writing 0 has no effect. Reading returns the effective register value.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	C2HSEM
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **C2HSEM**: CPU to HSP semaphore

Set by the CPU and cleared by the HSP processor. When the CPU writes this bit to 1, it sets the bit. Writing this bit to 0 has no effect. Reading returns the effective bit value.

0: The CPU to HSP MSGB is ready to send a new message (default after reset).

1: The CPU to HSP MSGB contains a message for the HSP not yet read.

20.7.3 HSP CPU-to-HSP message data register (HSP_C2HMSGDR)

Address offset: 0x044

Reset value: 0x0000 0000

This register is used by the CPU to write a message data for the HSP. Writing this register automatically sets C2HSEM in HSP_C2HSEMR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
C2HDATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
C2HDATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **C2HDATA[31:0]**: CPU message for the HSP

Set and reset by software.

20.7.4 HSP HSP-to-CPU semaphore register (HSP_H2CSEMR)

Address offset: 0x048

Reset value: 0x0000 0000

This register is used by the CPU to synchronize the messages. This register can also be accessed by the HSP processor. When the CPU writes a bit to 1, it clears the corresponding bit. Writing 0 has no effect. Reading returns the effective register value.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	H2CSEM
															rc_w1

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **H2CSEM**: HSP to CPU semaphore

Set by the HSP processor, and cleared by the CPU. When the CPU writes this bit to 1, it clears the bit. Writing this bit to 0 has no effect. Reading returns the effective bit value.
0: The HSP to CPU MSGB does not contain a new message from the HSP (default after reset).
1: The HSP to CPU MSGB contains a new message from the HSP.

20.7.5 HSP HSP-to-CPU message data register (HSP_H2CMSGDR)

Address offset: 0x04C

Reset value: 0x0000 0000

This register is used by the CPU to read a message data sent by the HSP.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
H2CDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
H2CDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **H2CDATA[31:0]**: HSP message for the CPU

Set and reset by software.

20.7.6 HSP DCMD command status register (HSP_DCMDSR)

Address offset: 0x058

Reset value: 0x0000 0000

This register is used by the CPU to check if the current direct command execution is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCBSY
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **DCBSY**: Direct command busy flag

Set by hardware and reset by SPE. This flag indicates if the SPE is ready to accept a new MSGD.

0: The current direct command execution is completed. A new CMDID can be written in HSP_DCMDIDR (default after reset).

1: The current direct command execution is ongoing.

20.7.7 HSP DCMD pointer status register (HSP_DCMDPTSR)

Address offset: 0x05C

Reset value: 0x0000 0000

This register is used by the CPU to check if the HSP_DCMDPTRx pointer registers have been read by the SPE.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDOG	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PTRF2	PTRF1	PTRF0
r													r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **RDOG**: Read ongoing indicator

Set and cleared by hardware. This flag indicates if the SPE is currently reading one of the data pointer. The level of this flag can change very fast. It can be used during the debug phase. For example, when the execution of a direct command is abnormally long: if RDOG is stable at 1, it means that the SPE is blocked on the reading of a data pointer. Typically this issue appears when the application did not respect the expected data format for a direct command.

0: SPE does not read a pointer (default after reset).

1: SPE is reading a pointer. The SPE may be blocked if no pointer is provided by the CPU.

Bits 14:3 Reserved, must be kept at reset value.

Bit 2 **PTRF2**: Address pointer 2 flag

Set and cleared by hardware. This flag indicates if the SPE read the last address pointer 2 written by the CPU in HSP_DCMDPTR2.

0: SPE read the address pointer 2. A new address pointer can be written in HSP_DCMDPTR2 (default after reset).

1: The current address pointer 2 has not been read by the SPE.

Bit 1 **PTRF1**: Address pointer 1 flag

Set and cleared by hardware. This flag indicates if the SPE read the last address pointer 1 written by the CPU in HSP_DCMDPTR1.

0: SPE read the address pointer 1. A new address pointer can be written in HSP_DCMDPTR1 (default after reset).

1: The current address pointer 1 has not been read by the SPE.

Bit 0 **PTRF0**: Address pointer 0 flag

Set and cleared by hardware. This flag indicates if the SPE read the last address pointer 0 written by the CPU in HSP_DCMDPTR0.

0: SPE read the address pointer 0. A new address pointer can be written in HSP_DCMDPTR0 (default after reset).

1: The current address pointer 0 has not been read by the SPE.

20.7.8 HSP DCMD command ID register (HSP_DCMDIDR)

Address offset: 0x060

Reset value: 0x0000 0000

This register is used by the CPU to provide the command ID to be executed to the direct command interface (DCMD).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMDID[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMDID[15:0]**: Command ID

Set and reset by software. This value represents the command ID of the command to be executed.

20.7.9 HSP DCMD address pointer register x (HSP_DCMDPTRx)

Address offset: 0x064 + 0x4 * x, (x = 0 to 2)

Reset value: 0x0000 0000

This register is used by the CPU to provide the address pointers to the DCMD.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PTCPU[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PTCPU[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PTCPU[31:0]**: Address pointer value

Set and cleared by CPU. The CPU writes in this bitfield the pointer value requested by direct commands. This pointer value represents a peripheral or memory buffer address ‘seen’ by the CPU. This pointer value is automatically translated into a value directly usable by the SPE.

When the CPU writes this register, the corresponding PTRFx flag is set.

20.7.10 HSP event enable register (HSP_EVTENR)

Address offset: 0x080

Reset value: 0x0000 0000

This register is used to control the generation of events, which trigger a task. Write access operations in this register are not allowed when REGLCK is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EVTEN[22:16]						
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EVTEN[15:1]															Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:1 **EVTEN[22:1]**: Events enable

Set and reset by software. EVTEN[n] controls the enabling/disabling of the event number n.

0: Event generation disabled (default after reset)

1: Event generation enabled

Note: This bitfield is write-protected when REGLCK = 1.

Bit 0 Reserved, must be kept at reset value.

20.7.11 HSP event synchronization enable register (HSP_ESYNCENR)

Address offset: 0x084

Reset value: 0x0000 0000

This register is used to enable or disable the synchronization mechanism for the event generation. Write access operations to this register are not allowed when REGLCK is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **CDEGSYNCEN**: CPU dedicated event synchronization enable

Set and cleared by software. This bit controls the enable/disable of the synchronization for the CPU dedicated event.

0: Synchronization disabled (default after reset)

1: Synchronization enabled.

Note: This bit is write-protected when REGLCK = 1.

Bits 25:23 Reserved, must be kept at reset value.

Bits 22:1 **EVTSYNCEN[22:1]**: Event synchronization enable

Set and cleared by software. EVTSYNCEN[n] controls the enable/disable of the synchronization for the event n.

0: Synchronization disabled (default after reset)

1: Synchronization enabled.

Note: This bitfield is write-protected when REGLCK = 1.

Bit 0 Reserved, must be kept at reset value.

20.7.12 HSP event synchronization source register 0 (HSP_ESYNC0SRCR)

Address offset: 0x088

Reset value: 0x0000 0000

This register is used to select the synchronization source for events 1 to 8. Write access operations to this register are not allowed when REGLCK is set, or when the corresponding EVTENx is set.

20.7.14 HSP event synchronization source register 2 (HSP_ESYNC2SRCR)

Address offset: 0x090

Reset value: 0x0000 0000

This register is used to select the synchronization source for events 17 to 22 and 27. Write access operations to this register are not allowed when REGLCK is set or when the corresponding EVTENx = 1.

11: **tsk_cmp**[3] selected as synchronization source
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[17] = 1.

20.7.15 HSP pending event level register (HSP_PEVTLR)

Address offset: 0x098

Reset value: 0x0000 0000

This register shows event states before the priority encoder. This register is mainly dedicated to debugging purposes.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **EVTL[27:0]**: Event level
Set and cleared by hardware. This bitfield shows the current events level. Bit n correspond to event n.
0: Level low (inactive)
1: Level high (pending)

20.7.16 HSP interface enable register (HSP_ITFENR)

Address offset: 0x0A0

Reset value: 0x0000 0000

This register is used by the application to enable the STREAM and TRGITF peripheral interfaces. CPU write access operations to this register are not allowed when REGLCK is set. This register can also be modified by the SPE.

			rw				rw								

Bit 31 **HDEGEN**: HDEG interface enable bit
Set and cleared by software.
0: HDEG interface disabled, and maintained in reset
1: HDEG interface enabled

Bit 30 **HSEGEN**: HSEG interface enable bit
Set and cleared by software.
0: HSEG interface disabled, and maintained in reset
1: HSEG interface enabled

Bit 29 **CDEGEN**: CDEG interface enable bit
Set and cleared by software.
0: CDEG interface disabled, and maintained in reset
1: CDEG interface enabled
Note: This bit is write-protected when REGLCK = 1.

Bit 28 **CSEGEN**: CSEG interface enable bit
Set and cleared by software.
0: CSEG interface disabled, and maintained in reset
1: CSEG interface is enabled
Note: This bit is write-protected when REGLCK = 1.

Bit 27 **DCMDDIS**: Direct command interface disable bit
Set and cleared by software. This bit can only be written once, after a HSP reset. By default the direct command interface is enabled. Reading returns the effective value.
0: Writing this bit to 0 enables the DCMD interface, and prevents other applications to disable it (default after reset).
1: Writing this bit to 1 disables the DCMD interface. Only an HSP reset can re enable it.
Note: This bit is write-protected when REGLCK = 1.

Bit 26 Reserved, must be kept at reset value.

Bits 25:16 **TRGIxEN**: TRGINx enable bit (x = 9 to 0)
Set and cleared by software.
0: TRGINx disabled, all the TRGIN logic maintained in reset
1: TRGINx enabled
Note: This bit is write-protected when REGLCK = 1.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **TRGOEN**: TRGO enable bit
Set and cleared by software.
0: TRGO function disabled. It is not possible to generate trigger pulses on hsp_trgo[3:0], nor to change the level of hsp_gpo[7:0].
1: TRGO function enabled
Note: This bit is write-protected when REGLCK = 1.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **STREAMEN**: STREAM enable
Set and cleared by software.
0: STREAM disabled
1: STREAM enabled
Note: This bit is write-protected when REGLCK = 1.

Bits 7:0 Reserved, must be kept at reset value.

20.7.17 HSP event source register 0 (HSP_EVTSRC0R)

Address offset: 0x0B4

Reset value: 0x0000 0000

This register is used to select the event source for the priority encoder inputs 1 to 8. Write access operations to this register are not allowed when REGLCK is set, or when the corresponding EVTENx is set.

Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[6] = 1.

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **EVT5SRC[2:0]**: Event source selection for priority encoder input 5
Set and cleared by software.
000: Reserved, no event selected
001: Reserved, no event selected
010: Event provided by the BUFF0 is selected (**buff_evt**[0])
011: Event provided by the TRGIN2 is selected (**trgin_evt**[2])
100: Event provided by the TRGIN7 is selected (**trgin_evt**[7])
101: Event provided by the HSEG is selected (**hseg_evt**[5])
110: Event provided by the CSEG is selected (**cseg_evt**[5])
Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[5] = 1.

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **EVT4SRC[2:0]**: Event source selection for priority encoder input 4
Set and cleared by software.
000: Reserved, no event selected
001: Reserved, no event selected
010: Event provided by the BUFF3 is selected (**buff_evt**[3])
011: Event provided by the TRGIN1 is selected (**trgin_evt**[1])
100: Event provided by the TRGIN6 is selected (**trgin_evt**[6])
101: Event provided by the HSEG is selected (**hseg_evt**[4])
110: Event provided by the CSEG is selected (**cseg_evt**[4])
Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[4] = 1.

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **EVT3SRC[2:0]**: Event source selection for priority encoder input 3
Set and cleared by software.
000: Reserved, no event selected
001: Reserved, no event selected
010: Event provided by the BUFF2 is selected (**buff_evt**[2])
011: Event provided by the TRGIN0 is selected (**trgin_evt**[0])
100: Event provided by the TRGIN5 is selected (**trgin_evt**[5])
101: Event provided by the HSEG is selected (**hseg_evt**[3])
110: Event provided by the CSEG is selected (**cseg_evt**[3])
Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[3] = 1.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **EVT2SRC[2:0]**: Event source selection for priority encoder input 2
Set and cleared by software.
000: Reserved, no event selected
001: Reserved, no event selected
010: Event provided by the BUFF1 is selected (**buff_evt**[1])
011: Event provided by the TRGIN4 is selected (**trgin_evt**[4])
100: Event provided by the TRGIN9 is selected (**trgin_evt**[9])
101: Event provided by the HSEG is selected (**hseg_evt**[2])
110: Event provided by the CSEG is selected (**cseg_evt**[2])
Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[2] = 1.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **EVT1SRC[2:0]**: Event source selection for priority encoder input 1
Set and cleared by software.
000: Reserved, no event selected
001: Reserved, no event selected
010: Event provided by the BUFF0 is selected (**buff_evt**[0])
011: Event provided by the TRGIN3 is selected (**trgin_evt**[3])
100: Event provided by the TRGIN8 is selected (**trgin_evt**[8])
101: Event provided by the HSEG is selected (**hseg_evt**[1])
110: Event provided by the CSEG is selected (**cseg_evt**[1])
Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[1] = 1.

20.7.18 HSP event source register 1 (HSP_EVTSRC1R)

Address offset: 0x0B8

Reset value: 0x0000 0000

This register is used to select the event source for the priority encoder inputs 9 to 16. Write access operations to this register are not allowed when REGLCK is set or when the corresponding EVTENx is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

110: Event provided by the CSEG is selected (**cseg_evt**[21])
Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[21] = 1.

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **EVT20SRC[2:0]**: Event source selection for priority encoder input 20
Set and cleared by software.
000: Reserved, no event selected
001: Reserved, no event selected
010: Event provided by the BUFF3 is selected (**buff_evt**[3])
011: Event provided by the TRGIN2 is selected (**trgin_evt**[2])
100: Event provided by the TRGIN7 is selected (**trgin_evt**[7])
101: Event provided by the HSEG is selected (**hseg_evt**[20])
110: Event provided by the CSEG is selected (**cseg_evt**[20])
Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[20] = 1.

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **EVT19SRC[2:0]**: Event source selection for priority encoder input 19
Set and cleared by software.
000: Reserved, no event selected
001: Reserved, no event selected
010: Event provided by the BUFF2 is selected (**buff_evt**[2])
011: Event provided by the TRGIN1 is selected (**trgin_evt**[1])
100: Event provided by the TRGIN6 is selected (**trgin_evt**[6])
101: Event provided by the HSEG is selected (**hseg_evt**[19])
110: Event provided by the CSEG is selected (**cseg_evt**[19])
Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[19] = 1.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **EVT18SRC[2:0]**: Event source selection for priority encoder input 18
Set and cleared by software.
000: Reserved, no event selected
001: Reserved, no event selected
010: Event provided by the BUFF1 is selected (**buff_evt**[1])
011: Event provided by the TRGIN0 is selected (**trgin_evt**[0])
100: Event provided by the TRGIN5 is selected (**trgin_evt**[5])
101: Event provided by the HSEG is selected (**hseg_evt**[18])
110: Event provided by the CSEG is selected (**cseg_evt**[18])
Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[18] = 1.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **EVT17SRC[2:0]**: Event source selection for priority encoder input 17
Set and cleared by software.
000: Reserved, no event selected
001: Reserved, no event selected
010: Event provided by the BUFF0 is selected (**buff_evt**[0])
011: Event provided by the TRGIN4 is selected (**trgin_evt**[4])
100: Event provided by the TRGIN9 is selected (**trgin_evt**[9])
101: Event provided by the HSEG is selected (**hseg_evt**[17])
110: Event provided by the CSEG is selected (**cseg_evt**[17])
Other: same as position 101
Note: This bitfield is write-protected when REGLCK = 1 or when EVTEN[17] = 1.

20.7.20 HSP BUFF configuration register (HSP_BUFFCFGR)

Address offset: 0x0F4

Reset value: 0x0000 0000

This register is used by the application to select the direction of each buffer (C2H or H2C), and to configure the buffer combiner. Write access operations to this register are not allowed when REGLCK is set or when BUFFEN is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COMB 2	COMB 1	COMB 0
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

							rw					rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **COMBx**: BUFCMB control for **buff_evt**[x] (x = 2 to 0)

Set and cleared by software. This bit defines how **buff_evt**[x] is activated.

0: **buff_evt**[x] activated when **buff_att**[x] is activated

1: **buff_evt**[x] activated when **buff_att**[x] and **buff_evt**[x+1] are activated

Note: This bit is write-protected when REGLCK = 1 or when BUFFEN = 1.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **I2FEN**: Integer to float32 conversion

Set and cleared by software. The integer to float only works for the RX buffers. The integer number must have one of the following format:

- signed integers
- unsigned 8-, 16-, or 24-bit integers

0: Integer to float32 conversion disabled

1: Integer to float32 conversion enabled

Note: This bit is write-protected when REGLCK = 1 or when BUFFEN = 1.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **BUFFxDIR**: Direction selection of BUFFx (x = 3 to 0)

Set and cleared by software.

0: BUFFx direction is C2H (means written by the CPU and read by the HSP).

1: BUFFx direction is H2C (means read by the CPU and written by the HSP).

Note: This bit is write-protected when REGLCK = 1 or when BUFFEN = 1.

20.7.21 HSP BUFFx data register x (HSP_BUFFxDR)

Address offset: 0x0F8 + 0x4 * x, (x = 0 to 3)

Reset value: 0x0000 0000

This register is used to read or write data into a C2H or H2CBUFF.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BUFFDAT[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BUFFDAT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **BUFFDAT[31:0]**: Data buffer

Set and cleared by software. The application can read H2CBUFFs, and write C2HBUFFs. Writing into a H2CBUFF has no effect, reading a C2HBUFF returns an invalid data.

20.7.22 HSP TRGIN configuration register (HSP_TRGINCFGR)

Address offset: 0x120

Reset value: 0x0000 0000

This register is used to enable and select the polarity of each TRGIN input. Write access operations to this register are not allowed when REGLCK is set or when TRGIxEN is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TRGxPOL**: Polarity selection for TRGINx (x = 9 to 0)

Set and cleared by software.

0: TRGINx triggers on rising edge of the input signal.

1: TRGINx triggers on falling edge of the input signal.

Note: This bit is write-protected when REGLCK = 1 or when TRGI[x]EN= 1.

20.7.23 HSP TRGO configuration register (HSP_TRGOCFGR)

Address offset: 0x124

Reset value: 0x0000 0000

This register is used to enable and select the signal sources generating a trigger output. Write access operations to this register are not allowed when REGLCK is set or when TRGOEN is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **TRGOxSRC[1:0]**: Trigger source selection for **hsp_trgo**[x] (x = 3 to 0)
Set and cleared by software.
00: **hsp_trgo**[x] disabled
01: **buff_trgo**[x] selected as trigger source
10: **spe_trgo**[x] selected as trigger source
11: **tsc_trgo** selected as trigger source
Note: This bitfield is write-protected when REGLCK = 1 or when TRGOEN = 1.

20.7.24 HSP TRGIN input selection register 0 (HSP_TRGINSELR0)

Address offset: 0x150

Reset value: 0x0000 0000

This register is used to select the input trigger signal for TRGIN0 to TRGIN3. Write access operations to this register are not allowed when REGLCK is set or when the corresponding TRGIxEN is set.

Note: The number of valid positions depends on the number of trigger inputs implemented in the product (see Section 20.3: HSP implementation).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	TRG1SEL[5:0]						Res.	Res.	TRG0SEL[5:0]					
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:24 **TRG3SEL[5:0]**: Input trigger selection for TRGIN3
Set and cleared by software.
0: **hsp_trgi**[0] input signal selected
1: **hsp_trgi**[1] input signal selected
x: **hsp_trgi**[x] input signal selected (x must be lower than 20)
Note: This bit is write-protected when REGLCK = 1 or when TRGI3EN= 1.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRG2SEL[5:0]**: Input trigger selection for TRGIN2
Set and cleared by software.
0: **hsp_trgi**[0] input signal selected
1: **hsp_trgi**[1] input signal selected
x: **hsp_trgi**[x] input signal selected (x must be lower than 20)
Note: This bit is write-protected when REGLCK = 1 or when TRGI2EN= 1.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **TRG1SEL[5:0]**: Input trigger selection for TRGIN1
Set and cleared by software.
0: **hsp_trgi**[0] input signal selected
1: **hsp_trgi**[1] input signal selected
x: **hsp_trgi**[x] input signal selected (x must be lower than 20)
Note: This bit is write-protected when REGLCK = 1 or when TRGI1EN= 1.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **TRG0SEL[5:0]**: Input trigger selection for TRGIN0
Set and cleared by software.
0: **hsp_trgi**[0] input signal selected
1: **hsp_trgi**[1] input signal selected
x: **hsp_trgi**[x] input signal selected (x must be lower than 20)
Note: This bit is write-protected when REGLCK = 1 or when TRGI0EN= 1.

20.7.25 HSP TRGIN input selection register 1 (HSP_TRGINSELR1)

Address offset: 0x154

Reset value: 0x0000 0000

This register is used to select the input trigger signal for TRGIN4 to TRGIN7. Write access operations to this register are not allowed when REGLCK is set or when the corresponding TRGIxEN is set.

Note: The number of valid positions depends on the number of trigger inputs implemented in the product (see Section 20.3: HSP implementation).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	TRG7SEL[5:0]						Res.	Res.	TRG6SEL[5:0]

Res.	Res.	TRG5SEL[5:0]						Res.	Res.	TRG4SEL[5:0]					
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:24 **TRG7SEL[5:0]**: Input trigger selection for TRGIN7
Set and cleared by software.
0: **hsp_trgi**[0] input signal selected
1: **hsp_trgi**[1] input signal selected
x: **hsp_trgi**[x] input signal selected (x must be lower than 20)
Note: This bit is write-protected when REGLCK = 1 or when TRGI7EN= 1.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRG6SEL[5:0]**: Input trigger selection for TRGIN6
Set and cleared by software.
0: **hsp_trgi**[0] input signal selected
1: **hsp_trgi**[1] input signal selected
x: **hsp_trgi**[x] input signal selected (x must be lower than 20)
Note: This bit is write-protected when REGLCK = 1 or when TRGI6EN= 1.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **TRG5SEL[5:0]**: Input trigger selection for TRGIN5
Set and cleared by software.
0: **hsp_trgi**[0] input signal selected
1: **hsp_trgi**[1] input signal selected
x: **hsp_trgi**[x] input signal selected (x must be lower than 20)
Note: This bit is write-protected when REGLCK = 1 or when TRGI5EN= 1.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **TRG4SEL[5:0]**: Input trigger selection for TRGIN4
Set and cleared by software.
0: **hsp_trgi**[0] input signal selected
1: **hsp_trgi**[1] input signal selected
x: **hsp_trgi**[x] input signal selected (x must be lower than 20)
Note: This bit is write-protected when REGLCK = 1 or when TRGI4EN= 1.

20.7.26 HSP TRGIN input selection register 2 (HSP_TRGINSELR2)

Address offset: 0x158

Reset value: 0x0000 0000

This register is used to select the input trigger signal for TRGIN8 to TRGIN9. Write access operations to this register are not allowed when REGLCK is set or when the corresponding TRGIxEN is set.

Note: The number of valid positions depends on the number of trigger inputs implemented in the product (see Section 20.3: HSP implementation).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	TRG9SEL[5:0]						Res.	Res.	TRG8SEL[5:0]					
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **TRG9SEL[5:0]**: Input trigger selection for TRGIN9
Set and cleared by software.
0: **hsp_trgi**[0] input signal selected
1: **hsp_trgi**[1] input signal selected
x: **hsp_trgi**[x] input signal selected (x must be lower than 20)
Note: This bit is write-protected when REGLCK = 1 or when TRGI9EN= 1.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **TRG8SEL[5:0]**: Input trigger selection for TRGIN8
Set and cleared by software.
0: **hsp_trgi**[0] input signal selected
1: **hsp_trgi**[1] input signal selected
x: **hsp_trgi**[x] input signal selected (x must be lower than 20)
Note: This bit is write-protected when REGLCK = 1 or when TRGI8EN= 1.

20.7.27 HSP CPU shared event generator register (HSP_CSEGR)

Address offset: 0x12C

Reset value: 0x0000 0000

This register is used by the application software to generate an event. Writing 1 sets the corresponding event. Writing 0 has no effect. Reading shows the events status.

Note: If, at the same time, the software sets one of the CSEVT[22:1] bits, and the hardware clears the same bit, the corresponding bit is cleared.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSEVT[15:1]															Res.
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:1 **CSEVT[22:1]**: CPU shared software event
Set by software, cleared by hardware. The application can activated any of the shared event inputs (**cseg_evt**[22:1]) (see *Section 20.3: HSP implementation*).
0: Writing 0 has no effect. Reading 0 means that the corresponding event trigger is not waiting to be served.
1: Writing 1 activates the corresponding event. Reading 1 means that the corresponding event trigger is waiting to be served.

Bit 0 Reserved, must be kept at reset value.

20.7.28 HSP CPU dedicated event generation register (HSP_CDEGR)

Address offset: 0x130

Reset value: 0x0000 0000

This register is used by the application to request the execution of a specific process. Writing into this register activates the event 27.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

										rw	rw	rw	rw	rw	rw

Bit 31 **CDEGBSY**: CPU dedicated event generator busy

Set by hardware and cleared by SPE when the event is taken into account. This flag informs the CPU if the CDEG is ready to accept the generation of a new event.

0: The CDEG ready

1: The CDEG busy: previous event still under processing

Bits 30:6 Reserved, must be kept at reset value.

Bits 5:0 **CTSKN[5:0]**: CPU task number

Set and cleared by software. This bitfield defines the task number associated to **prc_evt**[27]. When the priority encoder selected prc_evt[27], the task given by CTSKN[5:0] is executed.

20.7.29 HSP task comparator unit register (HSP_TCUCFGR)

Address offset: 0x340

Reset value: 0x0000 0000

This register is used to configure the task comparators 0 to 3 of the TCU. Write access operations to this register are not allowed when REGLCK is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TC3EN	Res.	TSKCMP3[5:0]						TC2EN	Res.	TSKCMP2[5:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TC1EN	Res.	TSKCMP1[5:0]						TC0EN	Res.	TSKCMP0[5:0]					
rw		rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw

Bit 31 **TC3EN**: Task comparator 3 enable

Set and cleared by software.

0: TSKCMP3 output disabled

1: TSKCMP3 output enabled

Note: This bit is write-protected when REGLCK = 1.

Bit 30 Reserved, must be kept at reset value.

Bits 29:24 **TSKCMP3[5:0]**: Task compare 3

Set and cleared by software to define which task must be detected by TSKCMP3 output. It is recommended to change this value when TC3EN = 0. This bitfield must be lower or equal to 39.

Note: This bitfield is write-protected when REGLCK = 1.

Bit 23 **TC2EN**: Task comparator 2 enable

Set and cleared by software.
0: TSKCMP2 output disabled
1: TSKCMP2 output enabled

Note: This bit is write-protected when REGLCK = 1.

Bit 22 Reserved, must be kept at reset value.

Bits 21:16 **TSKCMP2[5:0]**: Task compare 2

Set and cleared by software to define which task must be detected by TSKCMP2 output. It is recommended to change this value when TC2EN = 0. This bitfield must be lower or equal to 39.

Note: This bitfield is write-protected when REGLCK = 1.

Bit 15 **TC1EN**: Task comparator 1 enable

Set and cleared by software.
0: TSKCMP1 output disabled
1: TSKCMP1 output enabled

Note: This bit is write-protected when REGLCK = 1.

Bit 14 Reserved, must be kept at reset value.

Bits 13:8 **TSKCMP1[5:0]**: Task compare 1

Set and cleared by software to define which task must be detected by TSKCMP1 output. It is recommended to change this value when TC1EN = 0. This bitfield must be lower or equal to 39.

Note: This bitfield is write-protected when REGLCK = 1.

Bit 7 **TC0EN**: Task comparator 0 enable

Set and cleared by software.
0: TSKCMP0 output disabled
1: TSKCMP0 output enabled

Note: This bit is write-protected when REGLCK = 1.

Bit 6 Reserved, must be kept at reset value.

Bits 5:0 **TSKCMP0[5:0]**: Task compare 0

Set and cleared by software to define which task must be detected by TSKCMP0 output. It is recommended to change this value when TC0EN = 0. This bitfield must be lower or equal to 39.

Note: This bitfield is write-protected when REGLCK = 1.

20.7.30 HSP task overlap control register (HSP_TOVLPCR)

Address offset: 0x344

Reset value: 0x0000 0000

This register is used to configure the task overlap function of the TCU. Write access operations to this register are not allowed when REGLCK is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HTNB[5:0]					
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	LTNB[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	Res.	TOVLPEN
		rw	rw	rw	rw	rw	rw								rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **HTNB[5:0]**: Higher task number value

The selected task group where the task overlap is checked, is strictly higher than LTNB, and lower than HTNB[5:0]. This bitfield has no effect if TOVLPEN = 0.

Note: This bitfield is write-protected when REGLCK = 1.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **LTNB[5:0]**: Lower task number value

The selected task group where the task overlap is checked, is strictly higher than LTNB, and lower than HTNB[5:0]. This bitfield has no effect if TOVLPEN = 0.

Note: This bitfield is write-protected when REGLCK = 1.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **TOVLPEN**: Task overlap enable

Set and cleared by software.

0: Task overlap detector disabled

1: Task overlap detector enabled

Note: This bit is write-protected when REGLCK = 1.

20.7.31 HSP SNOOP register (HSP_SNPR)

Address offset: 0x378

Reset value: 0x0000 0000

This register is used by the CPU to select the bank of signals to observe (see *Section 20.4.18: Snoop function (SNOOP)*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SNPSELB[2:0]			Res.	SNPSELA[2:0]		
									rw	rw	rw		rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **SNPSELB[2:0]**: SNOOP group B signal selection
Set and cleared by software.
000: HSP_SNP[5:3] outputs are disabled.
001: Selects signal set 1 to HSP_SNP[5:3] outputs.
010: Selects signal set 2 to HSP_SNP[5:3] outputs.
011: Selects signal set 3 to HSP_SNP[5:3] outputs.
100: Selects signal set 4 to HSP_SNP[5:3] outputs.
101: Selects signal set 5 to HSP_SNP[5:3] outputs.
110: Selects signal set 6 to HSP_SNP[5:3] outputs.
111: Selects signal set 7 to HSP_SNP[5:3] outputs.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SNPSELA[2:0]**: SNOOP group A signal selection
Set and cleared by software.
000: HSP_SNP[2:0] outputs are disabled.
001: Selects signal set 1 to HSP_SNP[2:0] outputs.
010: Selects signal set 2 to HSP_SNP[2:0] outputs.
011: Selects signal set 3 to HSP_SNP[2:0] outputs.
100: Selects signal set 4 to HSP_SNP[2:0] outputs.
101: Selects signal set 5 to HSP_SNP[2:0] outputs.
110: Selects signal set 6 to HSP_SNP[2:0] outputs.
111: Selects signal set 7 to HSP_SNP[2:0] outputs.

20.7.32 HSP conflict counter register (HSP_CCNTR)

Address offset: 0x37C

Reset value: 0x0000 0000

This register is used by the CPU to get the number of conflicting accesses detected in the BRAM memory. A conflict does not mean that an error occurred. It means that several masters attempted to access the BRAM, and some of these accesses have been delayed by the local arbiter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CCNTR[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCNTR[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **CCNTR[31:0]**: Conflict counter
Set by hardware. This bitfield gives the amount of conflicts. This counter is reset by an HSP reset or when the CCNTREN bit is cleared.

20.7.33 HSP data capture register (HSP_CAPDR)

Address offset: 0x380

Reset value: 0x0000 0000

This register is used by the CPU to read the timestamp of the last captured task number change. This register can take two different formats according to FRCNTEN. Here is the format when FRCNTEN = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TSKNB[5:0]						IFCNT[3:0]				IFHIST[7:2]					
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IFHIST[1:0]		TSTAMP[13:0]													
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:26 **TSKNB[5:0]**: Last captured task number
Set by hardware. This bitfield gives the last captured task number.

Bits 25:22 **IFCNT[3:0]**: IF instruction counter
Set by hardware. This bitfield gives the number of IF instructions executed since the previous processing function.

Bits 21:14 **IFHIST[7:0]**: IF condition history
Set by hardware.
IFHIST[x] = 1 means that the comparison performed on the x^{th} IF instruction after the execution of the previous processing function was true.
IFHIST[x] = 0 means that the comparison was false.

Bits 13:0 **TSTAMP[13:0]**: Time-stamp value
Set by hardware. This bitfield gives the time-stamp of the last captured event.

20.7.34 HSP data capture register [alternate] (HSP_CAPDR)

Address offset: 0x380

Reset value: 0x0000 0000

This register is used by the CPU to read the timestamp of the last captured task number change. This register can take two different formats according to FRCNTEN. Here is the format when FRCNTEN = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TSKNB[5:0]						IFCNT[3:0]				PFCTNB[5:0]					
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	IFHIST[14:0]														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:26 **TSKNB[5:0]**: Last captured task number
Set by hardware. This bitfield gives the last captured task number.

Bits 25:22 **IFCNT[3:0]**: IF instruction counter
Set by hardware. This bitfield gives the number of IF instructions executed since the previous processing function.

Bits 21:16 **PFCTNB[5:0]**: Last captured processing function number
Set by hardware. This bitfield gives the last captured processing function. It is forced to 0 when CAPMOD = 2.

Bit 15 Reserved, must be kept at reset value.

Bits 14:0 **IFHIST[14:0]**: IF condition history
Set by hardware.
IFHIST[x] = 1 means that the comparison performed on the x^{th} IF instruction after the execution of the previous processing function was true.
IFHIST[x] = 0 means that the comparison was false.

20.7.35 HSP capture control register (HSP_CAPCR)

Address offset: 0x384

Reset value: 0x0000 0000

This register is used to control the capture function.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCNTREN

			rw				rw	rw	rw	rw	rw		rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **CCNTREN**: Conflict counter enable
Set and cleared by software. The conflict counter can be used to count the amount of conflicts reported by the MMC to access to the BRAM.
0: Conflict counter disabled, and reset to 0
1: Conflict counter enabled

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **TSKFLT**: Task filter enable
Set and cleared by software.
0: The trace controller asserts the **tsc_pfcttd** signal every time the processing function is executed, independently to the task number running.
1: The trace controller asserts the **tsc_pfcttd** signal every time the processing function executed when the task selected by TSKCMP0[5:0] is running.

Bits 11:9 Reserved, must be kept at reset value.

Bits 8:4 **PRESC[4:0]**: Time-stamp prescaler value
Set and cleared by software. This bitfield gives the division ratio to define the time-stamp granularity.
00000: Clock division is 1 (bypassed).
00001: Clock division is hsp_hclk_core_ck / 2.
00010: Clock division is hsp_hclk_core_ck / 4.
00011: Clock division is hsp_hclk_core_ck / 8.
00100: Clock division is hsp_hclk_core_ck / 16.
00101: Clock division is hsp_hclk_core_ck / 32.
00110: Clock division is hsp_hclk_core_ck / 64.
00111: Clock division is hsp_hclk_core_ck / 128.
01000: Clock division is hsp_hclk_core_ck / 256.
01001: Clock division is hsp_hclk_core_ck / 512.
01010: Clock division is hsp_hclk_core_ck / 1024.
01011: Clock division is hsp_hclk_core_ck / 2048.
01100: Clock division is hsp_hclk_core_ck / 4096.
01101: Clock division is hsp_hclk_core_ck / 8192.
01110: Clock division is hsp_hclk_core_ck / 16384.
01111: Clock division is hsp_hclk_core_ck / 32768.
Other: Reserved

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FRCNTEN**: Free-running counter enable
Set and cleared by software.
0: The free-running counter and prescaler are disabled and reset.
1: The free-running counter and prescaler are enabled.

Bits 1:0 **CAPMOD[1:0]**: Capture mode
Set and cleared by software.
00: Capture function is disabled.
01: A capture is performed every time the SPE breaks.
10: A capture is performed every time the task number changes.
11: A capture is performed every time the processing function number changes.

20.7.36 HSP break output configuration register x (HSP_BKOxCFGR)

Address offset: 0x168 + 0x4 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is used by the application to configure the break outputs 0, 1, 2 or 3 (**hsp_break_out**[3:0] signals). Write access operations to this register are not allowed when REGLCK is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw					rw	rw	rw	rw		rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **HDEGOVEN**: HSP dedicated event generator overrun break enable for HDEGOVRF
Set and cleared by software.
0: HDEGOVRF flag does not generate a break.
1: HDEGOVRF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1.

Bit 12 **FWEREN**: Firmware error break enable for FWERRF
Set and cleared by software.
0: FWERRF flag does not generate a break.
1: FWERRF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1.

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:4 **PFCTxEN**: Processing function flag break enable for PFCTF[x] (x = 31 to 28)
Set and cleared by software.
0: PFCTF[x] does not generate a break.
1: PFCTF[x] generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **OPCEREN**: Opcode error break enable for OPCOERRF
Set and cleared by software.
0: OPCOERRF flag does not generate a break.
1: OPCOERRF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1.

Bit 1 **FPUEREN**: FPU error break enable for FPUERRF
Set and cleared by software.
0: FPUERRF flag does not generate a break.
1: FPUERRF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1

Bit 0 **ACCEREN**: Access error break enable for ACCERRF
Set and cleared by software.
0: ACCERRF flag does not generate a break.
1: ACCERRF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1.

20.7.37 HSP break input configuration register (HSP_BKICFGR)

Address offset: 0x178

Reset value: 0x0000 0000

This register is used by the application to configure the break input. Write access operations to this register are not allowed when REGLCK is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw	rw	rw					rw	rw	rw	rw		rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **SSEN**: Single step enable
Set and cleared by software.
0: The single step function is disabled: the SPE is not frozen when the processing function transition detector provides a trigger.
1: The single step function is enabled: the SPE is frozen every time the processing function transition detector provides a trigger.
Note: This bit is write-protected when REGLCK = 1.

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **FSATEN**: FPU saturation break enable for FPUSATF
Set and cleared by software.
0: FPUSATF flag does not generate a break.
1: FPUSATF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1.

Bit 13 **HDEGOVEN**: HSP dedicated event generator overrun break enable for HDEGOVRF
Set and cleared by software.
0: HDEGOVRF flag does not generate a break.
1: HDEGOVRF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1

Bit 12 **FWEREN**: Firmware error break enable for FWERRF
Set and cleared by software.
0: FWERRF flag does not generate a break.
1: FWERRF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1.

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:4 **PFCTxEN**: Processing function flag break enable for PFCTF[x] (x = 31 to 28)
Set and cleared by software.
0: PFCTF[x] does not generate a break.
1: PFCTF[x] generates a break when asserted
Note: This bit is write-protected when REGLCK = 1.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **OPCEREN**: Opcode error break enable for OPCOERRF
Set and cleared by software.
0: OPCOERRF flag does not generate a break.
1: OPCOERRF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1.

Bit 1 **FPUEREN**: FPU error break enable for FPUERRF
Set and cleared by software.
0: FPUERRF flag does not generate a break.
1: FPUERRF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1.

Bit 0 **ACCEREN**: Access error break enable for ACCERRF
Set and cleared by software.
0: ACCERRF flag does not generate a break.
1: ACCERRF flag generates a break when asserted.
Note: This bit is write-protected when REGLCK = 1.

20.7.38 HSP SPE interrupt enable register (HSP_SPE_IER)

Address offset: 0x280

Reset value: 0x0000 0000

This register allows the SPE to enable or disable an interrupt source. This register is read-only for the CPU, only provided for debugging purposes.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	H2CMFREEIE	C2HMRDYIE
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **H2CMFREEIE**: SPE to CPU message free interrupt enable
Set and cleared by software.
0: Interrupt disabled
1: Interrupt enabled

Bit 0 **C2HMRDYIE**: CPU to SPE message ready interrupt enable
Set and cleared by software.
0: Interrupt disabled
1: Interrupt enabled

20.7.39 HSP SPE interrupt status register (HSP_SPE_ISR)

Address offset: 0x0284

Reset value: 0x0000 0000

This register provides the status flags handled by the HITC. This register is read-only for the CPU, only provided for debugging purposes.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BUF3EVTF	BUF2EVTF	BUF1EVTF	BUF0EVTF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RSTREQF	Res.	Res.	H2CMFREEF	C2HMRDYF
r	r	r	r								r			r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **BUFxEVTF**: BUFFx status (x = 3 to 0)
If configured in C2H direction, this bit is set by hardware when the SPE reads BUFFx. It is cleared when the CPU writes data in HSP_BUFFxDR.
If configured in H2C direction, this bit is set by hardware when the SPE writes BUFFx. It is cleared when the CPU reads a data from HSP_BUFFxDR register.
0: No event pending
1: An event is pending BUFFx empty (if set to C2H) or BUFFx not empty (if set to C2H).

Bits 11:5 Reserved, must be kept at reset value.

Bit 4 **RSTREQF**: HSP reset request
Set and cleared by software.
0: No pending reset request
1: A reset request from the application is pending.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **H2CMFREEF**: SPE to CPU message box status
Set and cleared by software.
0: The SPE to CPU message box is not free.
1: The SPE to CPU message box is free. A new message can be posted for the CPU.

Bit 0 **C2HMRDYF**: CPU to SPE message box status
Set and cleared by software.
0: No message from the CPU
1: A new message from the CPU is available.

20.7.40 HSP error interrupt enable register (HSP_ERR_IER)

Address offset: 0x398

Reset value: 0x0000 0000

This register controls the interrupt enables for all error events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DENORMIE	INVIE	DBZIE	OVFIE	UDFIE	ACCERRIE	OPCOERRIE	Res.	HDEGOVRIE	BKINIE	SCHERRIE	FWERRIE	CAPOVRIE
			rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
B3ERRIE	B2ERRIE	B1ERRIE	B0ERRIE	Res.	Res.	Res.	TRGIOVRIE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw				rw								

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **DENORMIE**: FPU denormal interrupt enable
Set and cleared by software. When this bit is enabled, FPUERRF is set when an invalid exception is reported by the FPU of the SPE.
0: Denormal exception does not activate the FPUERRF flag.
1: Denormal exception activates the FPUERRF flag.

Bit 27 **INVIE**: FPU Invalid exception interrupt enable
Set and cleared by software. When this bit is enabled, FPUERRF is set when an invalid exception is reported by the FPU of the SPE.
0: Invalid exception does not activate the FPUERRF flag.
1: Invalid exception activates the FPUERRF flag.

Bit 26 **DBZIE**: FPU division-by-zero exception interrupt enable
Set and cleared by software. When this bit is enabled, FPUERRF is set when a division-by-zero exception is reported by the FPU of the SPE.
0: Division-by-zero exception does not activate the FPUERRF flag.
1: Division-by-zero exception activates the FPUERRF flag.

Bit 25 **OVFIE**: FPU overflow exception interrupt enable
Set and cleared by software. When this bit is enabled, FPUERRF is set when an overflow exception is reported by the FPU of the SPE.
0: Overflow exception does not activate the FPUERRF flag.
1: Overflow exception activates the FPUERRF flag

Bit 24 **UDFIE**: FPU underflow exception interrupt enable
Set and cleared by software. When this bit is enabled, FPUERRF is set when an underflow exception is reported by the FPU of the SPE.
0: Underflow exception does not activate the FPUERRF flag.
1: Underflow exception activates the FPUERRF flag.

Bit 23 **ACCERRIE**: SPE access error interrupt enable
Set and cleared by software.
0: Access error interrupt disabled
1: Access error interrupt enabled

Bit 22 **OPCOERRIE**: Invalid OpCode error interrupt enable
Set and cleared by software.
0: OpCode error interrupt disabled
1: OpCode error interrupt enabled

Bit 21 Reserved, must be kept at reset value.

Bit 20 **HDEGOVRIE**: SPE event overrun interrupt enable
Set and cleared by software.
0: SPE event overrun interrupt disabled
1: SPE event overrun interrupt enabled

Bit 19 **BKINIE**: Break input interrupt enable
Set and cleared by software.
0: Break input interrupt disabled
1: Break input interrupt enabled

Bit 18 **SCHERRIE**: Scheduler error interrupt enable
Set and cleared by software.
0: Scheduler error interrupt disabled
1: Scheduler error interrupt enabled

Bit 17 **FWERRIE**: Firmware error interrupt enable
Set and cleared by software.
0: Firmware error interrupt disabled
1: Firmware error interrupt enabled

Bit 16 **CAPOVRIE**: Capture register overrun interrupt enable
Set and cleared by software.
0: Capture register overrun interrupt disabled
1: Capture register overrun interrupt enabled

Bits 15:12 **BxERRIE**: H2CBUFFx underrun or C2HBUFFx overrun interrupt enable (x = 3 to 0)
Set and cleared by software.
0: H2C/C2HBUFFx underrun/overrun interrupt disabled
1: H2C/C2HBUFFx underrun/overrun interrupt enabled

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGIOVRIE**: TRGITF overrun interrupt enable
Set and cleared by software.
0: TRGITF overrun interrupt disabled
1: TRGITF overrun interrupt enabled

Bits 7:0 Reserved, must be kept at reset value.

20.7.41 HSP events interrupt enable register (HSP_EVT_IER)

Address offset: 0x39C

Reset value: 0x0000 0000

This register controls the interrupt enable for control events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FPUSATIE	Res.	Res.	TOVLPIE	Res.	Res.	Res.	Res.	EOTECP3IE	EOTECP2IE	EOTECP1IE	EOTECP0IE	SOTECP3IE	SOTECP2IE	SOTECP1IE	SOTECP0IE

rw	rw	rw	rw			rw	rw	rw			rw		rw	rw	rw

Bit 31 **FPUSATIE**: Saturation flag interrupt enable
Set by hardware, and cleared by software.
0: Saturation interrupt disabled
1: Saturation interrupt enabled

Bits 30:29 Reserved, must be kept at reset value.

Bit 28 **TOVLPIE**: Task overlap flag interrupt enable
Set by hardware, and cleared by software.
0: Task overlap interrupt disabled
1: Task overlap interrupt enabled

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:20 **EOTECPxIE**: End of task generated by event comparator x interrupt enable (x = 3 to 0)
Set and cleared by software.
0: End of task interrupt generated by event comparator x disabled
1: End of task interrupt generated by event comparator x enabled

Bits 19:16 **SOTECPxIE**: Start of task generated by event comparator x interrupt enable (x = 3 to 0)
Set and cleared by software.
0: Start of task interrupt generated by event comparator x disabled
1: Start of task interrupt generated by event comparator x enabled

Bits 15:12 **BxEVTIE**: BUFFx event interrupt enable (x = 3 to 0)
Set and cleared by software. The buffer event is buffer empty for C2HBUFF, and buffer not empty for H2CBUFF.
0: BUFFx event interrupt disabled
1: BUFFx event interrupt enabled

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **EOFWFEIE**: End of WFE interrupt enable
Set and cleared by software.
0: End of WFE interrupt disabled
1: End of WFE interrupt enabled

Bit 8 **SOFWFEIE**: Start of WFE interrupt enable
Set and cleared by software.
0: Start of WFE interrupt disabled
1: Start of WFE interrupt enabled

Bit 7 **CDEGRDYIE**: CPU dedicated event generator ready interrupt enable
Set and cleared by software.
0: Dedicated software event generator ready interrupt disabled
1: Dedicated software event generator ready interrupt enabled

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **CAPRDYIE**: Capture buffer data ready interrupt enable
Set and cleared by software.
0: Capture buffer data ready interrupt disabled
1: Capture buffer data ready interrupt enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCDONEIE**: Direct command done interrupt enable
Set and cleared by software. This flag indicates that the execution of a direct command is completed.
0: End of direct command execution interrupt disabled
1: End of direct command execution interrupt enabled

Bit 1 **C2HMFREEIE**: CPU to HSP message box free interrupt enable
Set and cleared by software.
0: CPU to HSP message free interrupt disabled
1: CPU to HSP message free interrupt enabled

Bit 0 **H2CMRDYIE**: HSP to CPU message ready interrupt enable
Set and cleared by software.
0: HSP to CPU message ready interrupt disabled
1: HSP to CPU message ready interrupt enabled

20.7.42 HSP processing event interrupt enable register (HSP_PFCTEVT_IER)

Address offset: 0x3A0

Reset value: 0x0000 0000

This register controls the interrupt enable for flags/events generated by the SPE processing functions.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PFCTIE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PFCTIE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PFCTIE[31:0]**: Processing function flags interrupt enable
Set and cleared by software. These flags are generated by the SPE processing functions.
0: Interrupt not generated on flag activation
1: Interrupt generated on flag activation

20.7.43 HSP error interrupt status register (HSP_ERR_ISR)

Address offset: 0x3A4

Reset value: 0x0000 0000

This register shows the event status for all error events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPUERRF	ACCERRF	OPCOERRF	Res.	HDEGOVRF	BKINF	SCHERRF	FWERRF	CAPOVRF
							r	r	r		r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	r	r	r				r								

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **FPUERRF**: Computation error flag
Set by hardware, and cleared through the FPUERRC bit. This flag can be set if one of the enabled exception occurred: underflow, overflow, division-by-zero, invalid (see *HSP error information register (HSP_ERRINFR)* to get information on the root cause).
0: No computation error event detected
1: A computation error event detected

Bit 23 **ACCERRF**: SPE Access error flag
Set by hardware, and cleared through the ACCERRC bit. This bit is asserted when a SPE access error is detected (see *HSP error information register (HSP_ERRINFR)* to get information on the root cause).
0: No access error event detected
1: An access error event detected

Bit 22 **OPCOERRF**: Invalid OpCode error flag
Set by hardware, and cleared through the OPCOERRC bit.
0: No OpCode error event detected
1: An OpCode error event detected

Bit 21 Reserved, must be kept at reset value.

Bit 20 **HDEGOVRF**: SPE event overrun flag
Set by hardware, and cleared through HDEGOVRC bit.
0: No SPE event overrun event detected
1: An SPE event overrun event detected

Bit 19 **BKINF**: Break input flag
Set by hardware, and cleared through the BKINC bit.
0: No break input event detected
1: A break input event detected

Bit 18 **SCHERRF**: Scheduler error flag
Set by hardware, and cleared through the SCHERRC bit.
0: No scheduler error detected
1: A scheduler error detected

Bit 17 **FWERRF**: Firmware error flag
Set by hardware, and cleared through the FWERRC bit.
0: No firmware error detected
1: A firmware error detected (see *HSP firmware error register (HSP_FWERR)* to get the firmware error number)

Bit 16 **CAPOVRF**: Capture register overrun flag
Set by hardware, and cleared through the CAPOVRC bit.
0: No capture register overrun event detected
1: A capture register overrun event detected

Bits 15:12 **BxERRF**: H2CBUFFx underrun or C2HBUFFx overrun flag (x = 3 to 0)
Set by hardware, and cleared through the B3ERRC bit.
0: No H2C/C2HBUFFx underrun/overrun event detected
1: A H2C/C2HBUFFx underrun/overrun event detected

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGIOVRF**: TRGITF overrun flag
Set by hardware, and cleared through the TRGIOVRC bit (see *HSP error information register (HSP_ERRINFR)* to define which TRGIN block generated an overrun).
0: No TRGITF overrun event detected
1: An TRGITF overrun event detected

Bits 7:0 Reserved, must be kept at reset value.

20.7.44 HSP events interrupt status register (HSP_EVT_ISR)

Address offset: 0x3A8

Reset value: 0x0000 0000

This register shows the event status for all events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FPUSATF	Res.	Res.	TOVLPF	Res.	Res.	Res.	Res.	EOTECP3F	EOTECP2F	EOTECP1F	EOTECP0F	SOTECP3F	SOTECP2F	SOTECP1F	SOTECP0F
r			r					r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
B3EVTF	B2EVTF	B1EVTF	B0EVTF	Res.	Res.	EOFWFEF	SOFWFEF	CDEGRDYF	Res.	Res.	CAPRDYF	Res.	DCDONEF	C2HMFREEF	H2CMRDYF
r	r	r	r			r	r	r			r		r	r	r

Bit 31 **FPUSATF**: FPU saturation flag
Set by hardware, and cleared through the FPUSATC bit. This flag indicates that the FPU detected and performed a saturation.
0: No saturation detected
1: A saturation detected

Bits 30:29 Reserved, must be kept at reset value.

Bit 28 **TOVLPF**: Task overlap flag
Set by hardware, and cleared through the TOVLPC bit.
0: No task overlap situation detected
1: A task overlap situation in the specified task range detected

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:20 **EOTECPxF**: End of task flag, for event comparator x (x = 3 to 0)
Set by hardware, and cleared through the EOTECPxC bit. An end of task is detected by the event comparator x on falling edge of **tsk_cmp**[x].
0: No end of task event detected
1: An end of task event detected

Bits 19:16 **SOTECPxF**: Start of task flag, for event comparator x (x = 3 to 0)
Set by hardware, and cleared through the SOTECP3C bit. A start of task is detected by the event comparator x on rising edge of **tsk_cmp**[x].
0: No start of task event detected
1: A start of task event detected

Bits 15:12 **BxEVTF**: BUFFx event flag (x = 3 to 0)
Set by hardware, and cleared by software by writing C2HBUFFx or reading H2CBUFFx.
0: BUFFx not empty (if configured in C2H) or BUFFx empty if configured in H2C
1: BUFFx empty (if configured in C2H) or BUFFx not empty if configured in H2C

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **EOFWFEF**: End of WFE flag
Set by hardware and cleared by software through the EOFWFEC bit.
0: No end of WFE event detected
1: End of WFE event is detected

Bit 8 **SOFWFEF**: Start of WFE flag
Set by hardware and cleared by software through the SOFWFEC bit.
0: No start of WFE event detected
1: Start of WFE event detected

Bit 7 **CDEGRDYF**: CPU dedicated event generator ready flag
Set by hardware and cleared by software. This flag informs the CPU that the CDEG is ready to accept the generation of a new event. This flag goes to 1 when CDEGBSY goes from 1 to 0.
0: CDEG not ready
1: CDEG ready to accept the generation of a new event

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **CAPRDYF**: Capture buffer data ready flag
Set by hardware, and cleared when HSP_CAPDR is read.
0: No capture buffer data ready event detected
1: A capture buffer data ready event detected

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCDONEF**: Direct command done flag
Set by SPE, and cleared through the DCDONEC bit. This flag indicates that the execution of a direct command is completed.
0: No direct command under execution, or current execution not yet completed
1: Direct command execution completed

Bit 1 **C2HMFREEF**: CPU to HSP message box free flag
Set by hardware, and cleared through the C2HMFREEC bit.
0: No CPU to HSP message busy event detected
1: A CPU to HSP message busy event detected

Bit 0 **H2CMRDYF**: HSP to CPU message ready flag
Set by hardware, and cleared through the H2CMRDYC bit.
0: No HSP to CPU message ready event detected
1: A HSP to CPU message ready event detected

20.7.45 HSP processing event interrupt status register (HSP_PFCTEVT_ISR)

Address offset: 0x3AC

Reset value: 0x0000 0000

This register shows the flag status returned by the SPE processing functions.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PFCTF[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PFCTF[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **PFCTF[31:0]**: Flags generated by SPE processing functions
Set by SPE processing, cleared through the PFCTC[31:0] bits. For eah PFCTFn:
0: Flag not active
1: Flag active

20.7.46 HSP error interrupt clear register (HSP_ERR_ICR)

Address offset: 0x3B4

Reset value: 0x0000 0000

This register is used by the CPU to clear the status flags for error events. Writing 0 has no effect, writing 1 clears the corresponding flag in the HSP_ERR_ISR register. Reading returns zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPUERRC	ACCERRC	OPCOERRC	Res.	HDEGOVRC	BKINC	SCHERRC	FWERRC	CAPOVRC

w	w	w	w				w								

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **FPUERRC**: FPUERRF flag clear
0: No effect
1: Clears FPUERRF in HSP_ERR_ISR.

Bit 23 **ACCERRC**: ACCERRF flag clear
0: No effect
1: Clears ACCERRF in HSP_ERR_ISR, and also SAHBERR, MAHBERR, STIERR, DMERR, and CMERR in HSP_ERRINFR.

Bit 22 **OPCOERRC**: OPCOERRF flag clear
0: No effect
1: Clears OPCOERRF in HSP_ERR_ISR.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **HDEGOVRC**: HDEGOVRF flag clear
0: No effect
1: Clears HDEGOVRF in HSP_ERR_ISR.

Bit 19 **BKINC**: BKINF flag clear
0: No effect
1: Clears BKINF in HSP_ERR_ISR.

Bit 18 **SCHERRC**: SCHERRF flag clear
0: No effect
1: Clears SCHERRF in HSP_ERR_ISR.

Bit 17 **FWERRC**: FWERRF flag clear
0: No effect
1: Clears FWERRF in HSP_ERR_ISR.

Bit 16 **CAPOVRC**: CAPOVRF flag clear
0: No effect
1: Clears CAPOVRF in HSP_ERR_ISR.

Bit 15 **B3ERRC**: B3ERRF flag clear
0: No effect
1: Clears B3ERRF in HSP_ERR_ISR.

Bit 14 **B2ERRC**: B2ERRF flag clear
0: No effect
1: Clears B2ERRFin HSP_ERR_ISR.

Bit 13 **B1ERRC**: B1ERRF flag clear
0: No effect
1: Clears B1ERRF in HSP_ERR_ISR.

Bit 12 **B0ERRC**: B0ERRF flag clear
0: No effect
1: Clears B0ERRF in HSP_ERR_ISR.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGIOVRC**: TRGIOVRF flag clear
0: No effect
1: Clears TRGIOVRF in HSP_ERR_ISR.

Bits 7:0 Reserved, must be kept at reset value.

20.7.47 HSP events interrupt clear register (HSP_EVT_ICR)

Address offset: 0x3B8

Reset value: 0x0000 0000

This register shows the event status for all events. Writing 0 has no effect. Writing 1 clears the corresponding flag in HSP_EVT_ISR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FPUSATC	Res.	Res.	TOVLPC	Res.	Res.	Res.	Res.	EOTECP3C	EOTECP2C	EOTECP1C	EOTECP0C	SOTECP3C	SOTECP2C	SOTECP1C	SOTECP0C

Bit 31 **FPUSATC**: FPUSATF flag clear
0: No effect
1: Clears FPUSATF in HSP_EVT_ISR.

Bits 30:29 Reserved, must be kept at reset value.

Bit 28 **TOVLPC**: TOVLPF flag clear
0: No effect
1: Clears TOVLPF in HSP_EVT_ISR.

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:20 **EOTECPxC**: EOTECPxF flag clear (x = 3 to 0)
0: No effect
1: Clears EOTECPxF in HSP_EVT_ISR.

Bits 19:16 **SOTECPxC**: SOTECPxF flag clear (x = 3 to 0)
0: No effect
1: Clears SOTECP3F in HSP_EVT_ISR.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **EOFWFEC**: EOFWFEF flag clear
0: No effect
1: Clears EOFWFEF in HSP_EVT_ISR.

Bit 8 **SOFWFEC**: SOFWFEF flag clear
0: No effect
1: Clears SOFWFEFF in HSP_EVT_ISR.

Bit 7 **CDEGRDYC**: CDEGRDYF flag clear
0: No effect
1: Clears CDEGRDYF in HSP_EVT_ISR.

Bits 6:3 Reserved, must be kept at reset value.

Bit 2 **DCDONEC**: DCDONEF flag clear
0: No effect
1: Clears DCDONEF in HSP_EVT_ISR.

Bit 1 **C2HMFREEC**: C2HMFREEF flag clear
0: No effect
1: Clears C2HMFREEF in HSP_EVT_ISR.

Bit 0 **H2CMRDYC**: H2CMRDYF flag clear
0: No effect
1: Clears H2CMRDYF in HSP_EVT_ISR.

20.7.48 HSP processing event interrupt clear register (HSP_PFCTEVT_ICR)

Address offset: 0x3BC

Reset value: 0x0000 0000

This register is used to clear the flag status from SPE processing functions. Writing 0 has no effect. Writing 1 clears the corresponding flag in HSP_PFCTEVT_ISR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PFCTC[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PFCTC[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **PFCTC[31:0]**: PFCTF[31:0] flag clear
For each PFCTCn bit:
0: No effect
1: Clears PFCTFn in HSP_PFCTEVT_ISR.

20.7.49 HSP error information register (HSP_ERRINFR)

Address offset: 0x3B0

Reset value: 0x0000 0000

This register gives additional information on the error root cause in case of computation error, or SPE access error.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	TRGIERR[9:0]									
						r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	SAHBERR	MAHBERR	Res.	DMERR	CMERR	Res.	Res.	DENORM	INVALID	DIVZERO	OVFLOW	UDFLOW	INEXACT
			r	r		r	r			r	r	r	r	r	r

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:16 **TRGIERR[9:0]**: TRGIN error information
Updated by hardware when an overrun error occurs in one of the TRGINx. This bitfield is cleared by setting TRGIOVRC.
TRGIERR[x] = 0 means that TRGINx did not detect an overrun.
TRGIERR[x] = 1 means that TRGINx detected an overrun.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **SAHBERR**: Slave AHB access error flag

Updated by hardware when ACCERRF is set. This bit indicates the root cause of the ACCERRF assertion. This bit is cleared by setting ACCERRC.

0: The MMC did not detect invalid accesses from the device.

1: The MMC detected invalid accesses from the device. An invalid access is detected when the device performs an access to an invalid memory space, or when it accesses a memory area protected by CDRLCK[1:0]. Invalid read accesses return 0. Invalid write access operations are ignored.

Note: Accessing above BRAMAB_END (see Figure 160) also generates a bus error.

Bit 11 **MAHBERR**: Internal AHB access error flag

Updated by hardware when ACCERRF is set. This bit indicates the root cause of the ACCERRF assertion. This bit is cleared by setting ACCERRC.

0: The SPE did not generate an AHB access error.

1: The SPE generates an AHB error when accessing to HSP_CTRL.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **DMERR**: Data memory access error flag

Updated by hardware when ACCERRF is set. This bit indicates the root cause of the ACCERRF assertion. This bit is cleared by setting ACCERRC.

0: The SPE did not generate a DRAM/BRAM access error.

1: The SPE performed a load/store outside the DRAM/BRAM range.

Bit 8 **CMERR**: Code memory access error flag

Updated by hardware when ACCERRF is set. This bit indicates the root cause of the ACCERRF assertion. This bit is cleared by setting ACCERRC.

0: The SPE did not generate a CRAM/CROM access error..

1: The SPE performed a fetch/load outside the CRAM/CROM memory range

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **DENORM**: Denormal exception flag

Updated by hardware when a denormal number is detected. The application can clear this bit by writing FPUERRC to 1.

0: No Denormal exception detected

1: Denormal exception detected

Bit 4 **INVALID**: Invalid exception flag

Updated by hardware when an operation produces a result outside float32 domain (such as zero divided by zero or square root of a negative number). The application can clear this bit by writing FPUERRC to 1.

0: No Invalid exception detected

1: Invalid exception detected

Bit 3 **DIVZERO**: Division by zero exception flag

Updated by hardware when an operation produces a result beyond the finite range of float32 domain. The application can clear this bit by writing FPUERRC to 1.

0: No division by 0 exception detected

1: Division by 0 exception detected

Bit 2 **OVFLOW**: Overflow exception flag

Updated by hardware when an operation produces a result beyond the finite range of float32. The application can clear this bit by writing FPUERRC to 1.

0: No Overflow exception detected

1: Overflow exception detected

Bit 1 **UDFLOW**: Underflow exception flag

Updated by hardware when an operation produces a result closer to 0 than supported by the float32. The application can clear this bit by writing FPUERRC to 1.

0: No Underflow exception detected

1: Underflow exception detected

Bit 0 **INEXACT**: Inexact exception flag

Updated by hardware when an operation produces a result that does not fit into its intended destination. The result had to be altered by rounding it off to fit. The application can clear this bit by writing FPUERRC to 1.

0: No Inexact exception detected

1: Inexact exception detected

20.7.50 HSP firmware error register (HSP_FWERR)

Address offset: 0x188

Reset value: 0x0000 0000

This register allows the CPU to check the firmware error number reported by the SPE. This register is read-only for the CPU.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	FWERRN[9:0]									
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **FWERRN[9:0]**: Firmware error number

Set and cleared by SPE. The SPE writes in this register the error root cause to generate an interrupt to the CPU if enabled (see *Table 145: Firmware error number*).

20.7.51 HSP parameter register x (HSP_PARAMRx)

Address offset: 0x194 + 0x4 * x, (x = 0 to 15)

Reset value: 0xXXXX XXXX

These registers are used by the application to provide command parameters to the HSP. They are not reset. The application must initialize them when sending commands to the HSP.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PARAM[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PARAM[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PARAM[31:0]**: Parameter value

Set and cleared by the application, which uses these registers to provide the parameters of commands entered through MSGB or DCMD. These registers can be read and written by the application.

20.7.52 HSP firmware versions register (HSP_FWVERR)

Address offset: 0x3DC

Reset value: 0x0000 0000

This register gives the CROM and CRAM firmware versions. The values inside this register are valid only if BSTAT[3:0] differs from 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRAMAJREV[3:0]				CRAMINREV[7:4]			
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRAMINREV[3:0]				CROMAJREV[3:0]				CROMINREV[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **CRAMAJREV[3:0]**: Code RAM major revision
This bitfield returns the CRAM major revision

Bits 19:12 **CRAMINREV[7:0]**: Code RAM minor revision
This bitfield returns the CRAM minor revision

Bits 11:8 **CROMAJREV[3:0]**: Code ROM major revision
This bitfield returns the CROM major revision

Bits 7:0 **CROMINREV[7:0]**: Code ROM minor revision
This bitfield returns the CROM minor revision

20.7.53 HSP SPE version register (HSP_SPEVERR)

Address offset: 0x3E0

Reset value: 0x0000 0000

This register gives the SPE version and the product ID number. The values inside this register are valid only if BSTAT[3:0] differs from 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PRODID[7:0]								SPEVER[23:16]

SPEVER[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 **PRODID[7:0]**: Product ID number
This bitfield returns the ID of the CRAM/CROM firmware.

Bits 23:0 **SPEVER[23:0]**: SPE version
This bitfield returns the SPE version

20.7.54 HSP register map

Refer to (*Section 2.3.1: Introduction*) for the register boundary addresses.

21 Flexible memory controller (FMC)

The flexible memory controller (FMC) includes three memory controllers:

- The NOR/PSRAM memory controller
- The NAND memory controller
- The Synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) controller

21.1 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, SDRAM memories, and NAND flash memory. Its main purposes are:

- to translate AXI transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique Chip Select. The FMC performs only one access at a time to an external device.

The main features of the FMC are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR flash memory/OneNAND flash memory
  - PSRAM (4 memory banks)
  - NAND flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) memories
- Burst mode support for faster access to synchronous devices such as NOR flash memory, PSRAM and SDRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-,16-bit wide data bus
- Independent Chip Select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM and SDRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth

  The Write FIFO is common to all memory controllers and consists of:
  - a Write Data FIFO which stores the data to be written to the memory
  - a Write Address FIFO which stores the address (up to 28 bits) plus the data size (up to 2 bits). When operating in Burst mode, only the start address is stored except when crossing a page boundary (for PSRAM and SDRAM). In this case, the burst is broken into two FIFO entries.
- Cacheable Read FIFO with 6 x64-bit depth (6 x14-bit address tag) for SDRAM controller.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are set at boot time and do not change until the next reset or power-up. However, only a few bits can be changed on-the-fly:

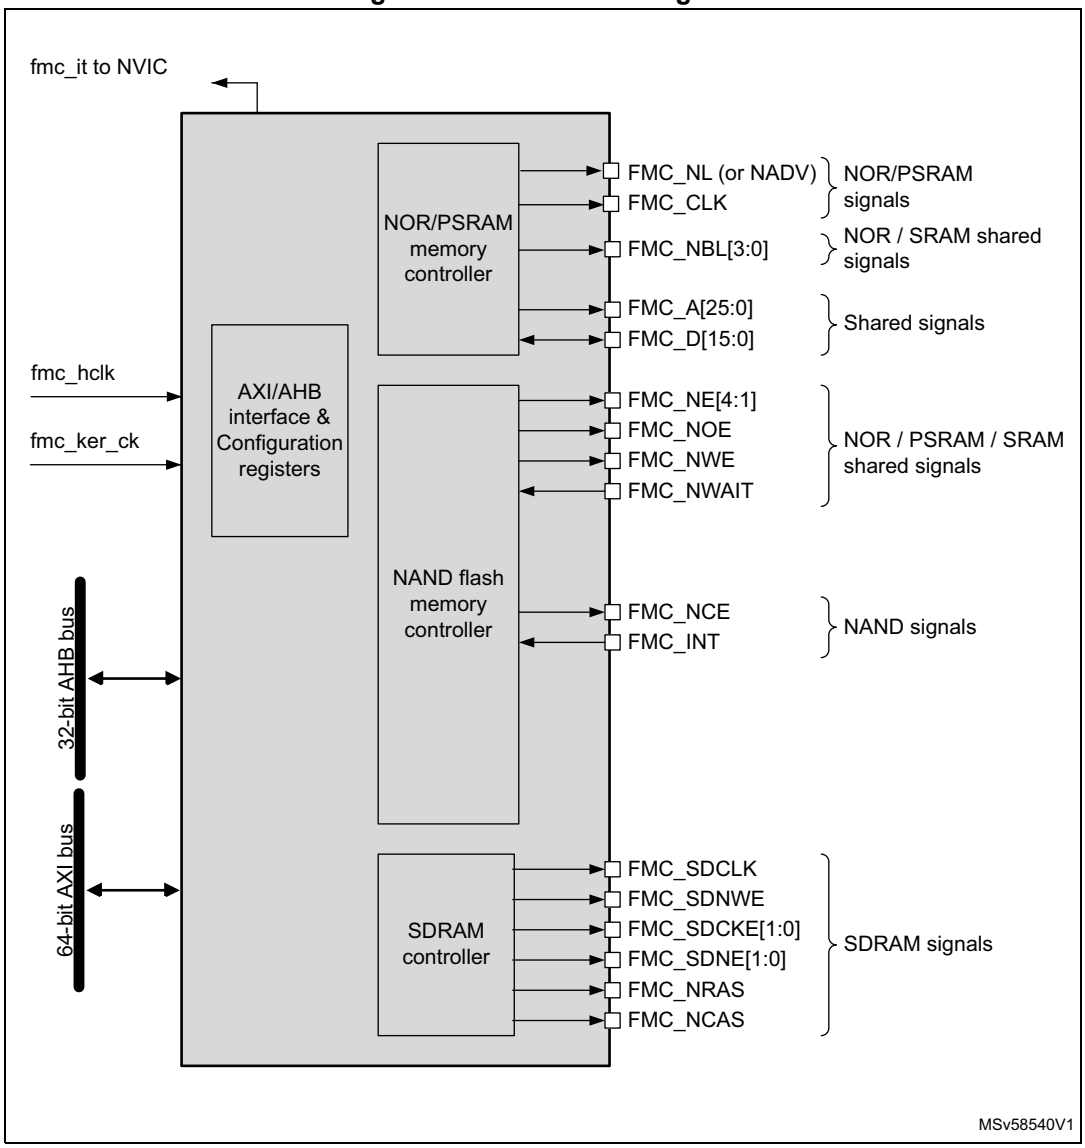
- ECCEN and PBKEN bits in the FMC_PCR register
- IFS, IRS and ILS bits in the FMC_SR register
- MODE[2:0], CTB1/CTB2, NRFS and MRD bits in the FMC_SDCMR register
- REIE and CRE bits in the FMC_SDRTR register.

Follow the below sequence to modify parameters while the FMC is enabled:

1. First disable the FMC to prevent further accesses to any memory controller while the register is modified.
2. Update all required configurations.
3. Enable the FMC again.

When the SDRAM controller is used, if the SDCLK Clock ratio or refresh rate has to be modified after initialization phase, the following procedure must be followed.

1. Put the SDRAM device in Self-refresh mode.
2. Disable the FMC by resetting the FMCEN bit in the FMC_BCR1 register.
3. Update the required parameters.
4. Enable the FMC once all parameters have been updated.
5. Then, send the Clock Configuration Enable command to exit Self-fresh mode.



21.2 FMC block diagram

The FMC consists of the following main blocks:

- The NOR flash/PSRAM/SRAM controller
- The NAND controller
- The SDRAM controller
- The AXI interface
- The AHB interface (including the FMC configuration registers)

The block diagram is shown in the figure below.

Figure 200. FMC block diagram

21.3 FMC internal signals

Table 155 gives the list of FMC internal signals. FMC pins (or external signals) are described in *Section 21.7.1: External memory interface signals*.

Table 155. FMC pins

Names	Signal type	Description
fmc_it	Digital output	FMC interrupt
fmc_ker_ck	Digital input	FMC kernel clock
fmc_hclk	Digital input	FMC interface clock

21.4 AHB interface

The AHB slave interface allows internal CPUs to configure the FMC registers.

The AHB clock (fmc_hclk) is the reference clock for the FMC register accesses.

21.5 AXI interface

The AXI slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AXI transactions are translated into the external device protocol. As the AXI data bus is 64-bit wide, the AXI transactions might be split into several consecutive 32-, 16- or 8-bit accesses according to data size accesses. The FMC Chip Select (FMC_NEx) does not toggle between consecutive accesses except in case of accesses in mode D when the Extended mode is enabled.

The FMC generates an AXI slave error when one of the following conditions is met:

- Reading or writing to an FMC bank (Bank 1 to 4) which is not enabled.
- Reading or writing to the NOR flash bank while the FACCEN bit is reset in the FMC_BCRx register.
- Writing to a write protected SDRAM bank (WP bit set in the FMC_SDCRx register).
- Violation of the SDRAM address range (access to reserved address range)
- Attempting to read/write access from/to SDRAM bank when it is not yet initialized

The FMC generates an AXI decoder error when ADDR[31:28] address bits are not supported by the FMC bank base address following the BMAP[1:0] bits configuration.

The kernel clock for the FMC is the asynchronous fmc_ker_ck clock (refer to for fmc_ker_ck clock source selection).

21.5.1 Supported memories and transactions

General transaction rules

The requested AXI transaction data size can be 8-, 16-, 32- or 64-bit wide whereas the accessed external device has a fixed data width. The best performance is always achieved with aligned AXI transactions whose size matches the external device data width.

When AXI transaction data size is different from the device data width, the result depends on the following factors:

- AXI transaction data size is greater than the device data width:
  - Read/Write transactions: the FMC splits the AXI transaction into smaller consecutive accesses matching the external device data width.
- AXI transaction data size is smaller than the external device data width and the device supports byte selection (SRAM, PSRAM, SDRAM):
  - Write transactions, the FMC manages the transaction using the byte lane signals.
  - Read transactions, the FMC returns all bytes according to the external device data width. The useless bytes are discarded by the system.
- AXI transaction data size is smaller than the external device data width and the device does not support byte selection (NOR and NAND flash memories):
  - Write transactions: the FMC writes some irrelevant bytes which may corrupt the external device
  - Read transactions: the FMC returns all bytes according to the external device data width. The useless bytes are discarded by the system.

Caution: Address alignment

- Read transactions with unaligned addresses (such as half-word starting at an odd address) are not supported by the FMC.
- Write transactions with unaligned addresses

  Their support depends on byte selection availability on the external device:
  - If the device does not support byte selection (NOR and NAND flash memories), narrow write transactions and/or unaligned write transaction are not supported since the FMC would write irrelevant bytes and corrupt the external device.

Wrap support for NOR flash/PSRAM and SDRAM

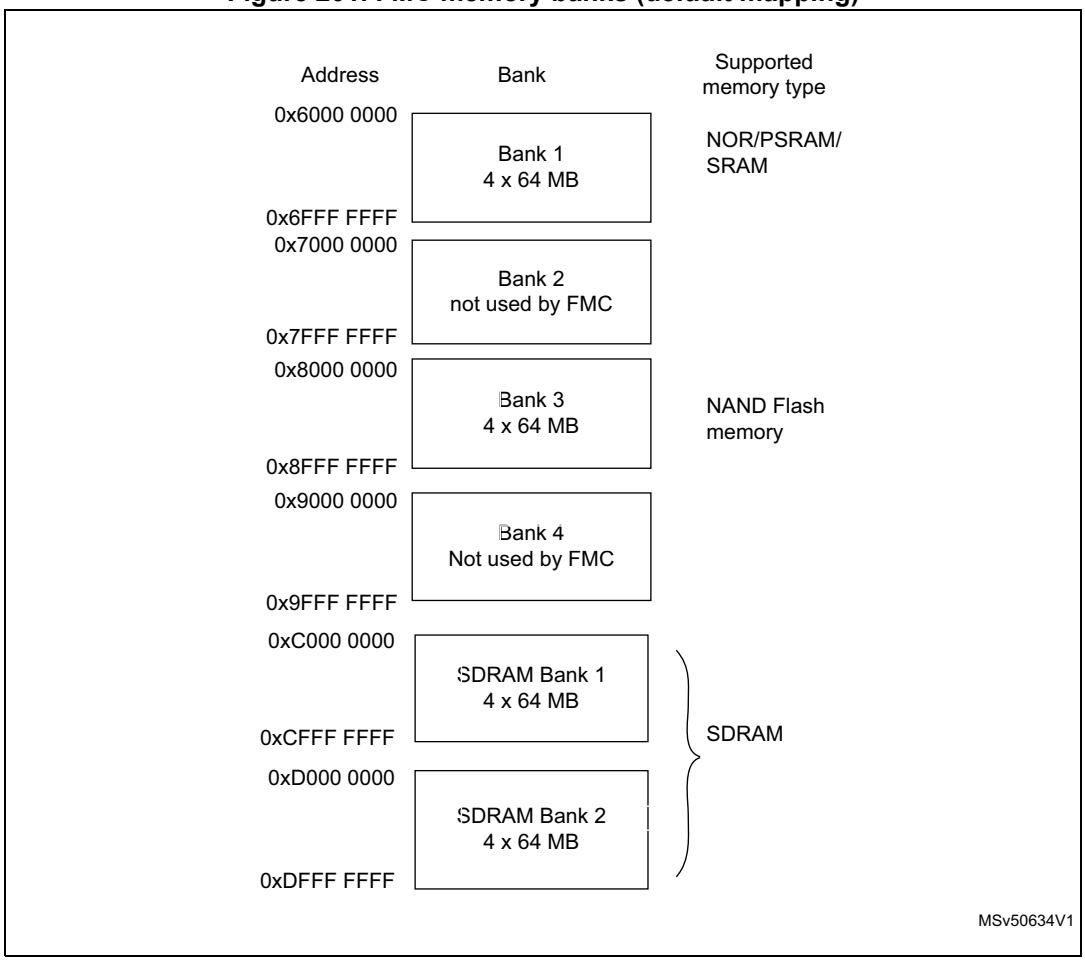
The synchronous memories must be configured in Linear burst mode of undefined length as not all masters can issue wrap transactions.

If a master generates a wrap transaction:

- The read is split into two linear burst transactions.
- The write is split into two linear burst transactions if the write FIFO is enabled and into several linear burst transactions if the write FIFO is disabled.

Configuration registers

The FMC can be configured through a set of registers. Refer to *Section 21.7.6*, for a detailed description of the NOR flash/PSRAM controller registers. Refer to *Section 21.8.7*, for a detailed description of the NAND flash registers and to *Section 21.9.5* for a detailed description of the SDRAM controller registers.



21.6 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see *Figure 201*):

- Bank 1 is used to address up to 4 NOR flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated Chip Selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 2 and Bank 4 are not used by the FMC.
- Bank 3 is used to address NAND flash memory devices.The MPU memory attribute for this space must be reconfigured by software to Device.
- Bank 5 and 6 are used to address SDRAM devices (1 device per bank).

For each bank the type of memory to be used can be configured by the user application through the Configuration register.

Figure 201. FMC memory banks (default mapping)

The FMC bank mapping can be modified through the BMAP[1:0] bits in the FMC_BCR1 register. *Table 156* shows the configuration to swap the NOR/PSRAM bank with SDRAM banks.

Table 156. FMC bank mapping options

Start -End address	BMAP[1:0]=00 (Default mapping)	BMAP[1:0]=01 NOR/PSRAM and SDRAM banks swapped
0x6000 0000 - 0x6FFF FFFF	NOR/PSRAM bank	SDRAM bank1
0x7000 0000 - 0x7FFF FFFF	Not used by FMC	
0x8000 0000 - 0x8FFF FFFF	NAND bank	NAND bank
0x9000 0000 - 0x9FFF FFFF	Not used by FMC	
0xC000 0000 - 0xCFFF FFFF	SDRAM bank1	NOR/PSRAM bank
0xD000 0000 - 0xDFFF FFFF	SDRAM bank2	SDRAM bank2

21.6.1 NOR/PSRAM address mapping

ADDR[27:26] bits are used to select one of the four memory banks as shown in *Table 157*.

Table 157. NOR/PSRAM bank selection

ADDR[27:26](1)	Selected bank
00	Bank 1 - NOR/PSRAM 1
01	Bank 1 - NOR/PSRAM 2
10	Bank 1 - NOR/PSRAM 3
11	Bank 1 - NOR/PSRAM 4

1. ADDR are internal address lines that are translated to external memory.

The ADDR[25:0] bits contain the external memory address. Since ADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 158. NOR/PSRAM External memory address

Memory width(1)	Data address issued to the memory	Maximum memory capacity (bits)
8-bit	ADDR[25:0]	64 Mbytes x 8 = 512 Mbit
16-bit	ADDR[25:1] >> 1	64 Mbytes/2 x 16 = 512 Mbit

1. In case of a 16-bit external memory width, the FMC internally uses ADDR[25:1] to generate the address for external memory FMC_A[24:0].
Whatever the external memory width, FMC_A[0] should be connected to external memory address A[0].

21.6.2 NAND flash memory address mapping

The NAND bank is divided into memory areas as indicated in *Table 159*.

Table 159. NAND memory mapping and timing registers

Start address	End address	FMC bank	Memory space	Timing register
0x8800 0000	0x8BFF FFFF	Bank 3 - NAND flash	Attribute	FMC_PATT (0x8C)
0x8000 0000	0x83FF FFFF		Common	FMC_PMEM (0x88)

For NAND flash memory, the common and attribute memory spaces are subdivided into three sections (see in *Table 160* below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

Table 160. NAND bank selection

Section name	ADDR[17:16]	Address range
Address section	1X	0x020000-0x03FFFF
Command section	01	0x010000-0x01FFFF
Data section	00	0x000000-0x0FFFF

The application software uses the 3 sections to access the NAND flash memory:

- **To send a command to NAND flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data,** the software reads or writes the data from/to any memory location in the data section.

Since the NAND flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

21.6.3 SDRAM address mapping

Two SDRAM banks are available as indicated in *Table 161*.

Table 161. SDRAM bank selection

Selected bank	Control register	Timing register
SDRAM Bank1	FMC_SDCR1	FMC_SDTR1
SDRAM Bank2	FMC_SDCR2	FMC_SDTR2

Table 162 shows SDRAM mapping for a 13-bit row and an 11-bit column configuration.

Table 162. SDRAM address mapping

Memory width(1)	Internal bank	Row address	Column address(2)	Maximum memory capacity (Mbytes)
8-bit	ADDR[25:24]	ADDR[23:11]	ADDR[10:0]	64 Mbytes: 4 x 8K x 2K
16-bit	ADDR[26:25]	ADDR[24:12]	ADDR[11:1]	128 Mbytes: 4 x 8K x 2K x 2

1. When interfacing with a 16-bit memory, the FMC internally uses the ADDR[11:1] internal address lines to generate the external address. When interfacing with a 32-bit memory, the FMC internally uses ADDR[12:2] lines to generate the external address. Whatever the memory width, FMC_A[0] has to be connected to the external memory address A[0].
2. The AutoPrecharge is not supported. FMC_A[10] must be connected to the external memory address A[10] but it is always driven low.

The ADDR[27:0] bits are translated into an external SDRAM address depending on the SDRAM controller configuration:

- Data size:8 or 16 bits
- Row size:11, 12 or 13 bits
- Column size: 8, 9, 10 or 11 bits
- Number of internal banks: two or four internal banks

The following tables show the SDRAM address mapping versus the SDRAM controller configuration.

Table 163. SDRAM address mapping with 8-bit data bus width(1)(2)

Row size configuration	ADDR(Internal Address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Res.					Bank [1:0]		Row[12:0]											Column[8:0]								BM[1:0	
	Res.					Bank [1:0]		Row[12:0]											Column[9:0]								BM[1:0	
	Bank [1:0]					Row[12:0]													Column[10:0]								BM[1:0	

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to ‘0’.
2. Access to Reserved space (Res.) generates an AXI slave error.
3. BM[1:0]: is the byte mask for 32-bit access.

21.7 NOR flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM and ROM
  - 8 bits
  - 16 bits
- PSRAM (Cellular RAM)
  - Asynchronous mode
  - Burst mode for synchronous accesses with configurable option to split burst access when crossing boundary page for CRAM 1.5.
  - Multiplexed or non-multiplexed
- NOR flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique Chip Select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC output Clock (FMC_CLK) is a sub-multiple of the fmc_ker_ck clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (FMC_CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see *Section 21.7.6: NOR/PSRAM controller registers*). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AXI data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AXI data transaction (refer to *Section 21.7.5: Synchronous transactions* for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see *Section 21.7.6: NOR/PSRAM controller registers*).

The programmable memory parameters include access times (see *Table 166*) and support for wait management (for PSRAM and NOR flash memory accessed in Burst mode).

Table 166. Programmable NOR/PSRAM access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Address setup	Duration of the address setup phase	Asynchronous	FMC clock cycle (fmc_ker_ck)	0	15
Address hold	Duration of the address hold phase	Asynchronous, muxed I/Os	FMC clock cycle (fmc_ker_ck)	1	15
Data setup	Duration of the data setup phase	Asynchronous	FMC clock cycle (fmc_ker_ck)	1	256
Bust turn	Duration of the bus turnaround phase	Asynchronous and synchronous read	FMC clock cycle (fmc_ker_ck)	0	15
Clock divide ratio	Number of FMC clock cycles (fmc_ker_ck) to build one memory clock cycle (CLK)	Synchronous	FMC clock cycle (fmc_ker_ck)	2	16
Data latency	Number of clock cycles to issue to the memory before the first data of the burst	Synchronous	Memory clock cycle (fmc_ker_ck)	2	17

21.7.1 External memory interface signals

Table 167, *Table 168* and *Table 169* list the signals that are typically used to interface with NOR flash memory, SRAM and PSRAM.

Note: The prefix “N” identifies the signals which are active low.

NOR flash memory, non-multiplexed I/Os

Table 167. Non-multiplexed I/O NOR flash memory

FMC pin name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:0]	O	Address bus
D[15:0]	I/O	Bidirectional data bus
NE[x]	O	Chip Select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR flash devices)
NWAIT	I	NOR flash wait input signal to the FMC

The maximum capacity is 512 Mbits (26 address lines).

NOR flash memory, 16-bit multiplexed I/Os

Table 168. 16-bit multiplexed I/O NOR flash memory

FMC pin name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip Select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR flash devices)
NWAIT	I	NOR flash wait input signal to the FMC

The maximum capacity is 512 Mbits.

PSRAM/SRAM, non-multiplexed I/Os

Table 169. Non-multiplexed I/Os PSRAM/SRAM

FMC pin name	I/O	Function
CLK	O	Clock (only for PSRAM synchronous access)
A[25:0]	O	Address bus
D[15:0]	I/O	Data bidirectional bus
NE[x]	O	Chip Select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid only for PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[1:0]	O	Byte lane output. Byte 0 and Byte 1 control (upper and lower byte enable)

The maximum capacity is 512 Mbits.

PSRAM, 16-bit multiplexed I/Os

Table 170. 16-Bit multiplexed I/O PSRAM

FMC pin name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip Select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[1:0]	O	Byte lane output. Byte 0 and Byte 1 control (upper and lower byte enable)

The maximum capacity is 512 Mbits (26 address lines).

21.7.2 Supported memories and transactions

Table 171 below shows an example of the supported devices, access modes and transactions when the memory data bus is 16-bit wide for NOR flash memory, PSRAM and SRAM. The transactions not allowed (or not supported) by the FMC are shown in gray in this example.

Table 171. NOR flash/PSRAM: Example of supported memories and transactions(1)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NOR flash (muxed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	
	Asynchronous	W	8	16	N	
	Asynchronous	R	16	16	Y	
	Asynchronous	W	16	16	Y	
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	
	Synchronous	R	16	16	Y	
	Synchronous	R	32/64	16	Y	
PSRAM (multiplexed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	
	Asynchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	16	16	Y	
	Asynchronous	W	16	16	Y	
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	
	Synchronous	R	16	16	Y	
	Synchronous	R	32/64	16	Y	
	Synchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Synchronous	W	16/32/64	16	Y	

Table 171. NOR flash/PSRAM: Example of supported memories and transactions(1) (continued)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
SRAM and ROM	Asynchronous	R	8/16	16	Y	
	Asynchronous	W	8/16	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses Use of byte lanes NBL[1:0]
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses Use of byte lanes NBL[1:0]

1. NBL[1:0] are also driven by AXI write strobes.

21.7.3 General timing rules

Signal synchronization is performed as follows:

- All controller output signals change on the rising edge of the fmc_ker_ck clock.
- In Synchronous read and write modes, all output signals change on the rising edge of fmc_ker_ck clock. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADVL/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

21.7.4 NOR flash/PSRAM controller asynchronous transactions

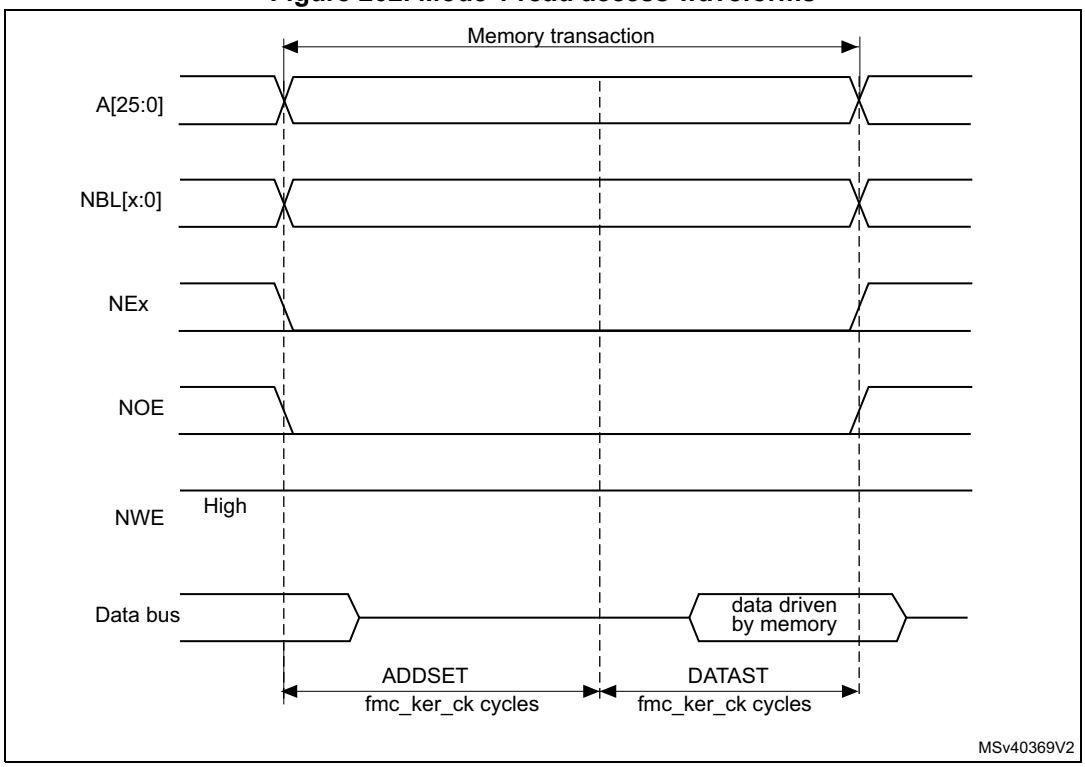
Asynchronous transactions on static memories (NOR flash memory, PSRAM, SRAM) are performed as follows:

- Signals are synchronized by the internal clock. This clock is not issued to the memory.
- The FMC always samples the data before deasserting the Chip Select signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in Mode1 or Mode2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

Mode 1 - SRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

Figure 202. Mode 1 read access waveforms



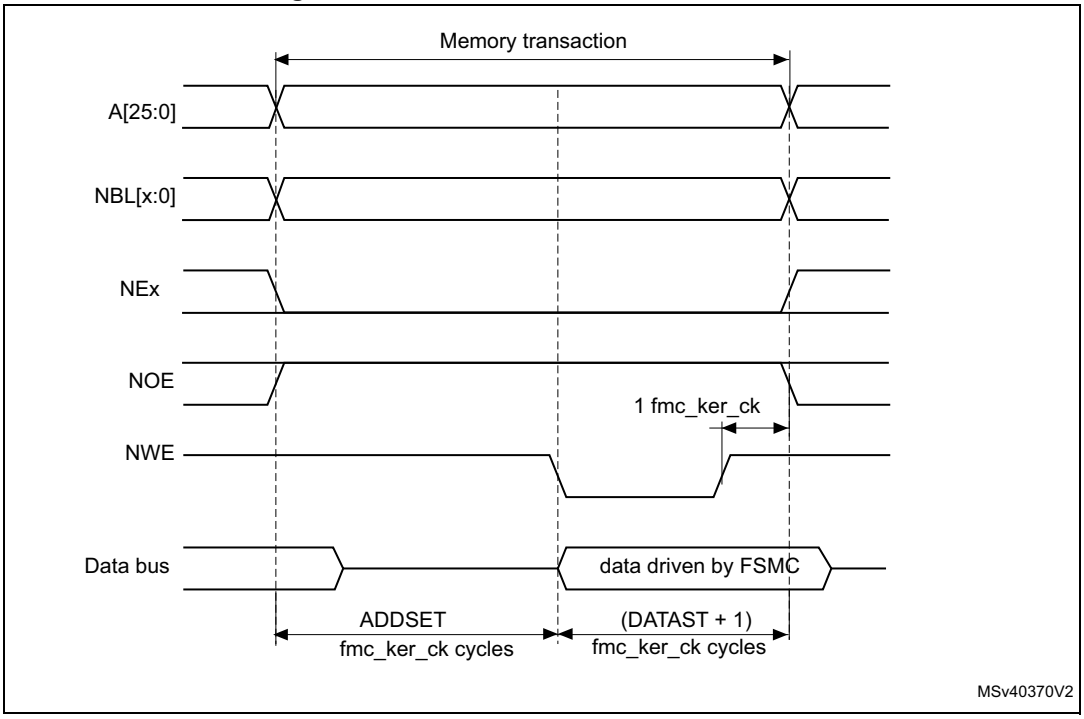


Figure 203. Mode 1 write access waveforms

The fmc_ker_ck cycle at the end of the write transaction helps guarantee the address and data hold time after the NWE rising edge. Due to the presence of this fmc_ker_ck cycle, the DATAST value must be greater than zero (DATAST > 0).

Table 172. FMC_BCRx bitfields (mode 1)

Bit number	Bit name	Value to set
31	FMCEN	0x1
30:26	Reserved	0x000

19:16	BUSTURN	Time between NEx high to NEx low (BUSTURN fmc_ker_ck)
15:8	DATAST	Duration of the second access phase (DATAST fmc_ker_ck cycles) for write accesses.
7:4	ADDHLD	Don’t care
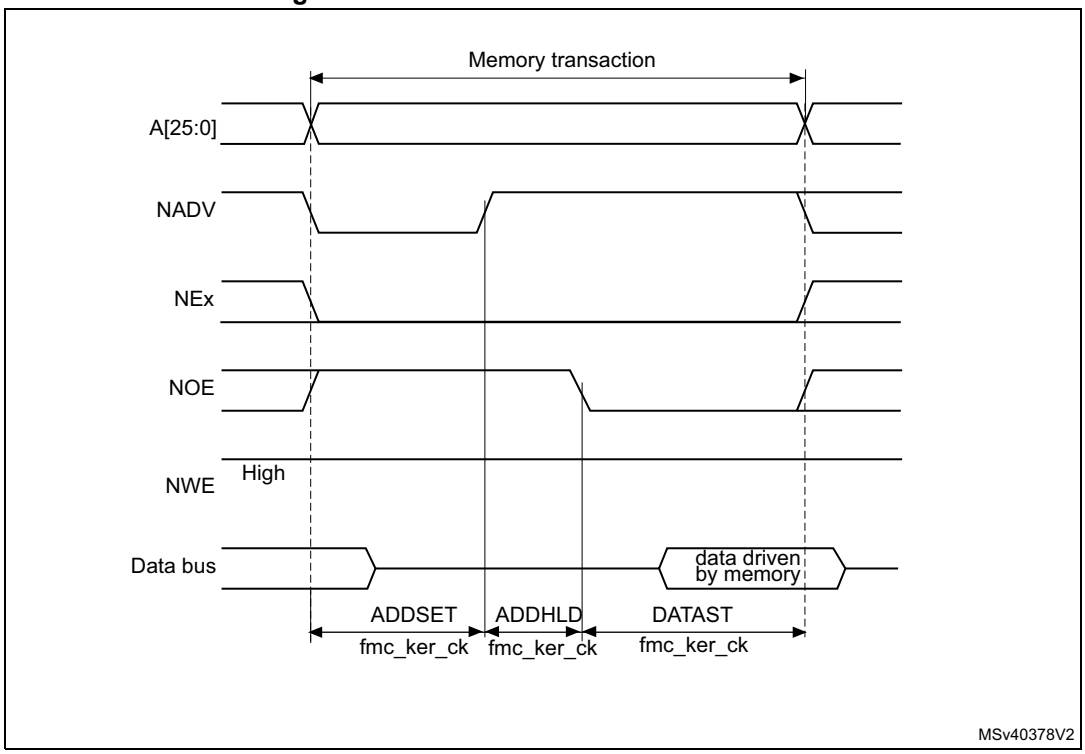
3:0	ADDSET	Duration of the first access phase (ADDSET fmc_ker_ck cycles) for write accesses. Minimum value for ADDSET is 0.

Mode D - asynchronous access with extended address

Figure 211. Mode D read access waveforms



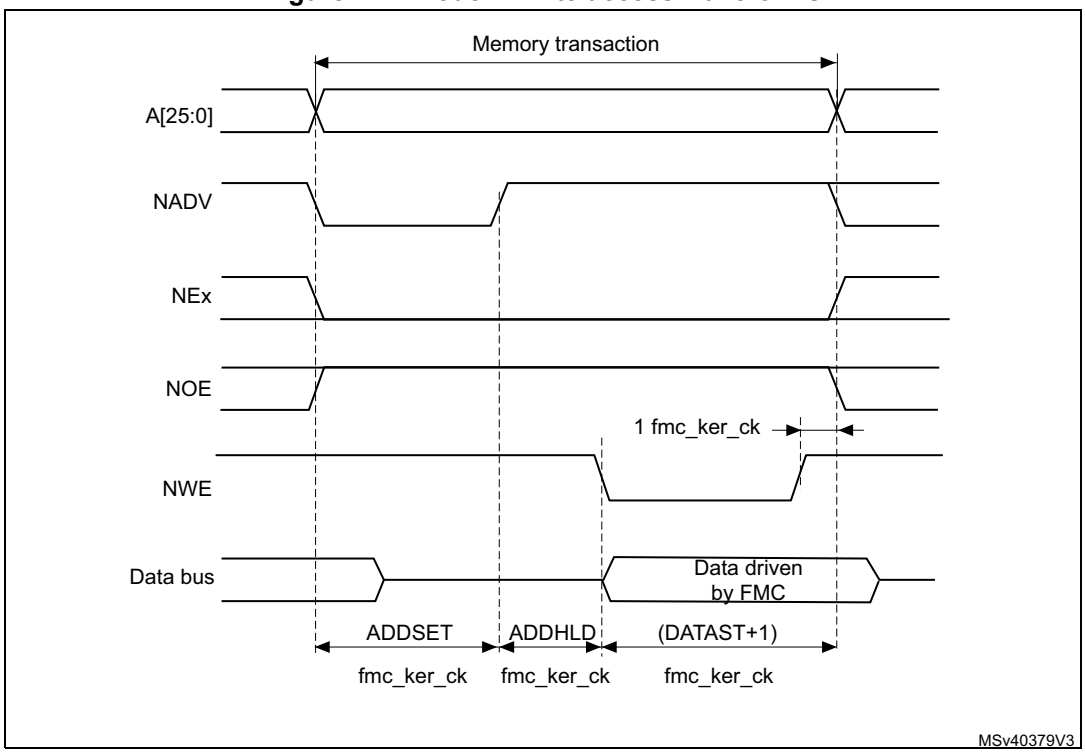


Figure 212. Mode D write access waveforms

The differences with Mode1 are the toggling of NOE that goes on toggling after NADV changes and the independent read and write timings.

Table 183. FMC_BCRx bitfields (mode D)

Bit No.	Bit name	Value to set

7:4	ADDHLD	Duration of the middle phase of the access (ADDHLD fmc_ker_ck cycles).
3:0	ADDSET	Duration of the first access phase (ADDSET fmc_ker_ck cycles). Minimum value for ADDSET is 1.

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 fmc_ker_ck cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:

$$\text{DATAST} \geq (4 \times \text{fmc_ker_ck}) + \text{max_wait_assertion_time}$$

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):

   if

$$\text{max_wait_assertion_time} > \text{address_phase} + \text{hold_phase}$$

   then:

$$\text{DATAST} \geq (4 \times \text{fmc_ker_ck}) + (\text{max_wait_assertion_time} - \text{address_phase} - \text{hold_phase})$$

   otherwise

$$\text{DATAST} \geq (4 \times \text{fmc_ker_ck})$$

   where max_wait_assertion_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

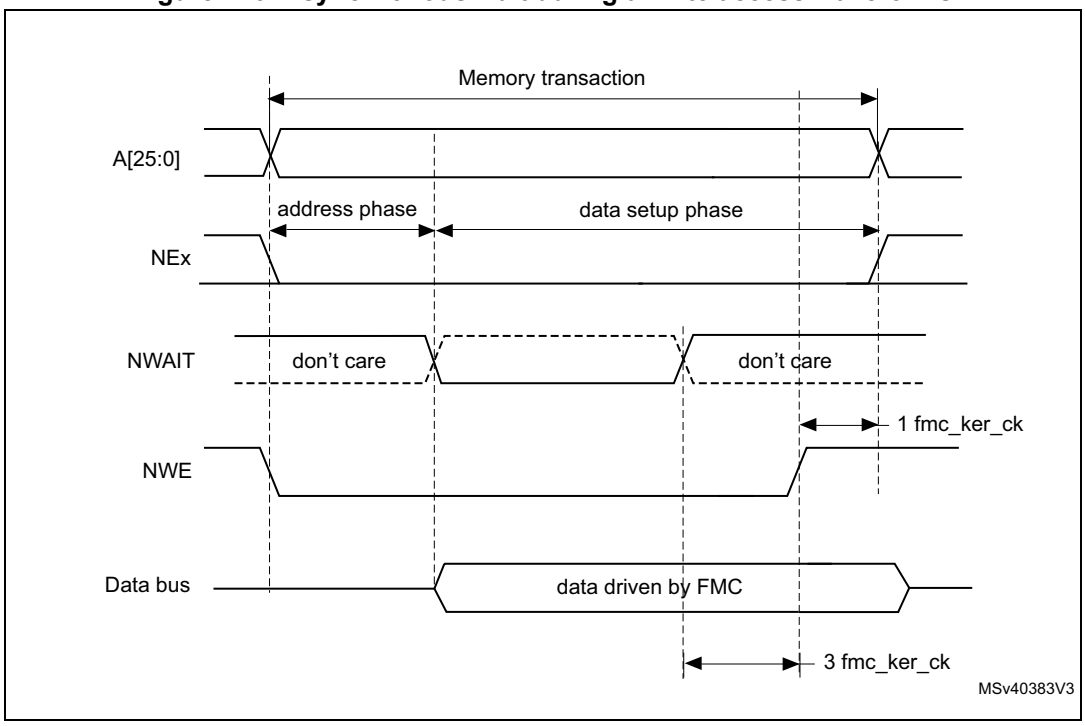

Figure 215 and *Figure 216* show the number of fmc_ker_ck clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

Figure 215. Asynchronous wait during a read access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

Figure 216. Asynchronous wait during a write access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

21.7.5 Synchronous transactions

The memory clock, FMC_CLK, is a sub-multiple of fmc_ker_ck. It depends on the value of CLKDIV and the MWID/ AXI data size, following the formula given below:

$$\text{FMC_CLK divider ratio} = \max(\text{CLKDIV} + 1, \text{MWID}(\text{AXI data size}))$$

Whatever MWID size: 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

Example:

- If CLKDIV=1, MWID = 16 bits, AXI data size=8 bits, FMC_CLK=fmc_ker_ck/2.

NOR flash memories specify a minimum time from NADV assertion to FMC_CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

For some PSRAM memories which must be configured to Synchronous mode, during the BCR register writing, the memory attribute space must be configured to device or strongly-ordered. Once PSRAM BCR register is configured, the memory attribute of PSRAM address space can be programmed to cacheable.

Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR flash configuration register. The FMC does not include the clock cycle when NADV is low in the data latency count.

Caution: Some NOR flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR flash latency and the FMC DATLAT parameter can be either:

- NOR flash latency = (DATLAT + 2) FMC_CLK clock cycles
- or NOR flash latency = (DATLAT + 3) FMC_CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

Single-burst transfer

When the selected bank is configured in Burst mode for synchronous accesses, if for example a single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AXI transfer is 16 bits), or length 2 (if the AXI transfer is 32 bits) and deassert the Chip Select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

Cross boundary page for Cellular RAM 1.5

Cellular RAM 1.5 does not allow burst access to cross the page boundary. The FMC allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

Wait management

For synchronous NOR flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) FMC_CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

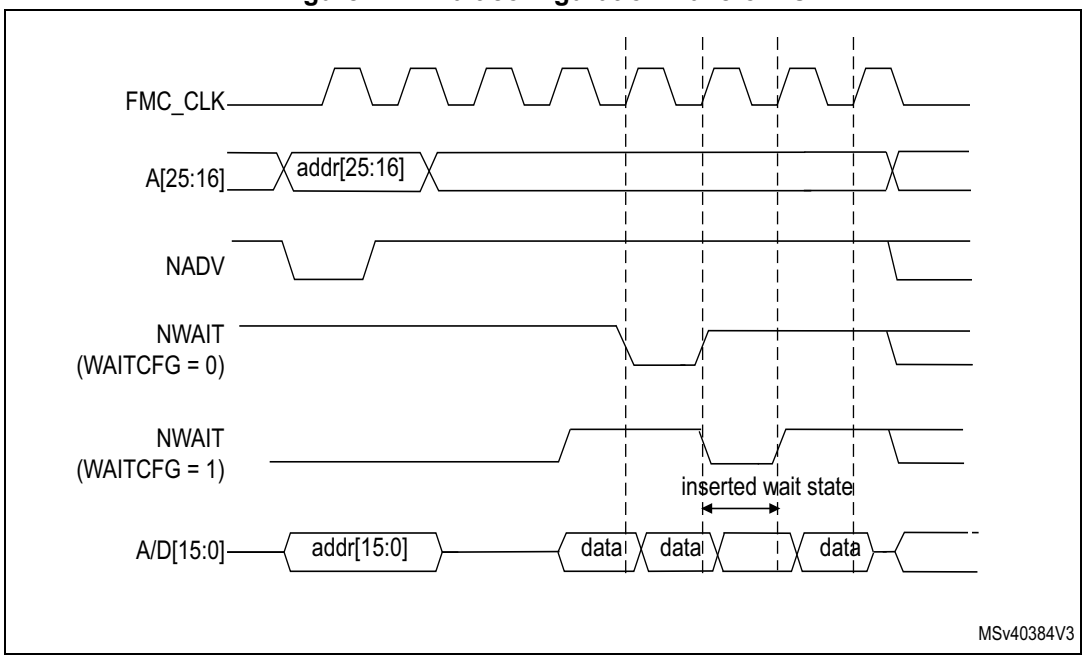
During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the Chip Select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR flash NWAIT signal:

- The flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR flash wait state configurations, for each Chip Select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0..3).

Figure 217. Wait configuration waveforms



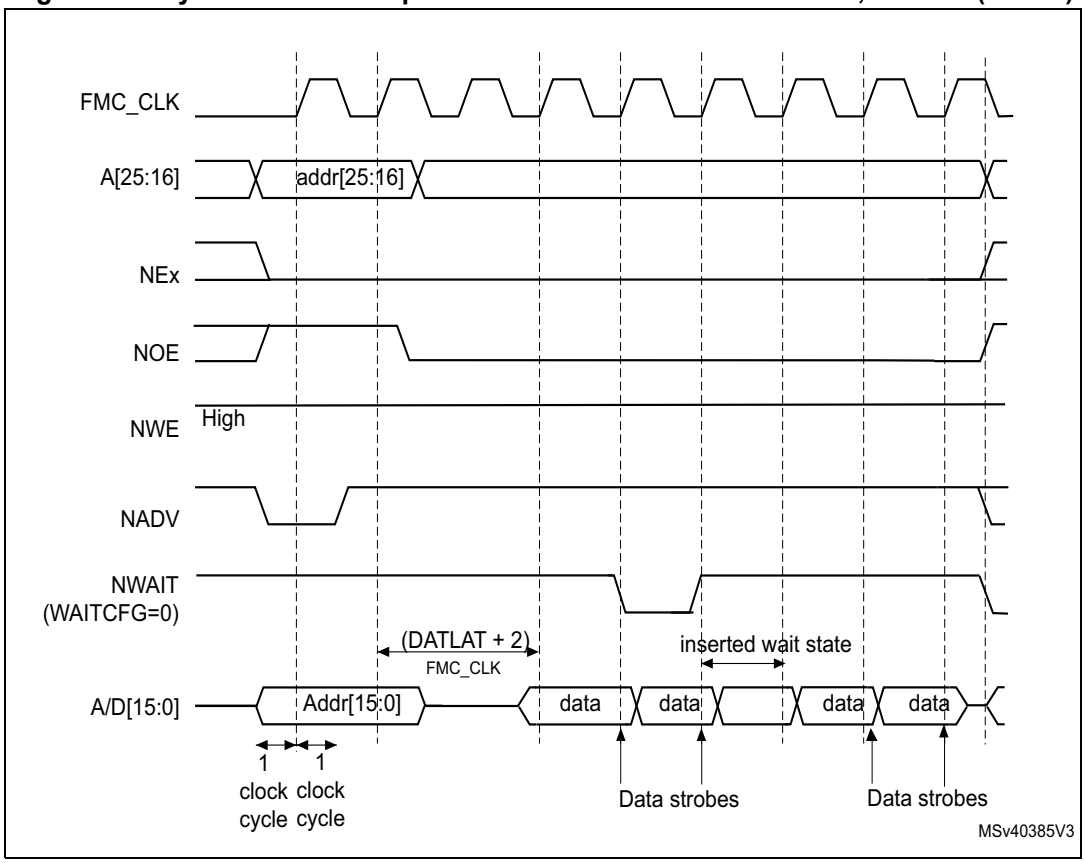


Figure 218. Synchronous multiplexed read mode waveforms - NOR, PSRAM (CRAM)

1. Byte lane outputs (NBL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

21.7.6 NOR/PSRAM controller registers

SRAM/NOR-flash chip-select control registers for bank x (FMC_BCRx)

Address offset: 0x00 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 30DB, 0x0000 30D2, Block 3: 0x0000 30D2, 0x0000 30D2

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories.

Bit 31 **FMCEN:** FMC Enable

This bit enables/disables the FMC.

0: Disable the FMC

1: Enable the FMC

Note: The FMCEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register.

Bits 30:26 Reserved, must be kept at reset value.

Bits 25:24 **BMAP[1:0]:** FMC bank mapping

These bits allow different remap or swap of the FMC NOR/PSRAM and SDRAM banks (refer to *Table 156*).

00: Default mapping (refer to *Figure 201* and *Table 156*).

01: NOR/PSRAM bank and SDRAM bank 1 are swapped.

10: Reserved

11: Reserved.

Note: The BMAP bits of the FMC_BCR2..4 registers are don't care. It is only enabled through the FMC_BCR1 register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **WFDIS:** Write FIFO Disable

This bit disables the Write FIFO used by the FMC.

0: Write FIFO enabled (Default after reset)

1: Write FIFO disabled

Note: The WFDIS bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register.

Bit 20 **CCLKEN:** Continuous Clock Enable

This bit enables the FMC_CLK clock output to external memory devices.

0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).

1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.

Note: The CCLKEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.

If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don't care.

If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)

Bit 19 **CBURSTRW:** Write burst enable

For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.

0: Write operations are always performed in Asynchronous mode

1: Write operations are performed in Synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM Page Size

These are used for Cellular RAM 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

000: No burst split when crossing page boundary (default after reset).

001: 128 bytes

010: 256 bytes

100: 1024 bytes

Other configuration: reserved.

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers

This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.

0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset)

1: NWAIT signal is taken in to account when running an asynchronous protocol

Bit 14 **EXTMOD**: Extended mode enable.

This bit enables the FMC to program the write timings for asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.

0: values inside FMC_BWTR register are not taken into account (default after reset)

1: values inside FMC_BWTR register are taken into account

Note: When the Extended mode is disabled, the FMC can operate in Mode1 or Mode2 as follows:

- *Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP =0x0 or 0x01)*
- *Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).*

Bit 13 **WAITEN**: Wait enable bit

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.

0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed flash latency period)

1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset)

Bit 12 **WREN**: Write enable bit

This bit indicates whether write operations are enabled/disabled in the bank by the FMC:

0: Write operations are disabled in the bank by the FMC, an AXI slave error is reported

1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG**: Wait timing configuration

The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:

0: NWAIT signal is active one data cycle before wait state (default after reset)

1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL**: Wait signal polarity bit

This bit defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode:

0: NWAIT active low (default after reset)

1: NWAIT active high.

Bit 8 **BURSTEN**: Burst enable bit

This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode:

0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode

1: Burst mode enable. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN**: Flash access enable

This bit enables NOR flash memory access operations.

0: Corresponding NOR flash memory access is disabled

1: Corresponding NOR flash memory access is enabled (default after reset)

Bits 5:4 **MWID[1:0]:** Memory data bus width

Defines the external memory device width, valid for all type of memories.

00: 8 bits

01: 16 bits (default after reset)

10: reserved

11: reserved

Bits 3:2 **MTYP[1:0]:** Memory type

These bits define the type of external memory attached to the corresponding memory bank:
00: SRAM (default after reset for Bank 2...4)
01: PSRAM (CRAM)
10: NOR flash/OneNAND flash (default after reset for Bank 1)
11: reserved

Bit 1 **MUXEN:** Address/data multiplexing enable bit

When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:
0: Address/Data non-multiplexed
1: Address/Data multiplexed on databus (default after reset)

Bit 0 **MBKEN:** Memory bank enable bit

This bit enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AXI bus.
0: Corresponding memory bank is disabled
1: Corresponding memory bank is enabled

SRAM/NOR-flash chip-select timing registers for bank x (FMC_BTRx)

Address offset: 0x04 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories.If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	ACCMOD[1:0]		DATLAT[3:0]				CLKDIV[3:0]				BUSTURN[3:0]			
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]:** Access mode

These bits specify the Asynchronous access modes as shown in the timing diagrams. They are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: access mode A

01: access mode B

10: access mode C

11: access mode D

Bits 27:24 **DATLAT[3:0]:** (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), these bits define the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in fmc_ker_ck periods, but in FMC_CLK periods.

For asynchronous access, this value is don't care.

0000: Data latency of 2 FMC_CLK clock cycles for first burst access

1111: Data latency of 17 FMC_CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]:** Clock divide ratio (for FMC_CLK signal)

These bits define the period of FMC_CLK clock output signal, expressed in number of fmc_ker_ck cycles:

0000: FMC_CLK period = 1 x fmc_ker_ck period

0001: FMC_CLK period = 2 × fmc_ker_ck periods

0010: FMC_CLK period = 3 × fmc_ker_ck periods

1111: FMC_CLK period = 16 × fmc_ker_ck periods (default value after reset)

In asynchronous NOR flash, SRAM or PSRAM accesses, this value is don’t care.

Note: Refer to Section 21.7.5: Synchronous transactions for FMC_CLK divider ratio formula)

Bits 19:16 **BUSTURN[3:0]:** Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write-to-read (and read-to-write) transaction. This delay allows to match the minimum time between consecutive transactions (t_{EHEL} from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access (t_{EHQZ}). The programmed bus turnaround delay is inserted between an asynchronous read (muxed or mode D) or write transaction and any other asynchronous /synchronous read or write to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed

as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 1 FMC clock cycle between:
  - –Two consecutive asynchronous read transfers to the same static memory bank except for muxed and D modes.
  - –An asynchronous read to an asynchronous or synchronous write to any static bank or dynamic bank except for muxed and D modes.
  - –An asynchronous (modes 1, 2, A, B or C) read and a read from another static bank.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to the same bank.
  - –A synchronous write (burst or single) access and an asynchronous write or read transfer to or from static memory bank (the bank can be the same or different for the case of read.
  - –Two consecutive synchronous reads (burst or single) followed by any synchronous/asynchronous read or write from/to another static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to different static bank.
  - –A synchronous write (burst or single) access and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc_ker_ck clock cycle added

...

1111: BUSTURN phase duration = 15 x fmc_ker_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration

These bits are written by software to define the duration of the data phase (refer to *Figure 202* to *Figure 214*), used in asynchronous accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × fmc_ker_ck clock cycles

0000 0010: DATAST phase duration = 2 × fmc_ker_ck clock cycles

...

1111 1111: DATAST phase duration = 255 × fmc_ker_ck clock cycles (default value after reset)

For each memory type and access mode data-phase duration, refer to the respective figure (*Figure 202* to *Figure 214*).

Example: Mode1, write access, DATAST = 1: Data-phase duration = DATAST+1 = 1 x fmc_ker_ck clock cycles.

Note: In synchronous accesses, this value is don't care.

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 202* to *Figure 214*), used in mode D or multiplexed accesses:
0000: Reserved
0001: ADDHLD phase duration =1 × fmc_ker_ck clock cycle
0010: ADDHLD phase duration = 2 × fmc_ker_ck clock cycle
...
1111: ADDHLD phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)
For each access mode address-hold phase duration, refer to the respective figure (*Figure 202* to *Figure 214*).

Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration

These bits are written by software to define the duration of the *address setup* phase (refer to *Figure 202* to *Figure 214*), used in SRAMs, ROMs and asynchronous NOR flash:
0000: ADDSET phase duration = 0 × fmc_ker_ck clock cycle
...
1111: ADDSET phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)
For each access mode address setup phase duration, refer to the respective figure (refer to *Figure 202* to *Figure 214*).

Note: In synchronous accesses, this value is don't care.
In Muxed mode or mode D, the minimum value for ADDSET is 1.
In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to extend the latency as needed.
On PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.
This method can be used also with the latest generation of synchronous flash memories that issue the NWAIT signal, unlike older flash memories (check the datasheet of the specific flash memory being used).

SRAM/NOR-flash write timing registers for bank x (FMC_BWTRx)

Address offset: 0x104 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	ACCMOD[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BUSTURN[3:0]			
		rw	rw									rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]:** Access mode.

These bits specify the asynchronous access modes as shown in the next timing diagrams.These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: access mode A

01: access mode B

10: access mode C

11: access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write transaction to match the minimum time between consecutive transactions (t_{EHEL} from ENx high to ENx low):

(BUSTRUN + 1) fmc_ker_ck period ≥ $t_{EHELmin}$.

The programmed bus turnaround delay is inserted between an asynchronous write transfer and any other asynchronous /synchronous read or write transfer to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different expect for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to the same bank.
  - –A synchronous write (burst or single) transfer and an asynchronous write or read transfer to or from static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to different static bank.
  - –A synchronous write (burst or single) transfer and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc_ker_ck clock cycle added

...

1111: BUSTURN phase duration = 15 fmc_ker_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration.

These bits are written by software to define the duration of the data phase (refer to *Figure 202* to *Figure 214*), used in asynchronous SRAM, PSRAM and NOR flash memory accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × fmc_ker_ck clock cycles

0000 0010: DATAST phase duration = 2 × fmc_ker_ck clock cycles

...

1111 1111: DATAST phase duration = 255 × fmc_ker_ck clock cycles (default value after reset)

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration.

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 202* to *Figure 214*), used in asynchronous multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration = 1 × fmc_ker_ck clock cycle

0010: ADDHLD phase duration = 2 × fmc_ker_ck clock cycle

...

1111: ADDHLD phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

Note: In synchronous NOR flash accesses, this value is not used, the address hold phase is always 1 flash clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration.

These bits are written by software to define the duration of the *address setup* phase in fmc_ker_ck cycles (refer to *Figure 202* to *Figure 214*), used in asynchronous accesses:

0000: ADDSET phase duration = 0 × fmc_ker_ck clock cycle

...

1111: ADDSET phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

Note: In synchronous accesses, this value is not used, the address setup phase is always 1 flash clock period duration. In muxed mode, the minimum ADDSET value is 1.

21.8 NAND flash controller

The FMC generates the appropriate signal timings to drive 8- and 16-bit NAND flash memories.

The NAND bank is configured through dedicated registers (*Section 21.8.7*). The programmable memory parameters include access timings (shown in *Table 192*) and ECC configuration.

Table 192. Programmable NAND flash access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Memory setup time	Number of clock cycles (fmc_ker_ck) required to set up the address before the command assertion	Read/Write	AHB clock cycle (fmc_ker_ck)	1	255
Memory wait	Minimum duration (in fmc_ker_ck clock cycles) of the command assertion	Read/Write	AHB clock cycle (fmc_ker_ck)	2	255
Memory hold	Number of clock cycles (fmc_ker_ck) during which the address must be held (as well as the data if a write access is performed) after the command deassertion	Read/Write	AHB clock cycle (fmc_ker_ck)	1	254
Memory databus high-Z	Number of clock cycles (fmc_ker_ck) during which the data bus is kept in high-Z state after a write access has started	Write	AHB clock cycle (fmc_ker_ck)	0	254

21.8.1 External memory interface signals

The following tables list the signals that are typically used to interface NAND flash memories.

Note: The prefix “N” identifies the signals which are active low.

8-bit NAND flash memory

Table 193. 8-bit NAND flash memory

FMC pin name	I/O	Function
A[17]	O	NAND flash address latch enable (ALE) signal
A[16]	O	NAND flash command latch enable (CLE) signal
D[7:0]	I/O	8-bit multiplexed, bidirectional address/data bus
NCE	O	Chip Select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND flash ready/busy input signal to the FMC

Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

16-bit NAND flash memory

Table 194. 16-bit NAND flash memory

FMC pin name	I/O	Function
A[17]	O	NAND flash address latch enable (ALE) signal
A[16]	O	NAND flash command latch enable (CLE) signal
D[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus
NCE	O	Chip Select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND flash ready/busy input signal to the FMC

Note: Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

21.8.2 NAND flash supported memories and transactions

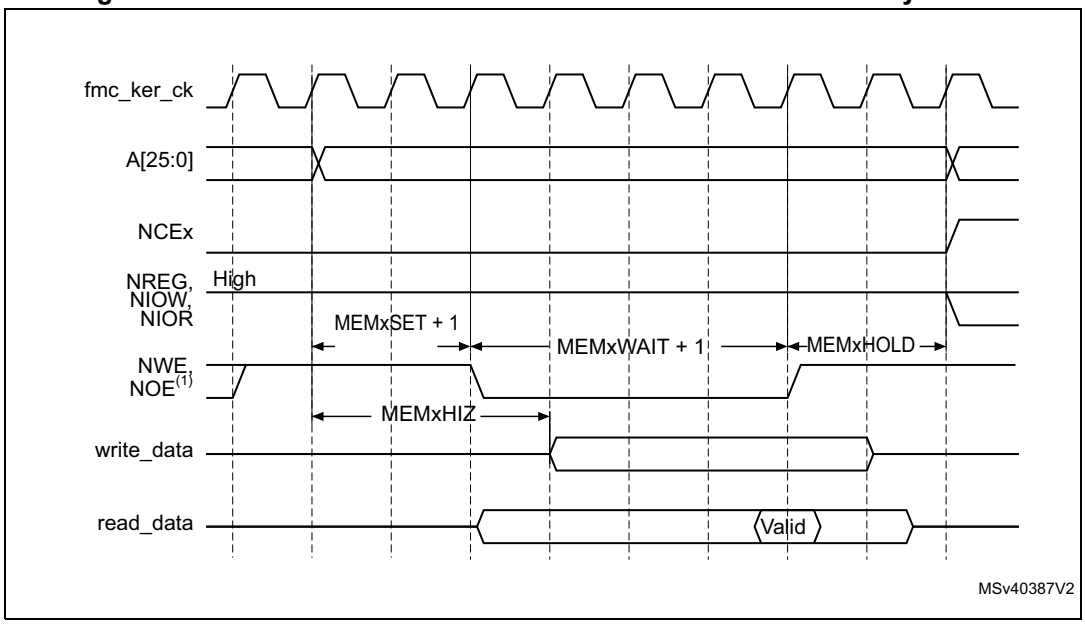
Table 195 shows the supported devices, access modes and transactions. Transactions not allowed (or not supported) by the NAND flash controller are shown in gray.

Table 195. Supported memories and transactions

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NAND 8-bit	Asynchronous	R	8	8	Y	-
	Asynchronous	W	8	8	Y	-
	Asynchronous	R	16	8	Y	Split into 2 FMC accesses
	Asynchronous	W	16	8	Y	Split into 2 FMC accesses
	Asynchronous	R	32	8	Y	Split into 4 FMC accesses
	Asynchronous	W	32	8	Y	Split into 4 FMC accesses
	Asynchronous	R	32	8	Y	Split into 8 FMC accesses
	Asynchronous	W	32	8	Y	Split into 8 FMC accesses

Table 195. Supported memories and transactions (continued)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NAND 16-bit	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	N	-
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	32	16	Y	Split into 4 FMC accesses
	Asynchronous	W	32	16	Y	Split into 4 FMC accesses



21.8.3 Timing diagrams for NAND flash memories

The NAND flash memory bank is managed through a set of registers:

- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define the number of fmc_ker_ck cycles for the three phases of any NAND flash access, plus one parameter that defines the timing to start driving the data bus when a write access is performed. *Figure 220* shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

Figure 220. NAND flash controller waveforms for common memory access

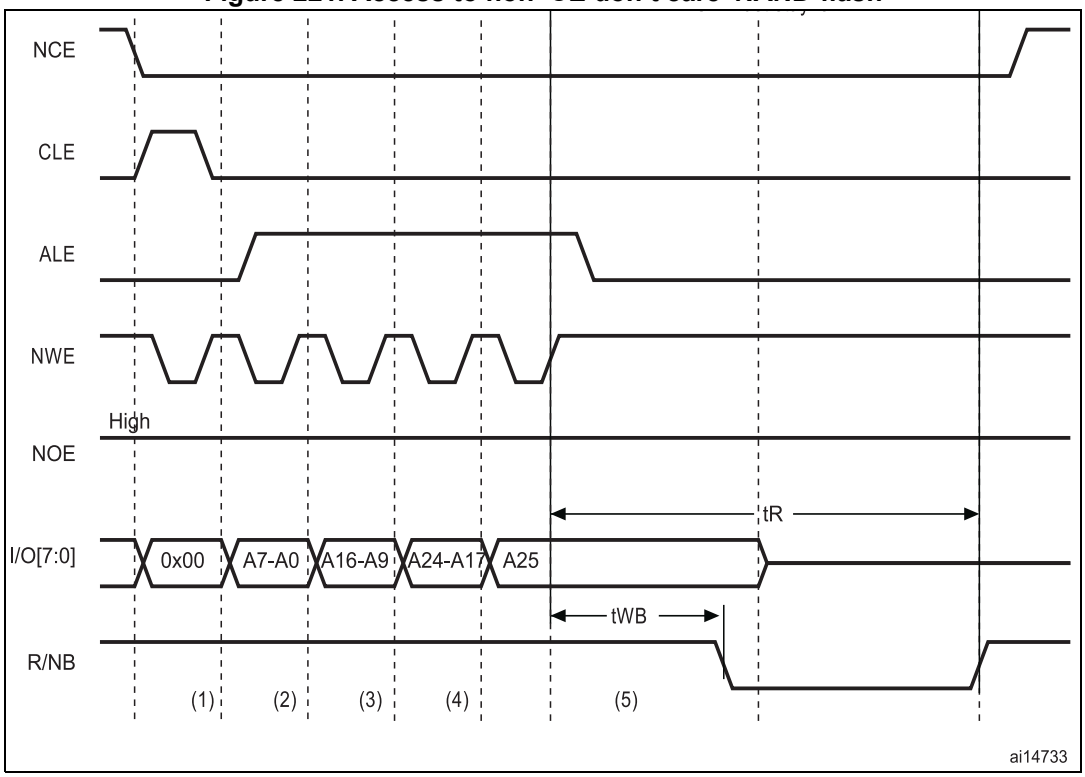
1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. For write accesses, the hold phase delay is (MEMHOLD) fmc_ker_ck cycles and for read access is (MEMHOLD + 1) fmc_ker_ck cycles.

21.8.4 NAND flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND flash memory device are driven by address signals from the FMC. This means that to send a command or an address to the NAND flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see *Section 21.8.5: NAND flash prewait feature*) registers according to the characteristics of the NAND flash memory (PWID bits for the data bus width of the NAND flash memory, PWAITEN = 0 or 1 as needed, see *Section 21.6.2: NAND flash memory address mapping* for timing configuration).
2. The CPU performs a byte write to the common memory space, with data byte equal to one flash command byte (for example 0x00 for Samsung NAND flash devices). The LE input of the NAND flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.
3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND flash memories) in the common memory or attribute space. The ALE input of the NAND flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used



to implement the prewait functionality needed by some NAND flash memories (see details in *Section 21.8.5: NAND flash prewait feature*).

4. The controller waits for the NAND flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).
5. The CPU can then perform byte read operations from the common memory space to read the NAND flash page (data field + Spare field) byte by byte.
6. The next NAND flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   – by simply performing the operation described in step 5
   – a new random address can be accessed by restarting the operation at step 3
   – a new command can be sent to the NAND flash device by restarting at step 2

21.8.5 NAND flash prewait feature

Some NAND flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see *Figure 221*).

Figure 221. Access to non 'CE don't care' NAND-flash

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x8802 0000: FMC performs a write access using FMC_PATT2 timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × fmc_ker_ck = 112 ns > t_{WB} max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND flash memories where NCE is not don't care).

When this function is required, it can be performed by programming the MEMHOLD value to meet the t_{WB} timing. However, any CPU read access to NAND flash memory has a hold delay of (MEMHOLD + 1) fmc_ker_ck cycles, and any CPU write access has a hold delay of (MEMHOLD) fmc_ker_ck cycles that is inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the t_{WB} timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND flash read and write accesses, except when writing the last address byte to the NAND flash device, where the CPU must write to the attribute memory space.

21.8.6 Computation of the error correction code (ECC) in NAND flash memory

The FMC includes an error correction code computation hardware block. It reduces the host CPU workload when processing the ECC by software.The ECC block is associated with NAND bank.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND flash data bus and read/write signals (NCE and NWE) each time the NAND flash memory bank is active.

The ECC operates as follows:

- When accessing NAND flash bank, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.

Execute below the sequence to perform an ECC computation:

1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Wait until the ECC code is ready (FIFO empty).
4. Read the ECC value available in the FMC_ECCR register and store it in a variable.
5. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
6. Read the new ECC value available in the FMC_ECCR register.
7. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

21.8.7 NAND flash controller registers

NAND flash control registers (FMC_PCR)

Address offset: 0x80

Reset value: 0x0000 0018

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCPS[2:0]			TAR3
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAR[2:0]			TCLR[3:0]				Res.	Res.	ECCEN	PWID[1:0]		Res.	PBKEN	PWAITEN	Res.
rw	rw	rw	rw	rw	rw	rw			rw	rw	rw		rw	rw	

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]:** ECC page size.
These bits define the page size for the extended ECC:
000: 256 bytes
001: 512 bytes
010: 1024 bytes
011: 2048 bytes
100: 4096 bytes
101: 8192 bytes

Bits 16:13 **TAR[3:0]:** ALE to RE delay.
These bits set time from ALE low to RE low in number of fmc_ker_ck clock cycles.
Time is: t_ar = (TAR + SET + 2) × $t_{fmc_ker_ck}$ where $t_{fmc_ker_ck}$ is the FMC clock period
0000: 1 x fmc_ker_ck cycle (default)
1111: 16 x fmc_ker_ck cycles
Note: Set is MEMSET or ATTSET according to the addressed space.

Bits 12:9 **TCLR[3:0]:** CLE to RE delay.
These bits set time from CLE low to RE low in number of fmc_ker_ck clock cycles. The time is give by the following formula:
t_clr = (TCLR + SET + 2) × $t_{fmc_ker_ck}$ where $t_{fmc_ker_ck}$ is the fmc_ker_ck clock period
0000: 1 x fmc_ker_ck cycle (default)
1111: 16 x fmc_ker_ck cycles
Note: Set is MEMSET or ATTSET according to the addressed space.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN:** ECC computation logic enable bit
0: ECC logic is disabled and reset (default after reset),
1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]:** Data bus width.
These bits define the external memory device width.
00: 8 bits
01: 16 bits (default after reset).
10: reserved.
11: reserved.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **PBKEN:** NAND flash memory bank enable bit.

This bit enables the memory bank. Accessing a disabled memory bank causes an ERROR on AXI bus

0: Corresponding memory bank is disabled (default after reset)

1: Corresponding memory bank is enabled

Bit 1 **PWAITEN:** Wait feature enable bit.

This bit enables the Wait feature for the NAND flash memory bank:

0: disabled

1: enabled

Bit 0 Reserved, must be kept at reset value.

FIFO status and interrupt register (FMC_SR)

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data.

This is used to quickly write to the FIFO and free the AXI bus for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FEMPT	IFEN	ILEN	IREN	IFS	ILS	IRS
									r	rw	rw	rw	rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **FEMPT:** FIFO empty.

Read-only bit that provides the status of the FIFO

0: FIFO not empty

1: FIFO empty

Bit 5 **IFEN:** Interrupt falling edge detection enable bit

0: Interrupt falling edge detection request disabled

1: Interrupt falling edge detection request enabled

Bit 4 **ILEN:** Interrupt high-level detection enable bit

0: Interrupt high-level detection request disabled

1: Interrupt high-level detection request enabled

Bit 3 **IREN:** Interrupt rising edge detection enable bit

0: Interrupt rising edge detection request disabled

1: Interrupt rising edge detection request enabled

Bit 2 **IFS:** Interrupt falling edge status
The flag is set by hardware and reset by software.
0: No interrupt falling edge occurred
1: Interrupt falling edge occurred
Note: If this bit is written by software to 1 it is set.

Bit 1 **ILS:** Interrupt high-level status
The flag is set by hardware and reset by software.
0: No Interrupt high-level occurred
1: Interrupt high-level occurred

Bit 0 **IRS:** Interrupt rising edge status
The flag is set by hardware and reset by software.
0: No interrupt rising edge occurred
1: Interrupt rising edge occurred
Note: If this bit is written by software to 1 it is set.

Common memory space timing register (FMC_PMEM)

Address offset: 0x88

Reset value: 0xFCFC FCFC

The FMC_PMEM read/write register contains the timing information for NAND flash memory bank. This information is used to access either the common memory space of the NAND flash for command, address write access and data read/write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEMHIZ[7:0]								MEMHOLD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEMWAIT[7:0]								MEMSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **MEMHIZ[7:0]:** Common memory x data bus Hi-Z time
These bits define the number of fmc_ker_ck clock cycles during which the data bus is kept Hi-Z after the start of a NAND flash write access to common memory space. This is only valid for write transactions:
0000 0000: 0 x fmc_ker_ck cycle
1111 1110: 254 x fmc_ker_ck cycles
1111 1111: reserved.

Bits 23:16 **MEMHOLD[7:0]:** Common memory hold time
These bits define the number of fmc_ker_ck clock cycles for write accesses and fmc_ker_ck+1 clock cycles for read accesses during which the address is held (and data for write accesses) after the command is deasserted (NWE, NOE), for NAND flash read or write access to common memory space:
0000 0000: reserved.
0000 0001: 1 fmc_ker_ck cycle for write access / 3 fmc_ker_ck cycle for read access
1111 1110: 254 fmc_ker_ck cycles for write access / 257 fmc_ker_ck cycles for read access
1111 1111: reserved.

Bits 15:8 **MEMWAIT[7:0]:** Common memory wait time

These bits define the minimum number of fmc_ker_ck (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to common memory space. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc_ker_ck:
0000 0000: reserved
0000 0001: x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)
1111 1110: 255 x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)
1111 1111: reserved.

Bits 7:0 **MEMSET[7:0]:** Common memory x setup time

These bits define the number of fmc_ker_ck (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for NAND flash read or write access to common memory space:
0000 0000: fmc_ker_ck cycles
1111 1110: 255 x fmc_ker_ck cycles
1111 1111: reserved

Attribute memory space timing registers (FMC_PATT)

Address offset: 0x8C

Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to *Section 21.8.5: NAND flash prewait feature*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ATTHIZ[7:0]								ATTHOLD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ATTWAIT[7:0]								ATTSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ATTHIZ[7:0]:** Attribute memory data bus Hi-Z time

These bits define the number of fmc_ker_ck clock cycles during which the data bus is kept in Hi-Z after the start of a NAND flash write access to attribute memory space on socket. Only valid for writ transaction:
0000 0000: 0 x fmc_ker_ck cycle
1111 1110: 254 x fmc_ker_ck cycles
1111 1111: reserved.

Bits 23:16 **ATTHOLD[7:0]:** Attribute memory hold time

These bits define the number of fmc_ker_ck clock cycles during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND flash read or write access to attribute memory space:
0000 0000: reserved
0000 0001: 1 x fmc_ker_ck cycle
1111 1110: 254 x fmc_ker_ck cycles
1111 1111: reserved.

Bits 15:8 **ATTWAIT[7:0]:** Attribute memory wait time

These bits define the minimum number of x fmc_ker_ck (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to attribute memory space. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc_ker_ck:

0000 0000: reserved

0000 0001: 2 x fmc_ker_ck cycles (+ wait cycle introduced by deassertion of NWAIT)

1111 1110: 255 x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: reserved.

Bits 7:0 **ATTSET[7:0]:** Attribute memory setup time

These bits define the number of fmc_ker_ck (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND flash read or write access to attribute memory space:

0000 0000: 1 x fmc_ker_ck cycle

1111 1110: 255 x fmc_ker_ck cycles

1111 1111: reserved.

ECC result registers (FMC_ECCR)

Address offset: 0x94

Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads/writes the data from a NAND flash memory page at the correct address (refer to *Section 21.8.6: Computation of the error correction code (ECC) in NAND flash memory*), the data read/written from/to the NAND flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register should be cleared after being read by setting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to ’1’.

21.9 SDRAM controller

21.9.1 SDRAM controller main features

The main features of the SDRAM controller are the following:

- Two SDRAM banks with independent configuration
- 8-bit, 16-bit data bus width
- 13-bits Address Row, 11-bits Address Column, 4 internal banks: 4x16Mx16bit (128 MB), 4x16Mx8bit (64 MB)
- Word, half-word, byte access
- SDRAM clock can be fmc_ker_ck/2 or fmc_ker_ck/3
- Automatic row and bank boundary management
- Multibank ping-pong access
- Programmable timing parameters
- Automatic Refresh operation with programmable Refresh rate
- Self-refresh mode
- Power-down mode
- SDRAM power-up initialization by software
- CAS latency of 1,2,3
- Cacheable Read FIFO with depth of 6 lines x32-bit (6 x14-bit address tag)

21.9.2 SDRAM External memory interface signals

At startup, the SDRAM I/O pins used to interface the FMC SDRAM controller with the external SDRAM devices must configured by the user application. The SDRAM controller I/O pins which are not used by the application, can be used for other purposes.

Table 197. SDRAM signals

SDRAM signal	I/O type	Description	Alternate function
SDCLK	O	SDRAM clock	-
SDCKE[1:0]	O	SDCKE0: SDRAM Bank 1 Clock Enable SDCKE1: SDRAM Bank 2 Clock Enable	-

SDNWE	O	Write Enable	-
NBL[1:0]	O	Output Byte Mask for write accesses (memory signal name: DQM[1:0]	FMC_NBL[1:0]

21.9.3 SDRAM controller functional description

All SDRAM controller outputs (signals, address and data) change on the falling edge of the memory clock (FMC_SDCLK).

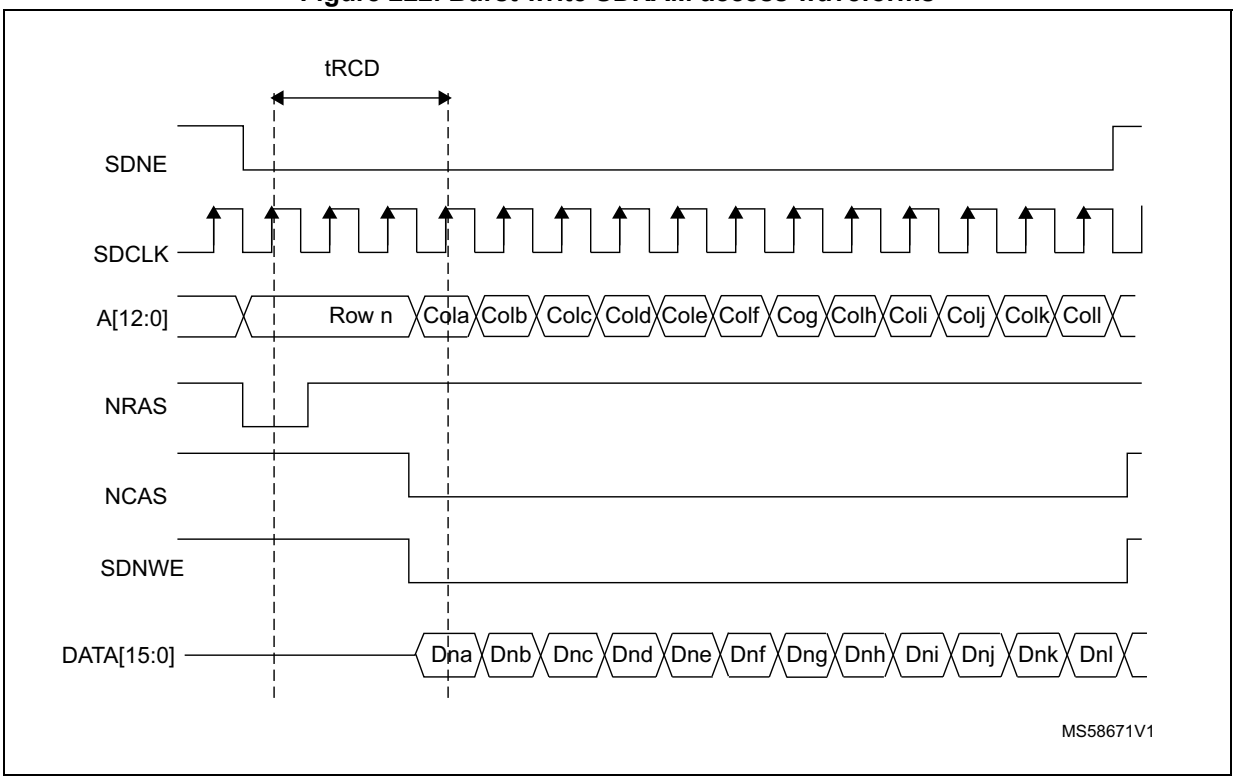
SDRAM initialization

The initialization sequence is managed by software. If the two banks are used, the initialization sequence must be generated simultaneously to Bank 1and Bank 2 by setting the Target Bank bits CTB1 and CTB2 in the FMC_SDCMR register:

1. Program the memory device features into the FMC_SDCRx register. The SDRAM clock frequency, RBURST and RPIPE must be programmed in the FMC_SDCR1 register.
2. Program the memory device timing into the FMC_SDTRx register. The TRP and TRC timings must be programmed in the FMC_SDTR1 register.
3. Set MODE bits to ‘001’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to start delivering the clock to the memory (SDCKE is driven high).
4. Wait during the prescribed delay period. Typical delay is around 100 µs (refer to the SDRAM datasheet for the required delay after power-up).
5. Set MODE bits to ‘010’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Precharge All” command.
6. Set MODE bits to ‘011’, and configure the Target Bank bits (CTB1 and/or CTB2) as well as the number of consecutive Auto-refresh commands (NRFS) in the FMC_SDCMR register. Refer to the SDRAM datasheet for the number of Auto-refresh commands that should be issued. Typical number is 8.
7. Configure the MRD field, set the MODE bits to ‘100’, and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Load Mode Register” command and program the SDRAM device. In particular the Burst Length (BL) has to be set to ‘1’) and the CAS latency has to be selected. If the Mode Register is not the same for both SDRAM banks, this step has to be repeated twice, once for each bank and the Target Bank bits set accordingly. For mobile SDRAM devices, the MRD field is also used to configure the extended mode register while issuing the Load Mode Register”
8. Program the refresh rate in the FMC_SDRTR register

   The refresh rate corresponds to the delay between refresh cycles. Its value must be adapted to SDRAM devices.

At this stage the SDRAM device is ready to accept commands. If a system reset occurs during an ongoing SDRAM access, the data bus might still be driven by the SDRAM device. Therefor the SDRAM device must be first reinitialized after reset before issuing any new access by the NOR flash/PSRAM/SRAM or NAND flash controller.



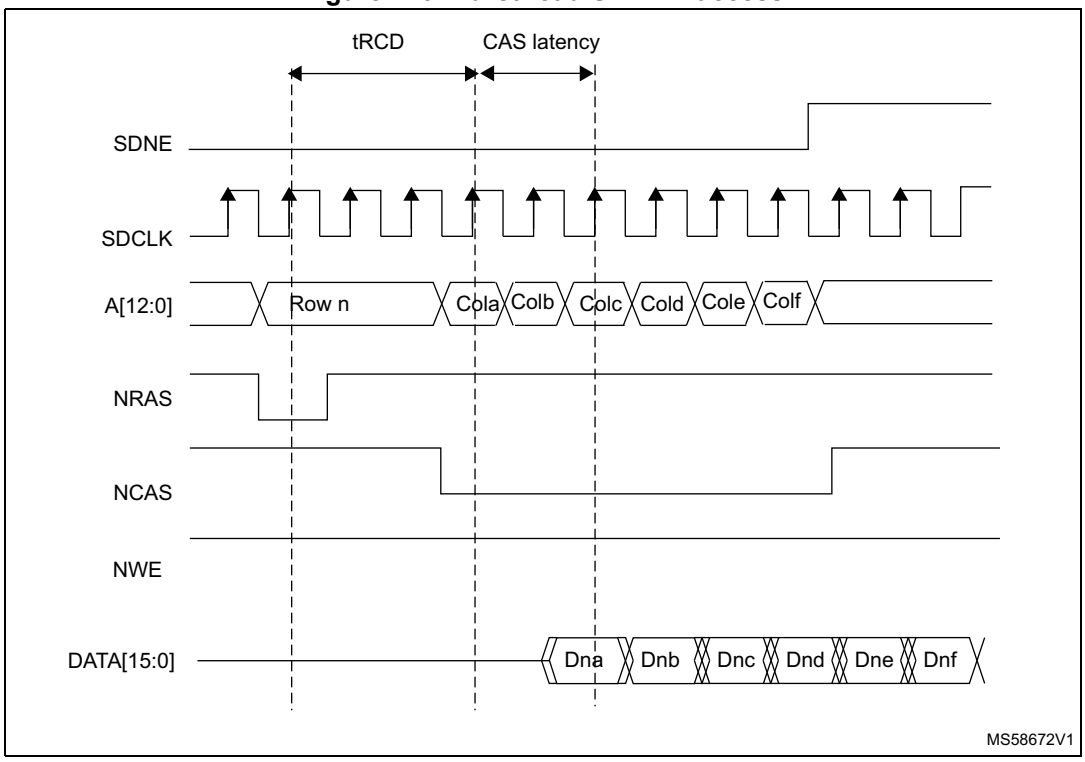
Note: If two SDRAM devices are connected to the FMC, all the accesses performed at the same time to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for SDRAM Bank 1 (TMRD andTRAS timings) in the FMC_SDTR1 register.

SDRAM controller write cycle

The SDRAM controller accepts single and burst write requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row for each bank to be able to perform consecutive write accesses to different banks (Multibank ping-pong access).

Before performing any write access, the SDRAM bank write protection must be disabled by clearing the WP bit in the FMC_SDCRx register.

Figure 222. Burst write SDRAM access waveforms



The SDRAM controller always checks the next access.

- If the next access is in the same row or in another active row, the write operation is carried out,
- if the next access targets another row (not active), the SDRAM controller generates a precharge command, activates the new row and initiates a write command.

SDRAM controller read cycle

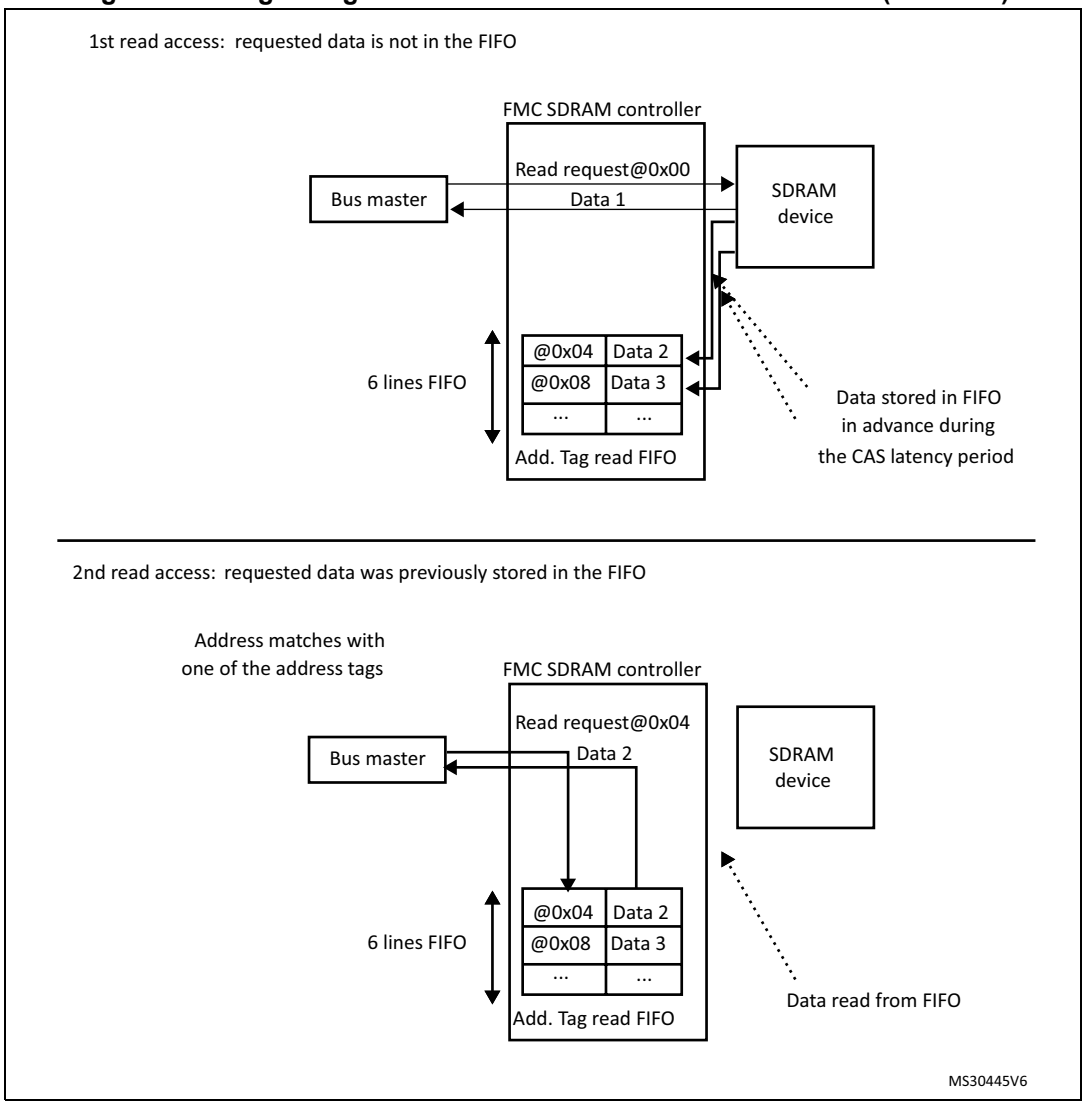
The SDRAM controller accepts single and burst read requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row in each bank to be able to perform consecutive read accesses in different banks (Multibank ping-pong access).

Figure 223. Burst read SDRAM access

The FMC SDRAM controller features a Cacheable read FIFO (6 lines x 32 bits). It is used to store data read in advance during the CAS latency period (up to 3 memory clock cycles, programmed FMC_SDCRx) and during the RPIPE delay when set to 2xfmc_ker_ck clock cycles as configured in FMC_SDCR1) following this formula: CAS Latency + 1 + (RPIPE DIV2). The RBURST bit must be set in the FMC_SDCR1 register to anticipate the next read access.

Examples:

- CAS=3, RPIPE= 2xfmc_ker_ck. In this case, 5 data (not committed) are stored in the FIFO (4 data during CAS latency and 1 data during RPIPE delay)
- CAS=3, RPIPE= 1xfmc_ker_ck. In this case, 4 data (not committed) are stored in the FIFO (4 data during CAS latency)



The read FIFO features a 14-bit address tag to each line to identify its content: 11 bits for the column address, 2 bits to select the internal bank and the active row, and 1 bit to select the SDRAM device

When the end of the row is reached in advance during an burst read transaction, the data read in advance (not committed) are not stored in the read FIFO. For single read access, data are correctly stored in the FIFO.

Each time a read request occurs, the SDRAM controller checks:

- If the address matches one of the address tags, data are directly read from the FIFO and the corresponding address tag/ line content is cleared and the remaining data in the FIFO are compacted to avoid empty lines.
- Otherwise, a new read command is issued to the memory and the FIFO is updated with new data. If the FIFO is full, the older data are lost.

Figure 224. Logic diagram of Read access with RBURST bit set (RPIPE=0)

During a write access or a Precharge command, the read FIFO is flushed and ready to be filled with new data.

After the first read request, if the current access was not performed to a row boundary, the SDRAM controller anticipates the next read access during the CAS latency period and the RPIPE delay (if configured). This is done by incrementing the memory address. The following condition must be met:

- RBURST control bit should be set to ‘1’ in the FMC_SDCR1 register.

The address management depends on the next AXI request:

- Next request is sequential (Burst access)

  In this case, the SDRAM controller increments the address.
- Next request is not sequential
  - If the new read request targets the same row or another active row, the new address is passed to the memory and the master is stalled for the CAS latency period, waiting for the new data from memory.
  - If the new read request does not target an active row, the SDRAM controller generates a Precharge command, activates the new row, and initiates a read command.

If the RBURST is reset, the read FIFO is not used.

Row and bank boundary management

When a read or write access crosses a row boundary, if the next read or write access is sequential and the current access was performed to a row boundary, the SDRAM controller executes the following operations:

1. Precharge of the active row,
2. Activation of the new row
3. Start of a read/write command.

At a row boundary, the automatic activation of the next row is supported for all columns and data bus width configurations.

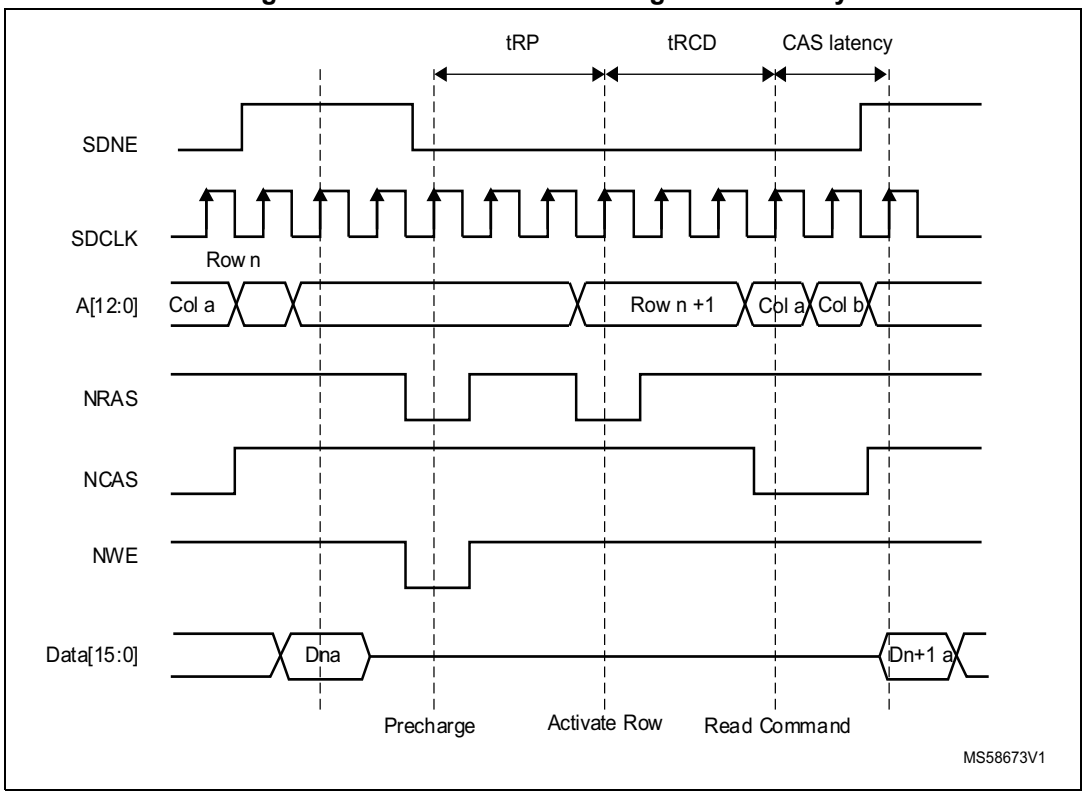
If necessary, the SDRAM controller inserts additional clock cycles between the following commands:

- Between Precharge and Active commands to match TRP parameter (only if the next access is in a different row in the same bank),
- Between Active and Read commands to match the TRCD parameter.

These parameters are defined into the FMC_SDTRx register.

Refer to *Figure 222* and *Figure 223* for read and burst write access crossing a row boundary.

Figure 225. Read access crossing row boundary



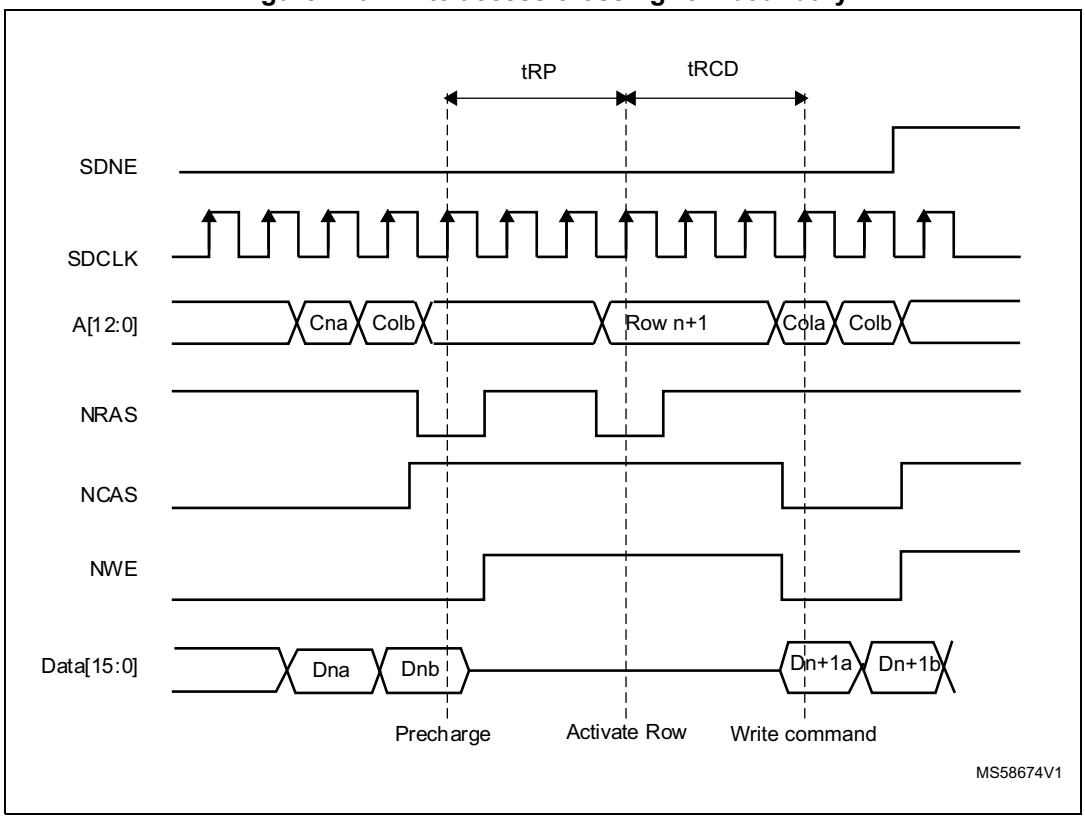


Figure 226. Write access crossing row boundary

If the next access is sequential and the current access crosses a bank boundary, the SDRAM controller activates the first row in the next bank and initiates a new read/write command. Two cases are possible:

- If the current bank is not the last one, the active row in the new bank must be precharged.At a bank boundary, the automatic activation of the next row is supported for all rows/columns and data bus width configuration.
- If the current bank is the last one and the selected SDRAM device is connected to Bank 1, the automatic activation of the next row in device connected to SDRAM Bank2 is not supported. A PALL software command must be issused on Bank1 before any any access on Bank2.

SDRAM controller refresh cycle

The Auto-refresh command is used to refresh the SDRAM device content. The SDRAM controller periodically issues auto-refresh commands. An internal counter is loaded with the COUNT value in the register FMC_SDRTR. This value defines the number of memory clock cycles between the refresh cycles (refresh rate). When this counter reaches zero, an internal pulse is generated.

If a memory access is ongoing, the auto-refresh request is delayed. However, if the memory access and the auto-refresh requests are generated simultaneously, the auto-refresh request takes precedence.

If the memory access occurs during an auto-refresh operation, the request is buffered and processed when the auto-refresh is complete.

If a new auto-refresh request occurs while the previous one was not served, the RE (Refresh Error) bit is set in the Status register. An Interrupt is generated if it has been enabled (REIE = ‘1’).

If SDRAM lines are not in idle state (not all row are closed), the SDRAM controller generates a PALL (Precharge ALL) command before the auto-refresh.

If the Auto-refresh command is generated by the FMC_SDCMR Command Mode register (Mode bits = ‘011’), a PALL command (Mode bits =’ 010’) must be issued first.

21.9.4 Low-power modes

Two low-power modes are available:

- Self-refresh mode

  The auto-refresh cycles are performed by the SDRAM device itself to retain data without external clocking.
- Power-down mode

  The auto-refresh cycles are performed by the SDRAM controller.

Self-refresh mode

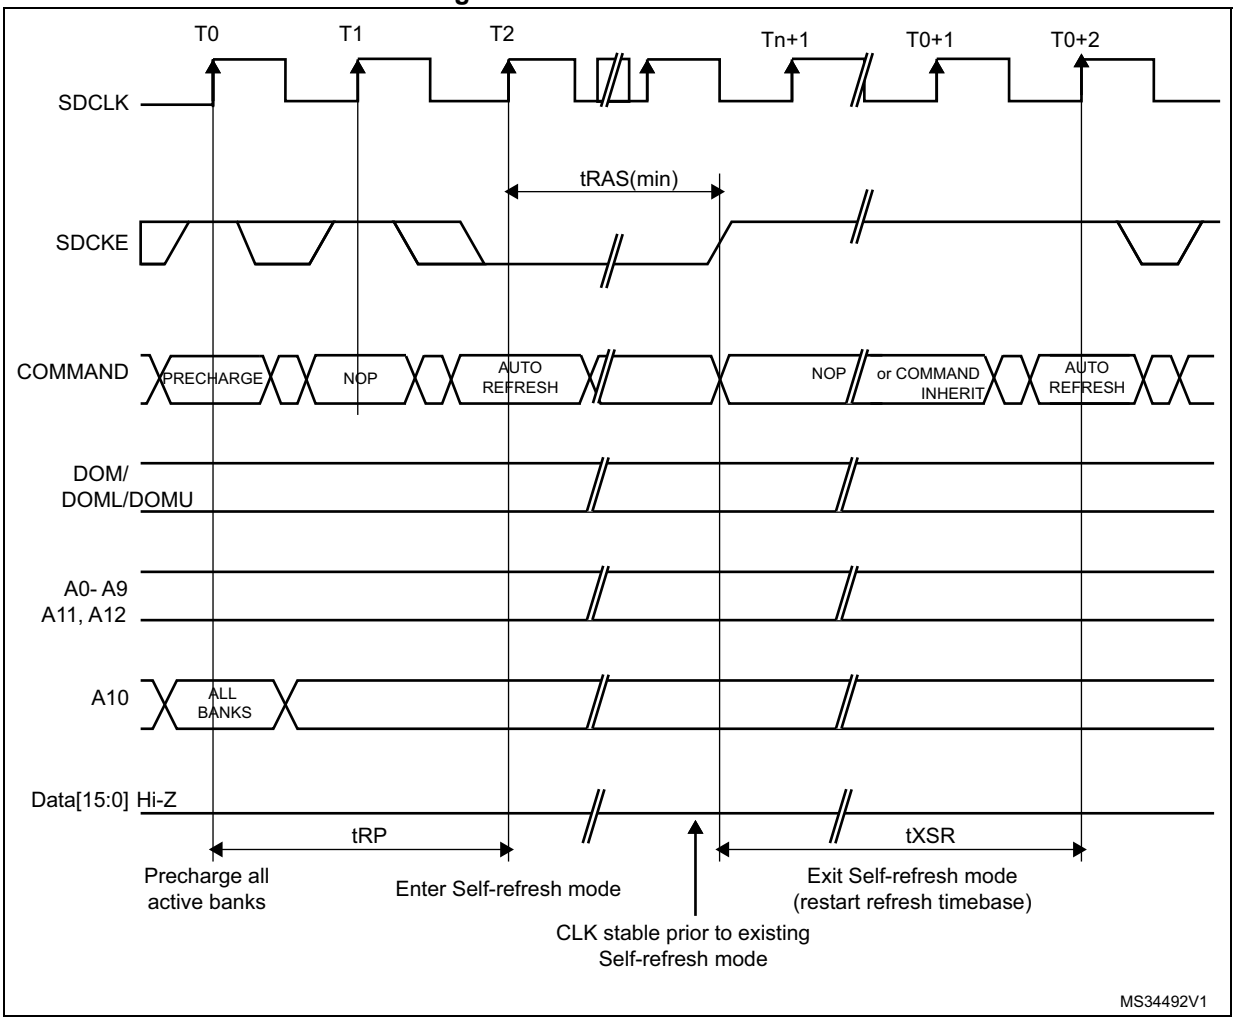
This mode is selected by setting the MODE bits to ‘101’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

The SDRAM clock stops running after a TRAS delay and the internal refresh timer stops counting only if one of the following conditions is met:

- A Self-refresh command is issued to both devices
- One of the devices is not activated (SDRAM bank is not initialized).

Before entering Self-Refresh mode, the SDRAM controller automatically issues a PALL command.

If the Write data FIFO is not empty, all data are sent to the memory before activating the Self-refresh mode and the BUSY status flag remains set.



In Self-refresh mode, all SDRAM device inputs become don't care except for SDCKE which remains low.

The SDRAM device must remain in Self-refresh mode for a minimum period of time of TRAS and can remain in Self-refresh mode for an indefinite period beyond that. To guarantee this minimum period, the BUSY status flag remains high after the Self-refresh activation during a TRAS delay.

As soon as an SDRAM device is selected, the SDRAM controller generates a sequence of commands to exit from Self-refresh mode. After the memory access, the selected device remains in Normal mode.

To exit from Self-refresh, the MODE bits must be set to '000' (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.

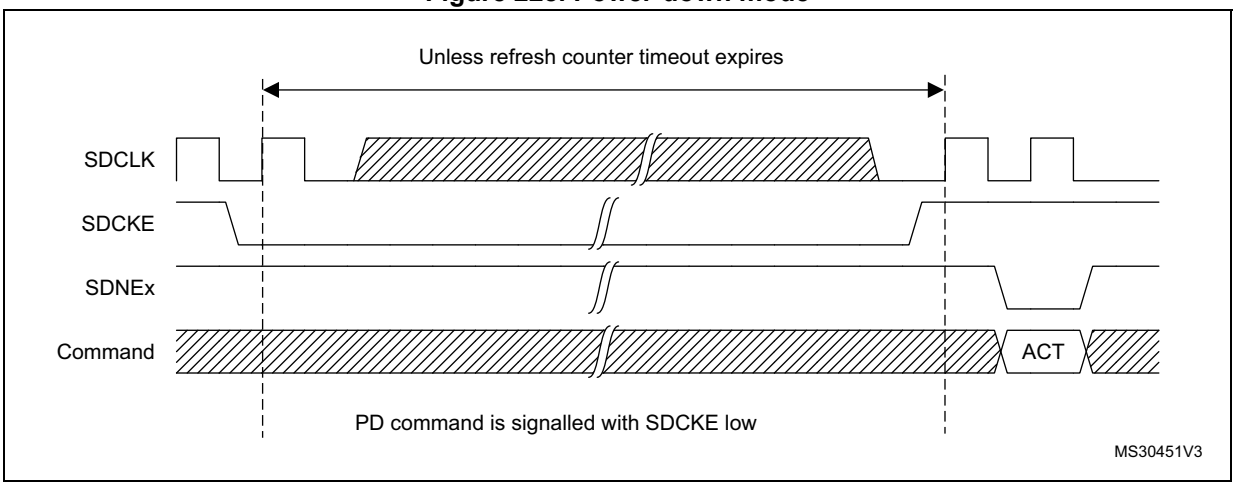


Figure 227. Self-refresh mode

Power-down mode

This mode is selected by setting the MODE bits to ‘110’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

Figure 228. Power-down mode

If the Write data FIFO is not empty, all data are sent to the memory before activating the Power-down mode.

As soon as an SDRAM device is selected, the SDRAM controller exits from the Power-down mode. After the memory access, the selected SDRAM device remains in Normal mode.

During Power-down mode, all SDRAM device input and output buffers are deactivated except for the SDCKE which remains low.

The SDRAM device cannot remain in Power-down mode longer than the refresh period and cannot perform the Auto-refresh cycles by itself. Therefore, the SDRAM controller carries out the refresh operation by executing the operations below:

1. Exit from Power-down mode and drive the SDCKE high
2. Generate the PALL command only if a row was active during Power-down mode
3. Generate the auto-refresh command
4. Drive SDCKE low again to return to Power-down mode.

To exit from Power-down mode, the MODE bits must be set to ‘000’ (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.

21.9.5 SDRAM controller registers

SDRAM Control registers for SDRAM memory bank x (FMC_SDCRx)

Address offset: 0x140+ 0x4* (x - 1), (x = 1 to 2)

Reset value: 0x0000 02D0

This register contains the control parameters for each SDRAM memory bank

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	RPIPE[1:0]		RBURST	SDCLK[1:0]		WP	CAS[1:0]		NB	MWID[1:0]		NR[1:0]		NC[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:13 **RPIPE[1:0]:** Read pipe

These bits define the delay, in fmc_ker_ck clock cycles, for reading data after CAS latency.

00: No fmc_ker_ck clock cycle delay

01: One fmc_ker_ck clock cycle delay

10: Two fmc_ker_ck clock cycle delay

11: reserved.

Note: The corresponding bits in the FMC_SDCR2 register is read only.

Bit 12 **RBURST:** Burst read

This bit enables Burst read mode. The SDRAM controller anticipates the next read commands during the CAS latency and stores data in the Read FIFO.

0: single read requests are not managed as bursts

1: single read requests are always managed as bursts

Note: The corresponding bit in the FMC_SDCR2 register is read only.

Bits 11:10 **SDCLK[1:0]:** SDRAM clock configuration

These bits define the SDRAM clock period for both SDRAM banks and allow disabling the clock before changing the frequency. In this case the SDRAM must be re-initialized.

00: SDCLK clock disabled

01: Reserved

10: SDCLK period = 2 x fmc_ker_ck periods

11: SDCLK period = 3 x fmc_ker_ck periods

Note: The corresponding bits in the FMC_SDCR2 register is read only.

Bit 9 **WP:** Write protection

This bit enables Write mode access to the SDRAM bank.

0: Write accesses allowed

1: Write accesses ignored

Bits 8:7 **CAS[1:0]:** CAS Latency

This bits sets the SDRAM CAS latency in number of memory clock cycles

00: reserved.

01: 1 cycle

10: 2 cycles

11: 3 cycles

Bit 6 **NB:** Number of internal banks

This bit sets the number of internal banks.

0: Two internal Banks

1: Four internal Banks

Bits 5:4 **MWID[1:0]:** Memory data bus width.

These bits define the memory device width.

00: 8 bits

01: 16 bits

10: 32 bits

11: reserved.

Bits 3:2 **NR[1:0]:** Number of row address bits
These bits define the number of bits of a row address.
00: 11 bit
01: 12 bits
10: 13 bits
11: reserved.

Bits 1:0 **NC[1:0]:** Number of column address bits
These bits define the number of bits of a column address.
00: 8 bits
01: 9 bits
10: 10 bits
11: 11 bits.

Note: Before modifying the RBURST or RPIPE settings or disabling the SDCLK clock, the user must first send a PALL command to make sure ongoing operations are complete.

SDRAM Timing registers for SDRAM memory bank x (FMC_SDTRx)

Address offset: 0x148 + 0x4 * (x - 1), (x = 1 to 2)

Reset value: 0x0FFF FFFF

This register contains the timing parameters of each SDRAM bank

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TRCD[3:0]				TRP[3:0]				TWR[3:0]			
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRC[3:0]				TRAS[3:0]				TXSR[3:0]				TMRD[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **TRCD[3:0]:** Row to column delay
These bits define the delay, tRCD, from the Activate command to a Read/Write command in number of memory clock cycles.
0000: 1 cycles
0001: 2 cycles
....
1111: 16 cycles
Note: tRCD delay is replaced by (TWR[3:0]+1) cycles when TWR[3:0] > TRCD[3:0].

Bits 23:20 **TRP[3:0]:** Row precharge delay
These bits define the delay, tRP, from a Precharge command to another command in number of memory clock cycles. The TRP timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP must be programmed with the timing of the slowest device.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles
Note: The corresponding bits in the FMC_SDTR2 register are don't care.

Bits 19:16 **TWR[3:0]:** Recovery delay

These bits define the delay, tWR, between a Write and a Precharge command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: TWR is a minimum of 2 cycles upon an auto refresh request

Note: TWR must be programmed to match the write recovery time (t_{WR}) defined in the SDRAM datasheet, and to guarantee that:

TWR ≥ TRAS - TRCD and TWR ≥ TRC - TRCD - TRP

Example: TRAS= 4 cycles, TRCD= 2 cycles. So, TWR ≥ 2 cycles. TWR must be programmed to 0x1.

If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TWR timing corresponding to the slowest SDRAM device.

If only one SDRAM device is used, the TWR timing must be kept at reset value (0xF) for the not used bank.

Bits 15:12 **TRC[3:0]:** Row cycle delay

These bits define the delay, tRC, from the Refresh command to the Activate command, as well as the delay between two consecutive Refresh commands. It is expressed in number of memory clock cycles. The TRC timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRC must be programmed with the timings of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: TRC must match the TRC and TRFC (Auto Refresh period) timings defined in the SDRAM device datasheet.

Note: The corresponding bits in the FMC_SDTR2 register are don't care.

Bits 11:8 **TRAS[3:0]:** Self refresh time

These bits define the minimum Self-refresh period in number of memory clock cycles.

0000: 2 cycle

0001: 3 cycles

....

1111: 17 cycles

Bits 7:4 **TXSR[3:0]:** Exit Self-refresh delay

These bits define the delay, tXSR, from releasing the Self-refresh command to issuing the Activate command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: tXSR delay is replaced by (TWR[3:0]+1) cycles when TWR[3:0] > TXSR[3:0].

Note: If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TXSR timing corresponding to the slowest SDRAM device.

Bits 3:0 **TMRD[3:0]:** Load Mode Register to Active

These bits define the delay between a Load Mode Register command and an Active or Refresh command in number of memory clock cycles.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles

Note: If two SDRAM devices are connected, all the accesses performed simultaneously to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for Bank 1 (TMRD and TRAS timings) in the FMC_SDTR1 register.

The TRP and TRC timings are only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP and TRC timings must be programmed with the timings of the slowest device.

SDRAM Command mode register (FMC_SDCMR)

Address offset: 0x150

Reset value: 0x0000 0000

This register contains the command issued when the SDRAM device is accessed. This register is used to initialize the SDRAM device, and to activate the Self-refresh and the Power-down modes. As soon as the MODE field is written, the command is issued only to one or to both SDRAM banks according to CTB1 and CTB2 command bits. This register is the same for both SDRAM banks.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MRD[13:7]						
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MRD[6:0]							NRFS[3:0]				CTB1	CTB2	MODE[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w	w	w	w	w

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:9 **MRD[13:0]:** Mode Register definition

This 14-bit field defines the SDRAM Mode Register content. The Mode Register is programmed using the Load Mode Register command. The MRD[13:0] bits are also used to program the extended mode register for mobile SDRAM.

Bits 8:5 **NRFS[3:0]**: Number of Auto-refresh

These bits define the number of consecutive Auto-refresh commands issued when MODE = ‘011’.
0000: 1 Auto-refresh cycle
0001: 2 Auto-refresh cycles
....
1110: 15 Auto-refresh cycles
1111: 16 Auto-refresh cycles

Bit 4 **CTB1:** Command Target Bank 1

This bit indicates whether the command is issued to SDRAM Bank 1 or not.
0: Command not issued to SDRAM Bank 1
1: Command issued to SDRAM Bank 1

Bit 3 **CTB2:** Command Target Bank 2

This bit indicates whether the command is issued to SDRAM Bank 2 or not.

0: Command not issued to SDRAM Bank 2

1: Command issued to SDRAM Bank 2

Bits 2:0 **MODE[2:0]:** Command mode

These bits define the command issued to the SDRAM device.

000: Normal Mode

001: Clock Configuration Enable

010: PALL (“All Bank Precharge”) command

011: Auto-refresh command

100: Load Mode Register

101: Self-refresh command

110: Power-down command

111: Reserved

Note: When a command is issued, at least one Command Target Bank bit (CTB1 or CTB2) must be set otherwise the command is ignored.

Note: If two SDRAM banks are used, the Auto-refresh and PALL command must be issued simultaneously to the two devices with CTB1 and CTB2 bits set otherwise the command is ignored.

Note: If only one SDRAM bank is used and a command is issued with it’s associated CTB bit set, the other CTB bit of the unused bank must be kept to 0.

SDRAM refresh timer register (FMC_SDRTR)

Address offset: 0x154

Reset value: 0x0000 0000

This register sets the refresh rate in number of SDCLK clock cycles between the refresh cycles by configuring the Refresh Timer Count value.

$$\text{Refresh rate} = (\text{COUNT} + 1) \times \text{SDRAM clock frequency}$$

$$\text{COUNT} = (\text{SDRAM refresh period} / \text{Number of rows}) - 20$$

Below an example of refresh rate calculation:

$$\text{Refresh rate} = 64\ \text{ms} / (8196\text{rows}) = 7.81\mu\text{s}$$

where 64 ms is the SDRAM refresh period.

$$7.81\mu\text{s} \times 60\text{MHz} = 468.6$$

The refresh rate must be increased by 20 SDRAM clock cycles (as in the above example) to obtain a safe margin if an internal refresh request occurs when a read request has been accepted. It corresponds to a COUNT value of ‘0000111000000’ (448).

This 13-bit field is loaded into a timer which is decremented using the SDRAM clock. This timer generates a refresh pulse when zero is reached. The COUNT value must be set at least to 41 SDRAM clock cycles.

As soon as the FMC_SDRTR register is programmed, the timer starts counting. If the value programmed in the register is ’0’, no refresh is carried out. This register must not be reprogrammed after the initialization procedure to avoid modifying the refresh rate.

Each time a refresh pulse is generated, this 13-bit COUNT field is reloaded into the counter.

If a memory access is in progress, the Auto-refresh request is delayed. However, if the memory access and Auto-refresh requests are generated simultaneously, the Auto-refresh takes precedence. If the memory access occurs during a refresh operation, the request is buffered to be processed when the refresh is complete.

This register is common to SDRAM bank 1 and bank 2.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	REIE	COUNT[12:0]													CRE
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **REIE:** RES Interrupt Enable

0: Interrupt is disabled

1: An Interrupt is generated if RE = 1

Bits 13:1 **COUNT[12:0]:** Refresh Timer Count

This 13-bit field defines the refresh rate of the SDRAM device. It is expressed in number of memory clock cycles. It must be set at least to 58 SDRAM clock cycles (0x34).

Refresh rate = (COUNT + 1) x SDRAM frequency clock

COUNT = (SDRAM refresh period / Number of rows) - 20

Bit 0 **CRE:** Clear Refresh error flag

This bit is used to clear the Refresh Error Flag (RE) in the Status Register.

0: no effect

1: Refresh Error flag is cleared

Note: The programmed COUNT value must not be equal to the sum of the following timings: TWR+TRP+TRC+TRCD+4 memory clock cycles .

SDRAM Status register (FMC_SDSR)

Address offset: 0x158

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:3 **MODES2[1:0]:** Status Mode for Bank 2
These bits define the Status Mode of SDRAM Bank 2.
00: Normal Mode
01: Self-refresh mode
10: Power-down mode

Bits 2:1 **MODES1[1:0]:** Status Mode for Bank 1
These bits define the Status Mode of SDRAM Bank 1.
00: Normal Mode
01: Self-refresh mode
10: Power-down mode

Bit 0 **RE:** Refresh error flag
0: No refresh error has been detected
1: A refresh error has been detected
An interrupt is generated if REIE = 1 and RE = 1

21.9.6 FMC register map

The following table summarizes the FMC registers.

Table 198. FMC register map

Refer to *Section 2.3 on page 132* for the register boundary addresses.

22 Extended-SPI interface (XSPI)

22.1 XSPI introduction

The XSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- indirect mode: all the operations are performed using the XSPI registers to preset commands, addresses, data, and transfer parameters.
- automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The XSPI supports the following protocol with associated frame format:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

22.2 XSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad, octal communication
- Dual-memory configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AXI acceptance 2: acceptance is offered based on a read transaction followed by a second write or read request (acknowledged on the bus), while the first one is being processed.
- Dual chip select support (NCS1 and NCS2)

- Extended external memory support: if two same size external memories (extmem1 and extmem2) are connected to the same I/O port, contiguously in the memory map and driven by a single XSPI. This XSPI automatically switches CS to extmem1 or extmem2, according to the address on interconnect side.
- Possibility to disable the automatic prefetch

22.3 XSPI implementation

Table 199. XSPI implementation

Feature	XSPI1
Octal mode configuration (8-bit)	X
16-bit mode configuration	-
HyperBus standard compliant	X
Xccela standard compliant	X
XSPI (JESD251C) standard compliant	X
AMBA® AXI compliant data interface	X
Asynchronous AXI clock versus kernel clock	X
Functional modes: indirect, automatic status-polling, and memory-mapped	X
Dual chip select support (NCS1 and NCS2)	X
Read and write support in memory-mapped mode	X
Dual-quad configuration	X
Dual-octal configuration	-
SDR (single-data rate) and DTR (double-transfer rate)	X
Data strobe (DS, DQS)	X
Fully programmable opcode	X
Fully programmable frame format	X
Integrated FIFO for reception and transmission	X
8, 16, and 32-bit data accesses	X
Interrupt on FIFO threshold, timeout, operation complete, and access error	X
Bus error bit	X
Address offset	-
Compliant with dual-XSPI arbiter (communication regulation)	-
Extended CSHT timeout	X
Memory-mapped write	X
Refresh counter	X
High-speed interface	-
GP/HPDMA interface	X
AXI acceptance 2	X

Prefetch disable	X
Prefetch hardware software	X

22.4 XSPI functional description

22.4.1 XSPI block diagram

Figure 229. XSPI block diagram for octal configuration

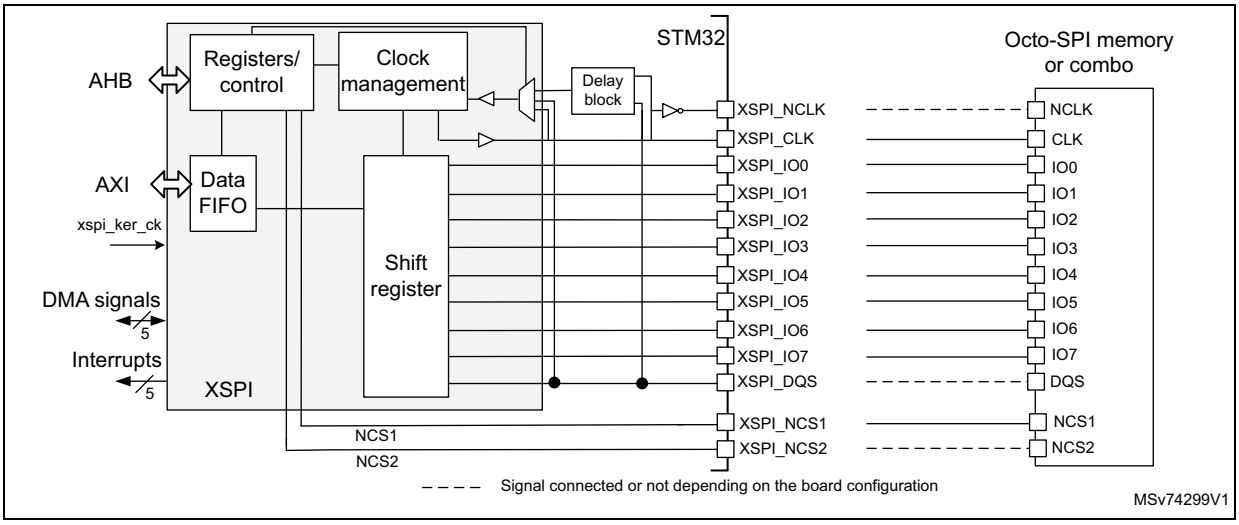

Figure 230. XSPI block diagram for quad configuration

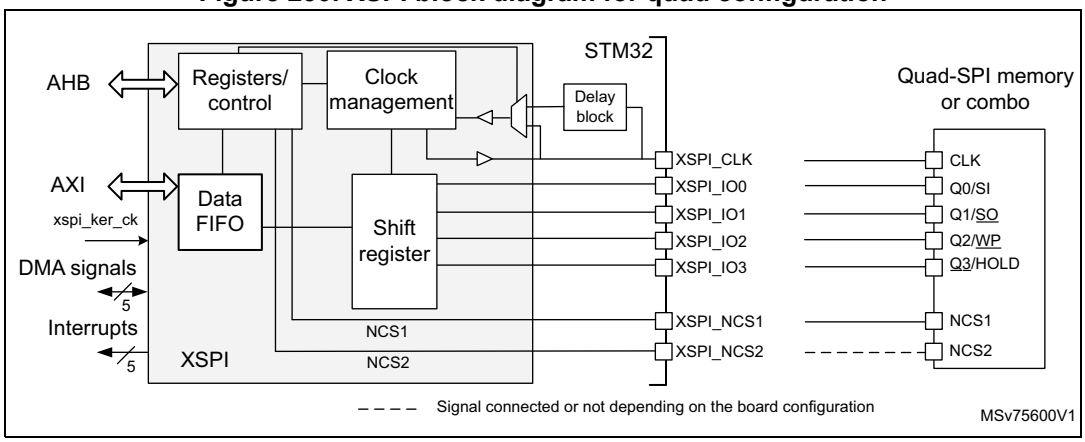

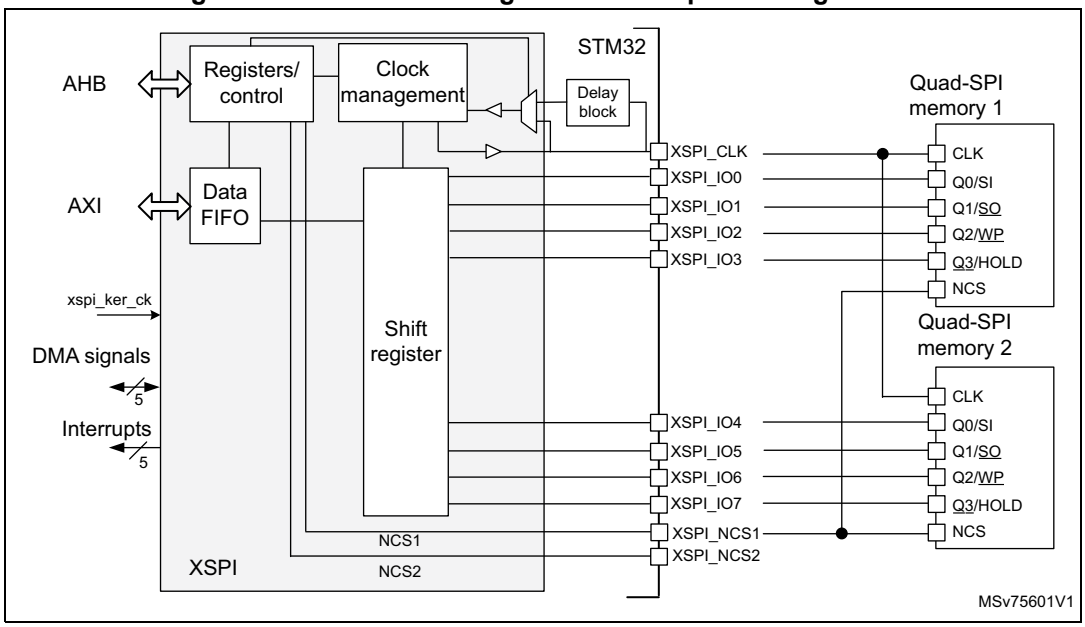

Figure 231. XSPI block diagram for dual-quad configuration

22.4.2 XSPI pins and internal signals

Table 200. XSPI input/output pins

Pin name	Type	Description
XSPI_NCLK	Output	XSPI inverted clock to support 1.8 V HyperBus protocol
XSPI_CLK	Output	XSPI clock
XSPI_IOn (n = 0 to 7)	Input/output	XSPI data pins
XSPI_NCS1,2	Output	Chip select for the memory
XSPI_DQS	Input/output	Data strobe/write mask signal from/to the memory

Caution: Use the same configuration (output speed, HSLV[(a)]) for all XSPI input/output pins to avoid any data corruption.

Table 201. XSPI internal signals

Signal name	Type	Description
xspi_hclk	Input	XSPI AHB clock
xspi_aclk	Input	XSPI AXI clock
xspi_ker_ck	Input	XSPI kernel clock
xspi_dma	N/A	DMA request signal
xspi_it	Output	Global interrupt line (see *Table 205* for the multiple sources of interrupt)

a. When applicable.

22.4.3 Clock constraints

The XSPI AXI clock (xspi_aclk) has to be greater or equal than the XSPI kernel clock (xspi_ker_ck).

22.4.4 XSPI interface to memory modes

The XSPI supports the following protocol:

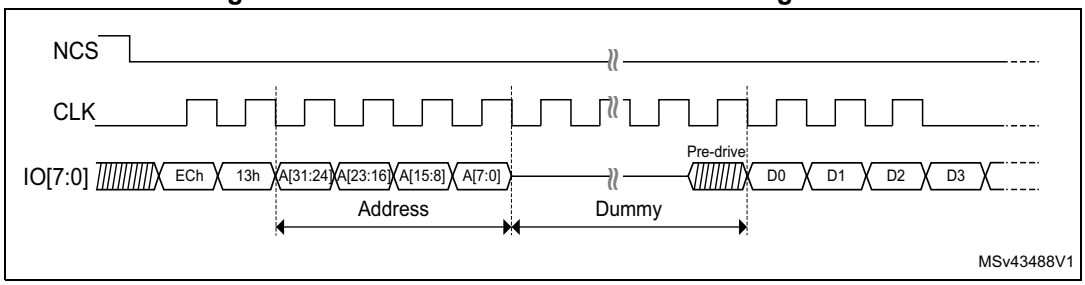
- regular-command protocol
- HyperBus protocol

The XSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select (in the following sections, unless otherwise specified, NCS applies for NCS1 or NCS2. Only one of these two signals is active at a given moment in time)
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS: data strobe used only in regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus can be used as possible remap for quad-SPI mode

22.4.5 XSPI regular-command protocol

When in regular-command protocol, the XSPI communicates with the external device using commands. Each command can include the following phases:



- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped but, in case of single-phase command, the only use case supported is instruction-phase-only.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operations are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

Figure 232. SDR read command in octal configuration

The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

Instruction phase

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured by ISIZE[1:0] in XSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of XSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using IMODE[2:0] of XSPI_CCR.

The instruction can be sent in DTR mode on each rising and falling edge of the clock, by setting IDTR in XSPI_CCR.

When IMODE[2:0] = 000 in XSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In memory-mapped mode, the instruction used for the write operation is specified in XSPI_WIR, and the instruction format is specified in XSPI_WCCR. The instruction used for the read operation and the instruction format are specified in XSPI_IR and XSPI_CCR.

Address phase

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured by ADSIZE[1:0] in XSPI_CCR.

In indirect and automatic status-polling modes, the address bytes to be sent are specified by ADDRESS[31:0] in XSPI_AR. In memory-mapped mode, the address is given directly via the AXI (from any master in the system).

The address phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ADMODE[2:0] in XSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in XSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in XSPI_WCCR. The address format for the read operation is specified in XSPI_CCR.

Alternate-byte phase

In the alternate-byte phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured by ABSIZE[1:0] in XSPI_CCR. The bytes to be sent are specified in XSPI_ABR.

The alternate-byte phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ABMODE[2:0] in XSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR in XSPI_CCR.

When ABMODE[2:0] = 000, the alternate-byte phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in XSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in XSPI_WABR, and the alternate byte format is specified in XSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in XSPI_ABR and XSPI_CCR.

Dummy-cycle phase (memory latency)

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified by DCYC[4:0] in XSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-, the quad-, or the octal-SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in XSPI_WTCR. The dummy cycles for the read operation are specified in XSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in XSPI_DLR. In this mode, the data to be sent to the external device must be written to XSPI_DR, while in indirect-read mode the data received from the external device is obtained by reading XSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in XSPI_DLR, and the data received from the external device can be obtained by reading XSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AXI to the Cortex core or to a DMA.

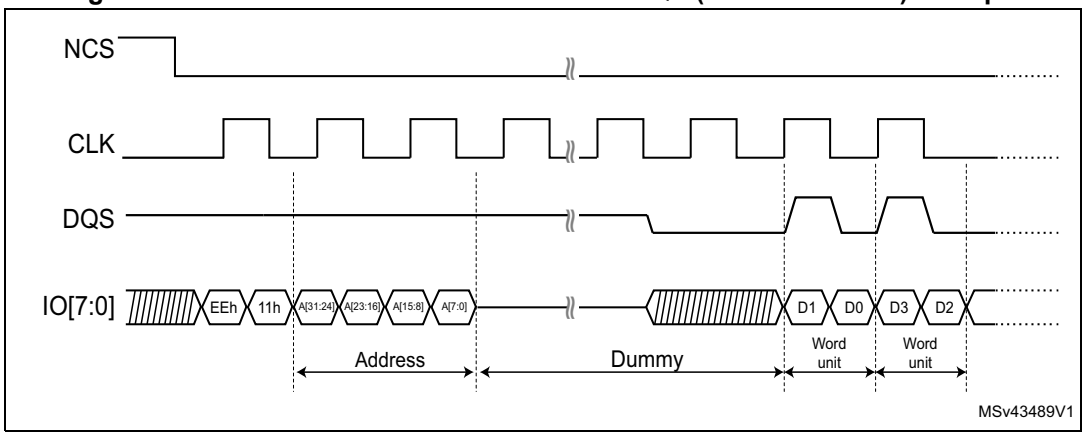
The data phase can send/receive:

- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using DMODE[2:0] in XSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR in XSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.



In memory-mapped mode, the data format for the write operation is specified in XSPI_WCCR. The data format for the read operation is specified in XSPI_CCR.

DQS use

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE in XSPI_CCR.

Figure 233. DTR read in octal-SPI mode with DQS (Macronix mode) example

22.4.6 XSPI regular-command protocol signal interface

Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (Single-SPI Output) (whose I/Os are shared with IO0). The data received from the external device arrives via SI (Single-SPI Input) (whose I/Os are shared with IO1).

Compared to the SPI legacy mode, I0/SO and I1/SI are respectively equivalent to MOSI and MISO, having the XSPI generating the clock.

The different phases can each be configured separately to use this single-SPI mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in single-SPI mode:

- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in dual-SPI mode:

- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase, when DMODE[2:0] = 010, IO0 and IO1 are in a high-impedance state during read transactions, and are forced to either high or low levels during write transactions.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in quad-SPI mode:

- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase, when DMODE[2:0] = 011, IO0 to IO3 are in a high-impedance state during read transactions, and are forced to either high or low levels during write transactions.

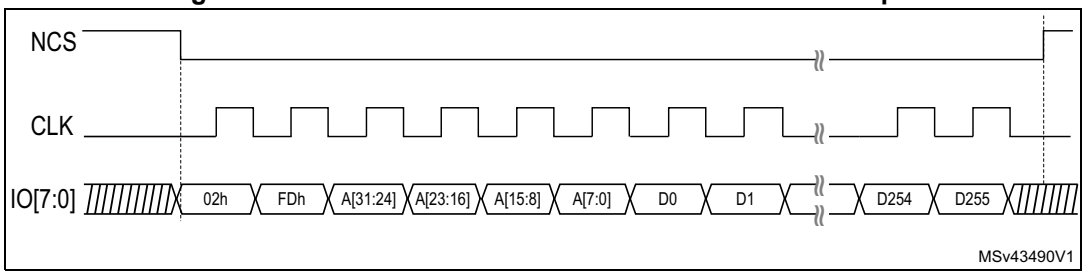
Octal-SPI mode

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase, when DMODE[2:0] = 100, IO[0:7] are in a high-impedance state during read transactions, and are forced to either high or low levels during write transactions.



Single-data rate (SDR) mode

By default, all the phases operate in single-data rate (SDR) mode.

In SDR mode, when the XSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the XSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in XSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

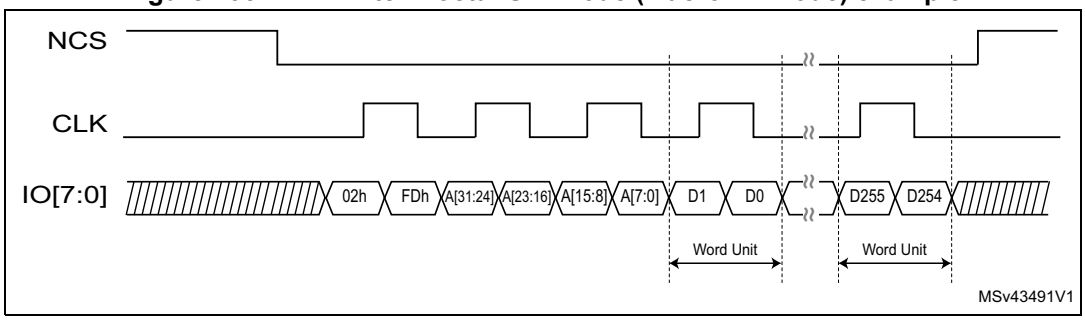
Figure 234. SDR write command in octal-SPI mode example

Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in XSPI_CCR.

In memory-mapped mode, the DTR mode for each phase of the write operations is specified in XSPI_WCCR. The DTR mode for each phase of the read operations is specified in XSPI_CCR.

In DTR mode, when the XSPI drives the IO0/SO and IO1 to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.



In DTR mode, when the XSPI drives the IO0 to IO7 signals in the data phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the XSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in XSPI_CCR, the software must clear SSHIFT in XSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of XSPI_TCR, to shift the outputs by a quarter of cycle and avoid holding issues on the memory side.

Note: DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Figure 235. DTR write in octal-SPI mode (Macronix mode) example

Dual-quad configuration

When DMM = 1 in XSPI_CR, the XSPI is in dual-memory configuration: if DMODE = 011, two external quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified by DEVSIZE[4:0] in XSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the XSPI gives for address X is the byte at the address X/2 of device A, and the byte that the XSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the XSPI must be configured with a data length of 2 bytes (16 bits), and the XSPI receives one byte from each device.

If each device gives a status of 16 bits, then the XSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The fourth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in XSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

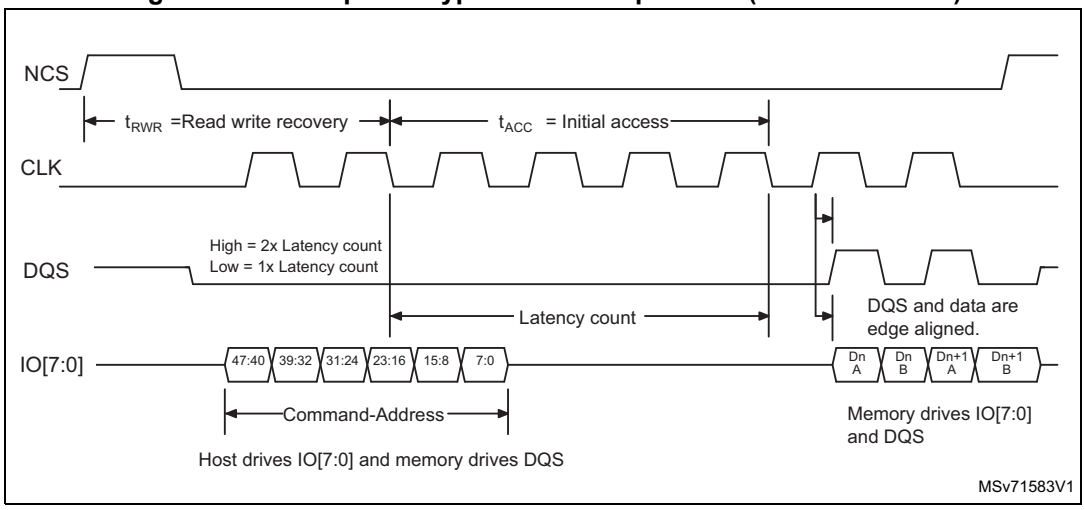
Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

22.4.7 HyperBus protocol

The XSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- DQS for read and write data strobe and latency insertion
- NCS
- CLK
- NCLK for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)



The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

Figure 236. Example of HyperBus read operation (8-bit data mode)

The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

Command/address phase

During this initial phase, the XSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

Table 202. Command/address phase description

CA bit	Bit name	Description
47	R/W#	Identifies the transaction as a read or a write.
46	Address space	Indicates if the transaction accesses the memory or the register space.
45	Burst type	Indicates if the burst is linear or wrapped.
44-16	Row and upper column address	Selects the row and the upper column addresses.
15-3	Reserved	-
2-0	Lower column address	Selects the starting 16-bit word within the half page.

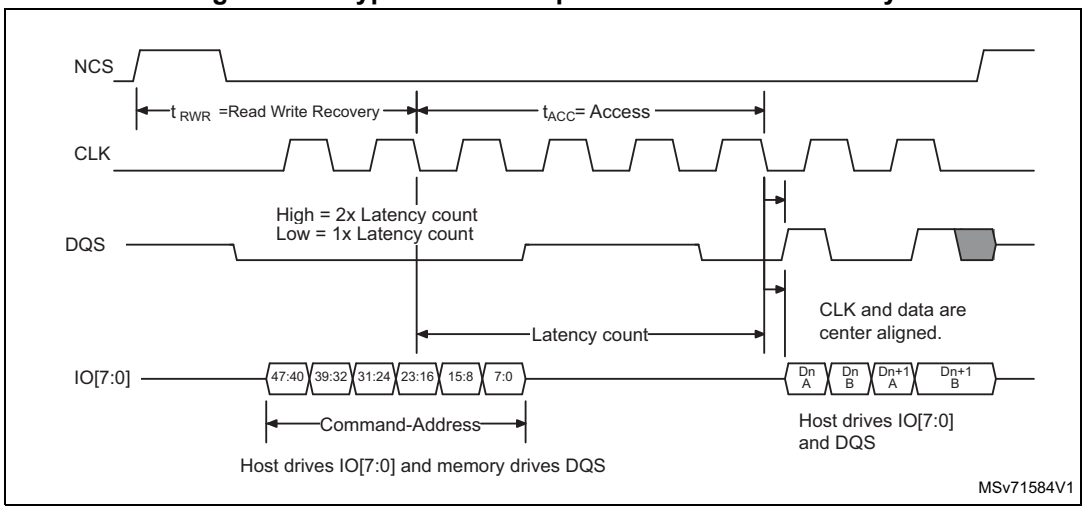
The address space is configured through the memory type MTYP[2:0] in XSPI_DCR1.

The total size of the device must be configured through DEVSIZE[4:0] of XSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- t_{RWR}: minimal read/write recovery time for the device (defined by TRWR[7:0] in XSPI_HLCR)
- t_{ACC}: access time for the device (defined by TACC[7:0] in XSPI_HLCR) according to the memory latency



During the read operation, the DQS is used by the device, in two ways (see *Figure 236*):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation, the DQS is used:

- by the device, during the command/address phase, to request an additional latency.
- by the XSPI, during the data phase, for write data masking.

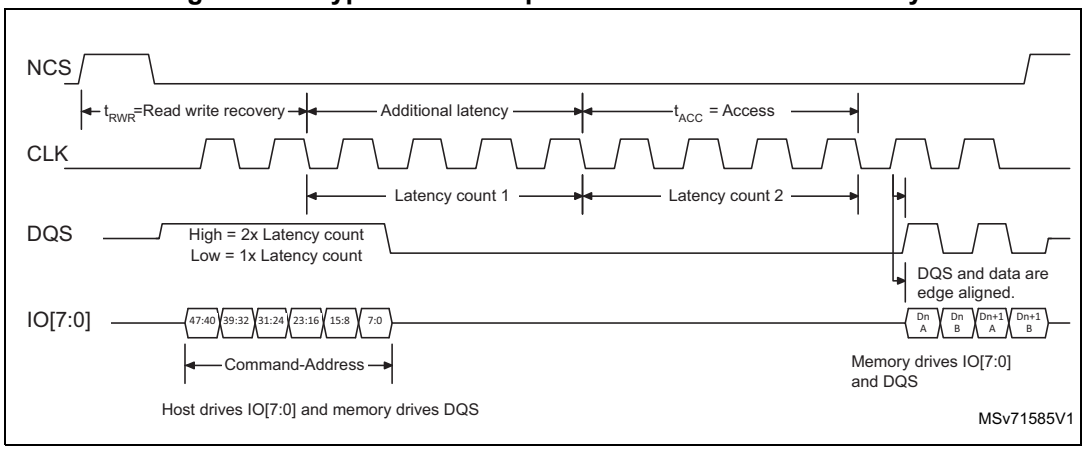
Figure 237. HyperBus write operation with initial latency

Read/write operation with additional latency

If the device needs an additional latency (during refresh period of an SDRAM for example), DQS must be tied to one during one of the DQS signals, during the command/address phase.

An additional t_{ACC} duration is added by the XSPI to meet the device request.

Figure 238. HyperBus read operation with additional latency



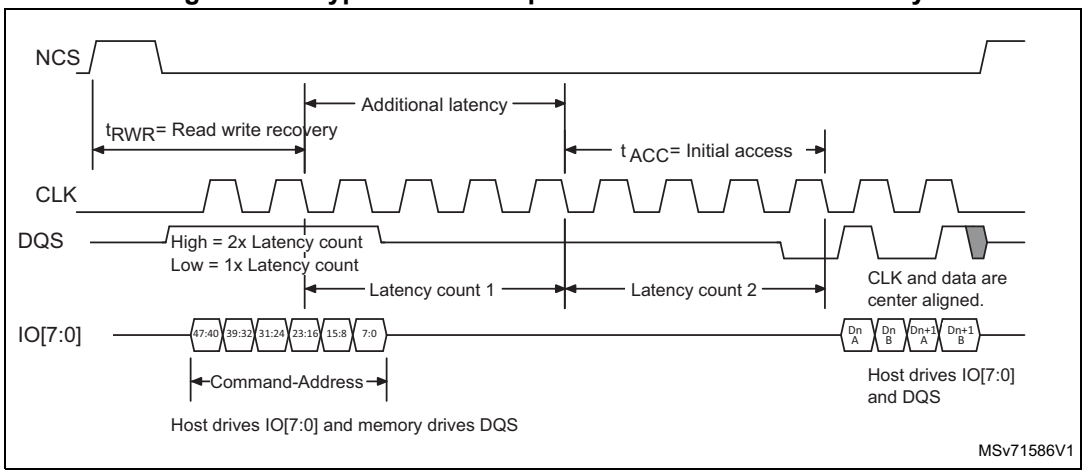


Figure 239. HyperBus write operation with additional latency

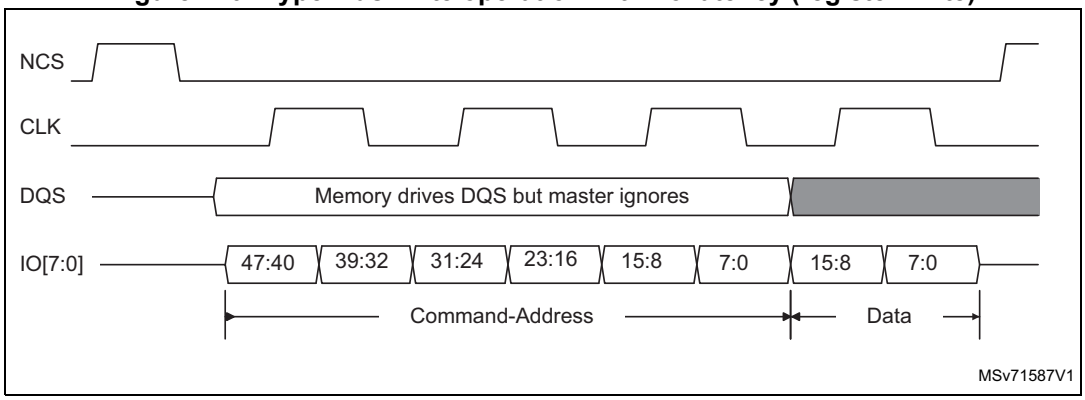
Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.



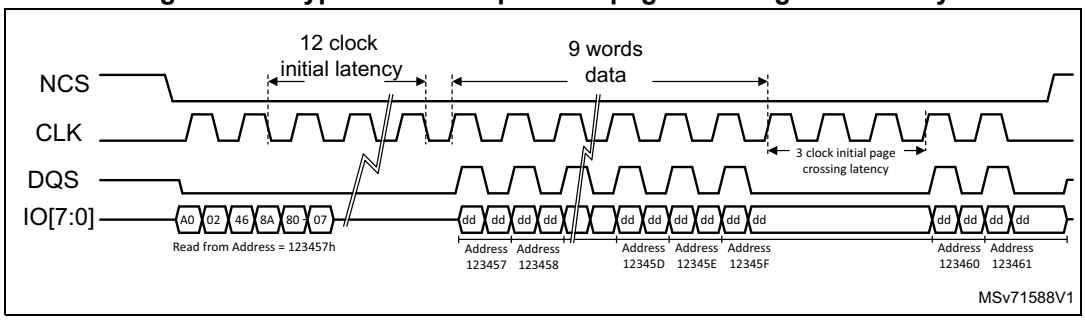
The latency can be forced to 2 x t_{ACC} by setting LM in XSPI_HLCR.

In this XSPI latency mode, the state of the DQS signal is not taken into account by the XSPI, and an additional latency is always added, leading to a fixed 2 x t_{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in XSPI_HLCR.

Figure 240. HyperBus write operation with no latency (register write)



Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the t_{ACC} time.

Figure 241. HyperBus read operation page crossing with latency

22.4.8 Specific features

The XSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh

Wrap support

The XSPI supports a hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in XSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 8 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated XSPI_WPxxx registers must be programmed according to the wrapped-read access characteristics. These registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

Note: Hybrid wrap requires that the nonwrapped registers (XSPI_CCR, XSPI_TCR, XSPI_IR) are set according to the memory configuration to satisfy its correct data prefetch (initiated after the wrap command).

The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.

NCS boundary and refresh

Two processes can be activated to regulate the XSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured by CSBOUND[4:0] in XSPI_DCR3: it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND(4:0] = 0x4, the boundary is set to 2^4 = 16 bytes. The NCS is then released each time the LSB address is equal to 0xF, and each time a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed by REFRESH[31:0] in XSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

22.4.9 XSPI operating mode introduction

The XSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):

- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

22.4.10 XSPI indirect mode

In indirect mode, the commands are started by writing to the XSPI registers, and data are transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in XSPI_CR, the XSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to XSPI_DR.

When FMODE[1:0] = 01, the XSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading XSPI_DR.

In indirect mode, when the XSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The XSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in XSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the XSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in XSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the XSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, the TCF bit is set in XSPI_SR, and an interrupt is generated if TCIE = 1 in XSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in XSPI_DCR1.

Triggering the start of a transfer in regular-command protocol

Depending on the XSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using the regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data need to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in XSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data need to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in XSPI_AR
- if data need to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in XSPI_DR

A write to XSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in XSPI_SR.

Triggering the start of a transfer in HyperBus protocol

Depending on the XSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (XSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01).
- when a write is performed to DATA[31:0] (XSPI_DR) in indirect-write mode (when FMODE = 00).
- when a (dummy) write is performed to INSTRUCTION[31:0] (XSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01).

As soon as a transfer is started, the BUSY bit (XSPI_SR[5]) is automatically set.

FIFO and data management

Data in indirect mode pass through a 32-byte FIFO that is internal to the XSPI. FLEVEL in XSPI_SR indicates how many bytes are currently being held in the FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in XSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to XSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the

last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

22.4.11 XSPI automatic status-polling mode

In automatic status-polling mode, the XSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value. The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in XSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in XSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in XSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in XSPI_CR, the AND-match mode is activated: SMF is set in XSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in XSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in XSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the XSPI is disabled (EN = 0).

XSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in XSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. As a consequence, the memory must then be configured in fixed latency.

22.4.12 XSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

Note: No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256-Mbyte range, then an AXI error is given. The effect of this error depends on the AXI master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the XSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the XSPI never stops its prefetch operation. It either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time. This prefetch feature can be disabled by setting the NOPREF bit in XSPI_DCR1. Disabling the prefetch can be beneficial for performance when the transfer requests are short and jumping frequently between non-consecutive addresses.

Since external devices tend to consume more power when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in XSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in XSPI_LPTR, when x cycles have elapsed without access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

It is not recommended to program the flash memory using the memory-mapped writes. The indirect-write mode fulfills this operation.

However, if the application requires the use of the MCE for encryption (check MCE product availability), the memory-mapped write mode may be used to program encrypted data to external flash memory under the following conditions:

- Prefetch must be enabled.
- In block cipher mode, the CPU must write a complete 128-bit data block to prevent the MCE from initiating read-modify-write operations when only a few bytes need to be programmed. This precaution avoids incorrect programming operations. There are no specific constraints to respect if the MCE is used in stream cipher mode.
- Apply the abort sequence to exit memory-mapped mode when the data linked to the page has been written in the external memory buffers. The abort sequence triggers the start of the page programming.
- Switch to the automatic status-polling mode to monitor the completion of the page programing phase.
- Relaunch the write enable command in indirect mode, then switch back to the memory-mapped mode configuration to continue to program additional pages if any.

It is recommended to add a synchronization barrier between the end of the controller registers configuration and the first memory-mapped access to the external memory when the controller is configured in memory-mapped mode.

22.4.13 XSPI configuration introduction

The XSPI configuration is done in three steps:

1. XSPI system configuration
2. XSPI device configuration
3. XSPI mode configuration

22.4.14 XSPI system configuration

The XSPI is configured using XSPI_CR. The user must program:

- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES
- the DMA use with DMAEN
- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in XSPI_LPTR.

The DMA channel must not be enabled during the XSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and XSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

22.4.15 XSPI device configuration

The parameters related to the external device targeted are configured through XSPI_DCR1 and XSPI_DCR2.The user must program:

- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[5:0]
- the clock mode with FRCK and CKMODE
- the associated delay block DLYB connected externally to the peripheral
- the device frequency with PRESCALER[7:0]

DEVSIZE[4:0] defines the size of external memory using the following formula:

$$\text{Number of bytes in the device} = 2^{[\text{DEVSIZE}+1]}$$

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

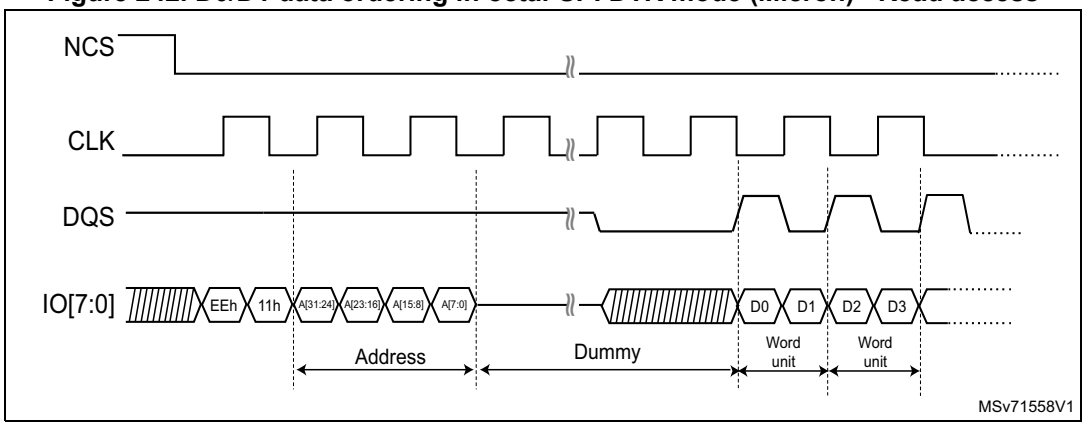
If DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

When the XSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for at least one CLK cycle by default.

If the external device requires more time between commands, CSHT[5:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

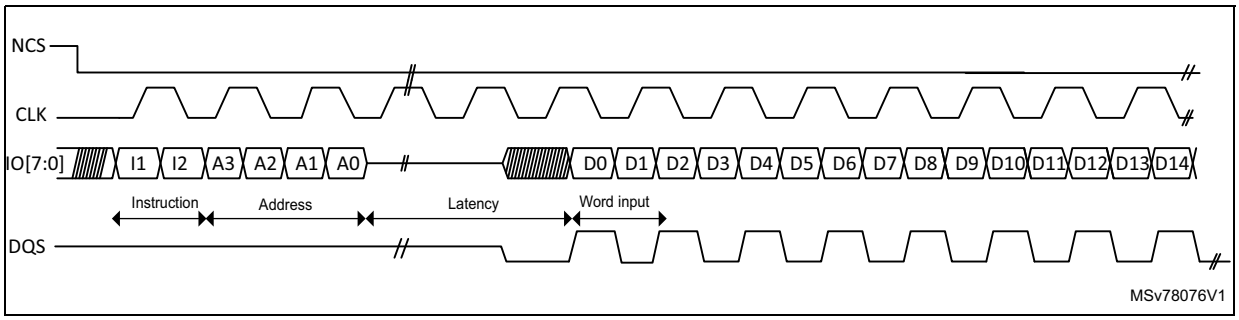
In HyperBus protocol, the device timing (t_{ACC} and t_{RWR}) and the latency mode must be configured in XSPI_HLCR.



Memory types

External memory providers may present some architecture and slight data formatting differences between them. The bitfield MTYP[2:0] into the XSPI_CR register allows targeting the right controller configuration depending on the associated memory type selected in the application. This is the responsibility of the software developer to align the controller configuration to fit with the targeted memory type.

The memory types are grouped in a such way:



- D0/D1 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 000. For instance, Micron is using such data ordering. In this configuration, the DQS is sent with a polarity inverted respect to the clock polarity.

Figure 242. D0/D1 data ordering in octal-SPI DTR mode (Micron) - Read access

- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 001. For instance, Macronix is using this reverse data ordering in its Octaflash portfolio (this configuration is not adapted to its OctaRAM™ memories). DQS is keeping the same polarity as the clock when reading data from the memory. Refer to *Figure 233: DTR read in octal-SPI mode with DQS (Macronix mode) example*.
- D0/D1 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 010. DQS is keeping the same polarity as the clock when reading data from the memory. It is defined as the standard mode since it is the configuration to select when the targeted memory does not fit with any others modes proposed by the MTYP configuration values.

Figure 243. D0/D1 data ordering in octal-SPI DTR mode with DQS and CLK polarity aligned during Read access

- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 011 with specific address phase built with row and column to fit with Macronix OctaRAM™ memories requirement (refer to *Table 203: OctaRAM command address bit assignment (based on 64 Mb OctaRAM)*. This is the controller which translates internally the targeted address provided by the software in row/column address formatting to sent to the memory. DQS is keeping the same polarity as the clock one when reading data from the memory.

Figure 244. OctaRAM read operation with reverse data ordering D1/D0

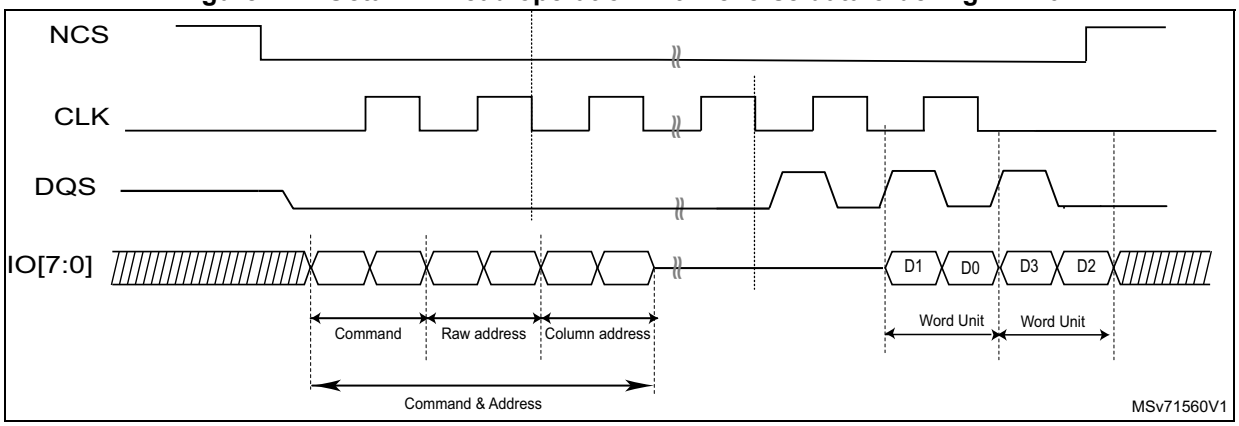


Table 203. OctaRAM command address bit assignment (based on 64 Mb(1) OctaRAM)

Clock	1st clock	2nd clock		3rd clock	
Function	Command	Row address		Column address	
SIO[7]	Command	Reserved	RA7	CA9	Reserved
SIO[6]		Reserved	RA6	CA8	Reserved
SIO[5]		Reserved	RA5	CA7	Reserved
SIO[4]		RA12	RA4	CA6	Reserved
SIO[3]		RA11	RA3	CA5	CA3
SIO[2]		RA10	RA2	CA4	CA2
SIO[1]		RA9	RA1	Reserved	CA1
SIO[0]		RA8	RA0	Reserved	CA0(2)

1. Example of 64 Mb OctaRAM address assignment:
   Row Address [RA12:RA0]: 8K. Column Address [CA9:CA0]: 1K. 64 Mb density = 8K x 1K x 8 bits
2. Column address A0 must be always 0.

- HyperBus memories need to be selected when targeted by the application. The configuration to set depends on the access type:
  - HyperBus memory mode: The protocol follows the HyperBus specification. MTYP[2:0] = 100 is the configuration to use to access the memory space.
  - HyperBus register mode (addressing register space): the memory-mapped accesses in this mode must be noncacheable, or the indirect read/write modes must be used. The configuration to be set for this particular register space access is MTYP[2:0] = 101.

22.4.16 XSPI regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected, and data can be read from the external device.

When the XSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the frame timing in XSPI_TCR.
3. Specify the frame format in XSPI_CCR.
4. Specify the instruction in XSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
6. Specify the targeted address in XSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

If neither the address register (XSPI_AR) nor the data register (XSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as XSPI_IR

is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through XSPI_DR.

Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and data are retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in XSPI_DLR, it is ignored, and only 4 bytes are read. The periodicity is specified in XSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in XSPI_PSMKR, and can be ORed or ANDed with the value stored in XSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The XSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in XSPI_DR.

When the XSPI is used in automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in XSPI_PSMKR.
2. Specify the comparison value in XSPI_PSMAR.
3. Specify the read period in XSPI_PIR.
4. Specify a number of data bytes to read in XSPI_DLR.
5. Specify the frame timing in XSPI_TCR.
6. Specify the frame format in XSPI_CCR.
7. Specify the instruction in XSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
9. Specify the optional targeted address in XSPI_AR.

If the address register (XSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as XSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

The memory-mapped mode is entered by setting FMODE[1:0] = 11 in XSPI_CR.

The programmed instruction and frame are sent when an AXI master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

When the XSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in XSPI_TCR for read operation.
2. Specify the frame format in XSPI_CCR for read operation.
3. Specify the instruction in XSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR for read operation.
5. Specify the frame timing in XSPI_WTCR for write operation.
6. Specify the frame format in XSPI_WCCR for write operation.
7. Specify the instruction in XSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_WABR for write operation.

All configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 has no effect and is not signaled with an error response. On the first access, the XSPI becomes busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

Memory-mapped write operations are not supported without write strobe.

XSPI delayed data sampling when no DQS is used

By default, when no DQS is used, the XSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in XSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

XSPI delayed data sampling when DQS is used

When external DQS is used as a sampling clock, it is shifted precisely by one quarter of the SPI clock cycle, for all frequencies above freq_min, to compensate the data propagation delay in the “high-speed interface” when the product embeds one.

This shift is performed by an external delay block (DLYB) located outside the XSPI. This external delay block has to be calibrated (by enabling FRCK) before starting the first transfer, and recalibrated regularly. The control of this feature depends on the device

implementation (see the delay block (DLYB) section in this document for more details about DLYB and calibration procedure, and the product datasheet for freq_min value).

In configurations where delay does not need to be compensated, the external delay block can be bypassed by setting DLYBYP in XSPI_DCR1.

22.4.17 XSPI HyperBus protocol configuration

Indirect mode configuration (HyperBus)

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the XSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the targeted address in XSPI_AR.
3. Enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In indirect-write mode, the communication start is triggered by a write in the FIFO through XSPI_DR.

Memory-mapped mode configuration (HyperBus)

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AXI master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the XSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit, or to abort by setting the ABORT bit.

22.4.18 XSPI error management

The following errors set the TEF flag in XSPI_SR and generates an interrupt if enabled (TEIE = 1 in XSPI_CR):

- in indirect or automatic status-polling mode, when a wrong address has been programmed in XSPI_AR (according to the device size defined by DEVSIZE[4:0]).

- in indirect mode, if the address plus the data length exceed the device size: TEF is set as soon as the access is triggered.

In memory-mapped mode, the XSPI generates an AXI slave error in the following situations, setting the BERRF flag in XSPI_SR and generating an interrupt if enabled (BERRIE = 1 in XSPI_CR) (if the Bus error bit feature is available in the product implementation table, otherwise the Slave bus error response is generated at system level as transaction response with no dedicated bit into the controller status register):

- The memory-mapped mode is disabled and an AXI read or write request occurs.
- A read or write address exceeds the size of the external memory.
- An abort is received while a read or write burst is ongoing when the abort condition is present at the moment of transfer phases preceding the data phase (In incremental or wrap burst type modes). To avoid the error, refer to *Section 22.4.19: XSPI BUSY and ABORT*.
- The XSPI is disabled while a read or write burst is requested.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in XSPI_WCCR in octal DTR mode, in dual-memory configuration, in HyperBus mode or 16-bit mode.
- A read or write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means that the AXI bus Transfer size (ARSIZE) is different from 8 bytes (only for memory-mapped mode).
- Bit DMM is set in XSPI_CR (dual-memory configuration) and octal mode is set.

22.4.19 XSPI BUSY and ABORT

Once the XSPI starts an operation with the external device, BUSY is automatically set in XSPI_SR.

In indirect mode, BUSY is reset once the XSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

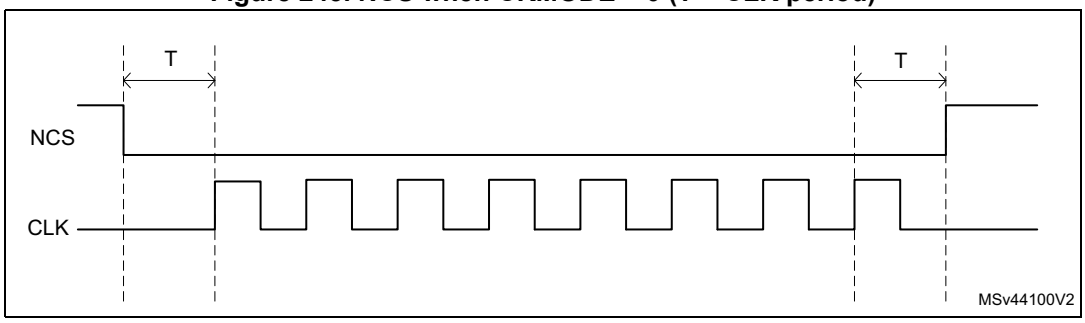
Any operation can be aborted by setting ABORT in XSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers. When DMA is enabled to handle the data read or write operations in XSPI_DR, it is recommended to disable the DMA channel before aborting the SPI.

Note: Some devices may misbehave if a write operation to a status register is aborted.

22.4.20 XSPI reconfiguration or deactivation

Before any XSPI reconfiguration, the software must ensure that all the transactions are completed:



- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier than an abort.

22.4.21 NCS behavior

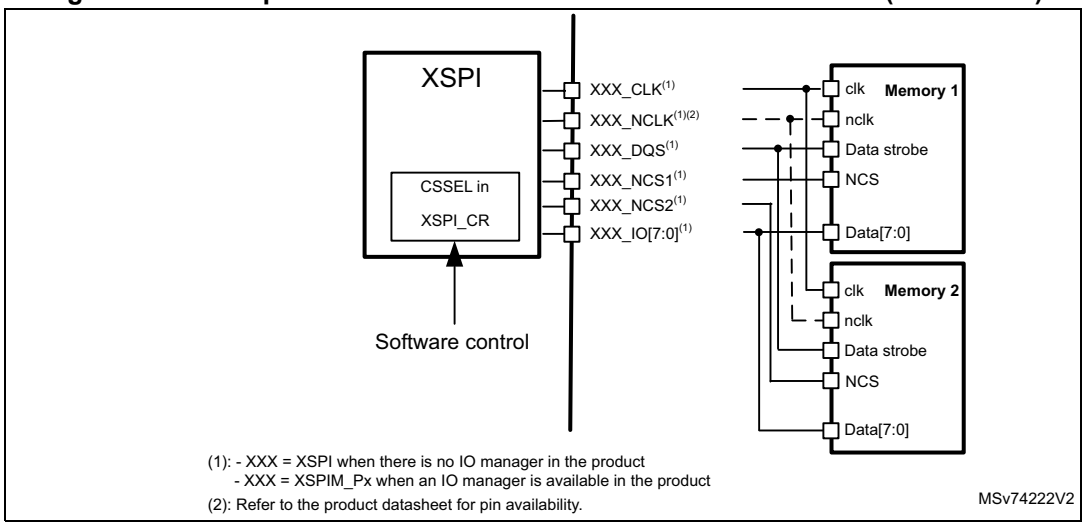
By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 245. NCS when CKMODE = 0 (T = CLK period)

Note: Clock mode 3 is not supported.

In dual-memory configuration, the NCS2 behaves exactly the same as the NCS1. The quad-SPI/octal-SPI memory 2 can then use the NCS1, and the NCS2 pin can be used for other functions.



22.4.22 Software control of two external memories

One XSPI instance is able to control the generation of the two chip-select signals (NCS1 and NCS2). This allows two external memories to be connected to the same I/O port driven by the XSPI.

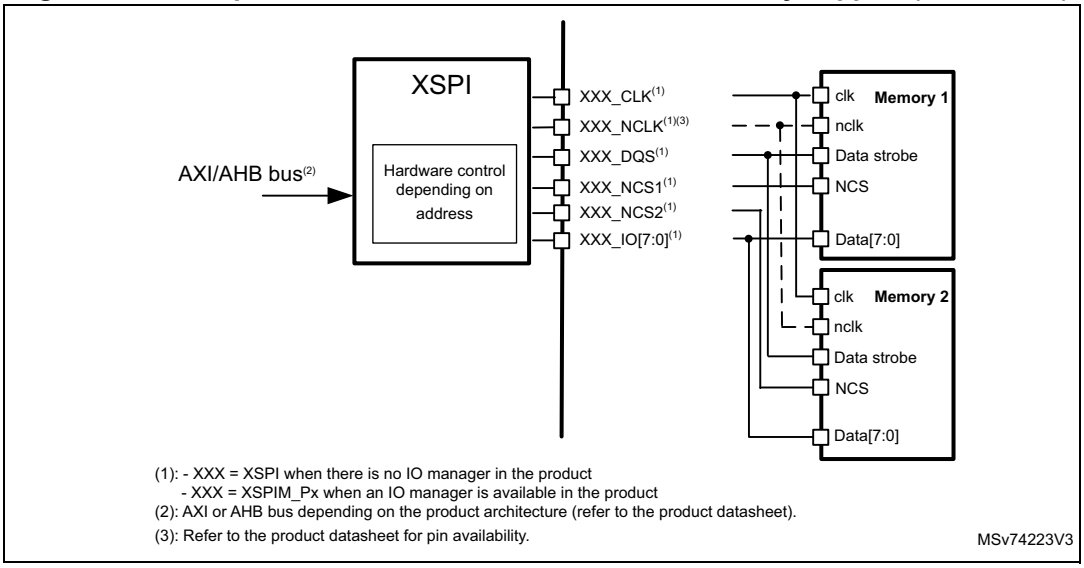
The XSPI generates one NCS signal and the user defines how the NCS is directed to NCS1 or NCS2, by setting the CSSEL bit in XSPI_CR. Intended operation is semistatic commutation, such as starting an application reading an external flash memory and then, for the rest of the application, use an external SRAM connected to the same I/O bus.

From a memory-map point of view, these two memories are located in the same address range.

Figure 246. Example of software control of two external memories (octal mode)

22.4.23 Hardware-controlled extended memory support

One XSPI instance is able to control autonomously the generation of the two chip-select signals (NCS1 and NCS2). This feature is activated by setting EXTENDMEM in XSPI_DCR1 and allows two external memories to be connected to the same I/O port driven by the XSPI.



The aim is to extend by a factor two, the available external memory size. Both memories must be contiguous in the memory map. Both external memories must be of the same type and size. The size of one external memory must be set in DEVSIZE of XSPI_CR.

- When the address presented on the interconnect bus in memory-mapped mode or in XSPI_AR in indirect mode is in the range [XSPI_base_address: XSPI_base_address + $2^{DEVSIZE}$ - 1], NCS1 is generated.
- When the address presented on the interconnect bus in memory-mapped mode or in XSPI_AR in indirect mode is in the range [XSPI_base_address + $2^{DEVSIZE}$: XSPI_base_address + 2 × $2^{DEVSIZE}$ - 1], NCS2 is generated.

Note: If the access crosses the middle boundary of the external memory, CS changes automatically (no write into XSPI_AR in indirect mode, or new memory access in memory-mapped mode is needed).

The EXTENDMEM feature (set in bit 21 of XSPI_DCR1) and the Dual-memory mode (set in bit 6 of XSPI_CR) are exclusive: EXTENDMEM = 1 and DMM = 1 as this configuration is not supported.

Figure 247. Example of hardware-controller extended memory support (octal mode)

Note: It is recommended to set EXTENDMEM = 0 for write transfers targeting flash memories (HyperFlash, NOR Flash, etc.).

These memories require preliminary commands that do not include an address phase used by the controller to select the targeted memory.

This recommendation does not apply to RAM memories, as those extra commands are not needed for RAM access.

22.5 Address alignment and data number

The table below summarizes the effect of the address alignment and programmed data number depending on the use case.

Table 204. Address alignment cases

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad flash or SRAM (DMM = 0)	IND(2) read	None	None	None	None
	MM(3) read				
	IND write				
	MM write				
Single, dual, quad flash or SRAM (DMM = 1)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.

Table 204. Address alignment cases (continued)

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Octal flash in SDR mode	IND read	None	None	None	None
	MM read				
	IND write				
	MM write				
Octal memory in DTR mode without WDM(6) or 8-bit HyperFLASH	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash or RAM in DTR mode with WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				
8-bit HyperRAM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				

1. To be respected by the software.
2. IND = indirect mode.
3. MM = memory-mapped mode.
4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.
7. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 2 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.

22.6 XSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

Table 205. XSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE
FIFO threshold	FTF	FTIE
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

22.7 XSPI registers

22.7.1 XSPI control register (XSPI_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	MSEL	FMODE[1:0]		Res.	NOPREF_AXI	NOPREF	CSSEL	PMM	APMS	BERRIE	TOIE	SMIE	FTIE	TCIE	TEIE
	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FTHRES[4:0]					Res.	DMM	Res.	Res.	TCEN	DMAEN	ABORT	EN
			rw	rw	rw	rw	rw		rw			rw	rw	w	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **MSEL**: External memory select

This bit selects the external memory to be addressed in single-, dual-, quad-SPI mode in single-memory configuration (when DMM = 0).

0: External memory 1 selected (data exchanged over IO[3:0])

1: External memory 2 selected (data exchanged over IO[7:4])

This bit is ignored when DMM = 1 or when octal-SPI mode is selected.

Note: This bitfield can be modified only when BUSY = 0.

Bits 29:28 **FMODE[1:0]**: Functional mode

This bitfield defines the XSPI functional mode of operation.

00: Indirect-write mode

01: Indirect-read mode

10: Automatic status-polling mode (relevant in regular-command protocol only)

11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value.

Note: This bitfield can be modified only when BUSY = 0.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **NOPREF_AXI**: No prefetch for signaled AXI transactions

This bit disables the automatic prefetch in the external memory when the corresponding AXI transaction is signaled as not-prefetchable.

0: Prefetch is enabled, whatever the AXI prefetch transaction request.

1: Prefetch is disabled when the AXI transaction is signaled as not-prefetchable.

Note: This bit has no effect when NOPREF = 1.

Bit 25 **NOPREF**: No prefetch data

This bit disables the automatic prefetch in the external memory.

0: Automatic prefetch enabled

1: Automatic prefetch disabled

Bit 24 **CSSEL**: Chip-select selection

This bit indicates if it must copy NCS to NCS1 or NCS2.

0: NCS1 active

1: NCS2 active

Note: This bit can be modified only when BUSY = 0.

Bit 23 **PMM**: Polling match mode

This bit indicates which method must be used to determine a match during the automatic status-polling mode.

0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.

1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.

Note: This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic status-polling mode stop

This bit determines if the automatic status-polling mode is stopped after a match.

0: Automatic status-polling mode is stopped only by abort or by disabling the XSPI.

1: Automatic status-polling mode stops as soon as there is a match.

Note: This bit can be modified only when BUSY = 0.

Bit 21 **BERRIE**: Bus error interrupt enable

This bit enables the bus error interrupt (if Bus error bit feature is available in the product implementation table).

0: Interrupt disabled

1: Interrupt enabled

Bit 20 **TOIE**: Timeout interrupt enable

This bit enables the timeout interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 19 **SMIE**: Status-match interrupt enable

This bit enables the status-match interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable

This bit enables the FIFO threshold interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable

This bit enables the transfer complete interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable

This bit enables the transfer error interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]**: FIFO threshold level

This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in XSPI_SR, to be set.

00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in indirect-read mode.

00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in indirect-read mode.

...

11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in indirect-read mode.

Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DMM**: Dual-memory configuration

This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity

0: Dual-memory configuration disabled

1: Dual-memory configuration enabled

Note: This bit can be modified only when BUSY = 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in memory-mapped mode.

1: The timeout counter is enabled, and thus the chip-select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Note: This bit can be modified only when BUSY = 0.

Bit 2 **DMAEN**: DMA enable

In indirect mode, the DMA can be used to input or output data via XSPI_DR. DMA transfers are initiated when FTF is set.

0: DMA disabled for indirect mode

1: DMA enabled for indirect mode

Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 **ABORT**: Abort request

This bit aborts the ongoing command sequence. This bit stops the current transfer.

0: No abort requested

1: Abort requested

Note: This bit is always read as 0.

Bit 0 **EN**: Enable

This bit enables the XSPI.

0: XSPI disabled

1: XSPI enabled

Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation.
In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

22.7.2 XSPI device configuration register 1 (XSPI_DCR1)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	MTYP[2:0]			Res.	Res.	EXTENDMEM	DEVSIZE[4:0]				
					rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CSHT[5:0]						Res.	Res.	Res.	Res.	DLYBYP	Res.	FRCK	CKMODE
		rw	rw	rw	rw	rw	rw					rw		rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **MTYP[2:0]**: Memory type

This bitfield indicates the type of memory to be supported.

000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes.

Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.

001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes.

010: Standard mode. D0/D1 ordering with DQS and CLK having the same polarity during read operation. This is the mode to use when the targeted memory does not fit with any others MTYP configuration values. This mode is typically the one targeting the APmemory 8-bit memories for instance.

011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes with dedicated address mapping (address is built with row and column to fit with Macronix requirements).

100: HyperBus memory mode, the protocol follows the HyperBus specification.

101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be noncacheable, or indirect-read/write modes must be used.

Other: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **EXTENDMEM**: Extended memory support

This bit is only relevant when one XSPI drives two same size external memories located in contiguous places in the memory map. In this case, DEVSIZE[4:0] represents the size of each external memory. When this bit is set, the XSPI automatically controls which of NCS1 or NCS2 is active.

0: NCS1 and NCS2 values depend from CSSEL bit in XSPI_CR (software controlled).

1: NCS1 and NCS2 values depend from the address of transfer (hardware controlled).

Note: It is recommended to keep EXTENDMEM = 0 for write operations targeting flash memories (such as NOR Flash and HyperFlash).

Bits 20:16 **DEVSIZE[4:0]**: Device size

This bitfield defines the size of the external device using the following formula:
Number of bytes in device = $2^{[DEVSIZE+1]}$.
DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.
In regular-command protocol, if DMM = 1 or EXTENDMEM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **CSHT[5:0]**: Chip-select high time

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

0x0: NCS stays high for at least 1 cycle between external device commands.

0x1: NCS stays high for at least 2 cycles between external device commands.

...

0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DLYBYP**: Delay block bypass

0: The internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the peripheral).

1: The delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **FRCK**: Free running clock

This bit configures the free running clock.

0: CLK is not free running.

1: CLK is free running (always provided).

Note: Free running clock mode is intended for delay calibration only. No memory or other device access is possible when FRCK is set. Once the bit has been set to 1, the BSY bit is set, the NCS signal remains set to 1 and the clock is sent. The only way to stop the clock is to perform an abort (which clears the BSY bit). Then, the FRCK bit must be cleared by software to allow controller transactions to take place with the external memory.

Bit 0 **CKMODE**: Clock mode 0

This bit is read-only and is read as zero.

22.7.3 XSPI device configuration register 2 (XSPI_DCR2)

Address offset: 0x00C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRAPSIZE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRESCALER[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WRAPSIZE[2:0]**: Wrap size

This bitfield indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in the XSPI_WPIR register.

000: Wrapped reads are not supported by the memory.

010: External memory supports wrap size of 16 bytes.

011: External memory supports wrap size of 32 bytes.

100: External memory supports wrap size of 64 bytes.

101: External memory supports wrap size of 128 bytes.

Other: Reserved

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: $F_{CLK} = F_{KERNEL}$, kernel clock used directly as XSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the XSPI a kernel clock that has 50% duty-cycle.

1: $F_{CLK} = F_{KERNEL}/2$

2: $F_{CLK} = F_{KERNEL}/3$

...

255: $F_{CLK} = F_{KERNEL}/256$

For odd clock division factors, the CLK duty cycle is not 50 %. The clock signal remains low one cycle longer than it stays high.

22.7.4 XSPI device configuration register 3 (XSPI_DCR3)

Address offset: 0x010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSBOUND[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This bitfield enables the transaction boundary feature. When active, a minimum value of 3 is recommended. The NCS is released on each boundary of $2^{CSBOUND}$ bytes.

0: NCS boundary disabled

Other: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:0 Reserved, must be kept at reset value.

22.7.5 XSPI device configuration register 4 (XSPI_DCR4)

Address offset: 0x014

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFRESH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFRESH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFRESH[31:0]**: Refresh rate

This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual- or quad-SPI mode, because the byte transmission must be completed.

0: Refresh disabled

Other: Maximum communication length is set to REFRESH + 1 clock cycles.

Note: REFRESH count is based on the memory clock period: if XSPI_DCR2 PRESCALER bitfield is changed, the REFRESH field must be updated accordingly.

22.7.6 XSPI status register (XSPI_SR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FLEVEL[5:0]						Res.	BERRF	BUSY	TOF	SMF	FTF	TCF	TEF
		r	r	r	r	r	r		r	r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level

This bitfield gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.

In automatic status-polling mode, FLEVEL is zero.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **BERRF**: Bus error flag

This bit is set when a bus error occurs. It is cleared by writing 1 to CBERRF. This bit has a meaning if Bus error bit feature is available in the product implementation table.

Bit 5 **BUSY**: Busy

This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (XSPI_PSMAR).

It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.

It is cleared automatically as soon as the threshold condition is no longer true.

In automatic status-polling mode, this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted.It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag

This bit is set in indirect mode when an invalid address is being accessed in indirect mode.

It is cleared by writing 1 to CTEF.

22.7.7 XSPI flag clear register (XSPI_FCR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CBERRF	Res.	CTOF	CSMF	Res.	CTCF	CTEF
									w		w	w		w	w

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CBERRF**: Clear bus error flag
Writing 1 clears the BERRF flag in the XSPI_SR register (if Bus error bit feature is available in the product implementation table).

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag
Writing 1 clears the TOF flag in the XSPI_SR register.

Bit 3 **CSMF**: Clear status match flag
Writing 1 clears the SMF flag in the XSPI_SR register.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag
Writing 1 clears the TCF flag in the XSPI_SR register.

Bit 0 **CTEF**: Clear transfer error flag
Writing 1 clears the TEF flag in the XSPI_SR register.

22.7.8 XSPI data length register (XSPI_DLR)

Address offset: 0x040

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DL[31:0]**: Data length

Number of data to be retrieved (value+1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode.

All 1's in indirect mode means undefined length, where XSPI continues until the end of the memory, as defined by DEVSIZE.

0x0000_0000: 1 byte is to be transferred.

0x0000_0001: 2 bytes are to be transferred.

0x0000_0002: 3 bytes are to be transferred.

0x0000_0003: 4 bytes are to be transferred.

...

0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.

0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.

0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This bitfield has no effect in memory-mapped mode.

22.7.9 XSPI address register (XSPI_AR)

Address offset: 0x048

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0 and FMODE ≠ 11.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDRESS[31:0]**: Address

Address to be sent to the external device. In dual-memory configuration, AR[0] is forced to 0.

Caution: Some memory specifications consider that each address corresponds to a 16-bit value. XSPI considers that each address corresponds to an 8-bit value. So the software needs to multiply the address by two when accessing the memory registers.

22.7.10 XSPI data register (XSPI_DR)

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31:0]**: Data

Data to be sent/received to/from the external SPI device

In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.

Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

22.7.11 XSPI polling status mask register (XSPI_PSMKR)

Address offset: 0x080

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MASK[31:0]**: Status mask

Mask to be applied to the status bytes received in automatic status-polling mode

For bit n:

0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.

1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.

22.7.12 XSPI polling status match register (XSPI_PSMAR)

Address offset: 0x088

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MATCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MATCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MATCH[31:0]**: Status match
Value to be compared with the masked status register to get a match

22.7.13 XSPI polling interval register (XSPI_PIR)

Address offset: 0x090

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INTERVAL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INTERVAL[15:0]**: Polling interval
Number of CLK cycles between a read during the automatic status-polling phases

22.7.14 XSPI communication configuration register (XSPI_CCR)

Address offset: 0x100

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	DQSE	Res.	DDTR	DMODE[2:0]			Res.	Res.	ABSIZE[1:0]		ABDTR	ABMODE[2:0]		
		rw		rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Other: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate- byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Other: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Other: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Other: Reserved

22.7.15 XSPI timing configuration register (XSPI_TCR)

Address offset: 0x108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift
By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle
0: No delay hold
1: 1/4 cycle hold

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

22.7.16 XSPI instruction register (XSPI_IR)

Address offset: 0x110

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]

INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

22.7.17 XSPI alternate bytes register (XSPI_ABR)

Address offset: 0x120

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALTERNATE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes

Optional data to be sent to the external SPI device right after the address.

22.7.18 XSPI low-power timeout register (XSPI_LPTR)

Address offset: 0x130

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

TIMEOUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15:0]**: Timeout period

After each access in memory-mapped mode, the XSPI prefetches the subsequent bytes and hold them in the FIFO.

This bitfield indicates how many CLK cycles the XSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

22.7.19 XSPI wrap communication configuration register (XSPI_WPCCR)

Address offset: 0x140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable

This bit enables the data strobe management.

0: DQS disabled

1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Other: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: no alternate bytes
001: alternate bytes on a single line
010: alternate bytes on two lines
011: alternate bytes on four lines
100: alternate bytes on eight lines
Other: reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Other: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Other: Reserved

22.7.20 XSPI wrap timing configuration register (XSPI_WPTCR)

Address offset: 0x148

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	DHQC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift
By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The firmware must assure that SSHIFT=0 when the data phase is configured in DTR mode (when DDTR = 1).

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle
Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.
0: No quarter cycle delay
1: 1/4 cycle delay inserted

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

22.7.21 XSPI wrap instruction register (XSPI_WPIR)

Address offset: 0x150

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address

22.7.23 XSPI write communication configuration register (XSPI_WCCR)

Address offset: 0x180

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Other: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate-bytes phase.
0: DTR mode disabled for alternate-bytes phase
1: DTR mode enabled for alternate-bytes phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Other: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Other: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for instruction phase
1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Other: Reserved

22.7.24 XSPI write timing configuration register (XSPI_WTCR)

Address offset: 0x188

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency. In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

22.7.25 XSPI write instruction register (XSPI_WIR)

Address offset: 0x190

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes

Optional data to be sent to the external SPI device right after the address

22.7.27 XSPI HyperBus latency configuration register (XSPI_HLCR)

Address offset: 0x200

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TACC[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	WZL	LM
rw	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TRWR[7:0]:** Read-write minimum recovery time

Device read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles

Bits 15:8 **TACC[7:0]**: Access time

Device access time according to the memory latency, expressed in number of communication clock cycles

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **WZL:** Write zero latency

This bit enables zero latency on write operations.

0: Latency on write accesses

1: No latency on write accesses

Bit 0 **LM:** Latency mode

This bit selects the latency mode.

0: Variable initial latency

1: Fixed latency

Note: This bit must be set when using the dual-octal HyperRAM configuration. It must be kept cleared for HyperFLASH memory.

22.7.28 XSPI register map

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

23 Secure digital input/output MultiMediaCard interface (SDMMC)

23.1 SDMMC main features

The SD/SDIO, embedded MultiMediaCard (*e*•MMC) host interface (SDMMC) provides an interface between the AHB bus and SD memory cards, SDIO cards and *e*•MMC devices.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website at www.jedec.org, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website at www.sdcard.org.

The SDMMC features include the following:

- Compliance with *Embedded MultiMediaCard System Specification Version 5.1*. Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit. (HS200 SDMMC_CK speed limited to maximum allowed I/O speed)(HS400 is not supported).
- Full compatibility with previous versions of MultiMediaCards (backward compatibility).
- Full compliance with *SD memory card specifications version 6.0*. (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Full compliance with *SDIO card specification version 4.0.* Card support for two different databus modes: 1-bit (default) and 4-bit. (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Data transfer up to 208 Mbyte/s for the 8-bit mode. (depending maximum allowed I/O speed).
- Data and command output enable signals to control external bidirectional drivers.
- IDMA linked list support

The MultiMediaCard/SD bus connects cards to the host.

The current version of the SDMMC supports only one SD/SDIO/*e*•MMC card at any one time and a stack of *e*•MMC.

23.2 SDMMC implementation

Table 207. SDMMC features

SDMMC modes/features(1)	SDMMC1
Variable delay	X
SDMMC_CKIN	X
SDMMC_CDIR, SDMMC_D0DIR	X
SDMMC_D123DIR	X

1. X = supported.

23.3 SDMMC bus topology

Communication over the bus is based on command/response and data transfers.

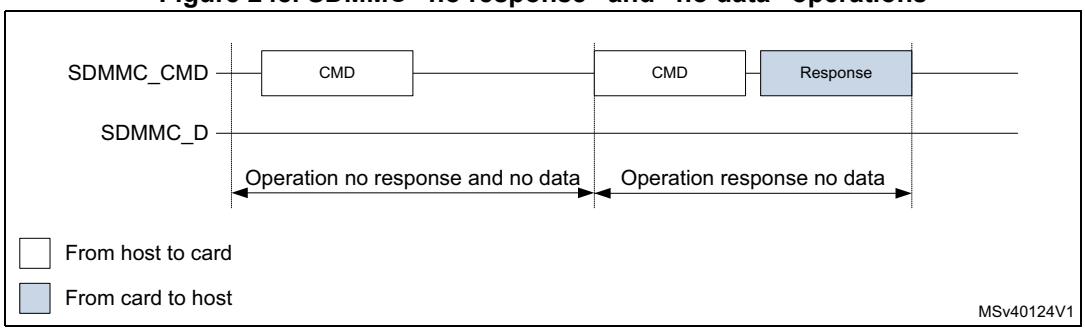
The basic transaction on the SD/SDIO/*e*•MMC bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

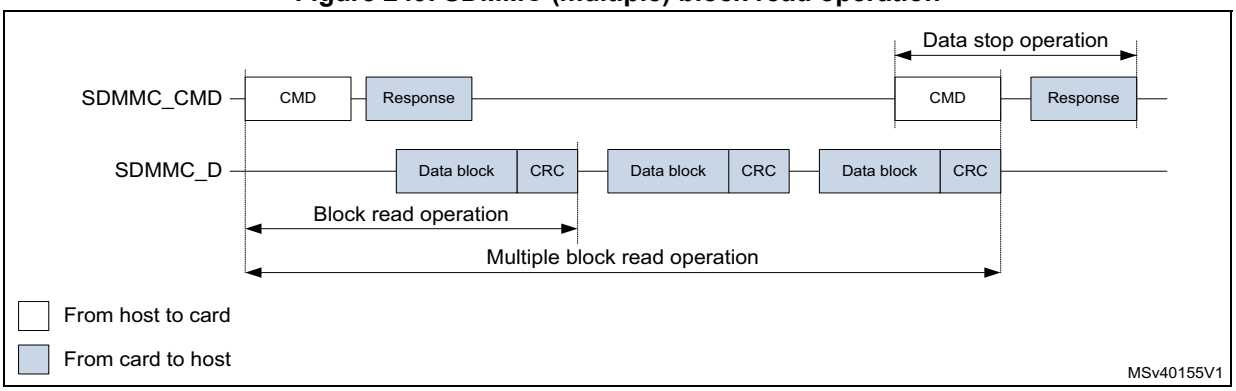
Data transfers are done in the following ways:

- Block mode: data block(s) with block size 2^N bytes with N in the range 0-14
- SDIO multibyte mode: single data block with block size range 1-512 bytes
- *e*•MMC Stream mode: continuous data stream

Data transfers to/from *e*•MMC cards are done in data blocks or streams.

Figure 248. SDMMC "no response" and "no data" operations





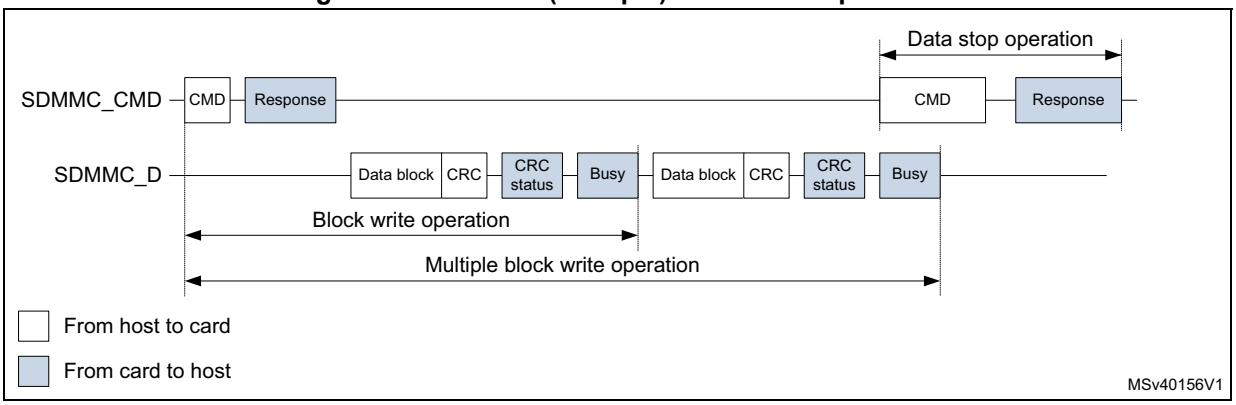


Figure 249. SDMMC (multiple) block read operation

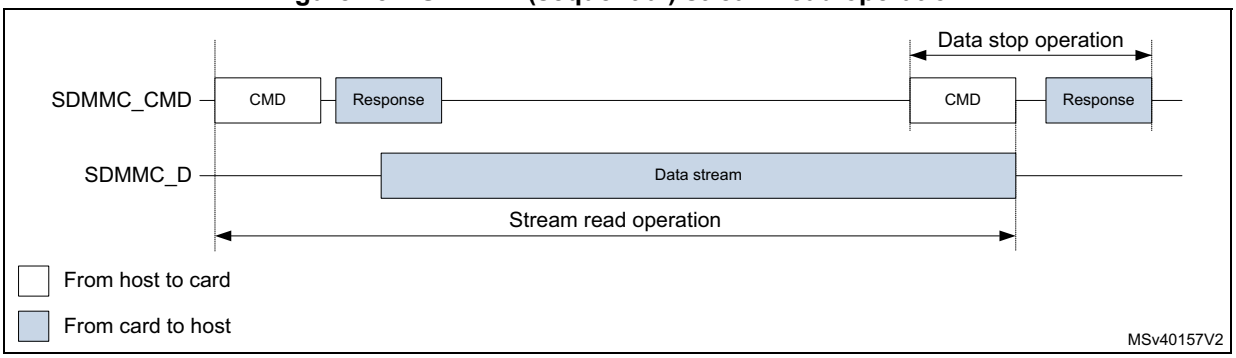
Note: The Stop Transmission command is not required at the end of a e•MMC multiple block read with predefined block count.

Figure 250. SDMMC (multiple) block write operation

Note: The Stop Transmission command is not required at the end of an e•MMC multiple block write with predefined block count.

The SDMMC does not send any data as long as the Busy signal is asserted (SDMMC_D0 pulled low).

Figure 251. SDMMC (sequential) stream read operation



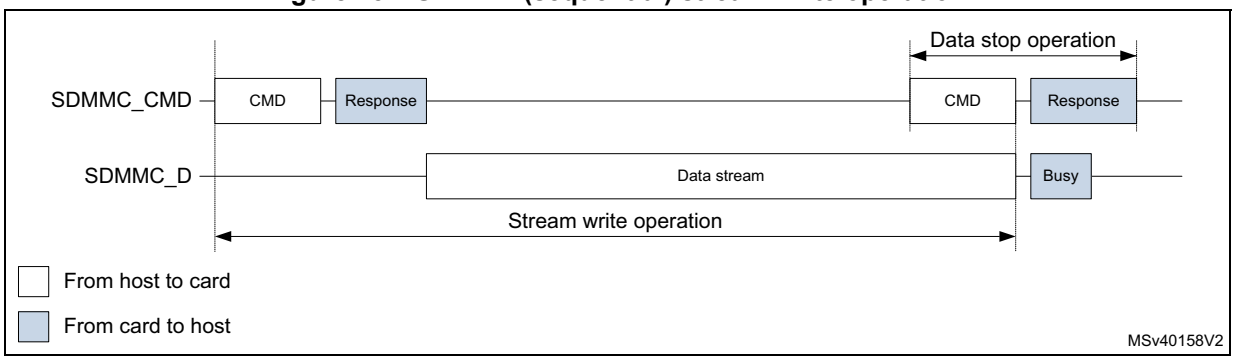


Figure 252. SDMMC (sequential) stream write operation

Stream data transfer operates only in a 1-bit wide bit bus configuration on SDMMC_D0 in single data rate modes (DS, HS, and SDR).

23.4 SDMMC operation modes

Table 208. SDMMC operation modes SD and SDIO

SDIO bus speed modes(1)(2)	Max bus speed (3) [Mbyte/s]	Max clock frequency [MHz](4)	Signal voltage [V]
DS (default speed)	12.5	25	3.3
HS (high speed)	25	50	3.3
SDR12	12.5	25	1.8
SDR25	25	50	1.8
DDR50	50	50	1.8
SDR50	50	100	1.8
SDR104	104	208	1.8

1. SDR single data rate signaling.
2. DDR double data rate signaling (data is sampled on both SDMMC_CK clock edges).
3. SDIO bus speed with 4-bit bus width.
4. Maximum frequency depending on maximum allowed I/O speed.

SDR104 mode requires variable delay support using sampling point tuning. The use of variable delay is optional for SDR50 mode.

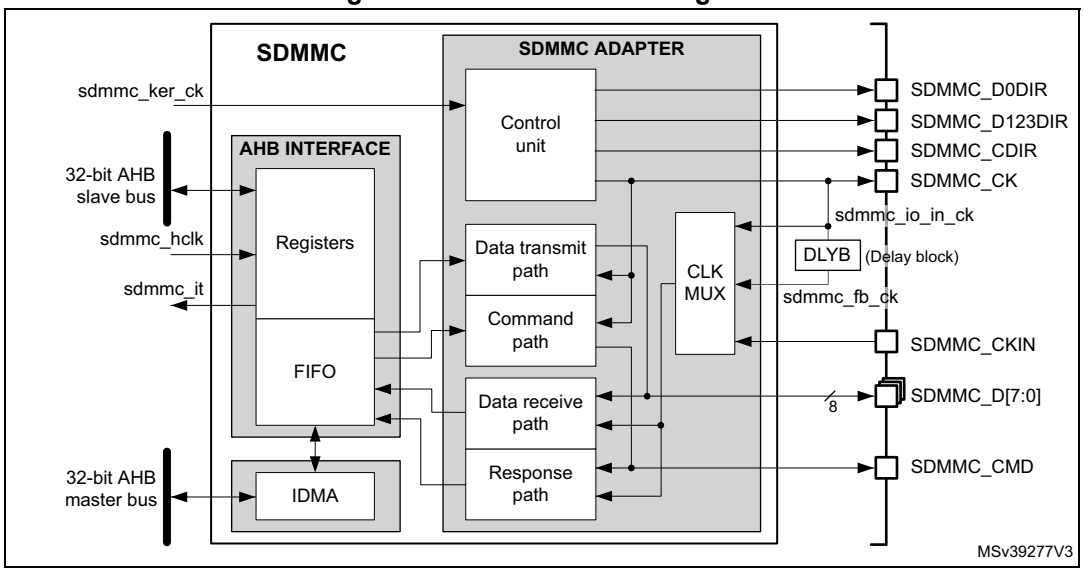
Table 209. SDMMC operation modes *e*•MMC

e•MMC bus speed modes (1)(2)	Max bus speed (3) [Mbyte/s]	Max clock frequency [MHz](4)	Signal voltage [V](5)
Legacy compatible	26	26	3/1.8/1.2V
High speed SDR	52	52	3/1.8/1.2V
High speed DDR	104	52	3/1.8/1.2V
High speed HS200	200	200	1.8/1.2V

1. SDR single data rate signaling.
2. DDR double data rate signaling. (data is sampled on both SDMMC_CK clock edges).
3. *e*•MMC bus speed with 8-bit bus width.
4. Maximum frequency depending on maximum allowed I/O speed.
5. Supported signal voltage level depends on I/O port characteristics, refer to device datasheet.

HS200 mode requires variable delay support using sampling point tuning.

23.5 SDMMC functional description



The SDMMC consists of four parts:

- The AHB slave interface accesses the SDMMC adapter registers, and generates interrupt signals and IDMA control signals.
- The SDMMC adapter block provides all functions specific to the *e*•MMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The internal DMA (IDMA) block with its AHB master interface.
- A delay block (DLYB) taking care of the receive data sample clock alignment. The delay block is NOT part of the SDMMC. A delay block is mandatory when supporting SDR104 or HS200.

23.5.1 SDMMC block diagram

Figure 253 shows the SDMMC block diagram.

Figure 253. SDMMC block diagram

23.5.2 SDMMC pins and internal signals

Table 210 lists the SDMMC internal input/output signals, *Table 211* the SDMMC pins (alternate functions).

Table 210. SDMMC internal input/output signals

Signal name	Signal type	Description
sdmmc_ker_ck	Digital input	SDMMC kernel clock
sdmmc_hclk	Digital input	AHB clock
sdmmc_it	Digital output	SDMMC global interrupt

Table 210. SDMMC internal input/output signals (continued)

Signal name	Signal type	Description
sdmmc_io_in_ck	Digital input	SD/SDIO/*e*•MMC card feedback clock. This signal is internally connected to the SDMMC_CK pin (for DS and HS modes).
sdmmc_fb_ck	Digital input	SD/SDIO/*e*•MMC card tuned feedback clock after DLYB delay block (for SDR50, DDR50, SDR104, HS200)

Table 211. SDMMC pins

Pin name	Pin type	Description
SDMMC_CK	Digital output	Clock to SD/SDIO/*e*•MMC card
SDMMC_CKIN	Digital input	Clock feedback from an external driver for SD/SDIO/*e*•MMC card. (for SDR12, SDR25, SDR50, DDR50)
SDMMC_CMD	Digital input/output	SD/SDIO/*e*•MMC card bidirectional command/response signal.
SDMMC_CDIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the SDMMC_CMD signal.
SDMMC_D[7:0]	Digital input/output	SD/SDIO/*e*•MMC card bidirectional data lines.
SDMMC_D0DIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the SDMMC_D0 data line.
SDMMC_D123DIR	Digital output	SD/SDIO/*e*•MMC card I/O direction indication for the data lines SDMMC_D[3:1].

23.5.3 General description

The **SDMMC_D[7:0]** lines have different operating modes:

- By default, SDMMC_D0 line is used for data transfer. After initialization, the host can change the databus width.
- For an *e*•MMC, 1-bit (SDMMC_D0), 4-bit (SDMMC_D[3:0]) or 8-bit (SDMMC_D[7:0]) data bus widths can be used.
- For an SD or an SDIO card, 1-bit (SDMMC_D0) or 4-bit (SDMMC_D[3:0]) can be used. All data lines operate in push-pull mode.

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the data lines is indicated with I/O direction signals. The **SDMMC_D0DIR** signal indicates the I/O direction for the SDMMC_D0 data line, the **SDMMC_D123DIR** for the SDMMC_D[3:1] data lines.

SDMMC_CMD only operates in push-pull mode:

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the SDMMC_CMD line is indicated with the I/O direction signal **SDMMC_CDIR**.

SDMMC_CK clock to the card originates from **sdmmc_ker_ck**:

- When the sdmmc_ker_ck clock has 50 % duty cycle, it can be used even in bypass mode (CLKDIV = 0).
